SOS SITES	The following SOS sites for the species have been proposed: • Dora Creek • Eastern Yengo • Castlereagh • Dharawal • Colymea SCA

RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Acacia bynoeana* (Bynoe's wattle) (DoE, 2013a)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species.
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=8575

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	Yes	Yes	Yes	Yes

EXPERT REPORT (BCAR PROCESS)	Yes (Douglas, 2019a). Available at Supporting Document C
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS** **Expert report polygons**. Potential habitat polygons were generated based on the occurrence of PCTs 725, 883, 1081, 1181 and 1395, with the application of riparian exclusion buffers to account for the fact that wetter and sometimes more thickly vegetated areas associated with drainage lines are unlikely habitat. To refine these potential habitat polygons, targeted surveys for the species were then undertaken in a number of locations within the nominated areas. The species was not recorded during surveys and these areas were removed from the potential habitat mapping. However, it was not possible to access and survey all areas of potential habitat within the nominated areas. Any remaining potential habitat is considered precautionary and does not necessarily equate with actual habitat. Douglas (2019a) notes that the species is naturally rare and patchily distributed, which means that it is unlikely that a large percentage of the potential habitat would actually support the species, even though it can sometimes be locally abundant in favourable conditions. **OUTSIDE THE NOMINATED AREAS** **Species distribution model (SDM).** Potential habitat outside the nominated areas was mapped using an SDM. The report for this process (Supporting Document F) notes that the model for the species predicts more potential habitat than would be expected based on soils and PCTs alone. The mapping is therefore considered to be highly precautionary. No targeted surveys as part of this project were undertaken outside the nominated areas.
POPULATION MAPPING	**RECORD SELECTION** Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset.

	POPULATION DEFINITION
	Biological populations were defined using the records dataset and available information about the nature of the species. It should be noted that limited information is available on the dispersal distance of *A. bynoeana*. However, the recovery plan for *A. pubescens* notes that dispersal over a distance of 300 m is considered likely for Acacia spp. (NSW NPWS, 2003). Based on this, plants within 300 m of each other were defined as one population.
	IMPORTANT POPULATION CRITERIA
	Populations of *A. bynoeana* were then categorised as important or not-important based on the methodology set out in Section 11.5.3 of Chapter 11. Populations were considered important because they met one or more of the following criteria: • They are considered necessary for maintaining the extent of the species' occurrence • They are relatively large in size (number of individuals), in the context of known information regarding species ecology and population characteristics • They occur within a conservation reserve • They are part of an SOS site

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.1 for a map of records and habitat across the Strategic Assessment Area
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 29-44 at the end of this species assessment for a breakdown of the occurrence of records and habitat for *A. bynoeana* in the Strategic Assessment Area. **Records** The species is known to occur in three main locations in the Strategic Assessment Area: • To the north of GPEC where there are a significant number of populations • Just to the north-east of GMAC • And within Wilton where it occurs in the conservation area for the previously approved Bingara Gorge development (EPBC 2014/7400) In total there are 45 populations within the Strategic Assessment Area. Of these populations, 37 are considered important, and 12 are wholly or partly located in existing conservation reserves. It is important to note that surveys undertaken for the strategic assessment within the nominated areas did not record the species. **Potential habitat** The baseline mapping for the assessment mapped approximately 30,678 ha of known and potential habitat within the Strategic Assessment Area. 2,434 ha of this occurs within protected lands. As a general trend, habitat within the Strategic Assessment Area is located in the north and south of the assessment area, with scattered areas towards the eastern and western edges. Specifically, potential habitat for *A. bynoeana* is located: • In the Londonderry area to the north of GPEC, where a large patch occurs in the area incorporating Agnes Banks, Wianamatta Nature Reserve, Castlereagh and Windsor Downs nature reserves and the Waste Assets Management Corporation stewardship on The Northern Road • In moderate patches to the north of the Londonderry area, including localities such as Scheyville, Freemans Reach and North Richmond • Within the Wianamatta Regional Park and Ropes Crossing, located within GPEC

	• In moderate to large connected areas occurring in the southern and south-eastern region of the Strategic Assessment Area, including areas around Buxton, Tahmoor and Bargo, Wilton, Douglas Park, vegetation corridors near Appin, and the Kentlyn/Minto Heights region • In small to moderate patches near Gulguer Nature Reserve in the west of the Strategic Assessment Area • In small scattered patches near Kemps Creek, from the mid-east to the east of the Strategic Assessment Area, with some habitat occurring within WSA Mapped potential habitat is relatively limited within GPEC, WSA and the northern half of GMAC, compared with Wilton and the southern half of GMAC where it is associated with most of the remnant vegetation.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.12.1 NOMINATED AREAS

The baseline mapping for the assessment mapped 1,814 ha of potential habitat within the nominated areas (not including excluded lands). Approximately 1,619 ha (89 per cent) was avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 1,556 ha was avoided for biodiversity purposes
- 63 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 29-45.

It is important to note that the avoidance calculations in Table 29-45, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', were calculated without including excluded lands as these lands are not covered by the Plan. Table 29-45 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

29.12.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.12.3 LOSS OF KNOWN POPULATIONS AND POTENTIAL HABITAT

Implementation of the Plan will lead to the loss of potential habitat for the species. However, it will not result in direct impacts to any known populations. A summary of these impacts is provided in Table 29-46.

Loss of potential habitat

Approximately 199 ha of potential habitat for the species will be lost as a result of the implementation of the Plan (195 ha within the nominated areas and 4 ha within transport corridors outside the nominated areas). This habitat occurs predominantly within Wilton and GMAC and represents 0.6 per cent of mapped potential habitat across the Strategic Assessment Area.

Risk of residual adverse impacts to the species

The risk of residual adverse impacts occurring to the species as a result of the loss of potential habitat is considered to be very low. This is because:

- The likelihood of actual impacts occurring to the species has been categorised as possible. There will be no impacts to known populations, and there is moderate confidence that the species could occur in the potential habitat to be impacted. As outlined in the Approach to Baseline Data section above, the potential habitat mapping is considered precautionary and does not necessarily equate with actual habitat
- The consequence of any impacts to the species (if they did occur) has been categorised as negligible. There will be loss of less than 2 per cent of mapped potential habitat in the Strategic Assessment Area, with moderate confidence of the species' occurrence in impacted areas. There are no impacts to known populations.

29.12.4 FRAGMENTATION OF HABITAT

The placement of urban capable land and transport corridors within the Strategic Assessment Area will not lead to fragmentation of records or habitat of *A. bynoeana*, as it will not lead to the removal of habitat which links other areas of habitat or records together. All impacts to habitat of *A. bynoeana* are to already fragmented patches.

Therefore, there is no residual adverse risk of fragmentation as a result of loss of potential habitat under the Plan.

29.12.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the very low risk of residual adverse impacts to the species, offsets were not considered necessary for *A. bynoeana*.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.12.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice (and other key documents) for *A. bynoeana* identifies a range of threats to the species (DoE, 2013a). Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Inappropriate habitat disturbance
- Weed invasion
- Inappropriate fire regimes

Browsing by native and introduced herbivores has also been identified as a key threat. However, this is not considered relevant to the implementation of the Plan as the Plan is unlikely to exacerbate the risk across the Strategic Assessment Area.

INAPPROPRIATE HABITAT DISTURBANCE

Disturbance to the species can occur:

- During road, trail and powerline maintenance
- By recreational vehicles, horse riding and pedestrian use on the margins of trails where the species can occur (DoE, 2013a)

Activities associated with maintenance are likely to be a current issue for the species where known records occur outside the nominated areas (particularly to the north of GPEC). It is considered unlikely that activities approved under the Plan would exacerbate this threat.

Disturbance due to recreational use of natural areas may increase due to development within the nominated areas. Populations of *A. bynoeana* considered most at risk of this threat are those that occur on:

- Public land, as these areas are accessible without the deterrent that comes with trespassing. Populations occur on the following public land managed for conservation: Castlereagh Nature Reserve, Wianamatta Nature Reserve and possibly Agnes Banks Nature Reserve (there is one historical record of the species in this reserve, yet detailed surveys for associated species in recent years have failed to detect the species (Douglas, 2019a)). While access is potentially an issue in all of these areas, the reserves are all managed for conservation purposes and have measures to control the impacts of public visitation
- An area of freehold land to the north of GPEC which is often mistaken for Crown land. This area contains a number of access tracks, and issues associated with rubbish dumping have been recorded for the site

In addition, some habitat for the species (around Populations 82 and 239) is subject to approval conditions to protect and manage it from indirect impacts, under a previous EPBC Act referral (EPBC 2014/7400). Conditions of approval include:

- Preparation of an environment management plan for the approval of the Commonwealth to address indirect impacts, which includes the following measures:
    - Fencing and signage to restrict access in the areas
    - Provision of bins to reduce littering

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for *A. bynoeana*. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations (which will include land obtained for conservation within the SCAs. It is noted that there is 5,482 ha of habitat for *A. bynoeana* within the SCAs)
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas. This commitment is consistent with a number of actions in the Conservation Advice around educating the community about *A. bynoeana*

The package of measures in the Plan is expected to adequately manage the risk to *P. spicata* from inappropriate habitat disturbance as a result of development. This is because:

- Avoided lands where mapped habitat for *A. bynoeana* occurs will be zoned appropriately to enable an adequate framework for management. It is noted there is approximately 1,814 of mapped potential habitat for *A. bynoeana* in avoided lands
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

WEED INVASION

A. bynoeana is threatened with invasion and competition by weeds. The species is most susceptible to the threat of weeds from development under the Plan where new urban growth or transport occur adjacent to known populations or habitat. Key risk areas include:

- The southern end of Shanes Park where the M7/Ropes Crossing Link occurs adjacent to potential habitat areas
- The north-eastern section of Wianamatta Regional Park, where the Outer Sydney Orbital corridor within GPEC occurs near potential habitat
- Within Wilton at Bingara Gorge (noting this area is subject of a previous EPBC Act approval (EPBC 2014/7400) which includes weed control requirements to protect the species)
- North east and south east of GMAC

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Area. This includes a number of actions, of which the following are the most relevant to the outcome for *A. bynoeana*:
    - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
    - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
    - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes:
    - Partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
    - Require proponents to undertake the following when applying for/undertaking development:
        - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
        - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
        - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

The Plan further includes a commitment to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA.

These measures are expected to adequately manage the potential threat to *A. bynoeana* from weed invasion.

INAPPROPRIATE FIRE REGIMES

Altered fire regimes are an identified potential threat to *A. bynoeana* (DoE, 2013a). Increased human activity within the nominated areas has the potential to increase the risk of fire within adjacent areas of habitat for the species. Key risk areas are those that are easily accessible to the public and in close proximity to urban development and roads.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant to the outcome for *A. bynoeana* being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
    - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for *A. bynoeana.* While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes.

These measures are considered to adequately mitigate the threat to potential habitat for the species.

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to:

- The development of essential infrastructure within nominated areas but outside the urban capable lands
- Tunnels associated with transport projects

29.12.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

A. bynoeana records occur within Wilton wholly within excluded lands. No records of the species occur within other nominated areas.

Mapped potential habitat for *A. bynoeana* occurs within avoided lands in all nominated areas, with the majority of habitat in avoided areas occurring in Wilton and GMAC. The development of essential infrastructure within avoided lands therefore has some potential to impact upon mapped habitat for *A. bynoeana*. It is noted that habitat which has the highest potential to be impacted would be habitat occurring at the edge of the urban capable lands and transport corridors, and therefore would likely constitute more marginal habitat with greater exposure to edge effects.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

29.12.8 POTENTIAL IMPACTS FROM TUNNELS

There is a total of 4.2 ha of potential habitat for *A. bynoeana* within the footprints of the Metro Rail Future Extension and OSO tunnels. No records of the species occur within or in the vicinity of the tunnel footprints. Given the small area of mapped potential habitat within the footprint and the absence of records, it is considered unlikely that *A. bynoeana* is present in the locality of the tunnel developments.

The Plan includes commitments to mitigate any potential indirect impacts (e.g. changes to hydrology, ground settling or subsidence) from the transport corridors as part of a future environmental impact assessment process.

These commitments are expected to adequately address threats to the species from the construction and operation of the tunnels. See Section 36.6 in Chapter 36 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.12.9 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DoE, 2013a) identifies the following key issues that are likely to have the greatest influence on the long-term viability of *A. bynoeana* in relation to implementation of the Plan:

- Habitat loss and fragmentation
- Indirect impacts including:
  - Inappropriate habitat disturbance
  - Weed invasion
  - Inappropriate fire regimes

HABITAT LOSS AND FRAGMENTATION

The risk of residual adverse impacts to the species from habitat loss and fragmentation under the Plan is very low. Although the Plan authorises the clearing of 199 ha of potential habitat, the mapping for this species is highly precautionary and the impacts relate to 0.6 per cent of the mapped habitat in the Strategic Assessment Area. The vast majority of mapped habitat in the nominated areas was avoided in the design of the urban capable lands. There will be no impacts to known populations or fragmentation of potential habitat. This clearing is not expected to influence the long-term viability of the species.

While specific offsets for this species are not considered necessary, the Plan includes broader commitments and actions that are likely to benefit the species. In particular:

- The SCAs contain approximately 5,842 ha of mapped potential habitat for the species. Although the final extent of potential habitat that will be secured in these areas is unclear, the opportunity to secure large, well connected and high quality vegetation that provides potential habitat makes it likely that the conservation program will deliver benefits for this species

The process of protecting land in the Strategic Assessment Area is likely to support a priority action from the Conservation Advice to increase the area of habitat for the species that is secured and managed for conservation.

INDIRECT IMPACTS

The potential indirect impacts associated with inappropriate habitat disturbance, weed invasion, and inappropriate fire regimes will be managed and mitigated through the generic management strategies in the Plan, and through an existing EPBC Act approval in the Bingara area.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

There will be no direct impacts to known populations. There are large areas of potential habitat (30,678 ha) and impacts to this are relatively minor (199 ha). There will be no fragmentation of potential habitat.

Potential indirect impacts are addressed through management measures in the Plan and a previous EPBC Act approval.

Collectively these will ensure that the implementation of the Plan does not adversely influence the long-term viability of *A. bynoeana*.

29.12.10 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

29.12.11 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-43 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For *A. bynoeana*, there are no relevant Threat Abatement Plans.

Table 29-43: Relevant key Threatening Processes and associated Threat Abatement Plans for *A. bynoeana*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant Threat Abatement Plan
Novel biota and their impact on biodiversity	There is no relevant Threat Abatement Plan

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

29.13 *ACACIA PUBESCENS* (DOWNY WATTLE, HAIRY-STEMMED WATTLE)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	*Acacia pubescens* is a weeping, spreading shrub with brilliant yellow flowers, bipinnate leaves and hairy branchlets. It grows approximately 1-5 m tall. (TSSC, 2016a)
ECOLOGY	Flowers between August and October. Pods mature between October and December. Plants first flower when they are around 3-5 years old. The species is pollinated by insects (most likely small native bees and wasps) and birds (Douglas, 2019b). Recruitment is often by vegetative means and this can reduce the genetic diversity of a population. The percentage of seed fall may be low, possibly due to predation when on the plant. The species is likely to have high seed dormancy and a long-lived persistent soil seed bank. Regeneration can occur following fire, however, severe fires kill the stems. (DoEE, 2018c)
DISTRIBUTION AND HABITAT	Records are restricted to the Sydney district predominantly in the Cumberland subregion (NSW NPWS, 2003) The species inhabits open woodland and forest in a variety of plant communities (Cooks River/Castlereagh Ironbark Forest, Shale Gravel Transition Forest and Cumberland Plain Woodland). It occurs on alluviums, shales and at the intergrade between shales and sandstones. (DoEE, 2018c)
POPULATIONS	As of 2003, there were 116 known populations of this species. At that time, just over half of those known populations contained fewer than 20 stems (NSW NPWS, 2003). Populations should be considered viable unless there is evidence to the contrary. This is because most recruitment is from vegetative reproduction and small population sizes are not necessarily relevant in the assessment of viability (NSW NPWS, 2003). Assessment of all BioNet records of the species indicates that over 90 per cent of known records occur within the Cumberland subregion. Therefore, for the purposes of this assessment, *A. pubescens* is considered to be an endemic species to the region.
SOS SITES	The following SOS sites for the species have been identified: • Mountain Lagoon • Hawkesbury

	• Bankstown-Liverpool

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	Yes	Yes	Yes	Yes

EXPERT REPORT (BCAR PROCESS)	Yes (Douglas, 2019b). Available at Supporting Document C
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS**
	Expert report polygons. Potential habitat polygons were generated based on the occurrence of PCTs 724, 725, 835, 849, 883, 1081 and 1395, with the application of riparian exclusion buffers to account for the fact that wetter and sometimes more thickly vegetated areas associated with drainage lines are unlikely habitat. All condition classes of vegetation for this species were considered to be suitable habitat as this species is able to occur in quite disturbed habitats. The species may also occur in sites which are so modified that they would not be mapped as native vegetation community. To refine these potential habitat polygons, targeted surveys for the species were then undertaken in a number of locations within the nominated areas. The species was not recorded during surveys and these areas were removed from the potential habitat mapping. However, it was not possible to access and survey all areas of potential habitat within the nominated areas. Douglas (2019b) notes that any remaining potential habitat is considered precautionary and does not necessarily equate with actual habitat. The species is naturally rare and patchily distributed, which means that it is unlikely that a large percentage of the potential habitat would actually support the species. It can sometimes be locally abundant in favourable conditions.
	OUTSIDE THE NOMINATED AREAS
	Species distribution model (SDM). Potential habitat outside the nominated areas was mapped using an SDM. The report for this process (Supporting Document F) notes that the model for the species predicts more potential habitat than would be expected based on soils and PCTs alone. The mapping is considered to be highly precautionary. No targeted surveys as part of this project were undertaken outside the nominated areas.
	RECORD SELECTION

<table>
<tr><td rowspan="5">POPULATION MAPPING</td><td>Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset.</td></tr>
<tr><td>POPULATION DEFINITION</td></tr>
<tr><td>Biological populations were defined using the records dataset and available information about the nature of the species.
The recovery plan for A. pubescens notes that dispersal over a distance of 300 m is considered likely for Acacia spp. (NSW NPWS, 2003). Based on this, plants within 300 m of each other have been defined as one population.</td></tr>
<tr><td>IMPORTANT POPULATION CRITERIA</td></tr>
<tr><td>Populations of A. pubescens were then categorised as important or not-important based on the methodology set out in Section 11.5.3 of Chapter 11. Populations were considered important because they met one or more of the following criteria:
• A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program
• A large population
• Is associated with a commitment made under the Sydney Growth Centres conservation program
• A population within a conservation area</td></tr>
</table>

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

<table>
<tr><td>MAP</td><td>See Map 36.2 for a map of records and habitat across the Strategic Assessment Area</td></tr>
<tr><td>OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA</td><td>See Table 29-48 at the end of this species assessment for a breakdown of the occurrence of records and habitat for A. pubescens in the Strategic Assessment Area.
Records
Known records for A. pubescens are distributed across two core areas which have been identified for site management under the NSW Saving our Species (SOS) program:
• One area associated with the Hawkesbury SOS site in the north-east of the Strategic Assessment Area, including Windsor Downs, Pitt Town and Scheyville National Park
• The second associated with the Bankstown-Liverpool SOS site, comprising an area that straddles the central-east boundary of the Strategic Assessment Area around Lansdowne
Scattered records occur more broadly, but still within the region of these two core areas. There are also a small number of outlier populations outside and to the west of the Strategic Assessment Area, at Mountain Lagoon in the north-west and The Oaks in the south-west.
There are a total of 97 important populations within the Strategic Assessment Area, of which 13 either wholly or partly occur within existing protected areas as shown in Table 29-48. None of these important populations occur within the nominated areas.
One of these populations is located at Kemps Creek just outside the southern boundary of WSA. This population has been identified as important because it is the subject of a commitment made under the Sydney Growth Centres Program.
The remaining 96 populations within the Strategic Assessment Area have been identified as important because they are all associated with the Saving our Species sites across the two core areas described above.</td></tr>
</table>

	A further 8 non-important populations have been mapped within the Strategic Assessment Area. These populations broadly occur around Minchinbury within GPEC and further south within the Austral and Hoxton Park areas, outside of the nominated areas. **Potential habitat** The baseline mapping for this assessment has mapped approximately 35,102 ha of known and potential habitat within the Strategic Assessment Area as shown in Table 29-48. The majority of this habitat is associated with the two core areas for the species and mostly occurs outside of the nominated areas. Within the nominated areas, potential habitat has been identified: • Within GPEC and WSA, where potential habitat areas align closely with patches of remnant vegetation. This potential habitat is within the western extent of the core area associated with the Bankstown-Liverpool SOS site • Within GMAC, where potential habitat areas again align closely with patches of remnant vegetation. A small proportion of this occurs within the northern section of the nominated area which forms part of the southern extent of the Bankstown-Liverpool SOS site. However, the majority of this potential habitat occurs within the southern half of the nominated area approximately 22 km south of this core area in a locality where the species has not previously been recorded • Within Wilton, where potential habitat is not just associated with remnant patches of vegetation, but has been mapped more broadly in a number of areas. However, it is noted that this area is well outside the core range of *A. pubescens* in areas where (according the expert report) the species is not known from or likely to occur (Douglas, 2019b) It is relevant to note that surveys throughout remnant vegetation within GMAC and Wilton undertaken as part of this assessment did not detect the species. This, combined with the fact that the majority of potential habitat mapped within these areas is outside the species' core range, suggests that *A. pubescens* is unlikely to occur within mapped potential habitat within GMAC and Wilton.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.13.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 2,853 ha of potential habitat within the nominated areas (not including excluded lands). Approximately 2,118 ha (74 per cent) has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 1,885 ha was avoided for biodiversity purposes
- 234 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 29-49.

It is important to note that the avoidance calculations in Table 29-49, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including 'excluded lands' as these lands are not covered by the Plan. Table 29-49 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

29.13.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.13.3 LOSS OF KNOWN POPULATIONS AND POTENTIAL HABITAT

Implementation of the Plan will not lead to any direct impacts to known populations. However, it will lead to a loss of potential habitat. A summary of these impacts is presented in Table 29-50.

Loss of potential habitat

Approximately 792 ha of potential habitat for the species will be lost as a result of the implementation of the Plan (735 ha within the nominated areas and 57 ha within transport corridors outside the nominated areas). This habitat occurs in the following areas:

- Within GPEC and WSA, at the western extent of the core area for the species associated with the Bankstown-Liverpool SOS site
- Potential habitat within Wilton and the southern section of GMAC

This habitat represents 2.3 per cent of mapped potential habitat across the Strategic Assessment Area.

Risk of residual adverse impacts

The risk of residual adverse impacts occurring to the species as a result of the loss of potential habitat is considered to be very low. This is because:

- The likelihood of actual impacts occurring to the species has been categorised as unlikely. There will be no impacts to known populations, and there is low confidence that the species could occur in the potential habitat to be impacted. The habitat which is to be impacted within GPEC and WSA consists of small, scattered and isolated patches which are considered unlikely to support the species. Impacted potential habitat within GMAC and Wilton is located outside of the core range of the species, and the species has never been recorded in these localities.
- The consequence of any impacts to the species (if they did occur) has been categorised as minor. There will be loss of between 2-5 per cent of mapped potential habitat in the Strategic Assessment Area with low confidence of the species' occurrence in impacted habitat (endemic species). Species mapping for this assessment is highly precautionary, with much impacted habitat being mapped beyond the known range of the species, suggesting the species is unlikely to occur in these localities, and as such there is low confidence of species presence in impacted habitat

29.13.4 FRAGMENTATION OF HABITAT

Fragmentation impacts

The placement of urban capable land and transport corridors within the Strategic Assessment Area will lead to fragmentation of a small area of potential habitat with no associated records. This habitat is located to the south of WSA in the vicinity of Cobbitty, which will be fragmented as a result of the development of the OSO.

Risk of residual adverse impacts

The risk of residual adverse impacts occurring to the species as a result of the loss of fragmentation is considered to be very low. This is because:

- The likelihood of fragmentation has been categorised as unlikely. This is because:

- The likelihood that development is presents a barrier to dispersal of the species is possible. *A. pubescens* is pollinated by insects and birds, and it is thought that individuals of the species within 300 m of each other are likely to be within the same population, suggesting that the species has the capacity to breed with and/or disperse up to 300 m from adult plants. While detailed planning for development within the transport corridors has not yet been completed, it is anticipated that the width of the OSO will be less than 300 m. The OSO is further thought to have potential to deter movement of pollinators and/or seed dispersers between adult plants.
- The type of fragmentation is impact to mapped habitat only. This is because there are no known records on, or in the vicinity of, mapped potential habitat which is impacted by the OSO near Cobbitty.

- The consequence of fragmentation has been categorised as negligible. This is because the area to be fragmented consists of a small area of potential habitat with no associated records.

29.13.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the very low risk of residual adverse impacts to the species, offsets were not considered necessary for *A. pubescens.*

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.13.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice (TSSC, 2016a) and Recovery Plan (NSW NPWS, 2003) (and other key documents) for *A. pubescens* identify a range of threats to the species. Where these threats are relevant to the implementation of the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Inappropriate habitat disturbance through illegal track creation and maintenance activities
- Weed invasion
- Inappropriate fire regimes

Hybridisation with non-naturally occurring bipinnate wattles within natural range and impacts to individuals from an unknown disease was also identified as a key threat. However, this is not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the threat across the Strategic Assessment Area.

However, it is considered unlikely that these indirect impacts will adversely affect the majority of populations of the species within or surrounding the Strategic Assessment Area for the following reasons:

- All populations within the nominated areas (population 485, 486 and 487 in GPEC and population 474 in GMAC) are non-important populations which are within landscapes which are already highly developed. These populations would be subject to a range of threatening processes from the existing urban environment and are unlikely to be affected by development under the Plan
- The important populations associated with the Bankstown-Liverpool SOS site occur approximately 6 km east of the nearest development within WSA, and are also in a landscape which is highly developed which is subject to existing threatening processes. Development under the Plan is unlikely to affect these populations
- The important populations associated with the Hawkesbury SOS site occur some distance from proposed development under the Plan (over 8 km from the nearest transport corridor outside of the nominated areas and over 12 km to the nearest urban capable land within GPEC) and a number of these populations are already managed for conservation within the Scheyville National Park

The only important population which has potential to be indirectly impacted by development under the Plan is population 479. This important population that forms part of a commitment under the Sydney Growth Centres Program which requires field validation of the records before habitat associated with the population will be protected.

A brief survey of the locality of Kemps Creek was undertaken in mid-November of 2018, as described in the expert report for this species. While no new records of the species were reported, it was considered possible that the species may occur on disturbance margins which were not traversed, or that the species may be restricted to seed bank at that location. Overall, the remnant habitat of this locality was largely unmanaged and degrading due to several threats at the time of survey. It is recognised that *A. pubescens* is relatively tolerant of significant disturbance and can persist as a long-lived seedbank or as root suckers, and therefore the species may persist in disturbed areas. It is recommended that the management of habitat at Kemps Creek under this program be improved. It is considered that improved and ongoing management of habitat at Kemps Creek will provide protection of *A. pubescens* within this locality from impacts associated with indirect impacts.

A small non-important population (population 487) has potential to be indirectly impacted by development under the Plan. The following sections outline the control measures under the Plan to manage indirect impacts to *A. pubescens*.

INAPPROPRIATE HABITAT DISTURBANCE

The Plan includes the following development controls to manage the risk of inappropriate habitat disturbance:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations (it is noted the SCAs contain approximately 3,475 ha of habitat for *A. pubescens*)
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas. This commitment is consistent with a number of actions in the Conservation Advice around educating the community about *P. parviflora*

The package of measures in the Plan is expected to adequately manage the risk to *A. pubescens* from inappropriate habitat disturbance as a result of development. This is because:

- Avoided lands where areas of mapped habitat for *A. pubescens* occur will be zoned appropriately to enable an adequate framework for management. It is noted there is approximately 2,118 ha of potential habitat for *A. pubescens* within avoided lands
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands (including mapped potential habitat for *A. pubescens* within the SCAs) will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

WEED INVASION

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- Implementation of mitigation measures to address the impacts of the spread of weeds on threatened species associated with and urban capable (Commitment 5) and transport (Commitment 6) development
- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Area. This includes a number of actions, of which the following are the most relevant to the outcome for *A. pubescens*:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes:
  - Partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

The package of measures in the Plan is expected to adequately manage the risk to *A. pubescens* from the increased risk of weeds associated with development. This is because:

- Commitments 5 and 6 will provide for mitigation measures to be implemented for the benefit of *A. pubescens* to address the impacts associated with the spread of weeds associated with urban capable and transport development
- There are commitments (Commitment 16 and Commitment 23) which will coordinate, enable and conduct effective weed control programs in strategic locations within the Strategic Assessment Area to manage priority weed species
- Proponents will be required to minimise the risk of weed spread, and to manage weeds, during the design, development and operational stages of development
- Establishment of environmental zoning of approximately 2,118 ha of mapped potential habitat of *A. pubescens* within avoided lands will enable establishment of an adequate framework for management of weeds in these areas

INAPPROPRIATE FIRE REGIMES

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for *A. pubescens*:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values (it is noted the SCAs contain approximately 3,475 ha of habitat for *A. pubescens*)
  - A process to work with delivery partners to implement the fire management strategy

  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for *A. pubescens.* While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes.

The package of measures in the Plan is expected to adequately manage the risk to *A. pubescens* from altered fire regimes as a result of development. This is because:

- Establishment of environmental zoning of approximately 2,118 ha of mapped potential habitat of *A. pubescens* within avoided lands will enable establishment of an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting mapped potential habitat for *A. pubescens* which is located adjacent to urban capable lands
- Fire management authorities will be engaged to ensure they understand the requirements of *A. pubescens* and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to:

- The development of essential infrastructure within nominated areas but outside the urban capable lands
- Tunnels associated with transport projects

29.13.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

A. pubescens records occur within GMAC and GPEC wholly within excluded lands. No records of the species occur within other nominated areas.

Mapped potential habitat for *A. pubescens* occurs within avoided lands in all nominated areas, with the majority of habitat in avoided areas occurring in Wilton and GMAC. The development of essential infrastructure within avoided lands therefore has some potential to impact upon mapped habitat for *A. pubescens.* It is noted that habitat which has the highest potential to be impacted would be habitat occurring at the edge of the urban capable lands and transport corridor, and therefore would likely constitute more marginal habitat with greater exposure to edge effects.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area

- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

29.13.8 POTENTIAL IMPACTS FROM TUNNELS

There is a total of 68.5 ha of mapped potential habitat for *A. pubescens* within the footprints of the Metro Rail Future Extension and OSO tunnels, which occurs as small and fragmented habitat patches. No records of the species occur within or in the vicinity of the tunnel footprints. Given the relatively small area and fragmented nature of mapped potential habitat within the footprint and the absence of records, it is considered unlikely that *A. pubescens* is present in the locality of the tunnel developments.

The Plan includes commitments to mitigate any potential indirect impacts (e.g. changes to hydrology, ground settling or subsidence) from the transport corridors as part of a future environmental impact assessment process.

These commitments are expected to adequately address threats to the species from the construction and operation of the tunnels. See Section 36.6 in Chapter 36 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.13.9 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (TSSC, 2016a) identifies the following key issues that are likely to be the highest risk threat to the long-term viability of *A. pubescens* in relation to implementation of the Plan:

- Habitat loss and fragmentation
- Indirect impacts including:
  - Weed invasion
  - Habitat disturbance through illegal track creation and maintenance activities
  - Inappropriate fire regimes

HABITAT LOSS AND FRAGMENTATION

The risk of residual adverse impacts to the species from habitat loss and fragmentation under the Plan is very low. Although the Plan authorises the clearing of 792 ha of potential habitat, the mapping for this species is highly precautionary and these impacts relate to approximately 2.3 per cent of the mapped habitat in the Strategic Assessment Area. The vast majority of mapped habitat in the nominated areas was avoided in the design of the urban capable lands. There will be no impacts to known populations, and the risk of fragmentation is very low. Direct impacts are not expected to negatively impact the long-term viability of the species.

While specific offsets for this species are not considered necessary, the Plan includes broader commitments and actions that are likely to benefit the species. In particular:

- The SCAs contain approximately 3,475 ha of mapped potential habitat for the species. Although the final extent of potential habitat that will be secured in these areas is unclear, the opportunity to secure large, well connected and high quality vegetation that provides potential habitat makes it likely that the conservation program will deliver benefits for this species

The process of protecting land in the Strategic Assessment Area is likely to support a priority action from the Conservation Advice to prevent further loss of habitat.

INDIRECT IMPACTS

The potential indirect impacts associated with inappropriate habitat disturbance, weed invasion, and inappropriate fire regimes will be managed and mitigated through the generic management strategies in the Plan.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

There will be no direct impacts to known populations. There are large areas of potential habitat (35,102 ha) and impacts to this are relatively minor (792 ha). The risk of fragmentation is very low.

Potential indirect impacts are addressed through management measures in the Plan.

This will ensure that the implementation of the Plan does not adversely influence the long-term viability of *A. pubescens*.

29.13.10 CONSISTENCY WITH RECOVERY PLAN

In accordance with Section 146K of the EPBC Act, this section considers whether the implementation of the Plan is not inconsistent with the species' Recovery Plan. It considers two questions:

- Does the Plan prevent achievement of the objectives of the Recovery Plan?
- Does the Plan prevent implementation of the Recovery Plan actions?

These questions are discussed below.

DOES THE PLAN PREVENT ACHIEVEMENT OF THE OBJECTIVES OF THE RECOVERY PLAN?

The overall objective of the Recovery Plan is to prevent the status of *A. pubescens* from becoming endangered, by reducing habitat loss and by implementing management regimes aimed at maintaining representative populations across the species' range (NSW NPWS, 2003).

Recovery plan strategies have been identified to support the overall objective. They are:

- To ensure that a representative sample of *A. pubescens* populations occurring on public and private lands are protected from habitat loss and managed for conservation;
- To reduce the impacts of threats at sites across the species' range;
- To ensure that any planning and management decisions that are made which affect the species, are made in accordance with the recovery objectives of this plan;
- To understand the biology, ecology, health and distribution of the species including the range of genetic variation;
- To develop the awareness and involvement of the broader community in the species and its conservation; and
- To re-assess the conservation status of the species.

Implementation of the Plan will support a number of these strategies by including development controls that manage and control the risks of potential indirect impacts consistent with actions in the Conservation Advice and will not prevent the achievement of the objectives of the Recovery Plan.

DOES THE PLAN PREVENT THE IMPLEMENTATION OF THE RECOVERY PLAN ACTIONS?

The Recovery Plan identifies a set of actions to support the overall recovery of *Acacia pubescens*. The Plan will not prevent implementation of any of the actions.

29.13.11 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-47 where they relate to:

- The potential direct impacts of the Plan, or

- The relevant indirect impacts

For *A. pubescens*, there are no relevant Threat Abatement Plans.

Table 29-47: Relevant key Threatening Processes and associated Threat Abatement Plans for *A. pubescens*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

Table 29-48: Occurrence of *A. pubescens* in the Strategic Assessment Area

29.14 *ALLOCASUARINA GLAREICOLA*

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Endangered
DESCRIPTION	*Allocasuarina glareicola* is an erect, smooth-barked shrub with cones that grows to approximately 2 m tall (DoEE, 2018c; OEH, 2018b)
ECOLOGY	The species is monoecious or dioecious and flowers around October each year. The time taken for the plants to flower and set seed is not known. Regeneration is commonly by suckers. Root suckers can appear up to 3 m from the parent plant, where clumps of up to hundreds of stems may be a single individual. Seedling recruitment has only been observed at one site. The species is wind pollinated which means the distance between individuals may be a critical factor in enabling pollination and seed set. (DoEE, 2018c; OEH, 2018b)
DISTRIBUTION AND HABITAT	Records are primarily restricted to the Castlereagh and Londonderry areas of the Cumberland subregion, with an outlier population found in Liverpool (Holsworthy Military Area). The total extent of occurrence (EOO) of the species is approximately 27 km^2. Inhabits Castlereagh woodland and open woodland (with *Eucalyptus parramattensis, Eucalyptus fibrosa, Angophora bakeri, Eucalyptus sclerophylla* and *Melaleuca decora*). It occurs on strongly acidic soils with low fertility. (DoEE, 2018c; OEH, 2018b)
POPULATIONS	There were 457 clumps of *A. glareicola* known in 1996. The largest population, which consisted of 405 clumps, is likely to have reduced due to the expansion of an adjacent rubbish tip. (DoEE, 2018c) Assessment of all BioNet records of the species indicates that over 90 per cent of known records occur within the Cumberland subregion. Therefore, for the purposes of this assessment, *A. glareicola* is considered to be an endemic species to the region. It is further noted that this species has been identified as an SAII species under the BCAR process. Refer to Chapter 25 for further information.
SOS SITES	The following SOS sites for the species have been proposed: • East of Agnes Banks Nature Reserve • Castlereagh Nature Reserve • Wianamatta Nature Reserve • Heathcote Rd

RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Allocasuarina glareicola* (DEWHA, 2008a)

SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=21932

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

<table>
<tr><td rowspan="3">NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)</td><td>ECOSYSTEM CREDIT SPECIES</td><td colspan="4">CANDIDATE SPECIES CREDIT SPECIES</td></tr>
<tr><td rowspan="2">No</td><td>WILTON</td><td>GMAC</td><td>WSA</td><td>GPEC</td></tr>
<tr><td>No</td><td>No</td><td>No</td><td>Yes</td></tr>
<tr><td>EXPERT REPORT (BCAR PROCESS)</td><td colspan="5">There is no expert report for this species.</td></tr>
<tr><td rowspan="4">HABITAT MAPPING</td><td colspan="5">WITHIN THE NOMINATED AREAS</td></tr>
<tr><td colspan="5">Knowledge based map (KBM). Potential habitat polygons were generated using BioNet PCT associations, vegetation condition parameters (intact, thinned) and soils including Blacktown, Agnes Banks, Berkshire Park and Gymea.
Potential habitat was confined to within GPEC, as there are no records in Wilton and GMAC, and no records or suitable habitat in WSA, suggesting the species is unlikely to be present in those areas.
To refine these potential habitat polygons, targeted surveys for the species were then undertaken in a number of locations within the nominated areas.
It was not possible to access and survey all areas of potential habitat within the nominated areas. However, the species was not observed as part of surveys conducted through sections of suitable habitat in urban capable land.</td></tr>
<tr><td colspan="5">OUTSIDE THE NOMINATED AREAS</td></tr>
<tr><td colspan="5">Knowledge based map (KBM). Potential habitat polygons were generated using BioNet PCT associations, vegetation condition parameters (intact, thinned), elevation (below 50 m), geographic restrictions (species is primarily restricted to the Richmond (NW Cumberland subregion) district, but with an outlier population found at Voyager Point, Liverpool), and patch size (>40 ha, based on exclusion of small patches of vegetation not meeting the known geographic extent of the species).</td></tr>
<tr><td rowspan="2">POPULATION MAPPING</td><td colspan="5">RECORD SELECTION</td></tr>
<tr><td colspan="5">Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset.</td></tr>
</table>

	POPULATION DEFINITION
	Biological populations were defined using the records dataset and available information about the nature of the species. Biological populations were defined based on clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollination
	IMPORTANT POPULATION CRITERIA
	All populations of *A. glareicola* were considered important as the species is endangered

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.3 for a map of records and habitat across the Strategic Assessment Area
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	A total of 10 populations (from 36 BioNet records) have been mapped within the Strategic Assessment Area. All populations are considered important and one population is wholly or partly located in an existing conservation reserve. Of these: • Nine are located within the Londonderry area, including a large population (Population 3) within the Castlereagh Nature Reserve to the north of GPEC • One (Population 1) is located within a rail corridor along Hobart St in St Marys The outlier population that has been recorded within the Holsworthy Military Area is outside the Strategic Assessment Area. The baseline mapping for this assessment has mapped approximately 4,417.6 ha of known and potential habitat within the Strategic Assessment Area. This potential habitat is primarily associated with the vegetation in the Londonderry area. In addition to this, there are: • Three moderate sized patches of potential habitat – one associated with Shanes Park and Wianamatta Regional Park, one near Kemps Creek, and one in the Holsworthy area • Scattered and more isolated patches of potential habitat within each of the nominated areas, including a number of patches in GPEC and fewer, smaller patches in GMAC and Wilton It is important to note that surveys of the Outer Sydney Orbital for this project within the Wianamatta Regional Park did not identify the species, and it had not previously been recorded in the Park. A breakdown of occurrence for *A. glareicola* in the Strategic Assessment Area is provided in Table 29-52.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.14.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 21.9 ha of potential habitat within the nominated areas (not including excluded lands). Approximately 10.1 ha (45.9 per cent) of this has been avoided as part of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 10.0 ha was avoided for biodiversity purposes
- 0.1 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 29-53.

It is important to note that the avoidance calculations in Table 29-53, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 29-53 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

29.14.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.14.3 LOSS OF KNOWN POPULATIONS AND POTENTIAL HABITAT

Implementation of the Plan will not lead to any direct impacts to known populations or fragmentation of habitat. However, it will lead to the loss of potential habitat.

LOSS OF POTENTIAL HABITAT

The Plan will lead to the loss of 11.9 ha of potential habitat. This represents a very small percentage of the mapped potential habitat across the Strategic Assessment Area. These impacts relate to urban development in GPEC, near Orchard Hills.

A summary of these impacts is provided in Table 29-54.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of direct impacts to mapped habitat are considered to be very low. This risk ranking is triggered for impacts to species' habitat, as follows:

- The likelihood of actual impacts occurring to the species within mapped habitat has been categorised as unlikely. While there will be direct impacts to potential habitat within the vicinity of Orchard Hills, there is low confidence that the species will occur in the impact area because:
  - A small section of suitable habitat within urban capable land which could be accessed as part of this biodiversity certification process was surveyed and the species was not observed
  - It is generally considered unlikely that suitable habitat in this area contributes to the ongoing survival or viability of the species more broadly
- The consequence of impacts to the species (if they did occur) has been categorised as negligible. There will be a loss of <0.5 per cent of mapped potential habitat (endemic species, SAII species), with low confidence that the species occurs in the impact area

29.14.4 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the very low risk of residual adverse impacts to the species, offsets were not considered necessary for *A. glareicola*.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.14.5 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice for *A. glareicola* identifies a range of threats to the species (DEWHA, 2008a). Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Habitat degradation from rubbish dumping and unrestricted access
- Weed invasion
- Inappropriate fire regimes

HABITAT DEGRADATION

Habitat degradation through unrestricted public access and rubbish dumping have been identified as a key threat to *A. glareicola* (DEWHA, 2008a). Development within GPEC and WSA may lead to an increase in human activity within the species' known and potential habitat areas, and this may exacerbate the threat.

Populations of *A. glareicola* considered most at risk of this threat are those that occur on:

- Public land, as these areas are accessible without the deterrent that comes with trespassing. Only one recorded population, labelled Population 3, occurs on public land, within the Castlereagh Nature Reserve. This population comprises 11 of the 36 records for the species within the Strategic Assessment Area, making it one of the most significant known occurrences. Impacts associated with public access are an identified threat to the biodiversity of the Castlereagh Nature Reserve and restrictions, signage and management measures (such as rationalising the network of management trails) are already in place to address potential impacts (NSW NPWS, 1999). Assuming this management continues and adapts to potential increasing visitation over the life of the Plan, the risk to *A. glareicola* from disturbance in this area is expected to be adequately addressed.
- An area of freehold land to the north of GPEC which is often mistaken for Crown land, contains a number of access tracks, and issues associated with rubbish dumping have been recorded for the site.

The Plan incorporates a range of broader measures that are considered adequate to mitigating the risks associated with inappropriate habitat disturbance. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in locations where species habitat occurs in protected areas
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure

compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing

- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

WEED INVASION

A. glareicola is threatened with invasion and competition by weeds, with African lovegrass *(Eragrostis curvula)*, Whisky grass (*Andropogon virginicus*), *Pennisetum clandestinum*, *Ricinus communis* and Asparagus fern considered to be the main competitors. These weeds are already present within the Strategic Assessment Area. However, urban, transport and agricultural development within the northern half of the Strategic Assessment Area has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity that are expected to adequately manage the risk to the species. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA. This includes a number of actions, of which the following are the most relevant to the outcome of the species:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes:
  - Partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

INAPPROPRIATE FIRE REGIMES

A. glareicola can regenerate following fire. However, plants may be damaged and fruit production and seed set prevented by too frequent fires (DEWHA, 2008a). Increased human activity within the nominated areas increases the risk of fire to habitat areas supporting the species.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity that are expected to adequately manage the risk to the species. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for the species being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
    - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for the species. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes.

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to the development of essential infrastructure within nominated areas but outside the urban capable lands.

Mapped habitat does not occur within the tunnel footprints and the species is not at risk from impacts in those locations.

29.14.6 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

A small area of species habitat has been mapped within avoided lands in GPEC. Given the limited extent of habitat, impacts to habitat are considered unlikely due to essential infrastructure.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a results of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.14.7 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DEWHA, 2008a) identifies the following key issues that are likely to have the greatest influence on the long-term viability of *A. glareicola* in relation to implementation of the Plan:

- Habitat loss and fragmentation
- Indirect impacts including:
  - Habitat degradation from rubbish dumping and unrestricted access
  - Weed invasion
  - Inappropriate fire regimes

HABITAT LOSS AND FRAGMENTATION

Given the very low risk to the species associated with habitat loss and fragmentation, implementation of the Plan will not adversely influence the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts associated with habitat degradation, weed invasion, and inappropriate fire regimes will be managed and mitigated through a number of commitments and actions in the Plan. Indirect impacts will not adversely influence the long-term viability of the species.

CONCLUSION

The limited scale of direct and indirect impacts to the species will ensure that implementation of the Plan does not adversely influence the long-term viability of the species.

29.14.8 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

29.14.9 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-43 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For *A. glareicola*, there are no relevant Threat Abatement Plans.

Table 29-51: Relevant key Threatening Processes and associated Threat Abatement Plans for *A. glareicola*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

29.15 *MELALEUCA DEANEI* (DEANE'S MELALEUCA)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	*Melaleuca deanei* is a flaky-barked shrub with narrow pointed leaves and white flowers. Grows to 3m tall. (DoEE, 2018c)
ECOLOGY	Flowers in mid-October to December. Produces seeds infrequently and relies on clonal reproduction. Seeds can be held for up to 15 years, until fire, frost or drought triggers their release. (DoEE, 2018c) Longevity of individuals can be 100 years. (NSW DECCW, Goeth et al., 2010)
DISTRIBUTION AND HABITAT	Records occur primarily in the Ku-ring-gai/Berowra and Holsworthy/Wedderburn areas. Isolated records also occur in Springwood, Wollemi National Park, Yalwal and Central Coast areas. It is known to occur in the Cumberland IBRA subregion (OEH, 2019e). More than 50 per cent of all populations are protected in nature reserves or national parks (NSW DECCW, Goeth et al., 2010). Inhabits ridgetop woodland and wet heath, on sandstone and sandy soils (DoEE, 2018c; OEH, 2019e). The majority of records come from ridgetop woodland (OEH, 2019e). *M. deanei* is associated with sandy loam soils which are low in nutrients (NSW DECCW, Goeth et al., 2010).
POPULATIONS	As of 1993, the species was known from 94 populations, of which very few were considered reproductively viable. In 1993, it was estimated that there were 1,000-3,000 individuals of this species though this was likely as a ramet (stem) count. Population distribution is fragmented. (DoEE, 2018c) An important population has been identified in Holsworthy Military Reserve, it contains 17 per cent of the known population outside formal conservation reserves (NSW DECCW, Goeth et al., 2010).
SOS SITES	The following SOS sites for the species have been identified: • Ku-ring-gai Chase National Park • Berowra Valley National Park • Holsworthy • Nepean-Avon Plateau • Nepean Dam

RELEVANT PLANS AND POLICIES	National Recovery Plan for *Melaleuca deanei* F. Muell. (Deane's Paperbark) (NSW DECCW, Goeth et al., 2010)
SPECIES-SPECIFIC GUIDELINES	There are no specific impact guidelines for this species
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=5818

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

</table>

	IMPORTANT POPULATION CRITERIA
	Populations of *M. deanei* were then categorised as important or not-important based on the methodology set out in Section 11.5.3 of Chapter 11. Populations of *M. deanei* were considered important because they met one or more of the following criteria: • A large population • A population within a conservation reserve • A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.13 for a map of records and habitat across the Strategic Assessment Area
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 29-56 at the end of this species assessment for a breakdown of the occurrence of records and habitat for *M. deanei* in the Strategic Assessment Area. **Records** There are two populations which have been identified within the Strategic Assessment Area, both of which are important populations. One population (population 77) is located adjacent to the confluence of Allens Creek with Stringybark Creek, within Wilton. This population occurs within the boundary of a previously approved development under the EPBC Act (EPBC 2014/7400). The other population (population 520) occurs on the eastern edge of the Strategic Assessment Area to the north-east of Campbelltown, within the footprint of the proposed Georges River Koala Reserve. It is noted that numerous additional records of this species occur in remnant vegetation outside of the Strategic Assessment Area boundary, in areas to the south of Wilton and to the east of Appin, Campbelltown and Macquarie Fields. **Potential habitat** The baseline mapping for this assessment has mapped 14,445.1 ha of known and potential habitat within the Strategic Assessment Area. Habitat for this species tends to occur along the south-eastern, southern, western and north-western boundary of the Strategic Assessment Area, with an absence of potential habitat throughout the middle and north-eastern areas of the assessment area. With respect to the nominated areas, well-connected habitat is mapped within Wilton and the southern section of GMAC, which strongly corresponds to the locations of wooded areas in these localities. There is no habitat mapped within GPEC or WSA. Outside of the nominated areas, habitat is mapped as follows: • Well-connected habitat occurs along the Strategic Assessment Area boundary, from the Holsworthy locality, down to the southern portion of the Strategic Assessment Area (including localities such as Douglas Park, Bargo and Tahmoor) • Moderately connected habitat patches occur along the western boundary of the Strategic Assessment Area between Orangeville in the south through to Mulgoa in the north • Small, scattered patches of habitat occur in the north-west corner of the Strategic Assessment Area in the Kurrajong locality

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.15.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 1,757.5 ha of potential habitat within the nominated areas (not including excluded lands). Approximately 1,655.1 ha (94.2 per cent) has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 1,553.3 ha was avoided for biodiversity purposes.
- 101.7 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 29-57.

It is important to note that the avoidance calculations in Table 29-57, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 29-57 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

29.15.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.15.3 LOSS OF KNOWN POPULATIONS AND POTENTIAL HABITAT

Implementation of the Plan will lead to loss of potential habitat. It will not lead to direct impacts to known populations or fragmentation of potential habitat or populations. A summary of these impacts is provided in Table 29-58.

LOSS OF POTENTIAL HABITAT

Approximately 102.5 ha of potential habitat for the species will be lost. This is 0.7 per cent of mapped potential habitat across the Strategic Assessment Area. The loss of potential habitat occurs within GMAC and Wilton.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of impacts to mapped habitat are considered to be very low. This risk ranking is triggered for impacts to species' habitat, as follows:

- The likelihood of actual impacts occurring to the species within mapped habitat has been categorised as possible. While there will be direct impacts to potential habitat, there is moderate confidence that the species will occur in the impact area. This is because of the small number of records of the species in the vicinity of impacted habitat, and based on knowledge that mapped habitat is precautionary as the species is naturally rare and patchily distributed (Douglas, 2019c)

- The consequence of impacts to the species (if they did occur) has been categorised as negligible. There will be a loss of <2 per cent of mapped potential habitat (vulnerable species), with moderate confidence that the species occurs in the impact area

29.15.4 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the very low risk of residual adverse impacts to the species, offsets were not considered necessary for *M. deanei.*

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the potential indirect impacts to the species that may occur as a result of development under the Plan. It also outlines if the generic management strategies in the Plan will be adequate for addressing indirect impacts, or if species-specific commitments are necessary.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.15.5 RELEVANT POTENTIAL INDIRECT IMPACTS

The Recovery Plan (NSW DECCW, Goeth et al., 2010) (and other key documents) for *M. deanei* identify a range of threats to the species. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats in key species documents) are considered relevant to implementation of the Plan:

- Inappropriate fire regimes and mechanical methods of bushfire fuel reduction
- Inappropriate habitat disturbance from construction and maintenance of tracks and easements, unrestricted access and rubbish dumping
- Weed invasion

Low fecundity and viability, hybridisation and trampling/plant damage due to army training exercises have also been identified as key threats. However, this is not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate these threats across the Strategic Assessment Area.

There are two known populations of *M. deanei* within the Strategic Assessment Area. Population 520 occurs on the eastern edge of the Strategic Assessment Area within the footprint of the proposed Georges River Koala Reserve, and subsequently is not considered to be at risk of indirect impacts under the Plan due to its distance from urban capable land and the fact that the site will be managed for conservation purposes.

Population 77 occurs within Wilton, and is located within habitat which is managed in accordance with an approved development under the EPBC Act (EPBC 2014/7400). Approval conditions which protect this population from indirect impacts include fencing to restrict access, and preparation of an environmental management plan for the approval of the Commonwealth to deal with pressures to the population. Overall, population 77 is not considered to be at risk of indirect impacts under the Plan as it has existing site management to protect the species from indirect impacts.

The following assessments therefore consider the potential impacts of development under the Plan upon mapped potential habitat for *M. deanei.* The areas which are most at risk of impact include mapped habitat within Wilton and the southern portion of GMAC, which occurs close to urban capable lands.

INAPPROPRIATE FIRE REGIMES AND MECHANICAL METHODS OF BUSHFIRE FUEL REDUCTION

Inappropriate fire regimes are an identified threat to *M. deanei* (NSW DECCW, Goeth et al., 2010). Increased human activity within the nominated areas has the potential to alter fire regimes, through potentially increasing fire frequencies in some areas, and decreasing fire frequencies in others, through the following mechanisms:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk

- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

It is additionally noted that mechanical bushfire reduction methods of habitat in close proximity to urban and other kinds of development pose a risk to *M. deanei* (NSW DECCW, Goeth et al., 2010).

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for *M. deanei* being:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the Strategic Conservation Areas that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for *M. deanei.* While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes.

The package of measures in the Plan is expected to adequately manage the risk to *M. deanei* from altered fire regimes as a result of development. This is because:

- Establishment of environmental zoning of approximately 1,655.1 ha of mapped potential habitat of *M. deanei* within avoided lands will enable establishment of an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting mapped potential habitat and/or known records for *M. deanei* which is located adjacent to urban capable lands
- Fire management authorities will be engaged to ensure they understand the requirements of *M. deanei* and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas (it is noted there is 7,288.6 ha for *M. deanei* mapped within the SCAs)

INAPPROPRIATE HABITAT DISTURBANCE FROM CONSTRUCTION AND MAINTENANCE OF TRACKS AND EASEMENTS, UNRESTRICTED ACCESS AND RUBBISH DUMPING

Impacts relating to construction and maintenance of tracks and easements, unrestricted site access and rubbish dumping have been identified as threats to *M. deanei* (NSW DECCW, Goeth et al., 2010). Areas most at risk included areas of mapped potential habitat within Wilton and GMAC.

The Plan includes a species-specific measure to consult with land managers of land containing known populations or habitat for *M. deanei* to mitigate indirect impacts from habitat disturbance during construction and operation of the development, including controlling public access, managing maintenance activities such as mowing and weed control, and managing rubbish dumping.

The Plan further incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for *M. deanei.* In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance. It is noted that 1,655.1 ha of potential habitat for *M. deanei* is mapped to occur within avoided lands

- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations. It is noted that approximately 7,288.6 ha of potential habitat for *M. deanei* is mapped to occur within SCAs
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas. This commitment is consistent with a number of actions in the Conservation Advice around educating the community about *M. deanei*

The package of measures in the Plan is expected to adequately manage the risk to *M. deanei* from inappropriate habitat disturbance as a result of development. This is because:

- A species-specific measure will require consultation with land managers to ensure protection of *M. deanei* from inappropriate habitat disturbance
- Avoided lands where mapped habitat for *M. deanei* occurs will be zoned appropriately to enable an adequate framework for management
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

WEED INVASION

Inappropriate fire regimes are an identified threat to *M. deanei* (NSW DECCW, Goeth et al., 2010). Areas most at risk of weed invasion due to development under the Plan included areas of mapped potential habitat within Wilton and GMAC.

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Area. This includes a number of actions, of which the following are the most relevant to the outcome for *M. deanei*:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes:
  - Partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:

- Require proponents to undertake the following when applying for/undertaking development:
  - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
  - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
  - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
- Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

The package of measures in the Plan is expected to adequately manage the risk to *M. deanei* from the increased risk of weeds associated with development. This is because:

- There are commitments (Commitment 16 and Commitment 23) which will coordinate, enable and conduct effective weed control programs in strategic locations within the Strategic Assessment Area to manage priority weed species
- Proponents will be required to minimise the risk of weed spread, and to manage weeds, during the design, development and operational stages of development
- Establishment of environmental zoning of 1,655.1 ha of mapped potential habitat of *M. deanei* within avoided lands will enable establishment of an adequate framework for management of weeds in these areas

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to the development of essential infrastructure within nominated areas but outside the urban capable lands.

It is noted that there is no mapped potential habitat, and no known records of the species, within either the OSO tunnel footprint or the Metro Rail Future Extension tunnel footprint. It is therefore considered unlikely that development within the tunnel footprints will negatively impact *M. deanei*.

29.15.6 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

There are no known records of *M. deanei* within avoided lands in any of the nominated areas. However, there is 1,655.1 ha of potential habitat mapped for the species within avoided lands within Wilton and GMAC, and therefore it is considered to be possible that the species may occur within avoided lands in these nominated areas.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.15.7 IMPLICATIONS FOR LONG-TERM VIABILITY

The Recovery Plan (NSW DECCW, Goeth et al., 2010) and other key documents identifies the following key issues that are likely to have the greatest influence on the long-term viability of *M. deanei* in relation to implementation of the Plan*:*

- Habitat loss and fragmentation
- Indirect impacts including:
  - Inappropriate fire regimes and mechanical methods of bushfire fuel reduction
  - Inappropriate habitat disturbance from construction and maintenance of tracks and easements, unrestricted access and rubbish dumping
  - Weed invasion

HABITAT LOSS AND FRAGMENTATION

As outlined above, implementation of the Plan will lead to loss of 102.5 ha of mapped habitat within the nominated areas and transport corridors. No fragmentation of species' habitat will occur.

Based on the application of the risk assessment method, the overall risk of residual adverse impacts associated with these direct impacts is <u>low.</u> The total area of potential habitat which will be impacted is a small proportion of available habitat for the species with only moderate confidence of the species' presence in impacted areas.

The Plan includes a broader set of commitments and actions which are likely to benefit the species, which includes commitments to protect land within the SCAs which contain approximately 7,288.6 ha of potential habitat for *M. deanei.*

On balance, direct impacts associated with implementation of the Plan are not expected to threaten the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts of development corridors associated with inappropriate fire regimes and mechanical methods of bushfire fuel reduction, inappropriate habitat disturbance from construction and maintenance of tracks and easements, unrestricted access and rubbish dumping, and weed invasion have been analysed and determined to be adequately managed and mitigated through the generic management strategies in the Plan, and through a species-specific commitment to minimise the impacts inappropriate habitat disturbance.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

The limited scale of direct impacts to the species habitat and the management measures in the Plan to address potential indirect impacts will ensure that the implementation of the Plan does not adversely influence the long-term viability of the species.

29.15.8 CONSISTENCY WITH RECOVERY PLAN

In accordance with Section 146K of the EPBC Act, this section considers whether the implementation of the Plan is not inconsistent with the species' Recovery Plan. It considers two questions:

- Does the Plan prevent achievement of the objectives of the Recovery Plan?
- Does the Plan prevent implementation of the Recovery Plan actions?

These questions are discussed below.

DOES THE PLAN PREVENT ACHIEVEMENT OF THE OBJECTIVES OF THE RECOVERY PLAN?

The overall objective of the Recovery Plan (NSW DECCW, Goeth et al., 2010) is to prevent the status of *M. deanei* from becoming critically endangered by reducing the further loss of populations and, by implementing in-situ management regimes aimed at maintaining representative populations of the species' across its natural range. Specific objectives include:

- Coordinate the recovery of *M. deanei*
- Protect known occurrences of *M. deanei* using land-use and conservation planning mechanisms
- To identify and minimise the threats operating at *M. deanei* sites
- To improve awareness of *M. deanei* amongst operational staff working within easements, walking tracks and fire trails
- To promote surveys, research and monitoring that will assist with the management of *M. deanei*
- To provide stakeholders with information that assist in conserving *M. deanei*
- To raise awareness about the threats to the species and involve the community in the recovery program
- To coordinate an ex-situ conservation program to safeguard genetic material from extinction

Implementation of the Plan will support a number of these strategies and will not prevent the achievement of the objectives of the Recovery Plan.

DOES THE PLAN PREVENT THE IMPLEMENTATION OF THE RECOVERY PLAN ACTIONS?

The Recovery Plan identifies a set of actions to support the overall recovery of *Melaleuca deanei*. The Plan will not prevent implementation of any of the actions.

29.15.9 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-55 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For *M. deanei*, there are no relevant Threat Abatement Plans.

Table 29-55: Relevant key Threatening Processes and associated Threat Abatement Plans for *M. deanei*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

29.16 *MICROMYRTUS MINUTIFLORA*

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	*Micromyrtus minutiflora* is a slender spreading shrub. Grows to 2 m high. Flowers are solitary but can be abundant on plants and have small white petals. (DEWHA, 2008f)
ECOLOGY	Flowers sporadically from June to March. Response to disturbance (such as fire or mechanical disturbance) is uncertain. Regeneration may occur as a result of re-sprouting, or germination of seeds stored within the soil. (OEH, 2019f)
DISTRIBUTION AND HABITAT	Endemic to the western parts of the Cumberland Plain in the Richmond-Castlereagh area of the Sydney Region. The distribution overlaps with the following TECs: • Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest • Cooks River/Castlereagh Ironbark Forest • Castlereagh Scribbly Gum and Agnes Banks Woodlands Grows in Scribbly Gum Woodland, Ironbark Forest, Shale Gravel Transition Forest, open forest on tertiary alluvium and consolidated river sediments. (DEWHA, 2008f; OEH, 2019f)
POPULATIONS	As of 1997, there were over 1,160 individuals in the ADI Site and 500 individuals present in Marsden Park. As of 2002, there were 11 population sites with approximately 1,800 individuals across the Blacktown, Hawkesbury and Penrith Local Government Areas. Populations range from fewer than 50 plants to over 1,000. (DEWHA, 2008f) The 2016 fire in Wianamatta Nature Reserve has seriously affected the total known individuals and regeneration post fire has not yet been seen. This may have led to the loss of more than 60 per cent of the known individuals. Assessment of all BioNet records of the species indicates that over 90 per cent of known records occur within the Cumberland subregion. Therefore, for the purposes of this assessment, *M. minutiflora* is considered to be an endemic species to the region. It is further noted that this species has been identified as an SAII species under the BCAR process. Refer to Chapter 25 for further information.

SOS SITES	The following SOS site for the species has been identified: Wianamatta Nature Reserve
RELEVANT PLANS AND POLICIES	Approved conservation advice for *Micromyrtus minutiflora* (DEWHA, 2008f)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=11485

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	No	No	Yes	Yes

EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS** **Knowledge based map (KBM).** Potential habitat polygons were generated using BioNet PCT associations, vegetation condition (intact, thinned, scattered trees) and elevation (up to 50 m). To refine these potential habitat polygons, targeted surveys for the species were then undertaken in a number of locations within the nominated areas. The species was not recorded during surveys. **OUTSIDE THE NOMINATED AREAS** **Species distribution model (SDM).** Potential habitat outside the nominated areas was mapped using an SDM. No targeted surveys as part of this project were undertaken outside the nominated areas.
POPULATION MAPPING	**RECORD SELECTION** Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset. **POPULATION DEFINITION** Biological populations were defined using the records dataset and available information about the nature of the species. Populations were defined by clustered records connected by relatively intact and continuous vegetation and not separated by a distance of >1 km (approx.). This is based on the distance travelled by insect pollinators and potential unrecorded individuals. **IMPORTANT POPULATION CRITERIA**

	All populations of *M. minutiflora* were considered important within the Strategic Assessment Area because the species is identified as an SAII entity through the BC Act process.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.14 for a map of records and habitat across the Strategic Assessment Area
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	A total of 15 populations (from 180 BioNet records) have been mapped within the Strategic Assessment Area. All populations are considered important and five populations are wholly or partly located in existing conservation reserves. The majority of the populations are located to the north of GPEC and one population (Population 108) occurs within GPEC. The baseline mapping for this assessment has mapped approximately 36,680.4 ha of known and potential habitat within the Strategic Assessment Area. This habitat is primarily associated with the vegetation in the Londonderry area. In addition to this, there are: • Small, scattered areas of habitat to the north and south of the Londonderry Area, including scattered habitat within GPEC and WSA • Scattered areas of habitat across the southern areas of the Strategic Assessment Area, in the area bounded by Silverdale in the north-west, Camden in the centre north, Liverpool in the north-east and the Strategic Assessment Area boundary along the south. It is noted that there is no mapped habitat within Wilton and only very small and isolated areas of potential habitat within GMAC It is also noted that the southernmost record known for this species occurs near Mulgoa, and that no records of the species have ever been found within or south of Silverdale or Liverpool. Therefore, whilst potential habitat has been mapped for this species within the southern portion of the Strategic Assessment Area through the SDM mapping, it is considered unlikely that this mapped habitat would be occupied by the species. A breakdown of occurrence for *M. minutiflora* in the Strategic Assessment Area is provided in Table 29-60.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.16.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 50.3 ha of potential habitat within the nominated areas (not including excluded lands). Approximately 28.3 ha (56.2 per cent) has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 27.9 ha was avoided for biodiversity purposes
- 0.3 ha was avoided for other reasons

A breakdown of avoidance across each nominated area is provided in Table 29-61.

It is important to note that the avoidance calculations in Table 29-61, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 29-61 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

29.16.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.16.3 LOSS OF KNOWN POPULATIONS AND POTENTIAL HABITAT

Implementation of the Plan will not lead to direct impacts to known populations. However, it will lead to:

- A loss of potential habitat
- Fragmentation of potential habitat

LOSS OF POTENTIAL HABITAT

Approximately 160.3 ha of potential habitat will be lost. This is 0.4 per cent of mapped potential habitat across the Strategic Assessment Area. Habitat will be impacted:

- In several parts of the Outer Sydney Orbital corridor to the west of GMAC. Impacts in these areas account for the majority of the habitat to be lost (138.3 ha). It is noted that these areas are to the south of the known range of the species, and occur in habitat mapped through the SDM process which is considered to be very precautionary
- In small areas in GPEC and WSA

A summary of these impacts is provided in Table 29-62.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of impacts to mapped habitat are considered to be very low. This risk ranking is triggered for impacts to species' habitat, as follows:

- The likelihood of actual impacts occurring to the species within mapped habitat has been categorised as unlikely. While there will be direct impacts to potential habitat, there is low confidence that the species will occur in the impact areas. This is because:
  - The majority of impacts occur beyond the known southern range of the species
  - Other impacts occur to small, fragmented patches of potential habitat that do not occur within the vicinity of records
- The consequence of impacts to the species (if they did occur) has been categorised as negligible. There will be a loss of <0.5 per cent of mapped potential habitat (SAII, endemic species), with low confidence that the species occurs in the impact areas

29.16.4 FRAGMENTATION OF HABITAT

FRAGMENTATION IMPACTS

The Plan will lead to fragmentation of mapped habitat in the several parts of the Outer Sydney Orbital corridor to the west of GMAC.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of fragmentation is considered to be very low. This is because:

- The likelihood of fragmentation has been categorised as unlikely. This is because:
  - The likelihood that development is presents a barrier to dispersal of the species is possible. While there are uncertainties about the ecology of the species, it is possible that the Outer Sydney Orbital would present a barrier to pollination if the species were present in that area
  - The type of fragmentation is impact to mapped habitat only
- The consequence of fragmentation has been categorised as negligible. This is because the Plan will lead to fragmentation of mapped habitat in an area that the species is unlikely to occur

29.16.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the very low risk of residual adverse impacts to the species, offsets were not considered necessary for *M. minutiflora*.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.16.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice for *M. minutiflora* identifies a range of threats to the species (DEWHA, 2008f). Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Habitat degradation

INAPPROPRIATE FIRE REGIMES

The response of *M. minutiflora* to fire is unknown. However, altered fire regimes are an identified threat (DEWHA, 2008f) and a 2016 fire in the Wianamatta Nature Reserve (outside of the nominated areas to the north of GPEC) may have substantially affected the species. Increased human activity within the nominated areas increases the risk of fire to habitat areas supporting the species.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity that are expected to adequately manage the risk to the species. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for the species being:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for the species. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

WEED INVASION

M. minutiflora is threatened with invasion and competition by weeds. Weeds are already present within the Strategic Assessment Area. However, urban, transport and agricultural development within the northern half of the Strategic Assessment Area has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

M. minutiflora is most susceptible to the threat of weeds from development under the Plan where new urban growth or transport occur adjacent to known populations or habitat. Key risk areas include:

- Population 108 that occurs within GPEC
- The various populations to the north of GPEC

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity that are expected to adequately manage the risk to the species. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA. This includes a number of actions, of which the following are the most relevant to the outcome of the species:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:

  - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
  - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
  - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
- Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

HABITAT DEGRADATION

Habitat degradation through unrestricted public access and rubbish dumping have been identified as a key threat to *M. minutiflora* (DEWHA, 2008f). Development within GPEC and WSA may lead to an increase in human activity within the species' known and potential habitat areas, and this may exacerbate the threat.

Populations of *M. minutiflora* considered most at risk of this threat are those that occur on:

- Public land, as these areas are accessible without the deterrent that comes with trespassing. Populations occur on the following public land managed for conservation: Castlereagh Nature Reserve, Wianamatta Nature Reserve, Wianamatta Regional Park and Agnes Banks Nature Reserve. Potential impacts associated with public access are managed in all of these areas. Assuming this management continues and adapts to potential increasing visitation over the life of the Plan, the risk to *M. minutiflora* from disturbance is expected to be adequately addressed
- An area of freehold land to the north of GPEC which is often mistaken for Crown land, contains a number of access tracks, and issues associated with rubbish dumping have been recorded for the site. In the absence of tighter controls over access, there is potential for increased disturbance to occurrences of *M. minutiflora* on this site as a result of the Plan

The Plan incorporates a range of measures that are considered adequate to mitigating the risks associated with inappropriate habitat disturbance. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in locations where species habitat occurs in protected areas
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to:

- The development of essential infrastructure within nominated areas but outside the urban capable lands
- Tunnels associated with transport projects

29.16.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

Small areas of species habitat have been mapped within avoided lands in GPEC and WSA. Given the limited extent of habitat, impacts to habitat are considered unlikely due to essential infrastructure.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a results of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

29.16.8 POTENTIAL IMPACTS FROM TUNNELS

Mapped habitat occurs within the footprint of the Metro Rail Future Extension tunnel. However, as noted previously this habitat is beyond the known southern range of the species and it is not considered likely to be present.

Nevertheless, the Plan includes commitments to:

- Avoid and minimise impacts to threatened species, populations and communities as a result of tunnel construction activities in major infrastructure corridor
- Mitigate any potential indirect impacts (e.g. changes to hydrology, ground settling or subsidence) from the transport corridors as part of a future environmental impact assessment process

These commitments are expected to adequately address threats to the species (if it was to be present) in the tunnel footprints from the construction and operation of the tunnels. See Section 36.6 in Chapter 36 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.16.9 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DEWHA, 2008f) identifies the following key issues that are likely to have the greatest influence on the long-term viability of *M. minutiflora* in relation to implementation of the Plan:

- Habitat loss
- Indirect impacts including:

- Inappropriate fire regimes
- Weed invasion
- Habitat degradation

HABITAT LOSS AND FRAGMENTATION

Given the very low risk to the species associated with habitat loss and fragmentation, implementation of the Plan will not adversely influence the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts associated with inappropriate fire regimes, weed invasion, and habitat degradation from increase public access and will be managed and mitigated through a number of commitments and actions in the Plan (see Chapter 15 for details). Indirect impacts will not adversely influence the long-term viability of the species.

CONCLUSION

The limited scale of direct and indirect impacts to the species will ensure that implementation of the Plan does not adversely influence the long-term viability of the species.

29.16.10 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

29.16.11 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-43 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For *M. minutiflora* there are no relevant Threat Abatement Plans.

Table 29-59: Relevant key Threatening Processes and associated Threat Abatement Plans for *M. minutiflora*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

29.17 *PERSICARIA ELATIOR* (TALL KNOTWEED)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	*Persicaria elatior* is an erect herb up to 90 cm tall. Leaves are 3 cm to 11 cm long and 1cm to 3 cm wide. Stalked, glandular hairs are present on most parts of the plant. Flowers on long, narrow, spikes of up to 5 cm long. Pink flower-segments are less than 4 mm in length. Fruits are lens-shaped nuts approximately 2.5 mm long. (DEWHA, 2008g; DoEE, 2018c)
ECOLOGY	*P. elatior* germinates from seed following rain events, and lives for up to two years. Plants grow rapidly; flowering and seed set occurs within six months of germination. Flowering mostly occurs during summer, and profuse flowering has been observed. Plants die back during dry periods, and regenerate during wet periods. This species has been observed to take advantage of areas of soil which had been made bare by dry periods. (DoEE, 2018c)
DISTRIBUTION AND HABITAT	This species has a patchy distribution along the south-eastern coastal regions of Australia, from south-east Queensland to south-east NSW. In NSW, the species occurs in the North Coast, Central Coast and South Coast Botanical Subdivisions, whilst it occurs in the Moreton Pastoral District in Queensland. The species has been recorded from a total of 15 sites across this area. *P. elatior* grows in damp places, such as along watercourses, streams and lakes, in swamp forest, in coastal swampy areas and in disturbed areas. The species grows on sandy, alluvial soil. Associated plant species include *Melaleuca linearifolia, M. quinquenervia, Pseudognaphalium luteoalbum, Persicaria hydropiper*, and *Cyperus semifertilis*. The distribution of this species overlaps with the distribution of the following EPBC Act-listed threatened ecological community: Coastal Swamp Oak (*Casuarina Glauca*) Forest. (DEWHA, 2008g; DoEE, 2018c)
POPULATIONS	There is limited information regarding populations of this species. As of 2008, 12 specimens were recorded at Cornubia Wetland in Queensland. Population data is not available for other sites of this species. (DoEE, 2018c)
SOS SITES	The following SOS sites for the species have been identified: • Mallanganee (proposed)

	• Gibberagee (proposed) • Wanda wetlands (proposed) • Bevian swamp (proposed)
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Persicaria elatior* (Knotweed) (DEWHA, 2008g)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species.
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=5831

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	No	Yes	Yes	Yes
EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.				
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS**				
	Knowledge based map (KBM). Mapping within the nominated areas was prepared using the following parameters: BioNet PCT associations, vegetation condition (intact, thinned, scattered trees, derived native grassland) and habitat mapped within vegetation polygons occurring within 50 m of the following HydroAreas: Anabranch, Backwater, Billabong, Branch, Cowal, Creek, Pond, River, Stream, Swamp, Watercourse, Waterway. Habitat PCTs restricted to soils South Creek, Richmond, Freemans Reach, Berkshire Park and Upper Castlereagh.				
	OUTSIDE THE NOMINATED AREAS				
	Knowledge based map (KBM). Mapping outside the nominated areas was prepared using the following parameters: BioNet PCT associations, vegetation condition (intact, thinned, scattered trees, derived native grassland) and habitat mapped within vegetation polygons occurring within 50 m of the following HydroAreas: Anabranch, Backwater, Billabong, Branch, Cowal, Creek, Pond, River, Stream, Swamp, Watercourse, Waterway.				
POPULATION MAPPING	**RECORD SELECTION**				
	Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset.				
	POPULATION DEFINITION				
	Biological populations were defined using the records dataset and available information about the nature of the species.				

	They were defined based on clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollination.
	IMPORTANT POPULATION CRITERIA
	Populations of *P. elatior* were considered important because they met one or more of the following criteria: A large population (number of individuals)

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.15 for a map of records and habitat across the Strategic Assessment Area
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	One important population of *P. elatior* has been mapped partially inside the Strategic Assessment Area. This population was recorded on the edge of a lake in moist soil. It comprises three BioNet records, two recorded from 2010 and one recorded from 1949. The 2010 records occur just outside the south-western boundary of the Strategic Assessment Area, in Thirlmere Lakes National Park. A "large number of plants" were noted in one of the 2010 records. The 1949 record is inaccurately mapped to the east of Picton, within the Strategic Assessment Area. The text descriptions of the record indicate this record should be placed at Thirlmere Lakes. The baseline mapping for this assessment has mapped 1,703.4 ha of potential habitat within the Strategic Assessment Area (see Table 29-64). Potential habitat has been mapped within the Strategic Assessment Area in the following localities: • Along the Nepean River and associated waterways between Douglas Park and Mulgoa, and between Emu Plains and Wilberforce • Along Wianamatta (South Creek) and associated waterways between Mulgrave and Kemps Creek • Along the Georges River and associated waterways near Liverpool Mapped habitat occurs within: • GPEC – 220.7 ha • WSA – 37.6 ha • GMAC – 7.3 ha

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.17.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 85 ha of potential habitat within the nominated areas (not including excluded lands). Approximately 37.8 ha (45.5 per cent) has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 13.2 ha was avoided for biodiversity purposes
- 24.6 ha was avoided for other reasons

A breakdown of avoidance across each nominated area is provided in Table 29-65.

It is important to note that the avoidance calculations in Table 29-65, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 29-65 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

29.17.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.17.3 LOSS OF KNOWN POPULATIONS AND POTENTIAL HABITAT

Implementation of the Plan will not lead to direct impacts to known populations. However, it will lead to the loss of potential habitat and possible fragmentation.

LOSS OF POTENTIAL HABITAT

The Plan will lead to the loss of 48.3 ha of potential habitat. This represents 2.8 per cent of potential habitat mapped across the Strategic Assessment Area. The majority of habitat loss occurs within GPEC, where the footprint of the proposed Outer Sydney Orbital coincides with Wianamatta (South Creek) and associated waterways. It is noted that no records of this species have been recorded within or near to GPEC, and the Strategic Assessment Area more broadly appears unlikely to support records of the species.

A summary of these impacts is provided in Table 29-66.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of direct impacts to mapped habitat are considered to be very low. This risk ranking is triggered for impacts to species' habitat, as follows:

- The likelihood of actual impacts occurring to the species within mapped habitat has been categorised as unlikely. While there will be direct impacts to potential habitat, there is low confidence that the species will occur in the impact area. There are no confirmed records of the species within the Strategic Assessment Area and it is considered that the habitat mapping is highly precautionary
- The consequence of impacts to the species (if they did occur) has been categorised as minor. There will be a loss of 2.8 per cent of mapped potential habitat, with low confidence that the species occurs in the impact area

29.17.4 FRAGMENTATION OF HABITAT

The footprint of the proposed Outer Sydney Orbital intersects mapped habitat along Wianamatta (South Creek) in GPEC.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of fragmentation is considered to be very low. This is because:

- The likelihood of fragmentation has been categorised as possible. This is because:
  - The likelihood that development would present a barrier to dispersal of the species is likely. While detailed planning for development within the transport corridors has not yet been completed, it is thought to be likely that the OSO will constitute a likely barrier to dispersal for the species
  - The type of fragmentation (as defined in the risk assessment approach in Section 29.3) is impact to mapped
- The consequence of fragmentation has been categorised as negligible. This is because the area to be fragmented relates to a small area of potential habitat with no associated records

29.17.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the very low risk of residual adverse impacts to the species, offsets were not considered necessary for *P. elatior*.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.17.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice for *P. elatior* identifies a range of threats to the species (DEWHA, 2008g). Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Hydrological changes to wetlands
- Damage to populations from road and track maintenance
- Weed invasion

However, it is considered unlikely that any of these potential impacts will adversely affect *P. elatior* within or surrounding the Strategic Assessment Area for the following reasons:

- There are no identified populations of this species within the Strategic Assessment Area
- The closest identified important population is located at Thirlmere Lakes National Park. This population is separated by a distance of approximately 7 km to the nearest urban capable land and is within an area already managed for conservation
- While potential habitat within and adjacent to GMAC, WSA and GPEC may be subject to indirect impacts, the species has not been recorded in this area and it is therefore unlikely to be important to the viability of the populations in the region

It is worth noting that the Plan includes a range of measures that will protect biodiversity (e.g. protection of large areas of land, fire management strategy, weed control implementation strategy, pest animal control implementation strategy, development controls to manage changes to hydrology). These measures will benefit all biodiversity in the Cumberland subregion and may potentially relate to this species if it is present in the Strategic Assessment Area.

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

Given the low likelihood of the species occurring within the Strategic Assessment Area, it is not considered likely that there will be additional risks due to essential infrastructure or tunnels.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.17.7 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DEWHA, 2008g) identifies the following key issues that are likely to have the greatest influence on the long-term viability of *P. elatior* in relation to implementation of the Plan:

- Habitat loss
- Indirect impacts including:
  - Hydrological changes to wetlands
  - Damage to populations from road and track maintenance
  - Weed invasion

HABITAT LOSS AND FRAGMENTATION

Given the very low risk to the species associated with habitat loss and fragmentation, implementation of the Plan will not adversely influence the long-term viability of the species.

INDIRECT IMPACTS

Indirect impacts associated with implementation of the Plan are not considered likely to be an issue for the species. However, there are a range of measures in the Plan that may provide a benefit to the species if it did exist in the Strategic Assessment Area.

CONCLUSION

The Plan will not lead to direct impacts to known populations of *P. elatior*. The Strategic Assessment Area does not appear to be a stronghold for the species and potential indirect impacts are addressed through management measures in the Plan.

This will ensure that implementation of the Plan does not adversely influence the long-term viability of *P. elatior*.

29.17.8 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

29.17.9 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-43 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For *P. elatior*, there are no relevant Threat Abatement Plans.

Table 29-63: Relevant key Threatening Processes and associated Threat Abatement Plans for *P. elatior*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

29.18 *PERSOONIA HIRSUTA* (HAIRY GEEBUNG)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Endangered
DESCRIPTION	The Hairy Geebung is a spreading shrub with small leaves of variable shape and yellow or orange tubular flowers on a short stem that grows into a leafy shoot. Long coarse hairs appear on flowers and short stiff ones on leaves. Grows from 0.3-1.5m tall. (DoE, 2014f; DoEE, 2018c)
ECOLOGY	Flowers in November to January, with flowers occasionally appearing as early as September. All *Persoonia* species rely upon insect pollination. It is likely that *Persoonia* pollination movement would occur within a distance of 130 m from each plant. This species is probably killed by fire, yet will regenerate from seed. All *Persoonia* species are dependent on heat or mechanical disturbance for germination. It is often found in disturbed areas such as along track edges. (DoE, 2014f; DoEE, 2018c)
DISTRIBUTION AND HABITAT	Records of this species are scattered around Sydney from Singleton in the north, along the east coast to Bargo in the south, and the Blue Mountains in the west. It is known to occur in the Cumberland IBRA subregion. Inhabits dry sclerophyll open forest and woodland with shrubby understory, on sandy to stony soils derived from sandstone. (DoE, 2014f; OEH, 2017d)
POPULATIONS	As of 2007, the species was known 21 populations, mostly containing fewer than 10 individuals. One population near Appin contains 88 individuals. Total number of individuals is not known. (DoE, 2014f; DoEE, 2018c)
SOS SITES	The following SOS sites for the species have been identified: • Yengo (proposed) • Parr (proposed) • Maroota Ridge (proposed) • Fred Caterson Reserve (proposed) • Cromer (proposed)

	• WestCliff Mine (proposed) • Bargo (proposed)
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Persoonia hirsuta* (DoE, 2014f)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=19006

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	No	No	No	No

EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS**
	Not applicable as the species is not a candidate species credit species. There is no habitat for *P. hirsuta* within the nominated areas. Mapping outside of the nominated areas was done as per species distribution model description below.
	OUTSIDE THE NOMINATED AREAS
	Species distribution model (SDM). Potential habitat outside the nominated areas was mapped using an SDM. The report for this process notes that this species has a small proportion of its records within the Cumberland Plain subregion, and therefore the SDM estimates that only a small proportion of available habitat for this species occurs within the Cumberland Plain. The mapping is considered to be highly precautionary. No targeted surveys as part of this project were undertaken outside the nominated areas.
POPULATION MAPPING	**RECORD SELECTION**
	Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset.
	POPULATION DEFINITION
	Biological populations were defined using the records dataset and available information about the nature of the species. Clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators.
	IMPORTANT POPULATION CRITERIA

	Populations of *P. hirsuta* were then categorised as important or not-important based on the methodology set out in Section 11.5.3 of Chapter 11. All populations if *P. hirsuta* are considered to be important as the species is endangered.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.18 for a map of records and habitat across the Strategic Assessment Area. It is important to note that the records for this species are sensitive and have been denatured for representation on the map.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 29-68 at the end of this species assessment for a breakdown of the occurrence of records and habitat for *P. hirsuta* in the Strategic Assessment Area. **Records** A total of six populations have been mapped within the Strategic Assessment Area. Of these: • Three are located in the south-west corner of the assessment area, in the Bargo/Buxton locality • One is located east of Campbelltown • Two are located to the north of GPEC **Potential habitat** The baseline mapping for this assessment has mapped 11,433.3 ha of potential habitat within the Strategic Assessment Area. This potential habitat is distributed as follows: • A large area of habitat is mapped within the Londonderry area to the north of GPEC • A large area of habitat is also mapped to occur in the Tahmoor/Bargo/Buxton locality in the south-west corner of the Strategic Assessment Area • Scattered habitat occurs in several disjunct locations It is noted that the Species Distribution Model (SDM) predicted that the majority of habitat for this species occurs outside of the Cumberland subregion. The SDM predicted the occurrence of significant areas of habitat outside of the western, southern, south-eastern and north-eastern boundaries of the Strategic Assessment Area.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.18.1 NOMINATED AREAS

There is no potential habitat for the species mapped within the nominated areas. Avoidance of habitat was therefore not necessary.

29.18.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.18.3 LOSS OF KNOWN POPULATIONS AND POTENTIAL HABITAT

Implementation of the Plan will lead to loss of potential habitat. A summary of these impacts is provided in Table 29-69.

LOSS OF POTENTIAL HABITAT

There will be approximately 6.2 ha of impacts to potential habitat (0.1 per cent of mapped habitat across the Strategic Assessment Area). These impacts are primarily due to the development of the M7/Ropes Crossing Link Road outside the north-eastern corner of GPEC, and the development of a transport corridor to the east of WSA.

The areas being impacted upon do not support known records or populations of *P. hirsuta.*

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of impacts to mapped habitat are considered to be very low. This risk ranking is triggered for impacts to species' habitat, as follows:

- The likelihood of actual impacts occurring to the species within mapped habitat has been categorised as possible. While there will be direct impacts to potential habitat, there is moderate confidence that the species will occur in the impact area (it is noted that the impacted habitat was modelled via the SDM process, which is considered to be precautionary and may over-predict habitat. There are no records in close proximity to the impacted areas of habitat)
- The consequence of impacts to the species (if they did occur) has been categorised as negligible. There will be a loss of 0.1 per cent of mapped potential habitat (endangered species), with moderate confidence that the species occurs in the impact area

29.18.4 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the very low risk of residual adverse impacts to the species, offsets were not considered necessary for *P. hirsuta.*

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the potential indirect impacts to the species that may occur as a result of development under the Plan. It also outlines if the generic management strategies in the Plan will be adequate for addressing indirect impacts, or if species-specific commitments are necessary.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.18.5 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice (DoE, 2014f) (and other key documents) for *P. hirsuta* identifies a range of threats to the species. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered:

- Inappropriate fire regimes
- Disturbance from recreational users
- Altered hydrology
- Weed invasion
- Infection with *Phytophthora cinnamomi*

Competition with dense native vegetation species, low population numbers, feral European honeybees making effective pollination unlikely have also been identified as key threats. However, this is not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate these threats across the Strategic Assessment Area.

INAPPROPRIATE FIRE REGIMES

P. hirsuta is threatened by altered fire regimes. The Plan has the potential to impact fire regimes as a result of increased human activity associated with development of urban capable land within the nominated areas and development of transport corridors outside of the nominated areas. As there is no mapped potential habitat within the nominated areas, the sites most at risk at the small areas of impacted potential habitat which are intercepted by the development of transport corridors.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity associated with development of transport corridors. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for *P. hirsuta* being:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values (it is noted that the SCA contains approximately 2,690 ha of mapped potential habitat for *P. hirsuta*).
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans

The package of measures in the Plan is expected to adequately manage the risk to *P. hirsuta* from altered fire regimes as a result of development. This is because:

- Fire management authorities will be engaged to ensure they understand the requirements of *P. hirsuta* and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas

DISTURBANCE FROM RECREATIONAL USERS

Habitat disturbance from recreational users has been identified as a threat for *P. hirsuta*. The sites most at risk at the small areas of impacted potential habitat which are intercepted by the development of transport corridors.

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for *P. hirsuta.* In summary, these include:

- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations. It is noted that approximately 2,690 ha of potential habitat for *P. hirsuta* is mapped to occur within SCAs
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping

- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas. This commitment is consistent with a number of actions in the Conservation Advice around educating the community about *P. hirsuta*

The package of measures in the Plan is expected to adequately manage the risk to *P. hirsuta* from inappropriate habitat disturbance as a result of development. This is because:

- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

ALTERED HYDROLOGY

Altered hydrology has been identified as a risk to *P. hirsuta*. As outlined above, sites most at risk at the small areas of impacted potential habitat which are intercepted by the development of transport corridors.

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for *P. hirsuta.* In particular, these include commitments which relate to mitigating indirect and prescribed impacts from transport development (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through the implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the TfNSW Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology.

The package of measures in the Plan is expected to adequately manage the risk to *P. hirsuta* from changes to hydrology because transport projects will apply best practice approaches to avoiding and minimising any potential impacts to biodiversity values, including potential habitat for *P. hirsuta.*

WEED INVASION

P. hirsuta is threatened with invasion and competition by weeds. Weeds are already present within the Strategic Assessment Area. However, urban, transport and agricultural development within the northern half of the Strategic Assessment Area has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

The Plan incorporates a range of measures to manage the risks associated with weed invasion. In summary, these include:

- A commitment (Commitment 6) will result in implementation of mitigation measures to address indirect and prescribed impacts to threatened species associated with the development of transport corridors
- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA. This includes a number of actions, of which the following are the most relevant to the outcome for *P. hirsuta:*
    - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
    - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
    - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes:
    - Partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16

The package of measures in the Plan is expected to adequately manage the risk to *P. hirsuta* from the increased risk of weeds associated with development. This is because:

- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to biodiversity values, including potential habitat for *P. hirsuta*
- There are commitments (Commitment 16 and Commitment 23) which will coordinate, enable and conduct effective weed control programs in strategic locations within the Strategic Assessment Area to manage priority weed species
- Proponents will be required to minimise the risk of weed spread, and to manage weeds, during the design, development and operational stages of development

INFECTION WITH PHYTOPHTHORA CINNAMOMI

P. hirsuta is threatened by exposure to *Phytophthora cinnamomi*, a soil-borne water mould which is fatal to many *Persoonia* species.

Development under the Plan has the potential to increase the spread of *Phytophthora cinnamomi* through increased site visitation rates and earthworks activities conducted during construction works. The areas which are most at risk are the small areas of impacted potential habitat which are intercepted by the development of transport corridors.

The Plan incorporates a range of measures to manage the risks associated with disease including *Phytophthora cinnamomi*. In summary, these include:

- A commitment (Commitment 6) will result in implementation of mitigation measures to address indirect and prescribed impacts to threatened species associated with the development of transport corridors
- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
  - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
  - Entering into written agreements with delivery partners to implement priority disease control programs
- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures methods to protect the environment during construction, including best practice site hygiene protocols to minimise spread of *Phytophthora* and Myrtle Rust

The package of measures in the Plan is expected to adequately manage the risk to *P. hirsuta* from *Phytophthora cinnamomi* because:

- Development controls will be put in place to address potential impacts associated with construction
- It supports a landscape scale approach to the issue across the Cumberland subregion

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

No habitat for *P. hirsuta* has been mapped in any of the nominated areas, nor in or adjacent to any of the tunnel footprints. Therefore, *P. hirsuta* is not considered to be at risk from development of essential infrastructure or tunnels.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.18.6 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DoE, 2014f) (and other key documents) identifies the following key issues that are likely to have the greatest influence on the long-term viability of *P. hirsuta* in relation to implementation of the Plan:

- Habitat loss and fragmentation
- Indirect impacts such as:
  - Inappropriate fire regimes
  - Disturbance from recreational users
  - Altered hydrology
  - Weed invasion
  - Infection with *Phytophthora cinnamomi*

HABITAT LOSS AND FRAGMENTATION

As outlined above, implementation of the Plan will lead to loss of 6.2 ha of mapped habitat within transport corridors. No fragmentation of species' habitat will occur.

Based on the application of the risk assessment method, the overall risk of residual adverse impacts associated with these direct impacts is very low. The total area of potential habitat which will be impacted is a small proportion of available habitat for the species with only moderate confidence of the species' presence in impacted areas.

The Plan includes a broader set of commitments and actions which are likely to benefit the species, which includes commitments to protect land within the SCAs which contain approximately 2,690 ha of potential habitat for *P. hirsuta.*

On balance, direct impacts associated with implementation of the Plan are not expected to threaten the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts associated with inappropriate fire regimes, disturbance from recreational users, altered hydrology, weed invasion and infection with *Phytophthora cinnamomi* have been analysed and determined to be adequately managed and mitigated through the generic management strategies in the Plan.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

The limited scale of direct impacts to the species habitat and the management measures in the Plan to address potential indirect impacts will ensure that the implementation of the Plan does not adversely influence the long-term viability of the species.

29.18.7 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

29.18.8 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-67 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The consistency of the Plan with relevant Threat Abatement Plans is discussed in detail in Chapter 15. The Plan is not inconsistent with any of the Threat Abatement Plans.

Table 29-67: Relevant key Threatening Processes and associated Threat Abatement Plans for *P. hirsuta*

29.19 *PIMELEA CURVIFLORA* VAR. *CURVIFLORA*.

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	An erect, open shrub with elliptical leaves and dark red to yellow flowers. Grows to 40-50 cm high. (DoEE, 2018c)
ECOLOGY	May flower all year round but mostly October to January. Can survive for some time without foliage following fire or grazing, during which time it relies on energy reserves from its root system. The species is likely to be fire tolerant. Seedlings have been observed following fire events. (DEWHA, 2008i; DoEE, 2018c)
DISTRIBUTION AND HABITAT	Occurs in the coastal area of the Sydney and Illawarra regions of NSW. As of 1998, it was known from around 20 locations between northern Sydney and Maroota including Baulkham Hills, Blacktown, Hornsby, Parramatta and Warringah Local Government Areas. In 2011, another population was found at in Shellharbour Local Government Area. Distribution overlaps with the following TECs: • Shale Sandstone Transition Forest • Blue Gum High Forest of the Sydney Basin Bioregion • Cumberland Plain Woodlands • Turpentine-Ironbark Forest in the Sydney Basin Bioregion Can be found on sandy soil, shaly soil or shale/sandstone transition soils. Occurs on ridge tops and upper slopes in open forest and woodland. (DEWHA, 2008i; DoEE, 2018c)
POPULATIONS	Total population size is not known. As of 1998, two sites at Maroota had around 300 plants. However, the majority of populations contain fewer than 100 individuals. (DoEE, 2018c)
SOS SITES	The following SOS sites for the species have been identified: • Muogamarra Nature Reserve • John Moroney Correctional Centre

	• Albion Park
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Pimelea curviflora* var. *curviflora* (DEWHA, 2008i)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species
SPRAT LINK	https://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=4182

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	No	No	No	Yes

EXPERT REPORT (BCAR PROCESS)	There is no expert report available for this species.
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS** **Knowledge based map (KBM).** Potential habitat polygons were generated for this species using BioNet PCT associations, vegetation condition (intact, thinned), geology ('Hawkesbury Sandstone', 'Minchinbury Sandstone', 'Mount Hercules Sandstone Member', 'Razorback Sandstone Member'), soil (all Blacktown soil landscape within a 500 m buffer on Wianamatta (South Creek) Plus all Berkshire Park soil), elevation (below 300 m) and LiDAR/DEM data (Sandstone units selected only within a 100 m buffer on "Ridge and Crest" DEM layer). To refine these potential habitat polygons, targeted surveys for the species were then undertaken in a number of locations within the nominated areas. These surveys either confirmed presence (known habitat) or absence (no longer considered potential habitat). The species was not recorded during surveys. **OUTSIDE THE NOMINATED AREAS** **Knowledge based map (KBM).** Potential habitat polygons were generated for this species using BioNet PCT associations, vegetation condition (intact, thinned), geology ('Hawkesbury Sandstone', 'Minchinbury Sandstone', 'Mount Hercules Sandstone Member, 'Razorback Sandstone Member'), soil (all Blacktown soil landscape within a 500 m buffer on Wianamatta (South Creek) Plus all Berkshire Park soil) and elevation (below 300 m). No targeted surveys as part of this project were undertaken outside the nominated areas.
POPULATION MAPPING	**RECORD SELECTION** Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset. **POPULATION DEFINITION**

	Biological populations were defined using the records dataset and available information about the nature of the species. Populations were defined by clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators.
	IMPORTANT POPULATION CRITERIA
	Populations of *P. curviflora* var. *curviflora* were considered important because they met one or more of the following criteria: a large population.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.20 for a map of records and habitat across the Strategic Assessment Area
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	Within the vicinity of the Cumberland subregion, the core area for the species is to the north east of the subregion (outside the Strategic Assessment Area) within areas of extensive remnant vegetation. The Strategic Assessment Area supports many fewer records and includes three populations (from three BioNet records dated 2000). One population is considered to be important (population 456). The populations are located as follows: • Population 456 is located within the John Morony Correctional Complex, adjacent to Windsor Downs Nature Reserve • Populations 79 and 80 are located to the south of Douglas Park, between GMAC and Wilton. Despite extensive surveys at nearby Bingara Gorge in suitable habitat, the species was not recorded, suggesting that these two records may be misapplications for *P. curviflora* var. *sericea* which is recorded in that area The baseline mapping for this assessment has mapped 13,064.1 ha of known and potential habitat within the Strategic Assessment Area. Habitat for this species occurs as follows: • Scattered habitat occurs in the northern portion of the Strategic Assessment Area in the Kurrajong, Scheyville and Londonderry localities. It is noted that the Londonderry locality supports a significant area of potential habitat • Thin and scattered areas of habitat occur along the western boundary of the Strategic Assessment Area, along the Nepean River to the north of Penrith, and southwards through Mulgoa to the locality of The Oaks • Scattered habitat occurs within and to the south of the GPEC nominated area, including the localities of Wianamatta Regional Park, North St Marys, Mount Druitt, Orchard Hills, Glenmore Park and Luddenham • Scattered habitat occurs between WSA and GMAC, in localities including Badgerys Creek, Kemps Creek, Middleton Grange, Catherine Field and Edmondson Park • Scattered habitat occurs to the west of Wilton and between Wilton and GMAC It is noted that no habitat is mapped as being present within WSA, Wilton or GMAC. A breakdown of occurrence for *P. curviflora* var. *curviflora* in the Strategic Assessment Area is provided in Table 29-71.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.19.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 91.1 ha of potential habitat within GPEC (not including excluded lands). Approximately 18.1 ha (19.9 per cent) has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 17.7 ha was avoided for biodiversity purposes.
- 0.5 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 29-72.

It is important to note that the avoidance calculations in Table 29-72, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 29-72 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

29.19.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.19.3 LOSS OF KNOWN POPULATIONS AND POTENTIAL HABITAT

Implementation of the Plan will not lead to direct impacts to known populations. However, it will lead to:

- A loss of potential habitat
- Fragmentation of potential habitat

LOSS OF POTENTIAL HABITAT

Approximately 75.9 ha of potential habitat for the species will be lost. This is 0.6 per cent of mapped potential habitat across the Strategic Assessment Area. A summary of these impacts is provided in Table 29-73.

Direct impacts to potential habitat occur:

- In Wianamatta Regional Park due to the Outer Sydney Orbital. However, there are no records of the species in that area despite the site being well visited in the past, and the fact that it was not identified in surveys undertaken as part of this project. The species is considered unlikely to occur in this location
- In scattered habitat within GPEC. There are no historical records of the species within the vicinity of these small habitat patches and, while it is possible the species may occur, it is considered to be unlikely

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of impacts to mapped habitat are considered to be very low. This risk ranking is triggered for impacts to species' habitat, as follows:

- The likelihood of actual impacts occurring to the species within mapped habitat has been categorised as possible. While there will be direct impacts to potential habitat, there is moderate confidence that the species will occur in the impact areas. This is considered a precautionary rating
- The consequence of impacts to the species (if they did occur) has been categorised as negligible. There will be a loss of <2 per cent of mapped potential habitat (vulnerable species), with moderate confidence that the species occurs in the impact areas

29.19.4 FRAGMENTATION OF HABITAT

FRAGMENTATION IMPACTS

The Plan will lead to fragmentation of mapped habitat in the several parts of the Outer Sydney Orbital corridor within GPEC.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of fragmentation is considered to be very low. This is because:

- The likelihood of fragmentation has been categorised as unlikely. This is because:
  - The likelihood that development is presents a barrier to dispersal of the species is possible
  - The type of fragmentation is impact to mapped habitat only
- The consequence of fragmentation has been categorised as negligible. This is because the Plan will lead to fragmentation of mapped habitat in:
  - An area that the species is unlikely to occur (Wianamatta Regional Park)
  - In other small, isolated areas of mapped habitat that do not occur within the vicinity of historical records

29.19.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the very low risk of residual adverse impacts to the species, offsets were not considered necessary for *P. curviflora* var. *curviflora*.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.19.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice for *P. curviflora* var. *curviflora* identifies a range of threats to the species (DEWHA, 2008i). Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered:

- Weed invasion
- Habitat degradation
- Inappropriate fire regimes

Grazing by pest fauna such as the European rabbit, feral goats and feral pigs have also been identified as key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate these threats across the Strategic Assessment Area.

WEED INVASION

P. curviflora var. *curviflora* is threatened with invasion and competition by weeds. Weeds are already present within the Strategic Assessment Area. However, urban and transport have the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

P. curviflora var. *curviflora* is most susceptible to the threat of weeds from development under the Plan where new urban growth or transport occur adjacent to known populations or habitat. Key risk areas include:

- Habitat within and to the north of GPEC
- Habitat adjacent to Wilton and GMAC

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity that are expected to adequately manage the risk to the species. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA. This includes a number of actions, of which the following are the most relevant to the outcome of the species:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

HABITAT DEGRADATION

Habitat degradation through unrestricted public access has been identified as a key threat to *P. curviflora* var. *curviflora* (DEWHA, 2008i). Development within GPEC, Wilton and GMAC may lead to an increase in human activity within the species' known and potential habitat areas, and this may exacerbate the threat.

Populations of *P. curviflora* var. *curviflora* on public land are considered most at risk from this impact. Population 456 (to the north of GPEC) is close to (and may occur within) Windsor Downs Nature Reserve where access is managed. The other two populations in the Strategic Assessment Area are not on public land managed for conservation.

The Plan incorporates a range of measures that are considered adequate to mitigating the risks associated with inappropriate habitat disturbance. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in locations where species habitat occurs in protected areas
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

INAPPROPRIATE FIRE REGIMES

Altered fire regimes are an identified threat (OEH, 2019h). Increased human activity within the nominated areas increases the risk of fire to habitat areas supporting the species.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity that are expected to adequately manage the risk to the species. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for the species being:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for the species. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the

sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to the development of essential infrastructure within nominated areas but outside the urban capable lands.

Mapped habitat does not occur within the tunnel footprints and impacts to the species will not occur in those locations.

29.19.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

Small areas of species habitat have been mapped within avoided lands in GPEC. Given the lack of records and the limited extent of habitat, impacts to habitat are considered unlikely due to essential infrastructure.

However, as outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a results of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.19.8 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DEWHA, 2008i) identifies the following key issues that are likely to have the greatest influence on the long-term viability of *P. curviflora* var. *curviflora* in relation to implementation of the Plan:

- Habitat loss
- Indirect impacts including:
  - Weed invasion
  - Habitat degradation from recreational activities, road and trail maintenance, and bush rock removal
  - Inappropriate fire regimes

HABITAT LOSS AND FRAGMENTATION

Given the very low risk to the species associated with habitat loss and fragmentation, implementation of the Plan will not adversely influence the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts on *P. curviflora* var. *curviflora* will be managed and mitigated through a number of commitments and actions in the Plan (see Chapter 15 for details). Indirect impacts will not adversely influence the long-term viability of the species.

CONCLUSION

The limited scale of direct and indirect impacts to the species will ensure that implementation of the Plan does not adversely influence the long-term viability of the species.

29.19.9 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

29.19.10 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-43 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For *P. curviflora* var. *curviflora*, there are no relevant Threat Abatement Plans.

Table 29-70: Relevant key Threatening Processes and associated Threat Abatement Plans for *P. curviflora* var. *curviflora*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant Threat Abatement Plan
Novel biota and their impact on biodiversity	There is no relevant Threat Abatement Plan

29.20 *PTEROSTYLIS SAXICOLA* (SYDNEY PLAINS GREENHOOD ORCHID)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Endangered
DESCRIPTION	A ground orchid with reddish brown and green flowers on a slender stem. Grows to 35 cm tall. (DoEE, 2018c)
ECOLOGY	Flowers from September to December and is probably dependent on climatic conditions. Following seed dispersal, the above ground parts of the plant die but the underground tuberoid remains until the following year. (DoEE, 2018c)
DISTRIBUTION AND HABITAT	Records are restricted to western Sydney between Freemans Reach in the north and Picton in the south. It is known from seven primary locations in Western Sydney: • Georges River National Park, near Yeramba Lagoon • Ingleburn • Holsworthy • Peter Meadows Creek • St Marys Towers, near Douglas Park • Freemans Reach near Windsor • Scheyville near Windsor (DEWHA, 2008j; DoEE, 2018c) Occurs on the Cumberland Plain along an ecological gradient from: • Clay soils on gently hilly landscapes in PCT 849 • To clay to sandy soils in PCT 1395 on the edge of the Cumberland Plain • To thin accumulations of humus-rich sandy soil on sandstone rock shelves in PCTs 1081, 1083, 1181 and 1789 (Weston, 2018a)
POPULATIONS	Total population size is approximately 500 individuals. Individual population sizes are typically small. (DoEE, 2018c)

SOS SITES	A ground orchid with reddish brown and green flowers on a slender stem. Grows to 35 cm tall. (DoEE, 2018c)
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Pterostylis saxicola* (Sydney Plains Greenhood) (DEWHA, 2008j) Threat Abatement Plan for Predation, Habitat Degradation, Competition and Disease Transmission by Feral Pigs (*Sus scrofa*) (DoEE, 2017c) Cumberland Plain Recovery Plan identifies actions at the state level (DECCW, 2011).
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species.

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	Yes	Yes	Yes	Yes

EXPERT REPORT (BCAR PROCESS)	Yes (Weston, 2018b, 2018a). Available at Supporting Document C
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS** **Expert report polygons**. Potential habitat polygons were generated based on the occurrence of the following parameters: • Vegetation type (suitable habitat included PCT 849, 1081, 1181 or 1395) • Vegetation condition (intact) • Soil type and topography (clay soils derived from Ashfield Shale on flat to gently hilly landscapes; clay to sandy soils derived from Hawkesbury Sandstone – Mittagong Formation – Ashfield Shale transition substrates on gently hilly landscapes; thin accumulations of humus-rich sandy soil on Hawkesbury Sandstone sheets and rock shelves on the either rims and steep sides of river valleys, sandstone plateaux, or dry sandstone gullies) To refine these potential habitat polygons, targeted surveys for the species were then undertaken in a number of locations within the nominated areas. These surveys either confirmed presence (known habitat) or absence (no longer considered potential habitat). The species was not recorded during the targeted surveys. It was not possible to access and survey all areas of potential habitat within the nominated areas. Any remaining potential habitat is considered precautionary and does not necessarily equate with actual habitat. **OUTSIDE THE NOMINATED AREAS** **Knowledge based map (KBM).** Mapping was prepared for this species using the following parameters: BioNet PCT associations, vegetation condition (intact), geology ('Hawkesbury

	Sandstone', 'Ashfield Shale', 'Mittagong Formation'), soil ('Lucas Heights', 'Woodlands') and elevation (<300 m).
POPULATION MAPPING	**RECORD SELECTION** Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset. **POPULATION DEFINITION** Biological populations of were defined using the records dataset and available information about the nature of the species. Records within 500 m of one another considered a single population. **IMPORTANT POPULATION CRITERIA** Populations of *P. saxicola* were then categorised as important or not-important based on the methodology set out in Section 11.5.3 of Chapter 11. All populations of this species were considered to be important as the species is endangered.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.23 for a map of records and habitat across the Strategic Assessment Area It is important to note that the records for this species are sensitive and have been denatured for representation on the map.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 29-75 at the end of this species assessment for a breakdown of the occurrence of records and habitat for *P. saxicola* in the Strategic Assessment Area. **Records** A total of nine important populations have been identified within the Strategic Assessment Area: • Two populations occur in the north of the Strategic Assessment Area • One population (unsubstantiated) is located near Emu Plains, to the west of the GPEC nominated area • Four populations occur to the east of the northern part of GMAC • Two population occur between Wilton and GMAC, one near Douglas Park and the other near Menangle It is noted that no species records are located within any of the nominated areas. **Potential habitat** The baseline mapping for this assessment has mapped 11,792.4 ha of potential habitat within the Strategic Assessment Area for this species. Habitat for this species is predominantly located towards the outer edges of the Strategic Assessment Area, with no mapped habitat located in the centre of the assessment area. Specifically, habitat is located as follows: • Scattered areas of habitat occur in the north of the Strategic Assessment Area, in the localities of Scheyville, Freemans Reach and Kurrajong • Thin areas of habitat occur between Mulgoa and Castlereagh, which are associated with the Nepean River • Areas of intermittently scattered and connected habitat occur in the localities of Mulgoa, Silverdale, Theresa Park and Werombi

	• Areas of intermittently scattered and connected habitat occur along the south-eastern and eastern boundary of the Strategic Assessment Area, from Mowbray Park, through Wilton and Douglas Park, up to Menangle and through to St Helens Park, Kentlyn and Macquarie Fields. It is noted that no potential habitat is mapped for this species within WSA.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.20.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 2,196.5 ha of potential habitat within the nominated areas (not including excluded lands). Approximately 2,149.9ha (97.9 per cent) has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 1,551.9 ha was avoided for biodiversity purposes
- 598.0 ha was avoided for other reasons

A breakdown of avoidance across each nominated area is provided in Table 29-76.

It is important to note that the avoidance calculations in Table 29-76, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 29-76 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

29.20.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.20.3 LOSS OF KNOWN POPULATIONS AND POTENTIAL HABITAT

Implementation of the Plan will lead to the loss of potential habitat. No known records will be impacted and habitat for the species will not be fragmented. A summary of these impacts is provided in Table 29-77.

LOSS OF POTENTIAL HABITAT

Approximately 46.6 ha of potential habitat for the species will be lost. This is 0.4 per cent of mapped potential habitat across the Strategic Assessment Area. The impacts occur predominantly within GMAC and Wilton.

The areas being impacted upon do not support known records or populations of *P. saxicola*.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of impacts to mapped habitat are considered to be very low. This risk ranking is triggered for impacts to species' habitat, as follows:

- The likelihood of actual impacts occurring to the species within mapped habitat has been categorised as possible. While there will be direct impacts to potential habitat, there is moderate confidence that the species will occur in the impact area (it is noted that *P. saxicola* is sporadically distributed rather than continuously spread through its habitat (Weston, 2018b, 2018a), and therefore it is considered that there is moderate potential for the species to be present within mapped habitat)
- The consequence of impacts to the species (if they did occur) has been categorised as negligible. There will be a loss of <1 per cent of mapped potential habitat (endangered species), with moderate confidence that the species occurs in the impact area

29.20.4 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the very low risk of residual adverse impacts to the species, offsets were not considered necessary for *P. saxicola.*

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the potential indirect impacts to the species that may occur as a result of development under the Plan. It also outlines if the generic management strategies in the Plan will be adequate for addressing indirect impacts, or if species-specific commitments are necessary.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.20.5 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice (DEWHA, 2008j) (and other key documents) for *P. saxicola* identify a range of threats to the species. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats in key species documents) are considered relevant to implementation of the Plan:

- Weed invasion
- Inappropriate fire regimes
- Inappropriate habitat disturbance including unauthorised collection, trampling, recreational and maintenance activities and rubbish dumping

Grazing from domestic stock, feral pigs, and small population size and restricted distribution have also been identified as key threats. However, this is not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate these threats across the Strategic Assessment Area.

WEED INVASION

P. saxicola is threatened with invasion and competition by weeds. Weeds are already present within the Strategic Assessment Area. However, urban, transport and agricultural development has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

P. saxicola is most susceptible to the threat of weeds from development under the Plan where new urban growth or transport occur adjacent to known populations or habitat. Key risk areas include vegetated areas in GPEC, Wilton and GMAC.

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA. This includes a number of actions, of which the following are the most relevant to the outcome for *P. saxicola*:

  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes:
  - Partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

Also relevant for the *P. saxicola* is that a known population of the species (population 67), in addition to mapped potential habitat, is located within the proposed footprint of the Georges River Koala Reserve (Commitment 10). The establishment of the Koala Reserve is a major focus of the Plan and will be managed for conservation purposes, which will include weed management practices.

The package of measures in the Plan is expected to adequately manage the risk to *P. spicata* from the increased risk of weeds associated with development. This is because:

- The proposed Georges River Koala Reserve (Commitment 10) intercepts mapped potential habitat and a known population of *P. saxicola.* Protection of this reserve and management for conservation purposes will contribute to long-term protection of known populations and habitat of *P. saxicola*
- There are commitments (Commitment 16 and Commitment 23) which will coordinate, enable and conduct effective weed control programs in strategic locations within the Strategic Assessment Area to manage priority weed species
- Proponents will be required to minimise the risk of weed spread, and to manage weeds, during the design, development and operational stages of development
- Establishment of environmental zoning of approximately 2,150 ha of mapped potential habitat of *P. saxicola* within avoided lands will enable establishment of an adequate framework for management of weeds in these areas

INAPPROPRIATE FIRE REGIMES

Altered fire regimes are an identified threat (DEWHA, 2008j). Increased human activity within the nominated areas has the potential to alter fire regimes, through potentially increasing fire frequencies in some areas, and decreasing fire frequencies in others, through the following mechanisms:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

It is noted *P. saxicola* is threatened by both very frequent and very infrequent fire. A minimum fire interval of 7 years and a maximum fire interval of 15 years is recommended for *P. saxicola* (DoEE, 2018c). Key risk areas include vegetated areas in GPEC, Wilton and GMAC.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for *P. saxicola* being:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for *P. saxicola*. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes.

Also relevant for the *P. saxicola* is that a known population of the species (population 67), in addition to mapped potential habitat, is located within the proposed footprint of the Georges River Koala Reserve (Commitment 10). The establishment of the Koala Reserve is a major focus of the Plan and will be managed for conservation purposes, which will include the application of the fire management strategy and a set of measures to control access to bushland which will help minimise risks around arson and accidental fires.

The package of measures in the Plan is expected to adequately manage the risk to *P. saxicola* from altered fire regimes as a result of development. This is because:

- The proposed Georges River Koala Reserve (Commitment 10) intercepts mapped potential habitat and a known population of *P. saxicola.* Protection of this reserve and management for conservation purposes will contribute to long-term protection of known populations and habitat of *P. saxicola*
- Establishment of environmental zoning of approximately 2,150 ha of mapped potential habitat of *P. saxicola* within avoided lands will enable establishment of an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting mapped potential habitat and/or known records for *P. saxicola* which is located adjacent to urban capable lands
- Fire management authorities will be engaged to ensure they understand the requirements of *P. saxicola* and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas

INAPPROPRIATE HABITAT DISTURBANCE INCLUDING UNAUTHORISED COLLECTION, TRAMPLING, RECREATIONAL AND MAINTENANCE ACTIVITIES AND RUBBISH DUMPING

Inappropriate habitat disturbance has been identified as a threat to *P. saxicola*. Key risk areas include mapped potential habitat and known populations of the species, which occur in the vicinity of Wilton and GMAC. It is noted that mapped potential habitat for the species within GPEC is also at risk of habitat disturbance, although as there are no reliable known records within or directly adjacent to GPEC, the risk to the species in the locality of GPEC is not considered to be major.

The Plan includes a species-specific measure to consult with land managers of land containing known populations or habitat for *P. saxicola* to mitigate indirect impacts from habitat disturbance during construction and operation of the development, including controlling public access, managing maintenance activities such as mowing and weed control, and managing rubbish dumping.

The Plan further incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for *P. saxicola*. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas. This commitment is consistent with a number of actions in the Conservation Advice around educating the community about *P. saxicola*

The package of measures in the Plan is expected to adequately manage the risk to *P. saxicola* from inappropriate habitat disturbance as a result of development. This is because:

- A species-specific measure will require consultation with land managers to ensure protection of *P. saxicola* from inappropriate habitat disturbance
- Avoided lands where areas of mapped habitat for *P. saxicola* occur will be zoned appropriately to enable an adequate framework for management (this includes 2,149.9 ha of mapped potential habitat for the species)
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas (it is noted there is 6,074.1 ha of potential habitat for *P. saxicola* mapped within the SCAs)
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to the development of essential infrastructure within nominated areas but outside the urban capable lands.

It is noted that there is no mapped potential habitat, nor known records of the species, within the footprint of the proposed tunnel developments within the transport corridors. Therefore, it is considered that development of tunnels under the Plan will not pose a threat to *P. saxicola*.

29.20.6 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

There are no known records of *P. saxicola* within avoided lands in any of the nominated areas. However, there is 2,149.9 ha of potential habitat mapped for the species within avoided lands within Wilton and GMAC, and therefore it is considered to be possible that the species may occur within avoided lands in these nominated areas.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.20.7 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DEWHA, 2008j) (and other key documents) identifies the following key issues that are likely to have the greatest influence on the long-term viability of *P. saxicola* in relation to implementation of the Plan:

- Loss of habitat
- Indirect impacts including:
  - Weed invasion
  - Inappropriate fire regimes
  - Inappropriate habitat disturbance including unauthorised collection, trampling, recreational and maintenance activities and rubbish dumping

HABITAT LOSS AND FRAGMENTATION

As outlined above, implementation of the Plan will lead to loss of 46.6 ha of mapped habitat within the nominated areas. No fragmentation of species' habitat will occur.

Based on the application of the risk assessment method, the overall risk of residual adverse impacts associated with these direct impacts is <u>very low.</u> The total area of potential habitat which will be impacted is a small proportion of available habitat for the species with only moderate confidence of the species' presence in impacted areas.

The Plan includes a broader set of commitments and actions which are likely to benefit the species, which includes commitments to protect land within the SCAs which contain approximately 6,074.1 ha of potential habitat for *P. saxicola.*

On balance, direct impacts associated with implementation of the Plan are not expected to threaten the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts associated with weed invasion, inappropriate fire regimes and inappropriate habitat disturbance including unauthorised collection, trampling, recreational and maintenance activities and rubbish dumping have been analysed and determined to be adequately managed and mitigated through the generic management strategies in the Plan, and through a species-specific commitment to manage habitat disturbance.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

The limited scale of direct impacts to the species habitat and the management measures in the Plan to address potential indirect impacts will ensure that the implementation of the Plan does not adversely influence the long-term viability of the species.

29.20.8 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

29.20.9 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-74 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The consistency of the Plan with relevant Threat Abatement Plans is discussed in detail in Chapter 15. The Plan is not inconsistent with any of the Threat Abatement Plans.

Table 29-74: Relevant key Threatening Processes and associated Threat Abatement Plans for *P. saxicola*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant Threat Abatement Plan
Novel biota and their impact on biodiversity	There is no relevant Threat Abatement Plan
Predation, habitat degradation, competition and disease transmission by feral pigs	Threat Abatement Plan for Predation, Habitat Degradation, Competition and Disease Transmission by Feral Pigs (*Sus scrofa*) (DoEE, 2017c)

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

SPECIES AT NO RISK OF DIRECT IMPACTS

29.21 *COMMERSONIA PROSTRATA* (DWARF KERRAWANG)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Endangered
DESCRIPTION	A prostrate, mat-forming shrub with trailing branches up to 2 m long. Shows hairy, star-shaped flowers that change from white to pale pink with age. Flowers appear in clusters of 3-12. (DoEE, 2018c; OEH, 2020)
ECOLOGY	Flowers between September and November. Germinates in response to disturbance such as fire or flooding. (DoEE, 2018c)
DISTRIBUTION AND HABITAT	Endemic to south-eastern Australia, distributed from central Gippsland in Victoria to the New South Wales coast. In NSW, it can be found near Tallong, Penrose and Goulburn on the Southern Tablelands, and near Newcastle. It is known to occur in the Cumberland IBRA subregion In NSW, the species can be found on sandy or peaty soils in several habitats, such as: • Snow Gum Woodland at Rose Lagoon • Blue Leaved Stringybark Open Forest at Tallong • Brittle Gum Low Open Woodland at Penrose • Scribbly Gun Swamp Mahogany Broad-leaved Paperbark Ecotonal Forest at Tomago • The ecotone between Sedge Swamp and Swamp Forest on the Tomago Sandbeds (DoEE, 2018c; OEH, 2017c, 2020)
POPULATIONS	As of 2010, there were over 100,000 plants in 40 populations. A population in the North of the Providence Ponds Flora and Fauna Reserve in east Victoria contains almost all of the plants. The majority of the remaining populations contain less than 50. (DoEE, 2018c) In NSW populations range in size from one individual to approximately 2,000 (Rowes Lagoon). (OEH, 2020)
SOS SITES	The following SOS sites for the species have been identified: • Tomago area

	• Thirlmere Lakes National Park • Rowes Lagoon area
RELEVANT PLANS AND POLICIES	National Recovery Plan for the Dwarf Kerrawang (*Rulingia prostrata*) (Carter & Walsh, 2010) Threat Abatement Plan for Competition and Land Degradation by Rabbits (DoEE, 2016a)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species.
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=87152

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	No	No	No	No

EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS** Not applicable as the species is not a candidate species credit species. Mapping was done as per the knowledge based mapping method described below. **OUTSIDE THE NOMINATED AREAS** **Knowledge based map (KBM).** Potential habitat maps were generated using BioNet PCT associations, vegetation condition parameters (intact, thinned, scattered trees), soil restrictions ('Berkshire Park', 'Freemans Reach', 'Hawkesbury', Monkey Creek, 'Richmond', 'South Creek', 'Theresa Park', 'Upper Castlereagh', 'Bakers Lagoon', 'Ettalong') and geology ('Hawkesbury Sandstone', 'Minchinbury Sandstone').
POPULATION MAPPING	**RECORD SELECTION** Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset. **POPULATION DEFINITION** Biological populations were defined using the records dataset and available information about the nature of the species. Populations were considered to constitute clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators. **IMPORTANT POPULATION CRITERIA**

	All populations were considered to be important as the species is endangered.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.4 for a map of records and habitat across the Strategic Assessment Area
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	A single important population of this species (from 18 BioNet records) has been mapped within Thirlmere Lakes National Park on the south western edge of the Strategic Assessment Area. The baseline mapping for this assessment has mapped approximately 61.9 ha of potential habitat within the Strategic Assessment Area. Mapped habitat shows very small and scattered occurrences of habitat on the edges of the Strategic Assessment Area, near Castlereagh, to the south of Wilton, to the south of Bargo and extremely small (<100 m^2) potential habitat patches occurring between Thirlmere and Mulgoa. No habitat is mapped within any of the nominated areas or transport corridors. See Table 29-79 at the end of this species assessment for a breakdown of the occurrence of records and habitat for *C. prostrata* in the Strategic Assessment Area.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

No species habitat or records occur within the nominated areas or transport corridors. Avoidance of habitat was therefore not necessary.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

Implementation of the Plan will not lead to direct impacts or fragmentation of the species. As a result the Plan does not provide offsets for the species.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*

- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.21.1 RELEVANT POTENTIAL INDIRECT IMPACTS

The Recovery Plan for *C. prostrata* identifies a range of threats to the species (Carter & Walsh, 2010). As outlined in Chapter 15 (Section 15.5 and Attachment A), consideration was given to the potential relevance of these threats as indirect impacts that may result from implementation of the Plan.

Given the limited extent of species habitat and records in the Strategic Assessment Area, and the distance that they occur from the nominated areas, it was considered unlikely that implementation of the Plan would exacerbate any of the identified threats and would therefore not result in any indirect impacts.

Climate change is a relevant threat to the species. The extent to which the Plan has considered adaptation to climate change impacts is addressed in Chapter 41.

It is worth noting that the Plan includes a range of landscape scale measures that will protect biodiversity (e.g. protection of large areas of land, fire management strategy, weed control implementation strategy, and pest animal control implementation strategy). These measures will benefit all biodiversity in the Cumberland subregion and may potentially relate to this species.

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

Given the species does not occur within the nominated areas or transport corridors, there is no risk of additional impacts from essential infrastructure or tunnels.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

As outlined above, implementation of the Plan will not lead to any direct or indirect impacts to the species. This will ensure that the implementation of the Plan does not adversely influence their long-term viability.

29.21.2 CONSISTENCY WITH RECOVERY PLAN

In accordance with Section 146K of the EPBC Act, this section considers whether the implementation of the Plan is not inconsistent with the species' Recovery Plan. It considers two questions:

- Does the Plan prevent achievement of the objectives of the Recovery Plan?

- Does the Plan prevent implementation of the Recovery Plan actions?

These questions are discussed below.

DOES THE PLAN PREVENT ACHIEVEMENT OF THE OBJECTIVES OF THE RECOVERY PLAN?

The overall objective of the Recovery Plan (Carter & Walsh, 2010) is to minimise the probability of extinction of the Dwarf Kerrawang in the wild and to increase the probability of important populations becoming self-sustaining in the long-term. Specific objectives include:

- Acquire accurate information as baseline data for ongoing monitoring
- Identify habitat that is critical, common or potential.
- Ensure that all populations and their habitat are protected and managed appropriately
- Manage threats to populations
- Identify key biological functions
- Determine the growth rates and viability of populations
- Establish populations in cultivation
- Build community support for conservation

Implementation of the Plan will not impact the species and will not prevent the achievement of the objectives of the Recovery Plan.

DOES THE PLAN PREVENT THE IMPLEMENTATION OF THE RECOVERY PLAN ACTIONS?

The Recovery Plan identifies a set of actions to support the overall recovery of *C. prostrata*. The Plan will not prevent implementation of any of the actions.

29.21.3 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-78 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For *C. prostrata*, there are no relevant Threat Abatement Plans.

Table 29-78: Relevant key Threatening Processes and associated Threat Abatement Plans for *C. prostrata*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant Threat Abatement Plan
Loss of climatic habitat caused by anthropogenic emissions of greenhouse gases	There is no relevant Threat Abatement Plan

DATA TABLES

This section sets out the data table for occurrence.

Table 29-79: Occurrence of *C. prostrata* in the Strategic Assessment Area

	SAA TOTAL	WITHIN PROTECTED LANDS
TOTAL POPULATIONS	1	1
(IMPORTANT POPULATIONS)	(1)	(1)
HABITAT MAPPING (Ha)	61.9	42.5

29.22 *DEYEUXIA APPRESSA*

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Endangered
DESCRIPTION	An erect perennial grass. Leaves are deeply grooved, hairy on top and rough underneath. Displays compound inflorescence containing spikelets. Grows to approximately 0.9 m tall. (OEH, 2018e)
ECOLOGY	Flowers in spring to summer, and grows in moist conditions. Given that the species hasn't been observed in over 60 years, very little is known of the species' ecology. (DEWHA, 2008c; OEH, 2018e)
DISTRIBUTION AND HABITAT	Records are highly restricted to the Sydney area (south of Bankstown, Killara). Records of this species have not been collected since pre-1942. This species may now be extinct as a result of habitat loss due to development. Grows in moist conditions and inhabits the following TECs: • Shale Sandstone Transition Forest • Cumberland Plain Woodlands • Turpentine-Ironbark Forest in the Sydney Basin Bioregion (DEWHA, 2008c; OEH, 2018e)
POPULATIONS	First collected in 1930 at Herne bay, Saltpan Creek off the Georges River south of Bankstown, then in 1941 at Killara, near Hornsby. This species has not been observed since and may be extinct in the wild. (DEWHA, 2008c)
SOS SITES	*D. appressa* has been allocated to the Data Deficient management stream of the Saving our Species program, as there is no known extant population in NSW.
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Deyeuxia appressa* (DEWHA, 2008c)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species.

SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=7438

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	No	No	No	No

EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS**
	Not applicable as the species is not a candidate species credit species. Mapping was done as per knowledge based mapping method described below.
	OUTSIDE THE NOMINATED AREAS
	Knowledge based map (KBM). Mapping was prepared for this species utilising the following parameters: BioNet PCT associations, vegetation condition (intact, thinned), and geographic restrictions (habitat restricted to 10 km around species records).
POPULATION MAPPING	**RECORD SELECTION**
	All available BioNet records were used to identify populations, with no date restrictions.
	POPULATION DEFINITION
	There are not thought to be any extant populations of this species (as there are no recent records) and it is considered possible that the species is now extinct.
	IMPORTANT POPULATION CRITERIA
	All populations were considered to be important as the species is endangered.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.7 for a map of records and habitat across the Strategic Assessment Area
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	*D. appressa* has no records or important populations within the Strategic Assessment Area. Two important populations (from 3 BioNet records) have been mapped in the north-east of the Cumberland subregion. It is noted that this species has not been recorded since 1942 and that it may be extinct in the wild.

	The baseline mapping for this assessment has mapped 19.3 ha of habitat for this species within the Strategic Assessment Area. Habitat occurs as very small and disjointed patches in the north-east of the Strategic Assessment Area, in the district of Holsworthy, Hammondville, Moorebank and Cabramatta. No habitat has been mapped within, or in close proximity to, any of the nominated areas or transport corridors. See Table 29-81 at the end of this species assessment for a breakdown of the occurrence of records and habitat for *D. appressa* in the Strategic Assessment Area.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

No species habitat or records occur within the nominated areas or transport corridors. Avoidance of habitat was therefore not necessary.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

Implementation of the Plan will not lead to direct impacts or fragmentation of the species. As a result the Plan does not provide offsets for the species.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.22.1 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice for *D. appressa* identifies a range of threats to the species if it is still extant. As outlined in Chapter 15 (Section 15.5 and Attachment A), consideration was given to the potential relevance of these threats as indirect impacts that may result from implementation of the Plan.

Given the lack of records and the limited extent of species habitat in the Strategic Assessment Area, and the distance that they occur from the nominated areas, it was considered unlikely that implementation of the Plan would exacerbate any of the identified threats and would therefore not result in any indirect impacts.

It is worth noting that the Plan includes a range of landscape scale measures that will protect biodiversity (e.g. protection of large areas of land, fire management strategy, weed control implementation strategy, and pest animal control implementation strategy). These measures will benefit all biodiversity in the Cumberland subregion and may potentially relate to this species if it is still extant.

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

Given the species does not occur within the nominated areas or transport corridors, there is no risk of additional impacts from essential infrastructure or tunnels.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

As outlined above, the species is now considered likely to be extinct. In addition, implementation of the Plan will not lead to any direct or indirect impacts to mapped habitat for the species. This will ensure that the implementation of the Plan does not adversely influence its long-term viability if it is still extant.

29.22.2 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

29.22.3 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-43 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For *D. appressa*, there are no relevant Threat Abatement Plans.

Table 29-80: Relevant key Threatening Processes and associated Threat Abatement Plans for *D. appressa*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant Threat Abatement Plan
Novel biota and their impact on biodiversity	There is no relevant Threat Abatement Plan

DATA TABLES

This section sets out the data table for occurrence.

Table 29-81: Occurrence of *D. appressa* in the Strategic Assessment Area

	SAA TOTAL	WITHIN PROTECTED LANDS
TOTAL POPULATIONS	0	0
(IMPORTANT POPULATIONS)	(0)	(0)
HABITAT MAPPING (Ha)	19.3	0.0

29.23 *GENOPLESIUM BAUERI* (YELLOW GNAT-ORCHID)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Endangered
DESCRIPTION	A terrestrial orchid growing to 6-15 cm high. Inflorescence is 1-3 cm long with 1-6 flowers that are 15 mm across. Flowers are green and red or reddish. (DoE, 2014i)
ECOLOGY	Flowers between December and April. Plants are visible above ground for approximately two months. Often seen after fire. (DoE, 2014i)
DISTRIBUTION AND HABITAT	Endemic to New South Wales. Occurs within coastal areas from Ulladulla on the south coast to Port Stephens on the mid-north coast, although it has been recorded from as far west as Woodford in the Blue Mountains and Penrose State Forest in the southern highlands. Area of occupancy is 168 km^2. It grows in heathland to shrubby woodland on sands or sandy loams, or in shrubby forest to heathy forest on well-drained sandy and gravelly soils. (DoE, 2014i)
POPULATIONS	As of 2010, total number of mature individuals was thought to be less than 250 (DoE, 2014i).
SOS SITES	The following SOS sites for the species have been identified: • Ku-ring-gai Chase National Park • Ku-ring-gai Wildflower Garden • Bomaderry Creek • Callala
RELEVANT PLANS AND POLICIES	Conservation Advice for *Genoplesium baueri* (brittle midge orchid, yellow gnat orchid) (DoE, 2014i)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species.
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=7528

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	ECOSYSTEM CREDIT SPECIES	CANDIDATE SPECIES CREDIT SPECIES			
		WILTON	GMAC	WSA	GPEC
	No	No	No	No	No

EXPERT REPORT (BCAR PROCESS)	There is no expert report available for this species.
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS**
	Not applicable as the species is not a candidate species credit species. Mapping was done as per knowledge based mapping method described below.
	OUTSIDE THE NOMINATED AREAS
	Knowledge based map (KBM). Potential habitat polygons were generated for this species using BioNet PCT associations, vegetation condition (intact), and elevation (below 500 m). No targeted surveys as part of this project were undertaken outside the nominated areas.
POPULATION MAPPING	**RECORD SELECTION**
	Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset.
	POPULATION DEFINITION
	Biological populations were defined using the records dataset and available information about the nature of the species. Records within 500 m of each other have been considered to be a single population.
	IMPORTANT POPULATION CRITERIA
	All populations of *G. baueri* have been considered as important as the species is endangered.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.9 for a map of records and habitat across the Strategic Assessment Area. It is important to note that the records for this species are sensitive and have been denatured for representation on the map.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	There is a single population (with a single record from June 2017) within the Strategic Assessment Area, which is found on the eastern side of Appin village within GMAC (outside urban capable land). The population is considered important. The baseline mapping for this assessment has mapped approximately 772.1 ha of known and potential habitat within the Strategic Assessment Area. Habitat for this species is located in the south of the Strategic Assessment Area, in the following areas: • A patch of habitat occurs to the south of Wilton, south of the intersection of Macarthur Drive and Picton Road • Long and thin stretches of habitat occur along the south-eastern boundary of the Strategic Assessment Area, spanning from Appin in the south through to Holsworthy in the north. It is likely that suitable habitat for this species continues to the east of this area, beyond the Strategic Assessment Area boundary and into adjacent remnant vegetation Overall, very little suitable habitat for this species occurs within the Strategic Assessment Area. A breakdown of occurrence for *G. baueri* in the Strategic Assessment Area is provided in Table 29-83.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.23.1 NOMINATED AREAS

The single record in GMAC occurs within a very small area of mapped habitat (<0.1 ha). This area has been avoided. See Table 29-84 for a breakdown of avoidance.

29.23.2 TRANSPORT

There is no mapped habitat within the transport corridors.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

Implementation of the Plan will not lead to direct impacts or fragmentation of the species. As a result the Plan does not provide offsets for the species.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.23.3 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice for the *G. baueri* identifies habitat disturbance as a key threat to the species (DoE, 2014i). This threat is considered relevant to implementation of the Plan and is discussed below.

HABITAT DISTURBANCE

Habitat disturbance through unrestricted public access and rubbish dumping have been identified as a key threat to the species (DoE, 2014i). Development within Wilton and GMAC may lead to an increase in human activity within the species' known and potential habitat areas, and this may exacerbate the threat. This is most relevant to the known population that occurs on avoided lands within GMAC.

The Plan includes a species-specific commitment (part of Commitment 5) to manage the risk of human disturbance to the population within GMAC (population 21).

The Plan also incorporates a range of broader measures to mitigate the risks associated with inappropriate habitat disturbance. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in locations where species habitat occurs in protected areas
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan is expected to adequately manage the risk to the species from inappropriate habitat disturbance as a result of development. This is because:

- There is a species-specific commitment to manage the threat to the known population
- Avoided lands will be zoned appropriately to enable an adequate framework for management
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to the development of essential infrastructure within nominated areas but outside the urban capable lands.

There is no mapped habitat within transport corridors and the species is not at risk of impacts in these locations.

29.23.4 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

The species occurs on avoided lands within GMAC. The Plan includes a commitment (Commitment 2.4) which requires avoidance of impacts to this species to be prioritised from impacts associated with essential infrastructure projects. Given the limited distribution of the species within avoided lands it is considered likely that avoidance of direct impacts will be possible.

In addition (as outlined in Chapter 37), any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a results of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.23.5 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DoE, 2014i) identifies the following key issues that are likely to have the greatest influence on the long-term viability of *G. baueri* in relation to implementation of the Plan:

- Habitat loss
- Habitat disturbance

HABITAT LOSS

There will be no habitat loss as a result of implementation of the Plan.

HABITAT DISTURBANCE

The Plan includes a range of measures (including a species-specific commitment) to ensure that habitat disturbance will not affect the species.

CONCLUSION

There are no direct impacts to the species and suitable management measures in the Plan to address potential indirect impacts. This will ensure that the implementation of the Plan does not adversely influence the long-term viability of the species.

29.23.6 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

29.23.7 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-43 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For *G. baueri*, there are no relevant Threat Abatement Plans.

Table 29-82: Relevant key Threatening Processes and associated Threat Abatement Plans for *G. baueri*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant Threat Abatement Plan
Novel biota and their impact on biodiversity	There is no relevant Threat Abatement Plan

DATA TABLES

This section sets out the data tables for occurrence and avoidance. Cross references to the tables are provided throughout the text above.

Table 29-83: Occurrence of *G. baueri* in the Strategic Assessment Area

29.24 *HIBBERTIA PUBERULA* SUBSP. *GLABRESCENS*

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the subspecies. It provides an overview of the subspecies' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key subspecies' documents that provide additional background information.

EPBC ACT LISTING	Critically Endangered
DESCRIPTION	A prostrate shrub with spreading, wiry branches which can be up to 40 cm long. Flowers are yellow with notched petals. (DoEE, 2018c)
ECOLOGY	Flowers from October to December. Seeds occur from October to January. Vegetative reproduction is theoretically possible as the subspecies is a prostrate shrub, however, occurrences of vegetative reproduction have not been observed for this species. (DoEE, 2018c)
DISTRIBUTION AND HABITAT	Only known from Bankstown Airport, south-west of Sydney. Occurs over an area covering two hectares. It is noted that since 1986, comprehensive surveys have been carried out in remnant vegetation throughout the suburb of Bankstown, and no further sites for this species have been located. Occurs in highly modified Georges River Tertiary Alluvium Floodplain Communities with sandy tertiary alluvium with high silt content. (DoEE, 2018c) Recent attempts were made to translocate the subspecies to Voyager Point Reserve. This occurs outside of the Strategic Assessment Area and the current status of that translocated population is not known.
POPULATIONS	As of 2009, there were estimated to be fewer than 50 individuals from one population in Area 5, Bankstown Airport. As the subspecies was first observed in 2006, historical population data is limited, although it is suspected the subspecies has undergone historical reduction in numbers based on aerial photography records showing ongoing destruction of suitable habitat. (DoEE, 2018c) Assessment of all BioNet records of the species indicates that over 90 per cent of known records occur within the Cumberland subregion. Therefore, for the purposes of this assessment, *H. puberula* subsp. *glabrescens* is considered to be an endemic species to the region.

SOS SITES	The following SOS sites for the subspecies have been identified: • Bankstown Airport • Voyager Point Reserve
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Hibbertia* sp. Bankstown (R.T. Miller & C.P. Gibson s.n. 18/10/06) (a shrub) (DEWHA, 2008l)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this subspecies.
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=81969

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the subspecies is a candidate species under the BCAR process*
- *If an expert report was prepared for the subspecies under the BCAR process*
- *An overview of the habitat mapping for the subspecies within and outside the nominated areas*
- *An overview of the population mapping for the subspecies*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	ECOSYSTEM CREDIT SPECIES	CANDIDATE SPECIES CREDIT SPECIES			
		WILTON	GMAC	WSA	GPEC
	No	No	No	No	No

EXPERT REPORT (BCAR PROCESS)	While *Hibbertia puberula* subsp. *glabrescens* is not a candidate species credit species, two expert reports were prepared for the *Hibbertia puberula* species group. These reports included some discussion about subsp. *glabrescens*. The reports were prepared because *Hibbertia puberula* subsp. *puberula* (which is not listed under the EPBC Act) is a candidate species credit species for the BCAR process. The two expert reports address the *Hibbertia puberula* species group in: • GPEC and WSA (Miller, 2018a) • Wilton and GMAC (Miller, 2018b)
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS** Not applicable as the subspecies is not a candidate species credit species. Mapping was done as per the knowledge based mapping method described below. **OUTSIDE THE NOMINATED AREAS** **Knowledge based map (KBM).** Mapping for this subspecies was undertaken using the following parameters: • BioNet PCT associations • Geographic restrictions. Given the very limited distribution of the subspecies, potential habitat was restricted to 1 km surrounding known records
POPULATION MAPPING	**RECORD SELECTION** All available BioNet records were used to identify populations, with no date restrictions. **POPULATION DEFINITION** The subspecies is known to occur naturally in one location, as a single population.

	The translocation site at Voyager Point Reserve has been planted with a number of individuals propagated from the Bankstown location.
	IMPORTANT POPULATION CRITERIA
	The population of *H. puberula* subsp. *glabrescens* was considered to be important due to the threat status of the subspecies.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the subspecies in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment.

This section also provides a discussion of how the occurrence information used in the assessment compares to information in the expert reports for the species.

MAP	See Map 36.11 for a map of records and habitat across the Strategic Assessment Area
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	*H. puberula* subsp. *glabrescens* has no records within the Strategic Assessment Area. The subspecies is only known from Bankstown Airport (which occurs just outside of the eastern edge of the Strategic Assessment Area). It has not been recorded at any other sites, despite targeted surveys throughout the Bankstown area. A total of 43 ha of potential habitat has been mapped on the edge of the Strategic Assessment Area, along the Georges River to the east of Moorebank. Mapped habitat is confined to areas in proximity to the Bankstown Airport. Overall, the area of potential habitat for this subspecies within the Strategic Assessment Area is very small. No habitat has been mapped within, or in close proximity to any of the nominated areas or transport corridors.
COMPARISON WITH EXPERT REPORTS	**Expert report for WSA and GPEC (Miller, 2018a)** The expert report for WSA and GPEC concludes that for *H. puberula* subsp. *glabrescens*: *"The likelihood of occurrence within or adjacent to the GPEC is considered to be low to moderate, and the likelihood of occurrence within or adjacent to the WSA is assessed as low."* The subspecies was not included in the BCAR as a candidate species credit species in these two nominated areas because: • Of a lack of suitable habitat in urban capable lands • Surveys for *H. puberula* subsp. *fumana* and *H. puberula* subsp. *puberula* did not identify any records for subsp. *glabrescens* Mapping for the subspecies within WSA and GPEC was therefore not prepared which is consistent with the approach taken in the expert report. **Expert report for Wilton and GMAC (Miller, 2018b)** The expert report for Wilton and GMAC concludes that the species is not likely to be present in Wilton. This is consistent with the BCAR which does not identify it as a candidate species credit species in that location, and the mapping for the project. However, it is noted that the expert report for Wilton and GMAC identifies an area of potential habitat for the subspecies at Menangle Park within GMAC. The expert report says: *"Likely habitat for Hibbertia puberula* subsp. *glabrescens occurs at Menangle Park. An area of approximately 92ha could contain likely habitat niches within the growth area footprint, and a further 31 ha of land containing likely habitat niches adjacent to the footprint"* At the time the expert report was prepared, the area in question near Menangle Park was part of the proposed urban capable land. This area has since been removed from urban capable land and is mapped as excluded land. The area is subject to a separate planning proposal and it is understood

	that it is undergoing a separate biodiversity approvals process. Ecological reports relating to that area have not identified the subspecies as being present. No areas identified by the expert as potential habitat for *H. puberula* subsp. *glabrescens* occur within urban capable lands and the subspecies is not a candidate credit species within GMAC for this assessment. Given the species is not a candidate credit species within GMAC, the habitat mapping was undertaken using the KBM approach described above for areas outside the nominated areas. This process appropriately mapped habitat for the subspecies only within the vicinity of Bankstown Airport.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the subspecies through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

No habitat or records for the subspecies occur within the nominated areas or transport corridors. Avoidance of habitat was therefore not necessary.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the subspecies occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

Implementation of the Plan will not lead to direct impacts or fragmentation of the subspecies. As a result the Plan does not provide offsets for the subspecies.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.24.1 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice for the *H. puberula* subsp. *glabrescens* identifies a range of threats to the subspecies (DEWHA, 2008l). However, given the lack of records, the limited extent of habitat in the Strategic Assessment Area, and the distance that they occur from the nominated areas, it was considered unlikely that implementation of the Plan would exacerbate any of the identified threats and would therefore not result in any indirect impacts.

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

Given the subspecies does not occur within the nominated areas or transport corridors, there is no risk of additional impacts from essential infrastructure or tunnels.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the subspecies. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

As outlined above, implementation of the Plan will not lead to any direct or indirect impacts to mapped habitat for the species. This will ensure that the implementation of the Plan does not adversely influence its long-term viability if it is still extant.

29.24.2 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

29.24.3 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-43 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For *H. puberula* subsp. *glabrescens*, there are no relevant Threat Abatement Plans.

Table 29-85: Relevant key Threatening Processes and associated Threat Abatement Plans for *H. puberula* subsp. *glabrescens*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant Threat Abatement Plan
Novel biota and their impact on biodiversity	There is no relevant Threat Abatement Plan

DATA TABLES

This section sets out the data table for occurrence.

Table 29-86: Occurrence of *H. puberula* subsp. *glabrescens* in the Strategic Assessment Area

	SAA TOTAL	WITHIN PROTECTED LANDS
TOTAL POPULATIONS	0	0
(IMPORTANT POPULATIONS)	(0)	(0)
HABITAT MAPPING (Ha)	43.3	0.0

29.25 *LEUCOPOGON EXOLASIUS* (WORONORA BEARD-HEATH)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	An erect shrub with pointed leaves and white, tubular flowers. Grows to 1m tall. (DoEE, 2018c)
ECOLOGY	Flowers in August and fruit matures in October. Seasonal changes trigger seed germination and fire may improve uptake. (DoEE, 2018c)
DISTRIBUTION AND HABITAT	Has a fragmented distribution over seven known locations. It is endemic to the Sydney region and central coast of NSW. It is known to occur in the Cumberland IBRA subregion. The species can be found: • Along the Georges River and Stokes Creek • Holsworthy Military Reserve • In Royal National Park and Heathcote National Park • Along the Grose River and Woronora River in the Blue Mountains The distribution overlaps with the Shale Sandstone Transition Forest TEC. It is found on rocky hillsides along creek banks and inhabits woodland on sandstone and sandy alluvium in areas with low nutrient soils. (DoEE, 2018c; OEH, 2017h)
POPULATIONS	There is limited population information for this species. BioNet Atlas of NSW Wildlife shows some occurrences in the Cumberland Plain south of Liverpool and east of Campbelltown. (OEH, 2019b)
SOS SITES	The following SOS sites for the species have been identified: • Dharawal/Heathcote • Upper Nepean State Conservation Area
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Leucopogon exolasius* (DEWHA, 2008e)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species

SPRAT LINK	https://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=14251

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	No	No	No	No
EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.				
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS**				
	Not applicable as the species is not a candidate species credit species. Mapping was done as per knowledge based mapping method described below.				
	OUTSIDE THE NOMINATED AREAS				
	Knowledge based map (KBM). Potential habitat mapping was completed for this species using the following parameters: BioNet PCT associations, vegetation condition (intact, thinned), waterways (restricted to within a 200 m buffer distance of the Cataract River and the Georges River), soil type ('Berkshire Park', 'Freemans Reach', 'Hawkesbury', 'Monkey Creek', 'Richmond', 'South Creek', 'Theresa Park', 'Upper Castlereagh'), geology ('Alluvial channel deposits- in-channel bar', 'Alluvial floodplain deposits', 'Alluvial terrace deposits', 'Alluvium', 'Hawkesbury Sandstone', 'Minchinbury Sandstone'), elevation (below 400 m) and rainfall (between 1,000 mm – 4,000 mm).				
POPULATION MAPPING	**RECORD SELECTION**				
	Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset.				
	POPULATION DEFINITION				
	Biological populations were defined using the records dataset and available information about the nature of the species. Clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators.				
	IMPORTANT POPULATION CRITERIA				
	There are no important populations of *L. exolasius* identified in the Strategic Assessment Area.				

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.12 for a map of records and habitat across the Strategic Assessment Area
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	A total of four populations occur in the Strategic Assessment Area. All are in the south or east, none of which are considered important. The baseline mapping for this assessment has mapped 267.2 ha of potential habitat within the Strategic Assessment Area (see Table 29-88). The potential habitat predominantly occurs along the Georges River, in the south-eastern edge of the Strategic Assessment Area. Habitat is located as follows: • A small area occurs along the Cataract River, at the intersection of the river with Wilton Road • Small, thin areas of habitat occur along the Georges River to the east of the Appin township • Small, thin areas of habitat occur along the Georges River, to the south east of Ruse and Airds • A small, isolated patch of habitat occurs at Voyager Point, adjacent to the Georges River

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.25.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 23.7 ha of potential habitat within the nominated areas (not including excluded lands). All of this has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 13.7 ha was avoided for biodiversity purposes
- 10.0 ha was avoided for other reasons

A breakdown of avoidance across each nominated area is provided in Table 29-89.

It is important to note that the avoidance calculations in Table 29-89, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 29-89 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

29.25.2 TRANSPORT

There is no mapped habitat within the transport corridors.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

Implementation of the Plan will not lead to direct impacts or fragmentation of the species. As a result the Plan does not provide offsets for the species.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.25.3 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice for *L. exolasius* identifies a range of threats to the species (DEWHA, 2008e). Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion

Stochastic events leading to localised extinctions, small range and population size, unknown distribution and abundance of individual populations have also been identified as key threats. However, this is not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate these threats across the Strategic Assessment Area.

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes are identified as a potential threat to the species (DEWHA, 2008e). This can be caused by:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

Increased human activity within the nominated areas has the potential to alter fire regimes, through potentially increasing fire frequencies in some areas, and decreasing fire frequencies in others, through the mechanisms outlined above.

Key risk areas are those that are easily accessible to the public and in close proximity to urban development and roads. Population 76 in particular occurs close to the southern part of GMAC.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity that are expected to adequately manage the risk to the species from altered fire regimes as a result of development. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for the species being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values

  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

WEED INVASION

Weed invasion is identified as a potential threat to the species. Weeds are already present within the Strategic Assessment Area and are unlikely to pose a novel threat. However, urban, transport and agricultural development has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

Key risk areas are those that are easily accessible to the public and in close proximity to urban development and roads. Population 76 in particular occurs close to the southern part of GMAC.

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity that are expected to adequately manage the risk to the species. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA. This includes a number of actions, of which the following are the most relevant to the outcome of the species:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes:
  - Partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to the development of essential infrastructure within nominated areas but outside the urban capable lands.

The species does not occur within the vicinity of the tunnels and will not be at risk of further impacts in those locations.

29.25.4 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

A small area of species habitat has been mapped within avoided lands in GMAC in the south of the nominated area. Given its location, impacts to habitat are considered unlikely due to essential infrastructure.

However, as outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a results of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.25.5 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DEWHA, 2008e) identifies the following key issues that are likely to have the greatest influence on the long-term viability of *L. exolasius* in relation to implementation of the Plan:

- Habitat loss
- Indirect impacts
    - Inappropriate fire regimes
    - Weed invasion

HABITAT LOSS

There will be no habitat loss as a result of implementation of the Plan.

INDIRECT IMPACTS

The potential indirect impacts associated with changed inappropriate fire regimes and weed invasion will be managed and mitigated through a number of commitments and actions in the Plan (see Chapter 15 for details).

CONCLUSION

The lack of direct impacts, limited scale of potential indirect impacts to the species' habitat and the management measures in the Plan to address indirect impacts will ensure that the implementation of the Plan does not adversely influence the long-term viability of the species.

29.25.6 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

29.25.7 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-43 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For *L. exolasius*, there are no relevant Threat Abatement Plans.

Table 29-87: Relevant key Threatening Processes and associated Threat Abatement Plans for *L. exolasius*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant Threat Abatement Plan
Novel biota and their impact on biodiversity	There is no relevant Threat Abatement Plan

DATA TABLES

This section sets out the data tables for occurrence and avoidance. Cross references to the tables are provided throughout the text above.

29.26 *PERSOONIA GLAUCESCENS* (MITTAGONG GEEBUNG)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	An erect shrub with greyish-green erect leaves, yellow flowers and fruit that resemble small plums. It grows up to 3 m tall. (OEH, 2019g)
ECOLOGY	Flowers from late summer to autumn. Fire-sensitive species, adults are killed by fire and recruitment is only by seed. Often seen following disturbance. (DEWHA, 2008h; OEH, 2019g)
DISTRIBUTION AND HABITAT	Restricted distribution in NSW from Picton to Kangaroo Valley. The species has been collected in Buxton, Hill Top, Nattai Creek, Welby and Kangaloon. It is known to occur in the Cumberland IBRA subregion. Distribution overlaps the following TECs: • Shale Sandstone Transition Forest • White Box-Yellow Box-Blakely's Red Gum Grassy Woodland and Derived Native Grassland • Turpentine-Ironbark Forest in the Sydney Basin Bioregion • Temperate Highland Peat Swamps on Sandstone Inhabits woodland to dry sclerophyll forest on clayey and gravely laterite, and well-drained soils. Prefers ridge-tops, plateau and upper slopes. (DEWHA, 2008h; OEH, 2017e, 2019g)
POPULATIONS	Population information is limited. The BioNet Atlas of NSW Wildlife shows several occurrences around Bargo and Buxton in the south of the Strategic Assessment Area. (OEH, 2019b)
SOS SITES	The following SOS sites for the species have been identified: • Bargo • Cordeaux record • Mt Alexandra, Welby and Jellore • Upper Nepean State Conservation Area

RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Persoonia glaucescens* (Mittagong Geebung) (DEWHA, 2008h)
SPECIES-SPECIFIC GUIDELINES	*Persoonia glaucescens* Environmental Impact Guidelines (NPWS, 2000b)
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=12770

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	No	No	No	No
EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.				
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS**				
	Not applicable as the species is not a candidate species credit species. Mapping was done as per knowledge based mapping method described below.				
	OUTSIDE THE NOMINATED AREAS				
	Knowledge based map (KBM). Mapping was prepared for this species using the following parameters: BioNet PCT associations, vegetation condition (intact, thinned) and elevation (250m-650m).				
POPULATION MAPPING	**RECORD SELECTION**				
	Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset.				
	POPULATION DEFINITION				
	Biological populations were defined using the records dataset and available information about the nature of the species. Individuals within 500 m of each other are likely to be interbreeding and are therefore considered to be the same population.				
	IMPORTANT POPULATION CRITERIA				
	Populations of *P. glaucescens* were considered important because they met one or more of the following criteria: • A population that is important for maintaining the Extent off Occurrence of a species • A population within a conservation reserve				

	• A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.17 for a map of records and habitat across the Strategic Assessment Area
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	Within the Strategic Assessment Area, the species occurs in the south western corner. A total of 10 important populations have been mapped, of which two populations are either wholly or partly located within existing conservation reserves. Important populations occur in the area between Buxton, Couridjah, Charlies Point Road and the northern boundary of Buxton. Two non-important populations have also been mapped within the Strategic Assessment Area. Non-important populations occur to the south of the Bargo township, in the area between Remembrance Drive and the western boundary of the Strategic Assessment Area. The baseline mapping for this assessment has mapped approximately 2,378.2 ha of potential habitat within the Strategic Assessment Area (see Table 29-91). This occurs as scattered habitat in the south western portion of the Strategic Assessment Area. No habitat is mapped in any of the nominated areas or transport corridors for this species.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

No species habitat or records occur within the nominated areas or transport corridors. Avoidance of habitat was therefore not necessary.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

Implementation of the Plan will not lead to direct impacts or fragmentation of the species. As a result the Plan does not provide offsets for the species.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.26.1 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice for *P. glaucescens* identifies a range of threats to the species (DEWHA, 2008h). However, given the distance of mapped habitat and records from the nominated areas and transport corridors implementation of the Plan is considered unlikely to exacerbate these threats for the species.

It is worth noting that the Plan includes a range of landscape scale measures that will protect biodiversity (e.g. protection of large areas of land, fire management strategy, weed control implementation strategy, and pest animal control implementation strategy). These measures will benefit all biodiversity in the Cumberland subregion and may potentially relate to this species.

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

Given the species does not occur within the nominated areas or transport corridors, there is no risk of additional impacts from essential infrastructure or tunnels.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.26.2 IMPLICATIONS FOR LONG-TERM VIABILITY

As outlined above, implementation of the Plan will not lead to any direct or indirect impacts to the species. This will ensure that the implementation of the Plan does not adversely influence their long-term viability.

29.26.3 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

29.26.4 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-43 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The consistency of the Plan with relevant Threat Abatement Plans is discussed in detail in Chapter 15. The Plan is not inconsistent with any Threat Abatement Plans.

Table 29-90: Relevant key Threatening Processes and associated Threat Abatement Plans for *P. glaucescens*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Dieback caused by the root-rot fungus *(Phytophthora cinnamomi*)	Threat Abatement Plan for Disease in Natural Ecosystems caused by *Phytophthora cinnamomi* (DoEE, 2018d)
Land clearance	There is no relevant Threat Abatement Plan
Novel biota and their impact on biodiversity	There is no relevant Threat Abatement Plan

DATA TABLES

This section sets out the data tables for occurrence.

30 Threatened fauna impact assessment

30.1 INTRODUCTION

There are 20 Category 1 threatened fauna species that are assessed in this Chapter. These species were identified as needing detailed assessment (see Part 3 for the approach, and Chapter 28 for the results) as they are reliant on the Cumberland subregion and have some potential to be impacted (directly, indirectly or cumulatively).

The Chapter is structured around the level of risk of residual adverse direct impacts (prior to the application of offsets) occurring to each species (see Table 30-1). Species most at risk from direct impacts from development under the Plan are discussed first, with species at lower levels of risk discussed subsequently.

The overall assessment approach for threatened fauna is presented below in Section 30.2, and the methodology for the risk assessment is set out in Section 30.3.

The analysis in this Chapter concludes that the avoidance, mitigation and offset measures in the Plan will ensure that the long-term viability of all 20 threatened fauna species will not be adversely influenced.

Given the amount of information and complexity of the assessment for Koala, it is assessed and presented differently to the other species (see Section 30.4).

Given their similarities, the five threatened migratory shorebirds are assessed together in the one section (see Section 30.19)

Table 30-1: Species assessed in the threatened flora chapter categorised according to the risk of residual adverse direct impacts

Level of risk of residual adverse direct impacts to species	Number of species	Species names
High risk	1	• *Phascolarctos cinereus* (Koala)
Medium risk	1	• *Lathamus discolor* (Swift Parrot)
Low risk	5	• *Anthochaera phrygia* (Regent Honeyeater) • *Botaurus poiciloptilus* (Australasian Bittern) • *Chalinolobus dwyeri* (Large-eared Pied Bat) • *Dasyurus maculatus maculatus* (Spot-tailed Quoll) • *Pteropus poliocephalus* (Grey-headed Flying Fox)
Very low risk	4	• *Litoria aurea* (Green and Golden Bell Frog) • *Petauroides volans* (Greater Glider) • *Pommerhelix duralensis* (Dural Land Snail) • *Rostratula australis* (Australian Painted Snipe)
No risk	9	• *Heleioporus australiacus* (Giant Burrowing Frog) • *Hirundapus caudacutus* (White-throated Needletail) • *Hoplocephalus bungaroides* (Broad-headed Snake) • *Macquaria australasica* (Macquarie Perch) • **Threatened migratory shorebirds:** o *Calidris canutus* (Red Knot) o *Calidris ferruginea* (Curlew Sandpiper) o *Charadrius leschenaultia* (Greater Sand Plover) o *Limosa lapponica baueri* (Bar-tailed Godwit) o *Numenius madagascariensis* (Eastern Curlew)

30.2 THREATENED FAUNA ASSESSMENT APPROACH

The assessments for threatened fauna follow a standard format. However, the content is tailored for the specific context of each species.

There are nine sections to the assessments. They are described below and include:

- Species background
- Approach to baseline data
- Occurrence in the Strategic Assessment Area
- Avoidance of impacts
- Direct impacts and offsets
- Potential indirect impacts and mitigation
- Potential additional impacts from essential infrastructure and tunnels
- Likely effects of implementation of the Planon the long-term viability of the species
- Data tables

To assist the reader, standard explanatory text about the purpose and content of each section is provided throughout the assessments in *blue italics text*. The text is repeated for each species. It enables the reader to quickly understand the content of each section and where in the broader report more detailed information is available about a particular issue.

30.2.1 SPECIES BACKGROUND

Sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

30.2.2 APPROACH TO BASELINE DATA

Provides a summary of the baseline information used in the assessment. It sets out:

- If the species is a candidate species under the BCAR process. A candidate species is a species that has been determined through the BCAR assessment as needing to be assessed because suitable habitat occurs in the nominated areas. A candidate species can be either an ecosystem credit species (ECS) (one that can be reasonably predicted to occur within a nominated area based on the habitat that occurs there - surveys are not required to determine the presence of these species); or a species credit species (SCS) (one that cannot be reasonably predicted to occur within a nominated areas based on habitat – species in these areas may either be assumed present, or their presence needs to be determined through surveys or a report prepared by an expert on that species). Understanding whether a species has been categorised as a candidate species is useful to know for the EPBC Act assessments as it is based on the application of a systematic method under the BCAR process and provides an initial indication of how development in the nominated areas might interact with the species. This helps to shape the assessment narrative
- If an expert report was prepared for the species under the BCAR process. Expert reports were prepared as part of the BCAR process for a subset of species that: could not be sufficiently surveyed for within the nominated areas due to either access restrictions, seasonality or their cryptic nature; or had highly specific habitat requirements and restrictions for which expert advice was required. It is relevant to note that the expert reports were prepared as a requirement of the BCAR process and were not specifically prepared to support the EPBC assessments. As a result, the expert reports are not relied on heavily in these assessments and instead, information (particularly relating to species ecology and distribution) has been identified and drawn on as relevant
- An overview of the habitat mapping for the species within and outside the nominated areas. Habitat maps were generated using either species distribution models (SDMs), knowledge-based maps (KBMs) reflecting broad habitat associations (for instance, with mapped PCTs) and expert polygons defined through the expert reports under the BCAR process
- An overview of the population mapping for the species. This includes:
  - Any filters applied to the use of species (BioNet) records
  - Assumptions made in identifying biological populations from the species records. It is relevant to note that the method used to define populations for this assessment was tailored to the available data and purpose of the baseline mapping. While the definition used is based on the theoretical definition of a biological population

used elsewhere in the literature, it is confounding to try to match or relabel these populations to corresponding populations in other publications, such as recovery plans or species profiles, which will be based on a different dataset, often with a different purpose, set of criteria and level of resolution. The population mapping presented in this report therefore needs to be considered as standalone and fit for purpose.

  - Any criteria met in determining the importance of populations

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

30.2.3 OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

Describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file (layered PDF). The map provides critical context for the assessment and should be viewed in conjunction with the text presented in the assessments. This section also provides a qualitative description of where records and habitat occur.

For threatened migratory shorebirds, habitat mapping was undertaken using a different approach. This is described in detail in Chapter 32 and is based on identifying the importance of habitat sites for shorebirds across the Cumberland subregion in accordance with the relevant significant impact guidelines.

30.2.4 AVOIDANCE OF IMPACTS

Provides an overview of the area of potential habitat that was avoided for each species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan.

The definition of what constitutes avoidance has been adopted from the BCAR process. Under the BAM, avoidance refers to land that is suitable for development and included in the area proposed for development or biodiversity certification, but has been avoided because of its biodiversity value. This is referred to as avoidance for 'biodiversity purposes' in this assessment.

Land not impacted because it is not suitable for development or biodiversity certification, or land that has been excluded from the area proposed for development is not considered to have been avoided under the BAM. This land is referred to as avoidance for 'other purposes' and includes:

- Riparian corridors consistent with the *Water Management Act 2000*:
  - Strahler stream order 2 - buffer 20 m either side
  - Strahler stream order 3 - buffer 30 m either side
  - Strahler stream order 4 and above - buffer 40 m either side
- State protected land (>18 degrees slope, considered too steep for urban development)

Some land within the nominated areas was not considered for inclusion in the area proposed for development and has therefore been identified as 'excluded' land. These lands include:

- Existing protected land, including reserves and established offset sites
- Council owned land which is zoned for environmental conservation, environmental management or recreation
- Commonwealth land, such as Defence Establishment Orchard Hills
- Lands within the nominated areas already assessed as part of another development approval (Bingara Gorge), or lands progressing through an alternate assessment (Mount Gilead, Menangle Park, Sydney Metro Stage 1)
- Lands already developed (existing urban areas, urban land zones and roads)

A further, detailed explanation of the avoidance process and terminology is provided in Chapter 14.

30.2.5 DIRECT IMPACTS AND OFFSETS

Provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts. Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat.

Direct impacts were determined based on an intersect of the urban capable lands and transport corridors with the baseline mapping generated for each threatened fauna species. It has been assumed that total permanent clearing will occur within the urban capable lands and transport corridors for the purposes of the assessment. However, it is important to note that in reality:

- Further avoidance will be undertaken within the transport corridors (see Chapter 7)
- Direct impacts will occur progressively over the life of the Plan, which reduces the severity of impacts

The extent or scale of loss is presented in terms of:

- Number and size of populations/important populations
- Hectares of potential habitat

The analysis also considers the likelihood of direct impacts leading to fragmentation of populations and areas of potential habitat.

To provide a sense of the magnitude and importance of direct impacts, the risk of residual adverse impacts to each species occurring as a result of any direct impacts was characterised as per the methodology set out in Section 30.3 below.

The Plan provides offsets for species that are considered to be at <u>medium</u> or <u>high</u> risk of residual adverse impacts. Offsets are not provided for species that are considered to be at <u>low</u> or <u>very low</u> risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

30.2.6 POTENTIAL INDIRECT IMPACTS AND MITIGATION

Identifies the potential indirect impacts to each species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to a species if:

- The indirect impact is identified as a threat in a relevant profile, conservation advice or recovery plan, *and*
- The threat is present in the Cumberland subregion, *and*
- The Plan has the potential to exacerbate the threat

Relevant indirect impacts were identified by drawing on ecological and life history information in species profiles, conservation advices and recovery plans, and species records and habitat maps prepared for this Assessment Report.

The indirect impacts section then goes on to determine if the generic management strategies in the Plan will be adequate for addressing indirect impacts, or if species-specific commitments are necessary. Species-specific commitments were generally considered necessary where a species was found to have a particular vulnerability or susceptibility to a potential indirect impact in a discrete location.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

31.1.1 POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

Considers the potential additional impacts to species due to essential infrastructure projects that are needed to support development within the nominated areas. These might include projects such as water and electricity utilities, communications facilities, stormwater management systems, and waste or resource management systems. The assessment covers projects that may need to be located outside urban capable lands and on areas that are identified as avoided lands <u>within the nominated areas</u>.

This section also assesses the likelihood of potential additional impacts to species due to the tunnel sections of the transport corridors. The impacts of tunnels were assessed separately to the rest of the transport corridors as only small areas of the footprints will be disturbed and it is not possible to determine at this stage the nature and extent of those impacts.

Please refer to the following chapters for details about these development types:

- Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels

- Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)

30.2.7 LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

Considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

30.2.8 DATA TABLES

Sets out the data tables for occurrence, avoidance and direct impacts for each species.

30.3 RISK ASSESSMENT APPROACH FOR THREATENED FAUNA

This section sets out:

- The purpose of the risk assessment approach
- The risk assessment framework
- A description of the risk ratings
- The likelihood and consequence definitions for direct impacts to populations and/or potential habitat
- The likelihood and consequence definitions for direct impacts leading to fragmentation

30.3.1 PURPOSE

The purpose of the risk assessment for threatened fauna was to determine the level of risk of residual adverse impacts occurring to a species as a result of direct impacts. Indirect impacts were assessed differently (see Chapter 15) and were not subject to the same risk assessment process.

The term “residual adverse impacts” was used as it forms part of the EPBC Act Environmental Offsets Policy (DSEWPC, 2012c). Offsets are typically required under the EPBC Act when residual adverse impacts remain after avoidance and mitigation measures have been applied. In this case, the Plan provides offsets for species which are considered to be at high or medium risk of residual adverse impacts. Offsets are not provided for species which are considered to be at low or very low risk. As outlined above, the rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

A risk based approach to considering residual adverse impacts is appropriate for the strategic assessment. The ToR (Clause 4.2) identify the need for the impact assessment to consider the “level of likely risk to each protected matter”. The spatial and temporal scale of the Plan means that there is an inherent level of uncertainty in the baseline data (both for habitat and records). In particular, the potential habitat mapping for the majority of species is highly precautionary and does not necessarily indicate with great certainty if a species will occur in an impact area. It is critical therefore to understand the level of risk to each species rather than take a simplistic view of direct impacts as presented in the impact numbers.

30.3.2 RISK ASSESSMENT FRAMEWORK

Risk is generally considered to be the combination of the likelihood and consequence of an event occurring. The methodology used in the assessment is based on an adapted version of the Australian Standard on Risk Management (Standards Australia, 2018).

The assessment for threatened fauna first considered if a species is restricted in its use of habitat (e.g. Green and Golden Bell Frog) or if it is mobile and wide ranging (e.g. Swift Parrot). This distinction was made as the criteria for risk differs depending on the nature of the species. A known location for a species which is restricted in terms or habitat or movement is generally going to be assessed as more important and vulnerable. A restricted species has limited ability or opportunity to disperse or seek refuge and the potential impacts to that location will necessarily be more concerning. In contrast, a record for a highly mobile species indicates the likely suitability and value of that area as habitat, and issues relating to barriers to movement and proportion of habitat impacted are more relevant to understanding the level of concern from potential impacts.

RESTRICTED SPECIES

The determination of the risk of residual adverse impacts for restricted species (see Section 30.3.4 for more information) was based on:

- The risk ratings in Table 30-2 Table 30-2
- Understanding the risk of residual adverse impacts due to direct impacts to populations and/or potential habitat based on:
    - The likelihood definitions in Table 30-3
    - The consequence definitions in Table 30-4, Table 30-5, Table 30-6 and Table 30-7
- Understanding the risk of residual adverse impacts due to fragmentation based on:
    - The likelihood definitions in Table 30-8
    - The consequence definitions in Table 30-11

The final level of risk for a species was determined on a precautionary basis. The highest level of risk based on the consideration of impacts to populations, potential habitat, or due to fragmentation was taken.

WIDE RANGING SPECIES

The determination of the risk of residual adverse impacts for wide ranging species (see Section 30.3.5 for more information) was based on:

- The risk ratings table shown in Table 30-2
- The likelihood definitions in Table 30-12
- The consequence definitions in Table 30-13

30.3.3 RISK RATINGS

Four levels of risk were defined through the process (see Table 30-2). They were:

- Very low risk = very low risk that residual adverse impacts to a species will occur. Offsets for residual impacts were not considered necessary
- Low risk = low risk that residual adverse impacts to a species will occur. Offsets for residual impacts were not considered necessary
- Medium risk = medium risk that residual adverse impacts to a species will occur. Offsets were considered necessary
- High risk = high risk that residual adverse impacts to a species will occur. Offsets were considered necessary

Where there were no direct impacts to a species, there was considered to be no risk of residual adverse impacts.

Table 30-2: Risk ratings table

	CONSEQUENCE				
LIKELIHOOD	**Negligible**	**Minor**	**Moderate**	**Major**	**Extreme**
Almost certain	Low	Medium	Medium	High	High
Likely	Low	Low	Medium	Medium	High
Possible	Very low	Low	Low	Medium	Medium
Unlikely	Very low	Very low	Low	Low	Medium

30.3.4 RISK APPROACH FOR RESTRICTED SPECIES

LIKELIHOOD AND CONSEQUENCE DEFINITIONS FOR DIRECT IMPACTS TO POPULATIONS AND/OR POTENTIAL HABITAT

Likelihood

Table 30-3 sets out the definitions for the likelihood that a threatened flora species will be directly impacted due to impacts to populations and/or potential habitat. These definitions:

- Draw on the baseline data for the species in terms of records and potential habitat mapping
- Consider the level of confidence in the records and potential habitat mapping. Strict definitions of "high", "moderate" and "low" confidence are not provided as they are species specific in relation to the baseline data. Judgements about the level of confidence in the data were instead determined based on the expert judgement of the assessment team who created the baseline data

Table 30-3: Likelihood definitions for direct impacts to populations and/or potential habitat

Likelihood	Definition
Almost certain	• Direct impacts to a known population with high confidence in the accuracy of the records
Likely	• Direct impacts to a known population with some uncertainty in the accuracy of the records OR • Direct impacts to potential habitat with high confidence that the species occurs in the impact area
Possible	• No direct impacts to a known population • Direct impacts to potential habitat with moderate confidence that the species occurs in the impact area
Unlikely	• No direct impacts to a known population • Direct impacts to potential habitat with low confidence that the species occurs in the impact area

Consequences

Consequence was determined by separately considering impacts to potential habitat as well as any impacts to known populations. The highest ranking of consequence was then taken for a species.

The criteria for determining consequence were based on a range of factors including:

- Conservation status. Impact thresholds for consequence were smaller for critically endangered species than for endangered species, and smaller for endangered species than for vulnerable species
- If the species is considered to be an SAII entity under the BCAR process or is endemic (>90 per cent of records in the subregion) to the Cumberland subregion. Species that met either of these criteria were treated under the consequence thresholds for critically endangered species even if they had a lower conservation status
- The application of both population impact thresholds and potential habitat impact thresholds. It should be noted that like all threshold approaches the numbers are arbitrary to a degree. However, the thresholds are considered to be appropriate because they:
    - Reflect the nature of the baseline data. In particular the potential habitat mapping which has been generated across the Strategic Assessment Area is precautionary in many cases and over-maps habitat
    - Are structured around conservation status
    - Reflect the expert view of the assessment team about the level of risk to species

The consequence definitions for direct impacts due to impacts to populations and/or potential habitat are set out in:

- Table 30-4, Table 30-5 and Table 30-6 for potential habitat
- Table 30-7for populations

Table 30-4: Consequence definitions for direct impacts to potential habitat for vulnerable species

Potential habitat thresholds	Confidence that species occurs in impact area		
	High	Moderate	Low
Loss of >15% of mapped potential habitat	Extreme	Extreme	Minor
Loss of 10-15% of mapped potential habitat	Extreme	Major	Minor
Loss of 6-10% of mapped potential habitat	Major	Moderate	Negligible
Loss of 2-6% of mapped potential habitat	Moderate	Minor	Negligible
Loss of <2% of mapped potential habitat	Minor	Negligible	Negligible

Table 30-5: Consequence definitions for direct impacts to potential habitat for endangered species

Potential habitat thresholds	Confidence that species occurs in impact area		
	High	Moderate	Low
Loss of >10% of mapped potential habitat	Extreme	Extreme	Minor
Loss of 7-10% of mapped potential habitat	Extreme	Major	Minor
Loss of 3-7% of mapped potential habitat	Major	Moderate	Negligible
Loss of 1-3% of mapped potential habitat	Moderate	Minor	Negligible
Loss of <1% of mapped potential habitat	Minor	Negligible	Negligible

Table 30-6: Consequence definitions for direct impacts to potential habitat for critically endangered, SAII* and/or endemic species**

Potential habitat thresholds	Confidence that species occurs in impact area		
	High	Moderate	Low
Loss of >5% of mapped potential habitat	Extreme	Extreme	Minor
Loss of 2-5% of mapped potential habitat	Extreme	Major	Minor
Loss of 1-2% of mapped potential habitat	Major	Moderate	Negligible
Loss of 0.5-1% of mapped potential habitat	Moderate	Minor	Negligible
Loss of <0.5% of mapped potential habitat	Minor	Negligible	Negligible

* SAII = species that are potentially subject to Serious and Irreversible Impacts as identified through the BCAR process

** Endemic = species that are considered endemic to Cumberland subregion because more than 90% of records of the species occur within the subregion

Table 30-7: Consequence definitions for direct impacts to populations

Consequence	TYPE OF IMPACT	MEASURE BY CONSERVATION STATUS		
		Vulnerable	Endangered	Critically endangered or SAII* or endemic**
Extreme	• Impacts to known population, OR	• Loss of 2 or more important populations	• Loss of 2 or more populations	• Loss of 1 or more populations
	• Impacts to population at edge of occurrence, OR	• Loss of 1 important population at edge of occurrence	• Loss of 1 population at edge of occurrence	• Loss of records within a population at the edge of occurrence
Major	• Impacts to known population, OR	• Loss of 1 important population	• Loss of 1 population	• Loss of records within a population
	• Impacts to population at edge of occurrence	• Loss of records within an important population at the edge of occurrence	• Loss of records within a population at the edge of occurrence	• N/A
Moderate	• Impacts to known population, OR	• Loss of records within an important population, or the loss of a non-important population	• Loss of records within a population	• N/A
	• Impacts to population at edge of occurrence	• N/A	• N/A	• N/A
Minor	• Impacts to known population, OR	• Loss of records within a non-important population	• N/A	• N/A
	• Impacts to population at edge of occurrence	• N/A	• N/A	• N/A
Negligible	• Impacts to known population, OR	• N/A	• N/A	• N/A
	• Impacts to population at edge of occurrence	• N/A	• N/A	• N/A

* SAII = species that are potentially subject to Serious and Irreversible Impacts as identified through the BCAR process

** Endemic = species that are considered endemic to Cumberland subregion because more than 90% of records of the species occur within the subregion

LIKELIHOOD AND CONSEQUENCE DEFINITIONS FOR FRAGMENTATION IMPACTS

Likelihood

Table 30-8 Table 30-8 sets out a matrix for determining the likelihood that a threatened flora species will be impacted by fragmentation. The two axes of the matrix are:

- Barrier likelihood which represents a judgement about how likely a particular development will disrupt connectivity for a species. Table 30-9 provides examples of different barrier likelihoods
- Fragmentation type which sets out how a species may be impacted. Table 30-10 provides criteria for fragmentation types

Table 30-8: Likelihood definitions for fragmentation

	FRAGMENTATION TYPE (see Table 30-10)			
BARRIER LIKELIHOOD (see Table 30-9)	**Certain impact within population**	**Likely impact within population OR certain impact between populations**	**Possible impact between populations OR likely impact to habitat connected to a population**	**Impact to mapped habitat only**
Certain barrier	Almost certain	Almost certain	Likely	Possible
Likely barrier	Almost certain	Likely	Possible	Possible
Possible barrier	Likely	Likely	Possible	Unlikely
Unlikely barrier	Possible	Possible	Unlikely	Unlikely

Table 30-9: Examples of barrier likelihood

Barrier likelihood	Examples
Certain barrier	• If species thought to be unable to cross barriers >100 m, a 1 km barrier is inconsistent with dispersal requirements • If species requires continuous or semi-continuous vegetated areas for dispersal (e.g. to provide shelter for fauna or to support pollinator populations), areas with little to no vegetation (such as high density urban and/or commercial areas) is inconsistent with dispersal requirements • If species is highly susceptible to being impacted by major roads with high traffic density (either through high roadkill rates, through aversion to noise and light, or through aversion to crossing open spaces) a major road is inconsistent with dispersal requirements
Likely barrier	• If species thought to be unable to cross barriers >100 m, a 300 m barrier is likely to be inconsistent with dispersal requirements • If species requires continuous or semi-continuous vegetated areas for dispersal (e.g. to provide shelter for fauna or to support pollinator populations), areas with sparse vegetation (such as low to moderate density urban areas with gardens) are likely to be inconsistent with dispersal requirements • If species is thought to be susceptible to being impacted by major roads with high traffic density (either through moderate roadkill rates, through moderate aversion to noise and light, or through moderate aversion to crossing open spaces) a major road is likely to be inconsistent with dispersal requirements
Possible barrier	• If species thought to be unable to cross barriers >100 m, a 150 m barrier may be inconsistent with dispersal requirements • If species requires continuous or semi-continuous vegetated areas for dispersal (e.g. to provide shelter for fauna or to support pollinator populations), areas with sparse vegetation

Barrier likelihood	Examples
	(such as rural residential areas and agricultural areas) may be inconsistent with dispersal requirements • If species is thought to have potential to be impacted by major roads with high traffic density (either through possible roadkill occurrences, possible aversion to noise and light, or through possible aversion to crossing open spaces), a major road may be inconsistent with dispersal requirements
Unlikely barrier	• If species thought to be unable to cross barriers >100 m, barrier of <100 m is unlikely to be inconsistent with dispersal requirements • If species requires continuous or semi-continuous vegetated areas for dispersal (e.g. to provide shelter for fauna or to support pollinator populations), areas with moderate vegetation density (such as parks, nature reserves and vegetated areas) are unlikely to be inconsistent with dispersal requirements • If species is not known to be impacted by major roads with high traffic density (the species is not known to be susceptible to roadkill, noise or light aversion, or aversion to open spaces), then a major road is unlikely to be inconsistent with dispersal requirements

Table 30-10: Criteria for fragmentation types

Fragmentation type	Criteria
Certain impact within population	• Barrier is placed between records of a single population, with high confidence in the accuracy of the records
Likely impact within population **OR** **certain impact between populations**	• Barrier is placed between records of a single population, with some uncertainty in the accuracy of the records, OR • Barrier is placed in mapped potential habitat between records of two or more different populations, with high confidence in the accuracy of the records
Possible impact between populations OR likely impact to habitat connected to a population	• Barrier is placed in mapped potential habitat between records of two or more different populations, with some uncertainty in the accuracy of the records, OR • Barrier is placed in mapped potential habitat, where the mapped habitat is in the vicinity of, or connected to, only one known population of the species
Impact to mapped habitat only	• Barrier is placed in mapped potential habitat, where the mapped habitat is not connected to any known populations of the species

Consequences

Consequence was determined by considering fragmentation type and applying different criteria depending on the conservation status of the species.

Table 30-11: Consequence definitions for fragmentation

Consequence	FRAGMENTATION TYPE	MEASURE BY CONSERVATION STATUS		
		Vulnerable	Endangered	Critically endangered or SAII* or endemic**
Extreme	Internal fragmentation	• Internal fragmentation of two or more important populations, OR • Internal fragmentation of an important population at edge of occurrence	• Internal fragmentation of two or more populations, OR • Internal fragmentation of a population at edge of occurrence	• Internal fragmentation of one population
	Fragmentation between populations	• Fragmentation between populations, which impacts an important population at the edge of occurrence	• Fragmentation between populations, which impacts a population at the edge of occurrence	• Fragmentation between populations, which impacts a population at the edge of occurrence, OR • Fragmentation between populations, which impacts two or more populations which are not at the edge of occurrence
	Fragmentation between a population and potential habitat	• N/A	• N/A	• N/A
	Fragmentation of potential habitat	• N/A	• N/A	• N/A
Major	Internal fragmentation	• Internal fragmentation of one important population	• Internal fragmentation of one population	• N/A
	Fragmentation between populations	• Fragmentation between populations, which impacts two or more important populations which are not at the edge of occurrence	• Fragmentation between populations, which impacts two or more populations which are not at the edge of occurrence	• N/A

Consequence	FRAGMENTATION TYPE	MEASURE BY CONSERVATION STATUS		
		Vulnerable	Endangered	Critically endangered or SAII* or endemic**
	Fragmentation between a population and potential habitat	• Fragmentation of one important population, where the population is separated from a large area of connected mapped potential habitat	• Fragmentation of one population, where the population is separated from a large area of connected mapped potential habitat, OR • Fragmentation of two or more populations, where each population is connected to either a moderate or small area of connected mapped potential habitat	• Fragmentation of one population, where the population is separated from a large area of connected mapped potential habitat, OR • Fragmentation of two or more populations, where each population is connected to either a moderate or small area of connected mapped potential habitat
	Fragmentation of potential habitat	• N/A	• N/A	• Fragmentation of a large area of potential habitat with no associated records
Moderate	Internal fragmentation	• Internal fragmentation of two or more non-important populations	• N/A	• N/A
	Fragmentation between populations	• Fragmentation between populations, which impacts one important population and one or more non-important populations not at the edge of occurrence	• N/A	• N/A
	Fragmentation between a population and potential habitat	• Fragmentation of one important population, where the population is separated from a moderate area of connected mapped potential habitat	• Fragmentation of one population, where the population is separated from a moderate area of connected mapped potential habitat	• Fragmentation of one population, where the population is separated from a moderate area of connected mapped potential habitat
	Fragmentation of potential habitat	• Fragmentation of a large area of potential habitat with no associated records	• Fragmentation of a large area of potential habitat with no associated records	• Fragmentation of a moderate area of potential habitat with no associated records
Minor	Internal fragmentation	• Internal fragmentation of one non-important populations	• N/A	• N/A
	Fragmentation between populations	• Fragmentation between populations, which impacts two or more non-	• N/A	• N/A

Consequence	FRAGMENTATION TYPE	MEASURE BY CONSERVATION STATUS		
		Vulnerable	Endangered	Critically endangered or SAII* or endemic**
		important populations not at the edge of occurrence		
	Fragmentation between a population and potential habitat	• Fragmentation of one important population, where the population is separated from a small area of connected mapped potential habitat, OR • Fragmentation of one or more non-important population, where the population is separated from a large area of connected mapped potential habitat	• Fragmentation of one or more populations, where the population is separated from a small area of connected mapped potential habitat	• Fragmentation of one population, where the population is separated from a small area of connected mapped potential habitat
	Fragmentation of potential habitat	• Fragmentation of a moderate area of potential habitat with no associated records	• Fragmentation of a moderate area of potential habitat with no associated records	• Fragmentation of a small area of potential habitat with no associated records
Negligible	Internal fragmentation	• N/A	• N/A	• N/A
	Fragmentation between populations	• N/A	• N/A	• N/A
	Fragmentation between a population and potential habitat	• Fragmentation of one or more non-important populations, where the population is separated from a moderate or small area of connected mapped potential habitat	• N/A	• N/A
	Fragmentation of potential habitat	• Fragmentation of a small area of potential habitat with no associated records, OR • Fragmentation of mapped habitat, where impacted habitat occurs outside of the known range of the species	• Fragmentation of a small area of potential habitat with no associated records, OR • Fragmentation of mapped habitat, where impacted habitat occurs outside of the known range of the species	• Fragmentation of mapped habitat, where impacted habitat occurs outside of the known range of the species

* SAII = species that are potentially subject to Serious and Irreversible Impacts as identified through the BCAR process

** Endemic = species that are considered endemic to Cumberland subregion because more than 90% of records of the species occur within the subregion

30.3.5 RISK APPROACH FOR WIDE-RANGING SPECIES

An amended risk assessment approach was applied for wide-ranging species. This reflected the difference in how wide-ranging species use habitat.

LIKELIHOOD

Table 30-12 sets out the definitions for the likelihood that a wide-ranging fauna species will be subjected to substantial impacts. "Substantial" in this case is defined as impacts that could materially affect the species' use of the Strategic Assessment Area.

These definitions:

- Draw on the baseline data for the species in terms of records and potential habitat mapping
- Consider the scale of impacts to records and potential habitat mapping. Strict definitions of "major", "moderate" and "minor" impacts are not provided as they are species specific in relation to the baseline data. Judgements about how to categorise the scale of impacts were instead determined based on the expert judgement of the assessment team who created the baseline data

Table 30-12: Likelihood definitions for direct impacts for wide ranging species

Likelihood	Definition
Almost certain	• Impacts to breeding or roosting habitat
Likely	• No impacts to breeding or roosting habitat • Major impacts to foraging habitat
Possible	• No impacts to breeding or roosting habitat • Moderate impacts to foraging habitat
Unlikely	• No impacts to breeding or roosting habitat • Minor impacts to foraging habitat

CONSEQUENCES

Consequence was determined by separately considering impacts to potential habitat as well as any impacts to known populations. The highest ranking of consequence was then taken for a species.

Consistent with the approach for restricted species, the criteria for determining consequence were based on a range of factors including:

- Conservation status. Impact thresholds for consequence were smaller for critically endangered species than for endangered species, and smaller for endangered species than for vulnerable species
- If the species is considered to be an SAII entity under the BCAR process or is endemic (>90 per cent of records in the subregion) to the Cumberland subregion. Species that met either of these criteria were treated under the consequence thresholds for critically endangered species even if they had a lower conservation status
- The application of both population impact thresholds and potential habitat impact thresholds. It should be noted that like all threshold approaches the numbers are arbitrary to a degree. However, the thresholds are considered to be appropriate because they:
    - Reflect the nature of the baseline data. In particular the potential habitat mapping which has been generated across the Strategic Assessment Area is precautionary in many cases and over-maps habitat
    - Are structured around conservation status
    - Reflect the expert view of the assessment team about the level of risk to species

Table 30-13: Consequence definitions for impacts to wide ranging species

Consequence	TYPE OF IMPACT	MEASURE BY CONSERVATION STATUS		
		Vulnerable	Endangered	Critically endangered or SAII* or endemic**
Extreme	• Impacts to core breeding or roosting area, OR	• Loss of a core breeding or roosting area	• Moderate impacts to a core breeding or roosting area	• Any impacts to a core breeding or roosting area
	• Impacts to mapped potential habitat	• Loss of >15% of mapped potential habitat	• Loss of >10% of mapped potential habitat	• Loss of >5% of mapped potential habitat
Major	• Impacts to core breeding or roosting area, OR	• Major impacts to a core breeding or roosting area	• Minor impacts to a core breeding or roosting area	• N/A
	• Impacts to mapped potential habitat	• Loss of 10-15% of mapped potential habitat	• Loss of 7-10% of mapped potential habitat	• Loss of 2-5% of mapped potential habitat
Moderate	• Impacts to core breeding or roosting area, OR	• Moderate impacts to a core breeding or roosting area	• N/A	• N/A
	• Impacts to mapped potential habitat	• Loss of 6-10% of mapped potential habitat	• Loss of 3-7% of mapped potential habitat	• Loss of 1-2% of mapped potential habitat
Minor	• Impacts to core breeding or roosting area, OR	• Minor impacts to a core breeding or roosting area	• N/A	• N/A
	• Impacts to mapped potential habitat	• Loss of 2-6% of mapped potential habitat	• Loss of 1-3% of mapped potential habitat	• Loss of 0.5-1% of mapped potential habitat
Negligible	• Impacts to core breeding or roosting area, OR	• No impacts to a core breeding or roosting area	• N/A	• N/A
	• Impacts to mapped potential habitat	• Loss of <2% of mapped potential habitat	• Loss of <1% of mapped potential habitat	• Loss of <0.5% of mapped potential habitat

* SAII = species that are potentially subject to Serious and Irreversible Impacts as identified through the BCAR process

** Endemic = species that are considered endemic to Cumberland subregion because more than 90% of records of the species occur within the subregion

SPECIES AT HIGH RISK OF DIRECT IMPACTS

30.4 *PHASCOLARCTOS CINEREUS* (KOALA)

30.4.1 INTRODUCTION

Phascolarctos cinereus (Koala) is recognised as one of Australia's most iconic animals. There is an important population of the species in Southern Sydney which is the focus of this assessment. The species is listed under the:

- EPBC Act as Vulnerable for the combined populations of Queensland, New South Wales and the Australian Capital Territory
- BC Act as Vulnerable

This section provides a detailed EPBC Act assessment of the outcomes for Koalas associated with implementation of the Plan in accordance with the requirements of the ToR. Given the extensive information available for the Koala assessment and the complexity of the issues, it is presented differently and in more detail than the other threatened species in this chapter.

It is noted that the risk assessment process set out in the previous section (Section 30.3) was not applied to Koalas as they were considered a high risk species due to the importance of the Southern Sydney population, and the potential for direct and indirect impacts.

The Koala assessment sets out:

- Implications of the 2019/20 bushfires
- Background to the species
- The regulatory context for assessing impacts to Koalas under the EPBC Act
- A summary of the baseline information
- Occurrence within the Strategic Assessment Area
- The efforts to avoid and minimise impacts
- The direct and indirect impacts to the species
- The proposed outcomes, commitments and actions to protect Koalas
- A detailed evaluation of the outcome for the species against the statutory and policy requirements
- A conclusion

Hyperlinks to maps are provided throughout the text and are not included directly within the document.

In addition, a detailed set of Koala attachments are provided at the end of the chapter. They include:

- Attachment A – Terminology used in this assessment
- Attachment B – Detailed background information on Koalas
- Attachment C – Habitat mapping used in the assessment

The impact assessment for Koalas in relation to the BC Act requirements is provided in Part 5 of the report.

30.4.2 IMPLICATIONS OF THE 2019/20 BUSHFIRES

As outlined in Part 1 of this report, the 2019/20 bushfires in NSW are unprecedented in their extent and intensity. As of 28 January 2020, the fires had burnt 5.3 million hectares (6.7 per cent of NSW), including 2.7 million hectares in national parks (37 per cent of the national park estate) and over 80 per cent of the Greater Blue Mountains World Heritage Area (EES, 2020).

The fires destroyed large areas of habitat and populations across NSW for some species potentially impacted by the development under the Plan. Because the extent and intensity of the fires are unprecedented, ultimate recovery of some of these species is uncertain and could be affected. This means that:

- The fires may increase the significance of the impacts of the development under the Plan for some species

- Additional commitments under the Plan may be needed for some species to help address the impacts of the fires

The full impact of the fires on biodiversity will not be understood for some time (EES, 2020).

As part of the process of preparing this report, an initial assessment of the implications of the fires for the Plan has been undertaken based on available information. The assessment will be reviewed as further information on the impacts of the fires becomes available.

Koalas were identified as one of the species that is likely to have been significantly impacted by the fires. In particular this relates to populations in the northern part of NSW and closer to the Plan Area in the Blue Mountains.

The assessment for Koalas in this report incorporates consideration of the implications of the fires as far as possible.

30.4.3 BACKGROUND TO KOALAS

This section provides an overview of the species and describes its status in NSW. More detailed information is provided at Attachment B.

OVERVIEW

Koalas are arboreal marsupials that are distributed within coastal and inland regions of eastern Australia, from South Australia to northern Queensland.

They are specialist folivores, meaning that they eat leaves and are highly selective in their choice of diet. They are known to eat the leaves of over 100 *Eucalyptus* species and over 30 non-*Eucalyptus* species (including genera such as *Angophora* and *Corymbia*) (OEH, 2018a). However, local Koala populations typically tend to select their diet from only a small number of trees in their local area, with the preferred tree species varying between populations (McAlpine, Rhodes et al., 2008).

Overall, Koalas typically preference trees growing on fertile soils, as fertile soils result in higher leaf nutrient content in trees.

They are territorial animals which exist in complex social networks. Males are more prone to dispersal, whereas female Koalas tend to remain close to natal sites (Houlden, Costello et al., 1999). Male ranges typically tend to be significantly larger than female ranges. The average size of a Koala's home range varies significantly between populations and between different areas and habitats (NSW Chief Scientist & Engineer, 2016).

Koalas had already undergone a series of population bottlenecks prior to European arrival (likely as a result of glacial/interglacial cycles). They therefore already had low genetic diversity prior to the impacts of European activities on the population (Black, Price et al., 2014). Predicting population trends has its challenges but it is thought that the species has declined across most of its range.

Koala populations have been declining as a result of a diverse number of threats, including (McAlpine, Lunney et al., 2015; OEH, 2017g):

- Habitat loss
- Habitat modification and fragmentation
- Predation from domestic and feral dogs
- Vehicle strike
- Fire (particularly increased fire intensity which burns the crown of trees)
- Disease (particularly *Chlamydia*)
- Heat stress through drought and heatwaves
- Climate change (which increases drought and heatwaves, but also alters habitat quality)

STATUS OF KOALAS IN NSW

In December 2016, the NSW Chief Scientist and Engineer released a Report of the Independent Review into the Decline of Koala Populations in Key Areas of NSW. Using up-to-date scientific information, that report described the status of Koalas in NSW as at 2016. The key findings of the report are as follows:

- Koalas were historically distributed throughout the woodlands and forests of NSW, but have experienced significant declines in both numbers and distribution
- Koala numbers continue to decline despite a range of initiatives to protect them
- Surveys indicate that populations of Koalas have disappeared from many areas (particularly from the southern and western edges of their distribution)
- Estimates at 2016 suggest there are approximately 36,000 Koalas in NSW, representing a 26 per cent decline over the past three Koala generations (15-21 years)
- Across 13 regional Koala populations in NSW, nine Koala populations were estimated to be in decline, three stable and one increasing

A more recent report (Lane, Wallis et al., 2020) set out to quantify the effects of the 2019-20 fires on Koalas in the context of broader population trends in NSW. That report concluded that over the past three Koala generations, numbers may have declined by a minimum of 28.52 per cent up to a possible 65.95 per cent. The report suggests declines are more likely to have occurred towards the upper estimate, and that the ongoing threats of climate change and high frequency fires will severely threaten the species in NSW over the coming years.

30.4.4 REGULATORY AND POLICY CONTEXT

The overall regulatory and policy framework surrounding Koala conservation in NSW is complex, with multiple layers of overlapping instruments, all of which aim to provide for the protection and preservation of the species.

Table 30-14 provides an overview of the key instruments and policies in place that regulate and guide Koala conservation activities within NSW. These documents provided a framework for assessing the impacts and commitments for Koalas. They are:

- Conservation advice for the species
- EPBC Act Koala referral guidelines
- An advice document from EES about conserving Koalas in the in Wollondilly and Campbelltown LGAs
- NSW Koala recovery plan (not a statutory document under the EPBC Act)
- Koala Habitat Protection SEPP (previously SEPP 44)
- Saving our Species program for Koalas
- NSW Koala strategy
- Draft Campbelltown Comprehensive Koala Plan of Management

EPBC ACT APPROVAL CONSIDERATIONS

Section 146K of the EPBC Act sets out the formal approval considerations in relation to threatened species. In summary, the outcomes of the Plan must:

- Not be inconsistent with:
    - Any of the international agreements relating to threatened species
    - A recovery plan
    - A relevant Threat Abatement Plan
- Have regard for a conservation advice

At present, there is no recovery plan for the species recognised under the EPBC Act or relevant Threat Abatement Plans. The key statutory consideration therefore relates to the conservation advice for Koalas (DSEWPC, 2012a).

EVALUATION APPROACH

The evaluation at the end of this analysis draws together the information from the Koala assessment to provide a robust way of:

- Understanding the predicted outcomes for the Southern Sydney Koala population as a result of implementation of the Plan
- Determining acceptability of the Plan for Koalas in an EPBC Act context

The evaluation is based on posing a series of questions that are structured around:

- The outcome for Koalas specified in the Plan
- The key regulatory and policy documents:
  - EES principles from *Conserving Koalas in Wollondilly and Campbelltown LGAs. Final* (OEH, 2018d)
  - EPBC referral guidelines for Koalas
  - The Koala Conservation Advice

The results of the evaluation are presented at Section 30.4.10.

Table 30-14: Overview of the key regulatory and policy documents for Koalas in NSW

Document	Type	Description
Commonwealth Documents		
Approved Conservation Advice for *Phascolarctos cinereus* (combined populations of Queensland, New South Wales and the Australian Capital Territory) (Koala Northern Designatable Unit) (DSEWPC, 2012a)	EPBC Act statutory document	The purpose of this document is to provide guidance on immediate recovery and threat abatement activities that can be undertaken to ensure the conservation of the listed species. It provides an overview of broad-scale conservation advice for Koalas across NSW, QLD and the ACT, through distilling key findings of a range of other publications concerning Koala conservation. Given its very broad scope and the diversity of conservation needs of Koala populations across the species' range, the document recognises that in many cases, other more detailed and targeted reports are likely to be more applicable at local and regional scales. Regard for the Conservation Advice in developing the Plan is a statutory consideration under the EPBC Act.
EPBC Act referral guidelines for the vulnerable Koala (combined populations of Queensland, New South Wales and the Australian Capital Territory) (DoE, 2014j)	EPBC Act policy document	The purpose of this document is to provide guidance to proponents undertaking impact assessments for the Koala, in accordance with a nationally consistent assessment framework and in accordance with assessment requirements outlined by the EPBC Act. These guidelines are a key document underpinning the current impact assessment of Koalas. The guidelines provide a range of definitions and assessment criteria which have been considered, including: • Definition of 'habitat critical to the survival of the species' • Definition of impacts that 'substantially interfere with the recovery of the species' • A suite of criteria around assessing impacts • Determining the requirements for implementation, monitoring and duration of mitigation measures

Document	Type	Description
NSW Documents		
Conserving Koalas in Wollondilly and Campbelltown LGAs. Final (OEH, 2018d)	NSW guidance document	The document provides key ecological context and information for the Southern Sydney population of Koalas around Wollondilly and Campbelltown LGAs. This includes habitat and corridor mapping based on recent Koala tracking. The document sets out four key principles for managing Koalas in the context of residential and urban development Wilton and GMAC. The principles aim to ensure an ongoing healthy population and are: 1. Avoid new residential development within core Koala habitat [identified as 'principal' habitat in this report] and primary corridors 2. Separate residential development and Koala populations to minimise ongoing threats from domestic dogs and vehicles 3. Identify critical revegetation zones that will augment and strengthen core habitat and corridors 4. Identify Koala roadkill hotspots requiring roadkill mitigation fencing and/or underpasses to allow safe passage of Koalas
Recovery plan for the Koala (*Phascolarctos cinereus*) (DECC, 2008b)	NSW statutory document	The objective of the Recovery Plan is "to reverse the decline of the Koala in NSW, to ensure adequate protection, management and restoration of Koala habitat, and to maintain healthy breeding populations of Koalas throughout their range." This document has been considered as a background document to help to identify key management considerations regarding the protection of Koalas. The Recovery Plan was originally intended to be implemented over a five-year period commencing in 2008 and reviewed at the conclusion of the five-year period. However, this review did not occur.
State Environmental Planning Policy (Koala Habitat Protection) 2019	NSW planning instrument	This SEPP replaces the long standing SEPP 44 (Koala Habitat Protection). It came into effect in March 2020. The aim of the SEPP is to "…encourage the conservation and management of areas of natural vegetation that provide habitat for Koalas to support a permanent free-living population over their present range and reverse the current trend of Koala population decline" The SEPP is supported by the Koala Habitat Protection Guideline (draft) which provides details around implementation. At the time of writing this report the guidelines were still in draft form and had not yet been finalised.

Document	Type	Description
Securing the Koala in the wild in NSW for 100 years: Saving Our Species Iconic Koala Project 2017-2021 (OEH, 2017g)	NSW funding program for threatened species	The Saving Our Species Iconic Koala Project (SOS Project) aims to secure the Koala in the wild in NSW for 100 years by reducing critical threats to the species, ensuring adequate protection, management and ecological restoration of Koala habitat, and maintaining healthy breeding populations of Koalas through their current range. The SOS Project aims to achieve these objectives through coordinating and funding a range of actions across NSW, including conservation, ecological restoration, research and strategic management actions. This assessment draws upon findings obtained through field surveys and associated research which have been funded and implemented by the SOS Project.
NSW Koala Strategy (OEH, 2018h)	NSW policy document	The NSW Koala Strategy aims to stabilise and increase Koala numbers over the long term, ensuring genetically diverse and viable populations across NSW. The Strategy provides additional resources to enable the completion of a range of actions to assist in conserving the Koala. It builds on the findings of, complements the works undertaken, as part of the SOS Project. This assessment draws upon findings obtained through research sponsored by the NSW Government’s investment in conserving Koala populations in the wild.
Draft Campbelltown Comprehensive Koala Plan of Management (Phillips & Biolink, 2016)	Campbelltown City Council planning document	This document is a draft planning document prepared in relation to SEPP 44. It has not been finalised but aims to provide a consistent, landscape-based approach to matters relating to how Koalas and their habitat are managed, and provides a strategic approach to protection, management and ecological restoration of Koala habitat throughout the Campbelltown City Council LGA.

30.4.5 SUMMARY OF BASELINE INFORMATION

There is a significant amount of information that was used in this assessment. Sources include:

- Literature on the ecology of Koalas
- Species records
- Cumberland subregion species distribution model
- Habitat mapping
- Connectivity analysis

Further details are provided at Attachments B and C.

LITERATURE ON THE ECOLOGY OF KOALAS

Literature on the ecology of Koalas was used to understand the broad context for the species, and the specific values and issues of the Koala populations. Information was gathered from academic publications, government research (e.g. information from the Saving our Species program), planning documents, and studies done specifically for this project.

The work had a particular focus on the Southern Sydney Koala population. For example, information about the population is available regarding:

- Koala home range sizes and densities (OEH, 2018d; Ward, 2002)
- Potential population size (Biolink, 2016; OEH, 2018d; Ward, 2002)
- Population trends (Biolink, 2016, 2018b)
- Preferred feed tree species (OEH, 2018d; Phillips & Callaghan, 2000; Sluiter, Close et al., 2002; Ward, 2002)
- Habitat connectivity requirements (Biolink, 2018a)
- Population genetics (Kjeldsen, Raadsma et al., 2019; Lee, Zenger et al., 2010)
- Key threats (Phillips & Biolink, 2016)

The available literature and resources provide a solid foundation with which to understand the key characteristics and conservation needs of the Koalas within (and near) to the Strategic Assessment Area.

SPECIES RECORDS

Koala records within and adjacent to the Strategic Assessment Area were accessed from the NSW BioNet Atlas database.

The BioNet Atlas contains species records within the Plan Area which were obtained during recent research conducted by the Saving Our Species program, and is considered a resource containing contemporary knowledge of Koala distributions within the area.

BioNet records were used in research to assess population trends (Biolink, 2016, 2018b) and identify Koala roadkill locations and hotspots (OEH, 2018d).

BioNet records have also been used to conduct Species Distribution Model mapping as part of the current assessment process (discussed below).

HABITAT MAPPING

Three types of Koala habitat mapping were prepared for this assessment. They are:

- A species distribution model
- Corridor mapping in a way that is consistent with EES work in the area (OEH, 2018d)
- Mapping of habitat critical to the survival of the species in accordance with the EPBC Act referral guidelines (DoE, 2014j)

See Attachment C for details of the mapping approaches.

Species distribution model

RMIT (see Supporting Document F) prepared a species distribution model (SDM) for the Koala across the Cumberland subregion. SDMs are statistical models used to estimate the relationship between species records at sites and the environmental and/or spatial characteristics of those sites. Once this relationship has been estimated, the model can be used to predict other locations in the landscape where a species is likely to occur. The model was developed using the software 'Maxent'.

The SDM provides useful context about the occurrence of the species within the Strategic Assessment Area. However, given the availability of more detailed habitat mapping (see below) it is not used for detailed analysis of impacts.

Corridor mapping

Corridor mapping was undertaken for each of the nominated areas, as well as areas within the vicinity of Wilton and GMAC for the Southern Sydney population. The process was based on work undertaken by EES (2018d). It mapped movement corridors and supporting habitat.

See Table 30-15 for categories within the mapping and definitions (further definitions are provided at Attachment A).

The NSW Threatened Biodiversity Data Collection requires the assessment of impacts on Koala to be determined on the basis of 'important habitat'. Important habitat comprises the species polygons for Koala as required by the BAM (see Part 5). For this BAM assessment, 'important habitat' was defined as primary and secondary corridors. Primary and secondary corridors provide stronger connections across Koala habitat than tertiary corridors and are therefore likely to provide the most important connections and contribute most to the long-term persistence of Koala in the region.

Table 30-15: Habitat definitions for Koala corridor mapping

Habitat category	Definition
Movement corridors	Areas of habitat (often but not always linear) which facilitate the movement and dispersal of Koalas between habitat patches which would otherwise be disconnected
Movement corridors are comprised of:	
• **Primary corridors**	Defined as connected areas of principal habitat (and associated supporting habitat) that provide for ecological function of a population
• **Secondary corridors**	Defined as corridor areas that become narrowed to less than 50 metres wide across the crown width, or that are not connected at both ends
• **Tertiary corridors**	Smaller corridor areas that are not connected at the landscape level
Supporting habitat	The remaining areas of suitable habitat and vegetation structure that are outside principal habitat. Comprises scattered trees peripheral to and outside of identified Koala movement corridors

Habitat critical to the survival

To provide additional information for the assessment, "habitat critical to the survival" of Koalas was mapped in accordance with the EPBC Act referral guidelines for the species (DoE, 2014j). The mapping process was based on scoring criteria and considered the following key parameters in determining the value of Koala habitat:

- Koala occurrence
- Vegetation composition
- Habitat connectivity
- Existing threats
- The value of the potentially impacted Koalas to the recovery of the wider Koala community

CONNECTIVITY ANALYSIS

In addition to habitat mapping, a connectivity analysis conducted by Biolink (2018a) was undertaken for the Southern Sydney population across Wilton and the southern portion of GMAC. The purpose of the assessment was to assess the current habitat connectivity of the area, and then model projected changes following development within the nominated areas and upgrading of Appin Road.

The analysis was undertaken using the modelling software GAPCLoSR.

30.4.6 OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

There are two known populations of Koalas that occur within or near to the Strategic Assessment Area. The most relevant to this assessment is the Southern Sydney population which occurs within and near to Wilton and GMAC. The other is the Blue Mountains population which has infrequent records in the western portion of the Strategic Assessment Area.

This section:

- Presents the results of the mapping for Koalas that has been undertaken across the Strategic Assessment Area
- Provides a high-level summary of each population

HABITAT IN THE STRATEGIC ASSESSMENT AREA

Table 30-16 presents the areas of habitat within the Strategic Assessment Area and the nominated areas using the three types of mapping. There are significant areas of important habitat (and habitat critical to the survival) within and around Wilton and GMAC. This reflects the fact that the area supports an important and recovering population of the species (see below for details about the Southern Sydney population). There is no important habitat (or habitat critical to the survival) for Koalas in GPEC or WSA. This reflects the lack of use of the area by the species and minimal records (see below for details about the Blue Mountains population).

Please refer to the following maps for information about habitat:

- Map 37 - Koala species distribution model with records
- Map 38 - Koala corridor mapping for WSA and GPEC
- Map 39 - Koala corridor mapping for Wilton and GMAC
- Map 40 - Habitat critical to the survival for Wilton and GMAC

SOUTHERN SYDNEY POPULATION

Overview

The Southern Sydney population includes Koalas in the Campbelltown and Wollondilly Local Government Areas. The population is important and thought to be in recovery.

The exact boundaries of the population are unknown. However, it is likely that it extends:

- East to the coast
- South from Holsworthy until it connects with the Koalas in the Southern Highlands
- An unknown distance to the west. It is unclear whether or not the Hume Highway poses a significant barrier to movement

In this report, the population is assessed in the areas between Campbelltown and Bargo (see Map 39 and Map 40 for the mapped extent of habitat). It is estimated that there were approximately 433 Koalas living in this region prior to the 2019-20 fires (OEH, 2018d). The majority of the area was not affected by fire. However, some vegetation within the vicinity of Bargo and Tahmoor was burnt (DPIE, 2020).

The Southern Sydney Koalas prefer habitat on Wianamatta shale soils (due to the high nutrient content of the shale). As these soils are fertile, much of the area has been heavily cleared for agriculture and associated development. This makes remaining areas of vegetation on Wianamatta shale soils a high conservation priority. While Koalas will live in low densities in forests in sandstone areas (e.g. to the east of the Strategic Assessment Area), these areas are considered to be not as important for conservation.

Historically, Koalas in the Campbelltown area have remained free from infection with *Chlamydia.* However, recent research is showing that the disease is moving north from the Southern Highlands towards Campbelltown (Saving Our Species, 2019). This is likely to be a result of increased connectivity between Koalas in these areas.

The Southern Sydney Koalas are exposed to a range of current threats. They include:

- Vehicle strike. This is particularly relevant to major roads in the area and is an increasing issue as traffic volumes increase
- Dog predation. There are a range of existing developed areas and Koalas would be subject to dog attack (particularly where habitat occurs close to houses)
- Disease (particularly *Chlamydia*). This is an emerging issue. The Koalas around Campbelltown have been recognised as disease free. However, Koalas further to the south have been recorded with the disease

See Attachment B for more detail on the population, and the indirect impacts section below for further discussion about threats.

Habitat and connectivity

There are significant areas of important habitat within the area between Campbelltown and Bargo (see Map 39). This includes approximately 12,000 ha of primary corridors, and 2,433 ha of secondary corridors. As a subset of this, the two nominated areas provide approximately:

- 1,529 ha of primary corridors in Wilton. There is no secondary corridor habitat
- 1,202 ha of primary corridors, and 1,166 ha of secondary corridors in GMAC

Koala populations rely upon habitat connectivity in order to be viable. Habitat connectivity permits the dispersal of individuals (particularly for the dispersal of young Koalas to new territories and for reproduction during breeding season) and also helps to protect Koala populations from localised extinctions following stochastic events such as fire.

The work by EES (2018d) on corridor mapping emphasised the importance of north to south corridors (particularly to the east of Campbelltown and Appin) for the viability of the population. It also identified the areas of east to west connectivity.

Connectivity analysis conducted by Biolink (2018a) supported the importance of north-south connectivity for Koalas through the area. It also emphasised the importance of east-west connection, and analysed the relative importance of east-west corridors which varied according to factors such as their existing width and barriers to movement.

Further discussion about connectivity is provided below in the section on indirect impacts.

BLUE MOUNTAINS POPULATION

Overview

The Blue Mountains Koala population is the closest population to the northern and western parts of the Cumberland subregion. The majority of the population occurs outside the Strategic Assessment Area.

There is less known about the population compared to the Koalas in Southern Sydney. Most of the research on these Koalas has occurred in the Kurrajong/Richmond/Wollemi area and Kanangra-Boyd/Hartley region. Preliminary surveys have also recently begun in the area between Yarramundi in the north and the Southern Highlands in the south.

The population is known to occur from the north of Kurrajong, and is thought to extend down through national parks to the west of the Cumberland subregion. It has high genetic diversity and is important for conservation purposes. However, it is uncertain how many Koalas are in the Blue Mountains. Increased sightings suggest that the population is expanding. This expansion is occurring even though up to one third of the population is infected with *Chlamydia*.

Significant areas of vegetation within the Blue Mountains were burnt in the 2019-20 fires (DPIE, 2020). It is unknown what the long-term implications of this are for the population.

Presence in the nominated areas

GPEC and WSA are heavily cleared and urbanised. Neither nominated area has any important Koala habitat, with only small areas of supporting habitat. Further, both nominated areas have significant existing threats to Koalas, including threats posed by roads and high traffic density, roaming and domestic dogs, barriers to movement (such as fences) and landscape hazards (such as swimming pools). There are very few Koala records in either nominated area, which suggests that Koalas are not living there.

Overall, GPEC and WSA do not contain suitable habitat to support resident Koala populations. Therefore, any Koala records in these areas would comprise dispersing Koalas, travelling between areas of suitable habitat. These Koalas are thought to originate from the Blue Mountains Koala population, which is the closest Koala population.

30.4.7 AVOIDANCE

CONTEXT

Avoidance of impacts within the nominated areas was a key process in developing the Plan. Chapter 14 of the assessment report describes this process in detail and provides the overall results.

Design of the urban capable footprints in each nominated area was an iterative process that involved:

- Compilation of data on biodiversity values of each nominated area
- Development of criteria to identify priorities for avoidance of biodiversity values
- Workshops to apply the avoidance criteria to each nominated area and refine urban capable footprints
- Consultation with key stakeholders and resolution of issues
- Finalisation of initial urban capable footprints

Importantly for Koala, the species was specifically identified in the avoidance criteria as a priority. Avoiding areas of important habitat or connectivity was a key driver for refining the footprints to reduce impacts. One of the significant results of the avoidance process was the decision by the Department not to allow intensification of development to the east of Appin Road (which was proposed at one point in the process). This decision was specifically made to protect Koalas and facilitate implementation of the proposed Koala park (see Section 30.4.9).

Two types of avoidance were undertaken (see Chapter 14 of the report for details):

- Avoidance of land because of its biodiversity value
- Avoidance of land for other reasons. For example, land that is not suitable for development such as steep slopes (>18 degrees) or land within riparian corridors (Strahler stream order 2 and above). Due to the nature of this land the areas identified for avoidance often contain areas of biodiversity value

Information is reported for both types of avoidance.

It is important to note that there are a range of lands which were excluded from the avoidance calculations as they were not considered for certification as part of this project. This means that there is additional habitat for Koalas that may not be impacted that is not included in the avoidance figures. The excluded lands include areas:

- Already assessed as part of another development approval (e.g. Bingara Gorge in Wilton)
- Progressing through an alternate development assessment (e.g. Mount Gilead in GMAC)
- Already developed (e.g. existing urban areas, urban land zones)
- Not available for development (e.g. easements, Orchard Hills Defence Establishment, existing protected lands)

RESULTS

The results of the avoidance processes for Koala habitat are presented in Table 30-17. Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

Approximately 2,865 ha of important Koala habitat (primary and secondary corridors) was avoided within the nominated areas as part of the urban capable footprint design. This represents approximately 92 per cent of important habitat within the nominated areas (not including excluded lands). 2,182 ha of was avoided for biodiversity purposes.

In terms of habitat critical to the survival of Koalas, approximately 2,961 ha (approximately 90 per cent of the nominated areas total not including excluded lands) was avoided. 2,257 ha of this was avoided for biodiversity purposes.

30.4.8 IMPACT ANALYSIS

The plan will lead to direct and indirect impacts to Koalas. These are addressed in the following sections.

The potential for additional impacts due to essential infrastructure and tunnels are also discussed.

DIRECT IMPACTS

Implementation of the Plan will lead to the loss of some habitat for Koalas. Table 30-18 sets out the impacts to habitat across the four nominated areas.

GPEC and WSA

There is no important habitat (or habitat critical to the survival) within GPEC and WSA. Impacts are therefore limited to supporting habitat.

In GPEC, development will result in the loss of approximately 331 ha of supporting habitat, or 10.3 per cent of the total in the nominated area. In WSA, development will result in the loss of approximately 329 ha of supporting habitat, or 41.0 per cent of the total in the nominated area.

There are very limited to no records of the species in either nominated area, and they do not support a viable population of the species. The impacts to supporting habitat are not considered to be notable for Koalas in this context.

Wilton and GMAC

Impacts in Wilton and GMAC occur for all habitat types. Approximately 261 ha of important habitat (144 ha of primary and 116 ha of secondary corridors) will be lost across the two nominated areas. This equates to:

- 5.3 per cent of primary corridors within the two nominated areas (including excluded lands) (or 1.2 per cent of mapped primary corridors for the Southern Sydney population)
- 10 per cent of secondary corridors within the two nominated areas (or 4.8 per cent of mapped secondary corridors for the Southern Sydney population)

In terms of habitat critical to the survival of Koalas, approximately 337 ha will be lost which equates to 8.1 per cent within the two nominated areas (or 2.29 per cent of mapped habitat critical to the survival for the Southern Sydney population).

There will also be additional impacts to tertiary corridors (17 ha) and supporting habitat (139 ha).

Direct impacts to primary corridors are the most significant as these corridors provide for ecological function of the population. Impacts to secondary corridors are also of concern as they have the potential to play a supporting role within the landscape. However secondary corridors are considered less important because they:

- Have narrow points (less than 50 m wide) which can create bottlenecks for movement and expose Koalas to greater edge effects, or
- Are not connected at both ends which means they lack important landscape function at the population level

Impacts to tertiary corridors and supporting habitat are less significant from a landscape perspective given they represent smaller, poorly connected, and lower quality habitats.

Table 30-18: Impacts to Koala habitat across the nominated areas

INDIRECT IMPACTS

The following potential indirect impacts have been identified in relation to Koalas:

- Vehicle strike
- Effects of urban development
- Disruption of connectivity
- Fire
- Disease (Chlamydiosis caused by infection with *Chlamydia*)

These impacts reflect the range of activities associated with implementation of the Plan when considered against the known threats to the species.

Given that GPEC and WSA do not support Koalas, the focus of this section is the Southern Sydney population within the vicinity of Wilton and GMAC.

Vehicle strike

Description

Vehicle strike refers to the collision of road-based vehicles (such as cars) and Koalas, and can result in the injury or death of the animal. Vehicle strike occurs when Koalas attempt to cross roads, and motorists are unable to avoid them.

Koalas are at risk from vehicle strike due to multiple factors:

- Koalas do not recognise roads and traffic as a potential threat and therefore are likely to cross roads even in dangerous environments
- Koalas are a highly mobile species prone to dispersal, increasing the likelihood of them crossing barriers in search of areas of new habitat
- Koalas are largely nocturnal, which decreases their visibility to motorists whilst crossing roads

Vehicle strikes are most likely to occur where busy roads cut through areas of Koala habitat, as Koalas will attempt to cross the road to reach habitat present on the other side of the road. Increased roadkill is associated with increased human population densities.

Current context

There are a number of major roads which occur within or adjacent to habitat areas occupied by the Southern Sydney Koala population. Vehicle strikes are increasingly common on these roads.

The distribution of Koala roadkill records is shown in Map 41. It is recognised that the total number of Koalas killed by vehicle strike is likely to be higher than the number of records, as not every incident would have been recorded.

Analysis of roadkill records shows that the rate has increased over the last few years, and that this increase has corresponded with increasing traffic densities in the region (OEH, 2018d). Roadkill hotspots were recognised to occur where greater than four Koalas are killed within a 2 km stretch of road. They are located in the following places (OEH, 2018d):

- Picton Road between Cordeaux Dam and Wilton
- Macarthur Drive
- Eastern end of Wilton Road
- Appin Road between Appin and Campbelltown
- Hume Highway at the Bargo exit

Transport for NSW (TfNSW) are currently proposing to upgrade a section of Appin Road from Mount Gilead in the south, and the intersection of St Johns Road, Ambarvale in the north (Roads and Maritime Services, 2018). This area occurs partly within and outside of GMAC and comprises one of the Koala roadkill hotspots (between Appin and Campbelltown). As part of this project, TfNSW are proposing to install Koala exclusion fencing on the eastern side of the road (from opposite Noorumba Reserve in the north to the southern end of the upgrade) and fauna fencing along the western side where it intersects with habitat with the aim of reducing fauna mortality. TfNSW are also undertaking targeted safety improvements to parts of Appin Road between Mt Gilead and Brian Road just north of Appin to improve safety for residents, motorists and freight operators, as well as create further traffic efficiencies. This project will also involve installation of fauna fencing on the eastern side and western sides of Appin Road where habitat is present.

How might development under the Plan contribute to vehicle strike?

The Plan will result in significant areas of new development. This will include roads within the nominated areas and broader transport corridors (noting the latter generally occur away from Koala habitat). The increasing population in the vicinity of the Southern Sydney population will:

- Lead to substantial increases in the number of vehicles
- Require road upgrades to a range of roads that are not directly part of the Plan

Without mitigation, the risk of vehicle strike to Koalas will increase substantially as development proceeds. The Plan includes measures to address this risk which are outlined below in Section 30.4.9 and evaluated in Section 30.4.10.

Effects of urban development

Description

Urban development in proximity to Koala habitat poses a number of threats to Koalas. These threats can impact dispersing Koalas which travel through urban areas, in addition to locally resident Koalas which live nearby. Threats include:

- Increased Koala predation by domestic and roaming dogs. This threat occurs both within urban areas (in which dispersing Koalas are at risk), and in bushland adjacent to urban areas (in which locally resident Koalas are at risk)
- Increased landscape hazards such as swimming pools (in which Koalas may become trapped and drown). This threat poses a risk to dispersing Koalas travelling through urban areas
- Habitat degradation due to increased edge effects from land clearing and increased risk of disturbance (e.g. slashing, pollution, illegal dumping). This threat may reduce habitat quality and poses a risk to locally resident Koalas

Current context

The vegetation in the western boundary of the Southern Sydney Koala population has been extensively cleared, for urban development in the north and primarily for agricultural development in the south. Whilst there is limited information available regarding mortality rates, it is likely that the northern Koalas would be under greater pressure from proximity to urban development than Koalas further to the south.

The draft Comprehensive Koala Plan of Management for Campbelltown City Council (Phillips & Biolink, 2016) recognises that urban development poses a significant risk to the local Koala population. The Plan of Management recommends a series of controls (such as urban fencing to control dogs, and pool design standards to minimise the risk of Koalas becoming trapped) to reduce pressure on the local Koala population. It is unclear the extent to which these recommendations have been implemented on the ground.

How might development under the Plan contribute to the effects of urban development?

The Plan will facilitate large scale urban expansion within the nominated areas. Without mitigation, the risk to Koalas associated with urban areas will increase substantially as development proceeds. The Plan includes measures to address this risk which are outlined below in Section 30.4.9 and evaluated in Section 30.4.10.

Disruption of connectivity

Description

Habitat connectivity refers to the degree of connectedness of areas of habitat. Koalas travel through the landscape primarily through wooded areas, spending large amounts of time in trees. Whilst Koalas will descend to the ground level to move between trees, the time they spend on the ground tends to be limited as they are more exposed to predation on the ground.

Well-connected areas of habitat constitute wooded areas to permit the safe passage of Koalas, preferably with feed trees present to meet the physiological needs of the animal. Whilst Koalas are known to move through large distances of open areas, extended travel on the ground increases the risk of exposure to predation. Large open areas are therefore not considered to be suitable habitat to enable safe movement of Koalas.

Greater habitat connectivity allows for unimpeded movement of Koalas, which enables:

- Safe dispersal of juvenile Koalas searching for territory
- Movement of Koalas during the breeding season throughout the landscape, which increases the probability of Koalas successfully finding suitable mates and decreases the risk of inbreeding
- Areas of suitable habitat to be easily accessed
- Escape routes for Koalas in the event of stochastic threats such as bushfire

Habitat connectivity becomes disrupted when barriers to movement are introduced in the landscape. Common examples of movement barriers include cleared areas, busy roads and fences.

Habitat corridors are areas of connectivity which link two or more areas of habitat which would otherwise be separated by barriers. The characteristics of habitat corridors influence the usefulness of the corridor for Koala movements. Thinner corridors have greater exposure to habitat degradation from edge effects and increase the threat of predation by forcing all Koalas to travel through bottleneck points. Corridors with gaps of open space within them also force Koalas to increase the time spent on the ground, which increases vulnerability to predation. Wide, continuous corridors have lesser impacts from edge effects and provide for greater protection of wildlife from predators.

Current context

Disruption of habitat connectivity is an existing threat for Koalas within Wilton and GMAC. Significant areas of land within both nominated areas have already been cleared and there are a number of barriers to movement (e.g. roads). Remaining habitat patches are linked by habitat corridors with varying degrees of connectivity.

As outlined previously, corridor mapping was undertaken in accordance with mapping carried out by EES (2018d). It shows the location and relative importance of Koala habitat corridors in Wilton and GMAC.

Of the corridors that were identified, primary corridors are the most well-connected and important. They are considered important for maintaining the viability of the population. Secondary corridors still provide connectivity, yet are narrow or discontinuous and so are not as important as primary corridors. Tertiary corridors and supporting habitat do not constitute important habitat for landscape connectivity. A more detailed overview of corridor mapping is provided in Section 30.4.5 and in Attachment C.

Map 42 indicates the distribution and location of key habitat corridors within Wilton and southern GMAC. Map 42 shows that primary habitat corridors provide for:

- North-south movements to the east of GMAC
- North-south movements along the Nepean River to the west of GMAC
- North-south and east-west movements through Wilton

Map 42 also shows that east-west movement across GMAC is mostly provided by secondary corridors, interspersed with small areas of supporting and tertiary habitat. The secondary corridors through GMAC connect primary habitat of the Nepean River in the west with the primary habitat associated with the Georges River in the east. These corridors are named as follows:

- Noorumba
- Woodhouse – Menangle
- Mallaty
- Ousedale
- Simpsons - Elladale

The connectivity analysis undertaken by Biolink (2018a) considered how easily Koalas could traverse different landscape types, and then modelled the locations and importance of different habitat corridors in southern GMAC and Wilton. The key findings of the report are as follows:

- North-south connectivity provided by intact habitat to the east of GMAC and Wilton is the most important area of connectivity for the local Koala population
- The Woodhouse – Menangle (referred to as Beulah in the GAPCLoSR report) and Ousedale corridors are recognised as being important for providing east-west connectivity across the southern half of GMAC
- Habitat corridors through Douglas Park (between the Wilton and GMAC nominated area boundaries) are of high importance for habitat connectivity

How might development under the Plan contribute to the disruption of connectivity?

Proposed development under the Plan will not result in the loss of primary or secondary habitat corridors through Wilton or GMAC due to land clearing. However, habitat connectivity has the potential to be impacted through:

- Increased threats posed by the effects of urban development
- Increased risk of vehicle strike
- Additional development concurrent to the Plan, such as the proposed installation of wildlife fencing along Appin Road to decrease the risk of vehicle strike (RMS, 2018)

Proposed measures to mitigate potential impacts to connectivity are outlined in Section 30.4.9 and evaluated in Section 30.4.10.

Fire

Description

Fire poses a threat to Koalas through direct mortality from exposure to fire events, and from starvation due to food shortages immediately following fire events.

The fires which pose the most risk to Koalas are high intensity fires which burn the crowns of trees. The intensity of fire events is impacted by available fuel loads, which are influenced by the length of time between fires, and whether fuel management activities (such as slashing) are carried out.

Fires may be caused by natural (such as lightning strikes) and unnatural (such as cigarette butts, campfires or arson) ignitions. Increased proximity of Koala habitat to developed areas increases the likelihood of more frequent fire events due to an increase in exposure to ignition sources.

The risks posed by fire events to Koalas are significantly increased by habitat fragmentation. Connectivity is required to allow:

- Koalas to escape fire events by moving to areas free from fire until the event has passed
- Koalas to re-colonise habitat following a fire event which may have caused a localised extinction within the area

Current context

The Southern Sydney Koala population occurs in extensive areas of bushland, which spans from Holsworthy in the north down to the Southern Highlands, and east to the coast.

Fire management activities occur in various locations within and on the edges of this bushland, which are conducted by various agencies including the NSW National Parks and Wildlife Service and the Rural Fire Service. However, large areas of bushland remain inaccessible, which limits the capacity for fire management and control. As the forested areas are well connected, there is significant potential for fires to easily grow and spread throughout this region.

The 2019-20 bushfires across NSW provide a clear indication that bushfire is an existing and potentially significant threat to the Southern Sydney Koala population.

Habitat connectivity is important for Koala conservation in Wilton and GMAC, to enable Koalas to access escape routes in the event of fire. Habitat corridors through otherwise cleared areas (such as those within and adjacent to Wilton and GMAC) are also important as such areas can serve as refuge sites for wildlife in the event of a bushfire, because such sites can be more easily protected from fire.

How might development under the Plan contribute to the risks of fire?

The Plan will result in significant urban development, which will increase the exposure of Koala habitat to anthropogenic fire sources. This may increase the frequency of fires occurring within Koala habitat and may result in negative impacts to the species without appropriate mitigation measures. The Plan proposes mitigation measures to manage these risks. These are outlined in Section 30.4.9 and evaluated in Section 30.4.10.

Disease (Chlamydiosis caused by infection with *Chlamydia*)

Description

Chlamydia is a bacterium which has a high infection rate in many Koala populations. However, infection with *Chlamydia* does not always lead to the development of disease symptoms. Some Koalas infected with *Chlamydia* will continue to present and act as healthy Koalas, whereas other Koalas will develop disease symptoms as a result of the infection (known as Chlamydiosis). The reasons why disease develops in some situations yet not in others is still being understood.

Chlamydiosis is a serious disease which results in a range of symptoms and can result in Koala infertility and death. McAlpine et al. (2017) found that proximity to urban development increases the risk that Koalas infected with *Chlamydia* will develop Chlamydiosis. It is thought that increased exposure to environmental pressures results in poorer body condition and weakened immune responses, which increases vulnerability to the disease.

Urban development has the potential to increase the severity of the threat posed by *Chlamydia* to Koala populations, by increasing the occurrence of clinical disease symptoms and therefore increasing infertility and mortality rates of Koalas due to *Chlamydia*.

Current context - Wilton and GMAC

To date, Koalas in the Campbelltown area are thought to be free of infection with *Chlamydia,* whilst Koalas in the Southern Highlands are known to have high rates of infection. Recent research conducted by Saving Our Species (2019) suggests that *Chlamydia* infection is moving northward from the Southern Highlands towards the Campbelltown locality.

It is unknown how Koalas within the Campbelltown locality will respond to infection with *Chlamydia.* There is potential for there to be significant rates of disease development, as:

- The Koalas in this locality have not previously been exposed to *Chlamydia* and therefore may not have resistance to the infection
- The strains of *Chlamydia* in the Southern Highlands are known to be virulent

Overall, infection with *Chlamydia* and the development of Chlamydiosis is considered to be an emerging threat which is likely to place greater pressures on the Southern Sydney Koala population over the next few years.

How might development under the Plan contribute to the risk of disease?

The Plan will introduce a range of pressures associated with urban development to the Koala population of Wilton and GMAC, which increases the susceptibility of Koalas in these localities to developing Chlamydiosis. A range of mitigation measures are recommended to minimise the pressures placed by urban development on Koala populations (as outlined above), in addition to specific measures associated with the monitoring and management of disease. Proposed measures are outlined in Section 30.4.9 and evaluated in Section 30.4.10.

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to Koalas from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels

- Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)

Potential impacts from essential infrastructure

In addition to predicted impacts due to urban development, there is the potential for impacts to Koala habitat to occur due to development of essential infrastructure within nominated areas but outside the urban capable lands.

Significant areas of important Koala habitat occur on avoided lands within Wilton and GMAC, but not WSA or GPEC. It is possible that some of this habitat on avoided land within Wilton and GMAC will be impacted by essential infrastructure.

As outlined in Chapter 37, any proposed essential infrastructure developments on avoided lands in the nominated areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values that are present
- Measures to avoid impacts to Koalas through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

The Plan includes two commitments that will limit the potential impacts to Koala habitat from essential infrastructure:

- The first (Commitment 2.4) requires that avoidance of impacts to important Koala corridors within Wilton and GMAC be prioritised in order to maintain their integrity
- The second (Commitment 2.3) relates to the EPBC Act listed TEC Shale Sandstone Transition Forest in the Sydney Basin Bioregion. This TEC occurs extensively on avoided lands in Wilton and GMAC and provides large parts of the important habitat for Koalas. The commitment limits the potential impacts to the TEC to a cumulative maximum over the life of the Plan to no more than 20 ha in Wilton and 20 ha in GMAC

Based on the application of these commitments and the overall requirements of the BAM process, impacts from essential infrastructure are not considered likely to substantially effect the scale, condition or functionality of Koala habitat within Wilton or GMAC. See Section 37.6 in Chapter 37 for more details.

Potential impacts from tunnels

Koala habitat does not occur within the vicinity of the tunnel footprints for transport and is therefore not at risk of additional impacts from tunnels.

30.4.9 OUTCOMES, COMMITMENTS AND ACTIONS TO PROTECT KOALAS

OUTCOMES

The Plan sets out a number of outcomes for biodiversity which are designed to be a "reported or measurable result of the desired goal of the Plan". The outcome for Koalas is contained within overall outcomes for threatened species which is:

> *Populations of targeted threatened species persist and the condition of suitable habitat improves within areas in the Cumberland subregion most likely to support long-term viability*

COMMITMENTS AND ACTIONS

The Plan then provides a series of commitments and actions to deliver the outcome for Koalas (see Table 30-19). These are set out in Sub-Plan B: Koalas which outlines how Koalas and their habitat will be protected and as part of the Plan's conservation program.

In summary, the Plan aims to:

- Mitigate indirect and prescribed impacts from urban, transport and agricultural development on biodiversity values. This includes:

- A number of general actions to mitigate impacts such as the application of development controls to ensure measures to address indirect impacts are applied
- A number of Koala specific actions such as:
  - Installing Koala-exclusion fencing between important Koala habitat and certified urban capable land within GMAC and Wilton
  - In areas where exclusion fencing is not feasible, applying mitigation actions 60 m from the Koala habitat. These actions include implementing controls from the Koala Habitat Protection Guidelines (linked to the new Koala SEPP) and including design requirements in relevant development control plan
  - Establishing an expert working group to provide input on managing Koalas as development proceeds

- Secure and protect habitat and corridors for the species. This includes establishing a new Koala reserve (the Georges River Koala Reserve) to protect north-south movement on the eastern side of Appin Road
- Implement a number of other actions to improve knowledge about Koalas, build awareness in the community, and support ecological restoration measures

Early in the proposed implementation phase of the Plan, the NSW Government has committed $63 million in the first three years. This includes:

- Funding to plant 100,000 trees as part of ecological restoration of Koala habitat including within the Georges River Koala Reserve
- 120 km of Koala exclusion fencing within Wilton and GMAC to protect Koalas from increasing threats such as vehicle strike and dog attacks

Table 30-19: Commitments for Koalas (taken from Sub-Plan B)

COMMITMENTS	ACTIONS
CONSERVATION PROGRAM	
Mitigate indirect and prescribed impacts	
Commitment 7 Mitigate indirect and prescribed impacts from urban, infrastructure and major infrastructure (transport) development on the Southern Sydney Koala population to best practice standards and in line with the Chief Scientist Koala Report	1. Install Koala-exclusion fencing between important Koala habitat and certified urban capable land within GMAC and Wilton as identified in Sub-Plan B except where exclusion fencing is not feasible due to slope, heritage or water courses. 2. Ensure all Koala-exclusion fencing is at least 3 metres from Koala habitat trees. 3. In areas where exclusion fencing is not feasible, apply mitigation actions 60 metres from the Koala habitat. These actions include implementing controls from the Koala Habitat Protection Guidelines and including design requirements in relevant development control plans. Specific locations are identified in Sub-Plan B. 4. Install Koala-exclusion fencing on both sides of Appin Road between Rosemeadow and Appin to mitigate Koala vehicle strikes at roadkill hotspots. 5. Where fencing must cross existing or planned linear infrastructure such as gas and electricity transmission, consider appropriate access treatments such as gates to ensure the integrity of the Koala-exclusion fencing. 6. Establish a Koala working group including Koala experts and relevant government agencies to determine priorities for Koala conservation consistent with the objectives of the NSW Koala Strategy
Conserve flora, fauna and habitat	
Commitment 10 Establish a reserve to protect the north-south Koala movement corridor along the Georges River between Appin and Kentlyn.	1. Protect up to 700 hectares of land between Appin and Kentlyn that is currently in ownership of NSW Government as the first stage in establishing the Georges River Koala Reserve. 2. Protect an additional 430 hectares of land between Appin and Kentlyn through the acquisition of land for the Georges River Koala Reserve. 3. Gazette the preliminary stages of the Georges River Koala Reserve as a conservation reserve under the management of National Parks and Wildlife Service. 4. Protect up to 755 hectares of land between Kentlyn and Long Point as future additions to the Georges River Koala reserve. 5. Restore up to 200 hectares of cleared land within the Georges River Koala reserve to strengthen the north-south Koala movement corridor.

COMMITMENTS	ACTIONS
Commitment 12 Secure priority habitat corridors in the Cumberland subregion in perpetuity, to support connectivity for ecological communities and species	1. Undertake ground-truthing within the strategic conservation area to confirm native vegetation extent and condition in areas identified as potential habitat corridors. 2. Secure priority habitat and Koala movement corridors in accordance with the Conservation Lands Implementation Strategy to protect habitat corridors in the Cumberland subregion. 3. Protect avoided Koala habitat through environmental conservation zoning in potential east-west Koala movement corridors between the Georges River and the Nepean River. 4. Through restoration, ensure at least one north-south corridor (the Georges River Koala Reserve) and one east-west corridor are each at least 390 m wide, for Koala viability and movement. 5. Facilitate Koala movement for at least one east-west corridor by constructing a Koala crossing at Appin Road. 6. Construct a Koala passage under Kings Fall Bridge to support north-south Koala movement from the Georges River Koala Reserve to the southern Koala habitat.
Commitment 13 Undertake ecological restoration of up to 25% of the Plan's offset target for native vegetation (Commitment 8) in areas secured for conservation within the Cumberland subregion	4. Plant around 100,000 trees to restore important Koala habitat in o Georges River Koala Reserve o along Ousedale Creek o around Appin o other priority locations in the strategic conservation area. The restoration of important Koala habitat will primarily include the restoration of Cumberland Plain Woodland and Shale/Sandstone Transition Forest.
BUILD KNOWLEDGE AND CAPACITY	
Commitment 21 Provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation including Koala conservation	7. Invest in the *NSW Koala Strategy* (hyperlink) to raise awareness of the Southern Sydney Koala population and encourage community participation in Koala conservation in Western Sydney, consistent with the Plan's education and engagement program.
Commitment 24 Invest in research that will help to secure threatened species and increase understanding of threats and land management issues.	4. Implement the research program with key outcomes including: o research that increases knowledge of population demographics, life-history and ecology of the Southern Sydney Koala population, as part of the *NSW Koala Strategy Research Plan*

COMMITMENTS	ACTIONS
Commitment 25 Support rehabilitation measures to help maintain Koala health and welfare.	1. Invest in the *NSW Koala Strategy* and other potential partners to implement the Koala health and welfare program in South Western Sydney with key deliverables including: o monitoring of Koalas including key threats and effectiveness of mitigation measures as part of the *NSW Koala Strategy Monitoring Framework* o providing enhanced training in wildlife treatment for veterinarians o providing grants for community wildlife organisations for resources and carer recruitment and training o establishing health and welfare programs to support Koalas from threats including vehicle strike, fire, disease and climate change.

STRATEGIC CONSERVATION AREAS

As part of delivering commitments to protect and restore land, the Plan is focusing its efforts into the SCAs. The method for defining these areas is described in Section 8.5 of Chapter 8.

The SCAs (see Map 45) include the proposed Koala park, as well a number of other areas that provide habitat for the species. See Table 30-20 for the areas of habitat in the SCAs. The Koala park is described in detail in Sub-Plan B: Koalas and shown in Figure 4 of Sub-Plan C. The new park would secure large parts of the north-south primary corridor to the east of Appin Road. It is proposed to be implemented in two stages:

- Stage 1 from Appin north encompassing approximately 875 ha of important habitat. This will be protected within the first 5 years of the Plan
- Stage 2 further north adjacent to GMAC encompassing an additional 722 ha of important habitat. This will be protected within the first 10 years of the Plan

The Koala park would also provide for a range of ecological restoration of up to 200 ha of cleared land to increase habitat over time and strengthen the north-south movement corridor.

Table 30-20: Koala habitat (ha) in the Strategic Conservation Areas

STRATEGIC CONSERVATION AREAS	SAA TOTAL	AREA CURRENTLY PROTECTED IN SAA	AREA IN STAGE 1 KOALA PARK	AREA IN STAGE 2 KOALA PARK	AREA REMAINING IN SCAs	TOTAL AREA IN SCAs
CORRIDORS						
PRIMARY CORRIDORS	11,998.9	1,064.9	869.5	721.8	4,635.6	6,226.9
SECONDARY CORRIDORS	2,433.2	115.2	5.5	0.0	1,114.4	1,119.9
IMPORTANT HABITAT SUBTOTAL*	**14,432.1**	**1,180.1**	**875.0**	**721.8**	**5,750.0**	**7,346.8**
TERTIARY CORRIDORS	724.3	0.0	1.1	0.0	154.0	155.1
SUPPORTING HABITAT	4,895.7	998.1	5.8	0.0	302.4	308.2
CORRIDOR TOTAL	**20,052.2**	**2,178.2**	**881.9**	**721.8**	**6,206.4**	**7,810.1**
HABITAT CRITICAL						
HABITAT CRITICAL TOTAL	**14,718.8**	**1,163.2**	**874.7**	**719.7**	**5,836.6**	**7,431.0**

* Important habitat comprises primary and secondary corridors

SUPPORTING MEASURES

In addition to the specific commitments and actions for Koalas, the Plan also includes a number of supporting measures that will be important for successful implementation and achieving a positive outcome for the species. These include:

- Monitoring, evaluation and reporting (MER) which will provide information about:
  - The status of Koalas in the Southern Sydney population
  - The Plan's progress in meeting its commitments and actions
- Adaptive management which will enable improvements to be made to management decisions over the life of the Plan

30.4.10 EVALUATION

The evaluation draws together the information from the Koala assessment to provide a robust way of understanding the predicted outcomes for the Southern Sydney Koala population as a result of implementation of the Plan. It also provides an evaluation against the relevant EPBC Act approval considerations.

The evaluation is based on understanding:

- If the outcomes for Koala specified in the Plan will be delivered?

- If the Plan addresses the EES principles from *Conserving Koalas in Wollondilly and Campbelltown LGAs*?
- If the Plan addresses the EPBC referral guidelines for Koalas?
- If the Plan has had regard for the Koala Conservation Advice?

To address these questions, the evaluation is structured around the following issues:

- Avoidance of impacts
- Extent and quality of habitat
- Landscape connectivity
- Level of threat

AVOIDANCE OF IMPACTS

As outlined in Chapter 14 and in Section 30.4.7, avoidance of impacts to Koala habitat was a key part of the process for developing the Plan. Design of the urban capable footprints in Wilton and GMAC was specifically guided by efforts to avoid impacts to Koala habitat which resulted in:

- More than 91 per cent of important habitat (not including excluded lands) being avoided within the two nominated areas
- Impacts being constrained to the edges of corridors within the nominated areas rather than cutting through any of the corridors

This level of avoidance is considered adequate when combined with the commitments and actions to:

- Mitigate indirect impacts
- Protect important habitat
- Restore habitat

EXTENT AND QUALITY OF HABITAT

As outlined in Section 30.4.8, the Plan will result in the loss of 260.6 ha of important habitat for Koalas within GMAC and Wilton. This equates to 1.8 per cent of the mapped important habitat for the Southern Sydney population.

In part to address these impacts, the Plan commits to protecting and managing a minimum of 610 ha of important Koala habitat. The Plan also commits to protecting and managing a minimum of 1,885 ha of land within the Georges River Koala Reserve (encompassing approximately 1,595 ha of important habitat), and restoring approximately 200 ha of cleared land, which significantly exceeds the 610 ha offset target for Koala. The action to restore land is consistent with Principle 3 of *Conserving Koalas in Wollondilly and Campbelltown LGAs* (OEH, 2018d) which is: "Identify critical revegetation zones that will augment and strengthen core habitat and corridors".

These commitments and actions also support a number of priority management actions from the Conservation Advice (DSEWPC, 2012a). These include:

- *Investigate formal conservation arrangements, management agreements and covenants on private land, and for Crown and private land investigate and/or secure inclusion in reserve tenure if possible*
- *Develop and implement options of vegetation recovery and re-connection in regions containing fragmented Koala populations*

It is noted that ecological restoration of habitat takes a significant amount of time and it will be important for ecological restoration efforts to start as early as possible to ensure the overall carrying capacity of habitat is not substantially reduced for a period of time. In response to this, the Plan commits funding over the first three years to plant at 100,000 trees as part of ecological restoration of Koala habitat including within the Georges River Koala Reserve.

Based on these commitments being met, the overall extent and quality of habitat for the population will be similar at the end of the life of the Plan as it is now. In addition, substantially greater areas of important habitat will be under active management. The outcomes for extent and quality of habitat for Koalas are considered adequate.

LANDSCAPE CONNECTIVITY

As outlined in Section 30.4.8, proposed development under the Plan will not result in the loss of primary or secondary habitat corridors through Wilton or GMAC due to land clearing. However, habitat connectivity has the potential to be impacted through:

- Increased threats posed by the effects of urban development
- Increased risk of vehicle strike
- Additional development concurrent to the Plan, such as the proposed installation of wildlife fencing along Appin Road to decrease the risk of vehicle strike (RMS, 2018)

Both EES (2018d) and Biolink (2018a) discuss the importance of the north-south primary corridor to the east of Appin Road. This will be protected (as a new reserve) and improved (through ecological restoration) under the Plan and is anticipated to play a critical role for the population over the life of the Plan.

East-west connectivity through Douglas Park (between the Wilton and GMAC nominated area boundaries) is also recognised for its importance to connectivity. This area will not be impacted by the Plan and parts of it are included in the SCAs which are targeted for protection.

The main risk to connectivity occurs to the east-west connections through GMAC. These are all secondary corridors and are currently compromised (from a connectivity perspective) in various ways. Biolink (2018a) suggests the most important of these connections are the Woodhouse – Menangle (referred to as Beulah in the GAPCLoSR report) and Ousedale corridors.

In developing the Plan, the Department investigated the viability of these corridors for Koala movement over the long term. The Plan commits to further investigations to determine how a permanent corridor can be implemented. Other relevant actions under Commitment 12 include:

- Protecting avoided Koala habitat through environmental conservation zoning in the potential east-west Koala movement corridors
- Ensuring at least one east-west corridor (at least 390 m wide) is maintained for Koala viability and movement. This is in addition to the north-south corridor to be protected through the Georges River Koala Reserve
- Constructing Koala crossings at:
    - Appin Road for east-west movement
    - Kings Fall Bridge (just to the east of the Strategic Assessment Area) to support north-south Koala movement from the Georges River Koala Reserve to the southern Koala habitat

The outcomes for connectivity are considered adequate as the Plan avoids disruptions to the primary movement corridors, enhances the most important corridor (north-south corridor to the east of Appin Road), and commits to maintaining at least one secondary east-west corridor.

LEVEL OF THREAT

As outlined in Section 30.4.8, development under the Plan has the potential to increase the level of threat to the Southern Sydney Koala population. This includes threats associated with:

- Vehicle strike
- Effects of urban development
- Fire
- Disease

The Plan includes a series of commitments and actions to address these threats.

Exclusion fencing is proposed as the primary control for managing Koalas within Wilton and GMAC. This is recognised in the EPBC Act Koala referral guidelines (DoE, 2014j) as one of the most important mitigation measures. It will be an important tool for separating Koalas from future urbanised areas and will help address many of the threats of urban development. It should be noted that there are a number of cases where fencing will not be possible (e.g. due to topography constraints, or community safety). In these instances, the Plan proposes that alternative controls from the Koala Habitat Protection Guidelines will be applied.

Fencing will also be installed on both sides of Appin Road between Rosemeadow and Appin to mitigate Koala vehicle strikes at roadkill hotspots.

The approach to managing Koalas will be guided by an expert working group that will have an ongoing role over the life of the Plan.

In addition to the specific Koala commitments, the Plan will:

- Require implementation of a range of general planning and development controls to address indirect impacts (these are assessed in detail in Chapter 15)
- Support the implementation of road mitigation measures on selected major roads that are identified roadkill hotspots
- Require the development and implementation of a fire management strategy that will support the management of Koala habitat

These commitments and actions are consistent with the following priority management actions from the Conservation Advice (DSEWPC, 2012a):

- *Develop and implement a management plan to control the adverse impacts of predation on Koalas by dogs in urban, peri-urban and rural environments*
- *Development plans should explicitly address ways to mitigate risk of vehicle strike when development occurs adjacent to, or within, Koala habitat.*

The package of measures to address indirect impacts is considered adequate when combined with the supporting measures around monitoring, evaluation and adaptive management.

30.4.11 OVERALL CONCLUSION

The efforts to avoid impacts to Koala habitat, and the commitments and actions in the Plan provide a strong framework for addressing the risks to the population from development under the Plan. The commitments and actions provide a range of positive contributions to the population (in particular the establishment of the Georges River Koala Reserve). They also address the key risks to the population and are designed to be implementable as development proceeds.

However, given the long timeframes associated with implementation there is uncertainty at this time about the ultimate effectiveness of these measures. This uncertainty can only be addressed in implementation and it will be critical that monitoring, evaluation and adaptive management measures are effective. Ongoing review of the success of the Plan in protecting Koalas will be critical.

SPECIES AT MEDIUM RISK OF DIRECT IMPACTS

30.5 *LATHAMUS DISCOLOR* (SWIFT PARROT)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Critically Endangered
DESCRIPTION	*Lathamus discolor* (Swift Parrot) is a medium-sized bright green parrot. It has dark-blue patches on the crown and a red face. It grows to approximately 25 cm in length, with a wingspan of 32-36 cm. It weighs around 65 g (TSSC, 2016d).
ECOLOGY	Swift Parrots breed in Tasmania in summer and migrate to mainland Australia in winter. They forage on flowers and psyllid insects on the mainland. Usually seen in groups of up to 30 birds, or larger flocks when around sources of abundant food. Disperses widely on the mainland to forage. The species shows high site fidelity (at both breeding and non-breeding sites) and return to the same locations on an irregular cyclic basis. (TSSC, 2016d)
DISTRIBUTION AND HABITAT	Can be found in the east and south-east of Tasmania in summer (where it breeds) and migrates to mainland Australia (coast of Victoria, NSW and south-eastern Queensland) during winter. The area of occupancy in Tasmania is estimated to be less than 500 km^2 (Saunders & Tzaros, 2011). Priority habitat areas are identified in the recovery plan (Saunders & Tzaros, 2011) as sites: • Used for nesting • By large proportions of the population • Used repeatedly between seasons (site fidelity) • Used for long periods of time (site persistence) In NSW, the species forages in forests and woodlands throughout the coastal and western slopes regions (TSSC, 2016d). In the Cumberland subregion, the following TECs contain habitat suitable for the Swift Parrot: • Cumberland Plain Woodland • Western Sydney Dry Rainforest and Moist Woodland on Shale • River-Flat Eucalypt Forest on Coastal Floodplains • Shale Sandstone Transition Forests • Shale Gravel Transition Forests

	• Swamp Sclerophyll Forest on Coastal Floodplains (Saunders & Tzaros, 2011)
POPULATIONS	The species occurs as one single, migratory population (Saunders & Tzaros, 2011). The population of swift parrots was estimated to be approximately 2,000 in 2010. It is likely to have declined since then (TSSC, 2016d).
SOS SITES	The following SOS sites for the species have been identified: • Central Coast • Tarcutta Hills – Co-investment site • Riverina None of these occur within the Cumberland subregion.
RELEVANT PLANS AND POLICIES	Conservation Advice for *Lathamus discolor* (Swift Parrot) (TSSC, 2016d) National recovery plan for the swift parrot *Lathamus discolor* (Saunders & Tzaros, 2011) Threat abatement plan for predation by feral cats (DoE, 2015g)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species.
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=744

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	Yes	No	No	No	No

EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS** **Knowledge based map (KBM)**. Habitat maps for the Swift Parrot were generated using BioNet PCT associations of intact and thinned vegetation, and scattered trees. Under the BAM process, the species was removed as a candidate species credit species in all nominated areas based on the understanding that no important habitat (as defined by the BAM) occurs in the urban capable land. No targeted surveys were undertaken, however, the species was recorded in Wilton in 2019 during surveys for this project. **OUTSIDE THE NOMINATED AREAS** **Knowledge based map (KBM)**. As above. No targeted surveys as part of this project were undertaken outside the nominated areas.

POPULATION MAPPING	**RECORD SELECTION** Species records were compiled from BioNet. All available records were considered in the assessment. **POPULATION DEFINITION** The species is considered to be a single migratory population. All records within the Strategic Assessment Area are therefore considered part of the same population. **IMPORTANT POPULATION CRITERIA** The population was considered to be important as the species is critically endangered.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 46.5 for a map of records and habitat across the Strategic Assessment Area. It is important to note that the records for this species are sensitive and have been denatured for representation on the map.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 30-22 at the end of this species assessment for a breakdown of the occurrence of records and habitat for the Swift Parrot in the Strategic Assessment Area. **Records** The species has been recorded throughout the Cumberland subregion and is associated with flowering woodland areas. There are 134 BioNet records within the Strategic Assessment Area. The species is known to occur in five broad locations in the Strategic Assessment Area: • In the area to the north of GPEC: 32 records ranging from 1968 to 2002. The majority of these records are from 1998 • Within and close to GPEC and WSA: 17 records from 1997 to 2014 • On the western side of the Strategic Assessment Area (south of WSA): 7 records from 2006 to 2013 • Immediately north of GMAC: 19 records from 1983 to 2014 • Within or close to Wilton (only 1 record) and GMAC: 8 records from the early 1900s to 2018 These records suggest the species occurs widely and regularly in the Strategic Assessment Area, but less frequently than some coastal areas of NSW. While records within the Cumberland subregion indicate the species uses foraging habitat repeatedly between seasons, it is not identified as a priority area in NSW in the National Recovery Plan (Saunders & Tzaros, 2011). **Potential foraging habitat** Given the Swift Parrot is a highly mobile species, this assessment is focussed on the occurrence of foraging habitat and potential impacts to this habitat. The baseline mapping for this assessment has mapped 59,460 ha of potential foraging habitat within the Strategic Assessment Area (see Table 30-22 for further details). This area is large because of the broad associations the species has with flowering woodland. The Swift Parrot does not breed on the mainland, and the foraging habitat mapped within the Strategic Assessment Area is part of the larger area in which the species forages. Records occur along the NSW coast from Nowra up to Newcastle and further inland near Wollemi National Park.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

30.5.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 4,627 ha of potential habitat for the Swift Parrot within the nominated areas (not including excluded lands). Approximately 3,513 ha (76 per cent) of this has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 2,620 ha was avoided for biodiversity purposes
- 893 ha was avoided for other purposes

In addition, the Plan includes a specific measure for the Swift Parrot to retain large trees (≥50cm DBH) during precinct planning where possible and avoid impacts to soil within the dripline of these trees during construction.

A breakdown of avoidance across each nominated area is provided in Table 30-23.

It is important to note that the avoidance calculations in Table 30-23, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 30-23 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

30.5.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 30.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

30.5.3 LOSS OF POTENTIAL HABITAT

Implementation of the Plan will lead to the loss of potential foraging habitat for the species. Given the species breeds only in Tasmania, there will be no impacts to breeding habitat under the Plan.

LOSS OF POTENTIAL FORAGING HABITAT

Approximately 1,285 ha of potential foraging habitat will be lost as a result of the implementation of the Plan (1,114 ha within the nominated areas and 171 ha within transport corridors outside the nominated areas). This habitat represents 2 per cent of mapped potential foraging habitat across the Strategic Assessment Area. It focuses on the poorer condition vegetation, with approximately 63 per cent of the impacted habitat in thinned condition, and only 12 per cent of the area impacted classified as intact.

A summary of these impacts is provided in Table 30-24.

Risk of residual adverse impacts to the species

The risk of residual adverse impacts occurring to the species as a result of the loss of potential foraging habitat is considered to be medium. This is because:

- The likelihood of substantial impacts occurring to the species has been categorised as possible. There will be moderate impacts to areas of potential foraging habitat where the species has been observed. However, the higher number of records in nearby coastal habitat indicates a relatively lower reliance on the Cumberland subregion, the area impacted represents a small proportion of available foraging habitat, and the mobile nature of the species means that the loss of small areas of the lower condition habitat within the Strategic Assessment Area is less likely to substantially impact the species. Importantly, there will be no impacts to priority sites/regions identified in the National Recovery Plan (Saunders & Tzaros, 2011)
- The consequence of any impacts to the species has been categorised as major. There will be loss of approximately 2 per cent of mapped potential foraging habitat in the Strategic Assessment Area and records occur close to and within areas that will be impacted

30.5.4 FRAGMENTATION OF HABITAT

Given the wide-ranging nature of the species and broad availability of potential habitat, it is considered unlikely that development within the nominated areas or transport corridors would lead to any fragmentation effects.

30.5.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the medium risk of residual adverse impacts to the species, the Plan provides offsets for the Swift Parrot. The Plan commits to protecting 4,470 ha of potential foraging habitat for the Swift Parrot.

Offsets will be located within the SCAs which identify well connected, high quality vegetation across the Strategic Assessment Areas. These areas contain 17,403 ha of potential foraging habitat for the species and provide the best opportunity for improving conservation planning across the subregion and delivering real benefits for the Swift Parrot.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

30.5.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice and Recovery Plan (and other key documents) for the Swift Parrot identify a range of threats to the species (TSSC, 2016d; Saunders & Tzaros, 2011). Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Collision mortality
- Inappropriate fire regimes
- Predation by feral cats

Predation by sugar gliders, competition from honeyeaters, Psittacine Beak and Feather Disease, and illegal wildlife capture and trade are also identified as key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the threat across the Strategic Assessment Area.

COLLISION MORTALITY

Mortality from collisions with human-made objects in urban areas is an identified threat to the species (TSSC, 2016d). The Conservation Advice states that:

- Continuing urban encroachment into breeding and foraging habitat is increasing the threat
- Collisions are a particular concern in the greater Hobart and Melbourne areas, and the New South Wales central and north coast regions where fatalities have been recorded

There are no records in BioNet of collision mortalities in the Strategic Assessment Area. However, expanding urban development within the nominated areas and development of transport corridors has the potential to increase the threat of collision mortality to the species.

While the threat will remain (and potentially increase), it is unlikely to significantly affect the species in the Strategic Assessment Area because:

- Western Sydney is not identified as a key area of concern
- Large parts of Western Sydney (including the nominated areas) are subject to current development
- The species occurs in the Strategic Assessment Area less frequently than other areas of NSW

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes, in particular frequent fire, is identified as a threat to the species (Saunders & Tzaros, 2011; TSSC, 2016d). Fire can reduce tree flowering events and affect maturation of nectar rich plant species, resulting in reduced foraging resources (Saunders & Tzaros, 2011).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact Swift Parrot habitat. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant including:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from potential foraging habitat. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the Swift Parrot from increased fire frequency as a result of development. This is because:

- Avoided lands supporting potential foraging habitat will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat
- Fire management authorities will be engaged to ensure they understand the values relevant to the Swift Parrot and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

PREDATION BY FERAL CATS

Predation from feral cats is identified as a threat to the Swift Parrot in the species recovery plan. New urban development within the nominated areas is very likely to increase the number of domestic cats in the local area, which in turn, may lead to an increase in feral cat populations within adjacent areas of potential Swift Parrot habitat.

Existing land use within the nominated areas and surrounding region includes residential areas and farming, which means cats are unlikely to pose a novel threat to the species in the area. However, the extent of proposed new urban development under the Plan means the threat is likely to be exacerbated.

As outlined in Chapter 15, development controls will be implemented under the Plan to:

- Ensure that domestic animals are appropriately contained at urban/bushland interfaces
- Appropriately manage and control pest animals as relevant to the site

These measures are considered to adequately mitigate the threat to the species.

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to:

- The development of essential infrastructure within nominated areas but outside the urban capable lands
- Tunnels associated with transport projects

30.5.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

The Swift Parrot has been recorded in all of the nominated areas, including on avoided land in GMAC and GPEC. Potential foraging habitat has been mapped on avoided lands. As a result, the species may be subject to additional impacts from essential infrastructure. However, the species is highly mobile and wide-ranging, and the scale of impacts is not expected to be significant.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to biodiversity through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

30.5.8 POTENTIAL IMPACTS FROM TUNNELS

Potential foraging habitat for the Swift Parrot occurs within the tunnel footprints for the Metro Rail Future Extension (69.6 ha) and the Outer Sydney Orbital (108.2 ha).

However, the Plan includes commitments to:

- Avoid any direct impacts to the areas where the species could occur, including the Mater Dei BioBank site and Camden Airport Registered Property Agreement, as discussed in Chapter 36
- Mitigate any potential indirect impacts (e.g. changes to hydrology, ground settling or subsidence) from the transport corridors as part of a future environmental impact assessment process

These commitments are expected to adequately address threats to the species from the construction and operation of the tunnels. See Section 36.6 in Chapter 36 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15

30.5.9 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice and Recovery Plan (and other key documents) identify the following key issues that are likely to have the greatest influence on the long-term viability of the Swift Parrot in relation to implementation of the Plan:

- Habitat loss and fragmentation
- Indirect impacts such as:
  - Collision mortality
  - Inappropriate fire regimes
  - Predation by feral cats

HABITAT LOSS AND FRAGMENTATION

Development under the Plan will lead to the clearing of 1,285 ha of potential Swift Parrot foraging habitat. Some of this clearing will be mitigated by the retention of large trees (≥50cm DBH) during precinct planning. However, all together the impact assessment has concluded that the scale of clearing presents a medium risk of residual adverse impacts to the species, which will need to be addressed through the protection of 4,470 ha of potential foraging habitat.

Importantly, the clearing of potential foraging habitat is unlikely to lead to fragmentation of connectivity for the species given its highly mobile nature and the availability of potential foraging resources throughout the landscape. The loss of potential habitat does not affect any of the priority sites identified in the National Recovery Plan and focuses on the poorer condition woodlands, with intact vegetation comprising only 12 per cent (or around 154 ha) of the impacted areas.

In contrast, the offset areas for the Swift Parrot will focus on the best condition vegetation strategically located to provide an improved conservation outcome within the subregion. These offsets will be located within the SCAs which contain 17,403 ha of potential foraging habitat for the Swift Parrot. It is very likely that areas of suitable Swift Parrot foraging habitat in addition to the 4,470 ha offset will be protected within these SCAs as part of offset commitments for other species and ecological communities under the Plan.

It is relevant to note that the offsets for the Swift Parrot support a management priority included in the species conservation advice to *increase the area of habitat for the species that is secured and managed for conservation.*

In summary, the loss of potential habitat under the Plan is not expected to negatively influence the long-term viability of the species because the impacts:

- Will not fragment landscape connectivity
- Will not affect any of the priority sites/regions identified in the National Recovery Plan
- Focus on poorer condition woodland, and
- Are compensated for through a strategic offset program designed to improve the conservation outcome within the subregion

INDIRECT IMPACTS

The potential indirect impacts associated with collision mortality, inappropriate fire regimes and predation from feral cats have been analysed and determined to be adequately managed and mitigated through the generic management strategies in the Plan.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

Development under the Plan will lead to potential impacts to Swift Parrot foraging habitat. However, implementation of the Plan is not expected to adversely influence the long-term viability of the species for the following key reasons:

- Direct impacts comprise a small proportion (2 per cent) of available habitat within the subregion. These impacts will not affect any identified priority sites/regions, focus on poorer condition habitat and will not lead to fragmentation
- The Plan commits to the delivery of a 4,470 ha offset for the Swift Parrot which will be located in the SCAs. These areas have been designed to pick-up well-connected vegetation in the best condition in order to improve landscape scale conservation across the subregion
- Potential indirect impacts are addressed through management measures in the Plan

30.5.10 CONSISTENCY WITH RECOVERY PLAN

In accordance with Section 146K of the EPBC Act, this section considers whether the implementation of the Plan is not inconsistent with the species' Recovery Plan. It considers two questions:

- Does the Plan Prevent achievement of the objectives of the Recovery Plan?
- Does the Plan prevent implementation of the Recovery Plan actions?

These questions are discussed below.

DOES THE PLAN PREVENT ACHIEVEMENT OF THE OBJECTIVES OF THE RECOVERY PLAN?

The overall objective of the Recovery Plan is to prevent further decline of the Swift Parrot population, and achieve a demonstrable sustained improvement in the quality and quantity of Swift Parrot habitat to increase carrying capacity (Saunders & Tzaros, 2011).

Specific actions have been identified to support the overall objective. These are:

- Identify the extent and quality of habitat
- Manage and protect Swift Parrot habitat at the landscape scale
- Monitor and manage the impact of collisions, competition and disease
- Monitor population and habitat
- Increase community involvement in, and awareness of, the recovery program
- Coordinate, review and report on recovery process

The outcome for the Swift Parrot under the Plan will not make it impossible to the achieve any of the objectives of the Recovery Plan.

Does the Plan prevent implementation of the Recovery Plan actions?

The Recovery Plan identifies a set of actions to be implemented in order to deliver on the objectives. The Plan will not prevent implementation of any of the actions.

The commitment to strategically protect large patches of well connected, high quality vegetation across the Strategic Assessment Area offers real conservation benefits for the Swift Parrot. This process is consistent with one of the main strategies in the Recovery Plan to "manage and protect Swift Parrot habitat at the landscape scale".

30.5.11 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 30-21 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The Plan has been developed to ensure that it is not inconsistent with any relevant TAPs. This analysis around consistency is presented in Chapter 15.

Table 30-21: Relevant Key Threatening Processes and associated Threat Abatement Plans for Swift Parrot

KEY THREATENING PROCESS	THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Predation by feral cats	Threat abatement plan for predation by feral cats (DoE, 2015g)

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

Table 30-22: Occurrence of the Swift Parrot in the Strategic Assessment Area

SPECIES AT LOW RISK OF DIRECT IMPACTS

30.6 *ANTHOCHAERA PHRYGIA* (REGENT HONEYEATER)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Critically Endangered
DESCRIPTION	*Anthochaera phrygia* (Regent Honeyeater) is a predominantly black, medium sized honeyeater with yellow trimming on the tail and wing feathers. Its head and breast are black, transitioning to pale yellow trimming and a pure pale yellow belly (DoE, 2015a, 2016).
ECOLOGY	Breeds mostly throughout spring and summer, from August to January. Breeding times appear to have a correlation with the flowering of certain eucalypt and mistletoe species. Primary food source is nectar from eucalypts and mistletoe as well as invertebrates (DoE, 2015a). Movement patterns have been associated with the regional flowering of certain eucalypt species and the species is capable of travelling large distances (DoE, 2015a). However, there is still a high level of variability with these patterns. Some individuals have been found to return to the same area in successive breeding seasons, while others have not (DoE, 2016). The area of occupancy is approximately 300 km^2 (DoE, 2015a).
DISTRIBUTION AND HABITAT	Endemic to the south-eastern Australian mainland and is patchily distributed. Its distribution extends from south-east Queensland to central Victoria. The species is observed widely across its range, but it is only known to occur regularly to breed and forage at four locations (DoE, 2015a). These are identified in the recovery plan (along with surrounding subsidiary areas) as Bundarra-Barraba (NSW), Capertee Valley (NSW) and Hunter Valley (NSW), and the Chiltern area (VIC) (DoE, 2016). A recent paper on the breeding ecology of the species (Crates, Rayner et al., 2018) also identifies breeding sites at the Severn River (northern NSW) and in the Burragorang Valley in the Blue Mountains to the west of the Strategic Assessment Area. At the end of 2019, a breeding pair was observed near Mulgoa within the Strategic Assessment Area. Mostly associated with box ironbark eucalypt woodland and dry sclerophyll forest and has also been found in riparian corridors with she-oak (*Casuarina* spp.). The species has a preference for trees that are taller and have a larger diameter, as they typically produce more nectar (DoE, 2015a). Nesting generally occurs in the canopy of mature trees. The breeding areas often consist of a nest tree and the food sources surrounding it (DoE, 2015a). The species is thought to prefer larger, better quality patches that support all woodland structural elements, including large trees which are important for breeding and foraging. Better quality patches buffer against the negative impacts of edge effects and provide the necessary productive

	resources. The quality of remnants is also thought to influence the species' ability to undertake large-scale movements, as degraded vegetation is likely to be missing important ecological features, such as the larger trees and/or high quality nectar flows (DoE, 2016). Habitat critical to the survival is defined in the recovery plan (DoE, 2016) as: • *Any breeding or foraging habitat in areas where the species is likely to occur, and* • *Any newly discovered breeding or foraging locations*
POPULATIONS	Occurs as a single population that was estimated to be 350-400 mature individuals in 2010 (DoE, 2016).
SOS SITES	The following SOS sites for the species have been identified: • Capertee Valley • Lower Hunter Valley • Taronga Zoo • Bundarra – Barraba • Mudgee / Wollar • Western Plains Zoo (Proposed)
RELEVANT PLANS AND POLICIES	Conservation Advice *Anthochaera phrygia* Regent Honeyeater (DoE, 2015a) National Recovery Plan for the Regent Honeyeater (*Anthochaera phrygia)* (DoE, 2016) Threat abatement plan for competition and land degradation by rabbits (DoEE, 2016a)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for the Regent Honeyeater.

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	Yes	No	No	No	No
EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.				
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS**				
	Knowledge based map. Habitat maps outside the nominated areas for the Regent Honeyeater were generated using BioNet associations of intact and thinned vegetation conditions, and scattered trees. Targeted surveys for this species were not undertaken and the species was not recorded during surveys for this project.				
	OUTSIDE THE NOMINATED AREAS				

	Knowledge based map. As above. No targeted surveys as part of this project were undertaken outside the nominated areas.
POPULATION MAPPING	**RECORD SELECTION** All available BioNet records were considered in the assessment. **POPULATION DEFINITION** The Regent Honeyeater comprises a single population (DoE, 2016). **IMPORTANT POPULATION CRITERIA** The population was considered to be important as the species is critically endangered.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 46.3 for a map of records and habitat across the Strategic Assessment Area.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 30-26 at the end of this species assessment for a breakdown of the occurrence of records and habitat for the Regent Honeyeater in the Strategic Assessment Area. **Records** The Regent Honeyeater occurs throughout the Strategic Assessment Area with the majority of records associated with the larger patches of vegetation towards the north. There is a total of 92 records within the Strategic Assessment Area. Until very recently, all records related to foraging birds. However, at the end of 2019 a pair was observed successfully breeding near Mulgoa at Fernhill Estate, just west of the boundary between the WSA and GPEC. The nest was recorded in vegetation mapped as Shale Sandstone Transition Forest. It is connected to the much broader areas of intact vegetation west of the Strategic Assessment Area; although the nest site itself is towards the interface of this vegetation and cleared rural land. The site is protected and managed in perpetuity under a biobanking agreement. **Potential habitat** The baseline mapping for this assessment has mapped approximately 59,460 ha of potential habitat across the Strategic Assessment Area. This area is so large because of the broad associations the species has with a variety of PCTs. However, it is noted that the actual area of suitable habitat is likely to be smaller given the species preference for larger, high quality patches of woodland which are generally more limited within the subregion due to historical clearing and land degradation. EES has mapped important habitat for the Regent Honeyeater as part of the BAM process. There is no mapped important habitat within the nominated areas or transport corridors for the species. The known breeding site near Mulgoa has been mapped as important as part of this BAM process.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

30.6.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 4,627 ha of potential habitat for the Regent Honeyeater within the nominated areas (not including excluded lands). Approximately 3,513 ha (76 per cent) of this has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 2,620 ha was avoided for biodiversity purposes
- 893 ha was avoided for other purposes

In addition, the Plan includes a specific measure for the Regent Honeyeater to retain large trees (≥50cm DBH) during precinct planning where possible and avoid impacts to soil within the dripline of these trees during construction.

A breakdown of avoidance across each nominated area is provided in Table 30-27.

It is important to note that the avoidance calculations in Table 30-27, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 30-27 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

30.6.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 30.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

30.6.3 LOSS OF POTENTIAL HABITAT

Implementation of the Plan will lead to the loss of potential habitat for the species. It will not result in direct impacts to any known breeding habitat or key areas identified in the species recovery plan and conservation advice.

LOSS OF POTENTIAL HABITAT

Approximately 1,285 ha of potential habitat will be lost as a result of the implementation of the Plan (1,114 ha within the nominated areas and 171 ha within transport corridors outside the nominated areas). This habitat represents 2 per cent of mapped potential habitat across the Strategic Assessment Area. As identified below, potential habitat within each of the nominated areas and the transport corridors is unlikely to be used much or at all by the species due to the level of clearing and fragmentation.

Impacts are proposed to occur as follows:

- GPEC: Loss of 330 ha of potential habitat. Most of which occurs as fragmented patches in an existing urbanised environment. Unlikely that the nominated area is used or important to the species. Only one post-1990 record is present which occurs in a cleared location
- WSA: Loss of 330 ha of potential habitat. Most of which occurs as fragmented patches in an existing, heavily cleared rural landscape. Unlikely that the nominated area is important to the species. No records of the species
- GMAC: Loss of 284 ha of potential habitat. Most of which occurs to the edges of vegetated areas. Unlikely that the nominated area is used or important for the species. No records of the species
- Wilton: Loss of 170 ha of potential habitat. Most of which occurs to the edges of vegetated areas. Unlikely that the nominated area is used or important for the species. No records of the species
- Transport outside the nominated areas: Loss of 171 ha of potential habitat. Occurs to mostly fragmented vegetation patches across the Outer Sydney Orbital

A summary of these impacts is provided in Table 30-28.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of the loss of potential habitat is considered to be low. This is because:

- The likelihood of substantial impacts occurring to the species has been categorised as unlikely. There will be no impacts to known breeding habitat or key areas identified in the species Recovery Plan or Conservation Advice. While the extent of clearing of mapped potential habitat for the Regent Honeyeater is large, the likely impacts to the species are considered to be minor. Impacts focus on the more fragmented and degraded remnants which are unlikely to provide the ecological elements preferred or needed by the species. This is reflected in the almost complete absence of records within the impacted areas and the lack of important habitat mapping by EES within the nominated areas or transport corridors. The Cumberland subregion more broadly has been subject to large levels of historical clearing and land use practices that have reduced its capacity to support the species and this is again reflected in relatively low number of records across the subregion
- The consequence of any impacts to the species has been categorised as major. There will be loss of approximately 2 per cent of mapped potential foraging habitat in the Strategic Assessment Area, however, there are very few records close to and within areas that will be impacted

30.6.4 FRAGMENTATION OF HABITAT

Given the wide-ranging nature of the species, it is considered unlikely that development within the nominated areas or transport corridors would lead to any fragmentation effects. The lack of records within the nominated areas and transport corridors suggests that these mapped potential habitat areas may already be in too degraded a state to contain enough of the important ecological features needed to support foraging movements (DoE, 2016).

30.6.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the low risk of residual adverse impacts to the species, offsets were not considered necessary for the Regent Honeyeater.

However, it is worth noting that mapped habitat prepared for this project for Regent Honeyeater and the Swift Parrot are the same. And that the offsets that the Plan will provide for Swift Parrot (4,470 ha of potential foraging habitat within the SCAs) may provide benefits for the Regent Honeyeater.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

30.6.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice and Recovery Plan (and other key documents) for the Regent Honeyeater identify a range of threats to the species (DoE, 2015a, 2016). Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts.

The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan: degradation of habitat especially through the removal of large mature trees, firewood collection, spread of weeds, and inappropriate fire regimes.

Eucalypt dieback, grazing by livestock and rabbits, competition with other nectivorous birds and honeybees, increased predation by native nest predators, and loss of genetic diversity are also identified as key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the risk across the Strategic Assessment Area.

The main area of concern for indirect impacts is the Mulgoa region west of GPEC and WSA where the species has recently been observed breeding. Importantly, this site is protected and managed in perpetuity as part of a biobanking agreement. Management of this site will substantially minimise the threat of any indirect impacts on the species associated with development.

More broadly across the Strategic Assessment Area, the level of historical clearing and degrading land uses has reduced the value of habitat. This limits the extent that any threatening processes potentially exacerbated under the Plan, might lead to actual impacts on the species.

However, it is recognised that the package of commitments and actions under the Plan will lead to the protection and management of large areas of the better-quality, better-connected vegetation within the SCAs. Although the protection of these areas is required to compensate for the impacts of development on other threatened species and ecological communities, there is considerable overlap with vegetation types that have the potential to provide foraging resources for the Regent Honeyeater. With greater protection and management, these areas are likely to improve the foraging capacity of the subregion to the species. This means the potential indirect impacts from development on these areas is likely to become more relevant in the future as the species' numbers begin to recover within these areas as they are managed and protected.

REMOVAL OF TREES AND FIREWOOD COLLECTION

Removal of large, mature trees and the collection of firewood are identified in the Conservation Advice and Recovery Plan as threats to the Regent Honeyeater. These threats have the potential to increase within the Strategic Assessment Area due to development within the nominated areas. Habitat considered most at risk are areas that occur in close proximity to new urban development.

The Plan incorporates a range of measures to mitigate the risks associated with these things, including:

- A commitment to retain large trees (≥50cm DBH) during precinct planning where possible and avoid impacts to soil within the dripline of these trees during construction
- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when assessing development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance to habitat
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will help address issues such as illegal firewood collection in those locations
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal activities such as vegetation clearing and firewood collection
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan is expected to adequately manage the risk to the species from tree removal and firewood collection. This is because:

- Avoided lands that support areas of potential foraging habitat will be zoned appropriately to enable an adequate framework for management
- Development controls will be put in place to address potential impacts associated with construction

- Conservation lands will be actively managed which will address disturbance and illegal activities in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

SPREAD OF WEEDS

Invasive weeds are identified as a threat to the Regent Honeyeater as they degrade foraging remnants. Weed incursion in the habitat areas is associated with agricultural activities as well as urban development.

Key weeds that occur within the subregion include: African Olive (*Olea europaea* subsp. *cuspidata*), Fireweed (*Senecio madagascariensis*), Spear Thistle (*Cirsium vulgare*), Cat's Ear (*Hypochaeris radicata*), Pigeon Grass (*Setaria gracilis*), Plantain (*Plantago lanceolata*), Paddy's Lucerne (*Sida rhombifolia*), Bridal Creeper (*Myrsiphyllum asparagoides*), Sow Thistle (*Sonchus oleraceus*), and Broad-leafed and Small-leaf Privet (*Ligustrum lucidum* and *L. Sinense*) in wetter areas.

The most serious threats are from Bridal Creeper and African Olive as they are highly competitive and difficult to manage.

These weeds are already present within the Strategic Assessment Area. However, urban development and transport have the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or changing conditions to favour weeds.

Foraging habitat is most susceptible to the threat of weeds from development under the Plan where new urban development occurs adjacent to the habitat and introduces edge effects.

The Plan incorporates a range of measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCAs. This includes a number of key actions:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

Weeds will be actively managed within all areas added to conservation as part of the offset program.

The package of measures in the Plan is expected to adequately manage the risk posed to the Regent Honeyeater from invasive weeds. This is because:

- Avoided lands will be zoned appropriately to enable an adequate framework for management
- The Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy. This includes the land to be protected under the conservation program which is expected to provide large areas of potential foraging habitat for the Regent Honeyeater
- There will be a range of planning controls to minimise the potential spread of weeds during and after construction

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes, in particular frequent fire, is identified as a threat to the Regent Honeyeater. Where fire intervals are too frequent, flowering events and maturation of nectar rich plant species can be reducing, leading to a reduction in foraging resources (DoE, 2016).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact Regent Honeyeater habitat. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant including:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from potential foraging habitat. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the Regent Honeyeater from increased fire frequency as a result of development. This is because:

- Avoided lands supporting potential foraging habitat will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat
- Fire management authorities will be engaged to ensure they understand the values relevant to the Regent Honeyeater and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to:

- The development of essential infrastructure within nominated areas but outside the urban capable lands
- Tunnels associated with transport projects

30.6.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

While mapped potential habitat for the Regent Honeyeater occurs on avoided land, and these areas may be subject to impacts from essential infrastructure, it is very unlikely the species will be adversely affected. There are no records of the Regent Honeyeater on avoided land and very few elsewhere in the nominated areas, the species is highly mobile and wide-ranging, and the scale of impacts is not expected to be significant.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to biodiversity through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

30.6.8 POTENTIAL IMPACTS FROM TUNNELS

Potential habitat for the Regent Honeyeater occurs within the tunnel footprints for the Metro Rail Future Extension (69.6 ha) and the Outer Sydney Orbital (108.2 ha). These areas are not associated with records and are not considered important to the species.

However, the Plan includes commitments to:

- Avoid any direct impacts to the areas where the species could occur, including protected lands and the Nepean River and associated riparian vegetation, as discussed in Chapter 36
- Mitigate any potential indirect impacts (e.g. changes to hydrology, ground settling or subsidence) from the transport corridors as part of a future environmental impact assessment process

These commitments are expected to adequately address threats to the species from the construction and operation of the tunnels. See Section 36.6 in Chapter 36 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15

30.6.9 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice and Recovery Plan identify the following key issues that are likely to have the greatest influence on the long-term viability of the Regent Honeyeater in relation to implementation of the Plan:

- Habitat loss and fragmentation
- Indirect impacts associated with degradation of habitat through the removal of large mature trees, firewood collection, spread of weeds, and inappropriate fire regimes

HABITAT LOSS AND FRAGMENTATION

Loss and fragmentation of Regent Honeyeater habitat within the Strategic Assessment Area is not likely to be an issue and the risk of residual adverse impacts to the species has been assessed here as low. Although the Plan authorises the clearing of 1,285 ha of potential habitat, this does not relate to any key breeding or foraging areas identified in the Conservation Advice or Recovery Plan and predominantly occurs:

- In already fragmented and degraded areas that offer low habitat value
- In areas where the species has not been recorded recently (or at all)
- In areas that have not been mapped as important habitat by EES as part of the BAM process

More generally, the Cumberland subregion has been subject to extensive historical clearing and land use practices that have reduced its capacity to support the species.

The package of commitments and actions under the Plan will lead to the protection and management of large areas of the better quality, well-connected vegetation within the SCAs. The protection of these areas is required to compensate for the impacts of development on other threatened species and ecological communities (including Swift Parrot which shares the same areas of mapped habitat). With greater protection and management, these areas are likely to improve the foraging capacity of the subregion to the Regent Honeyeater.

This outcome directly supports one of the conservation and management actions in the Conservation Action to *improve the extent and quality of regent honeyeater habitat*, as well as a number of the on ground actions identified to achieve the strategies and objectives in the Recovery Plan.

INDIRECT IMPACTS

The potential indirect impacts associated with degradation of habitat will be managed and mitigated through a specific measure and generic management strategies in the Plan.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

There is a low risk that development under the Plan will adversely impact the Regent Honeyeater and any long-term impacts to viability in the subregion have the potential to be positive for the following key reasons:

- There will be no direct impacts to areas identified as important for breeding or foraging
- The nominated areas and transport corridors offer limited habitat values and the Regent Honeyeater has barely been observed in these areas
- The majority of the Cumberland subregion is currently likely to offer only marginal habitat for the species due to extensive levels of historical vegetation clearing and degrading land use practices. However, the protection and management of large areas (at least 5,470 ha) of vegetation types associated with foraging habitat is expected to improve the capacity of the subregion to support the species
- Potential indirect impacts are addressed through management measures in the Plan

30.6.10 CONSISTENCY WITH RECOVERY PLAN

In accordance with Section 146K of the EPBC Act, this section considers whether the implementation of the Plan is not inconsistent with the species' Recovery Plan. It considers two questions:

- Does the Plan prevent achievement of the objectives of the Recovery Plan?

- Does the Plan prevent implementation of the Recovery Plan actions?

These questions are discussed below.

DOES THE PLAN PREVENT ACHIEVEMENT OF THE OBJECTIVES OF THE RECOVERY PLAN?

The objectives of the Recovery Plan for the Regent Honeyeater are to:

- Reverse the long-term population trend of decline and increase the numbers of regent honeyeaters to a level where there is a viable, wild breeding population, even in poor breeding years; and to
- Enhance the condition of habitat across the Regent Honeyeater's range to maximise survival and reproductive success, and provide refugia during periods of extreme environmental fluctuation (DoE, 2016)

Specific strategies have been identified to support the overall objectives. These are:

- Improve the extent and quality of Regent Honeyeater habitat
- Bolster the wild population with captive-bred birds until the wild population becomes self-sustaining
- Increase understanding of the size, structure, trajectory and viability of the wild population
- Maintain and increase community awareness, understanding and involvement in the recovery program (DoE, 2016)

The outcome for the Regent Honeyeater under the Plan will not prevent achievement of any of the objectives of the Recovery Plan.

DOES THE PLAN PREVENT IMPLEMENTATION OF THE RECOVERY PLAN ACTIONS?

The Recovery Plan identifies a set of strategies in order to deliver on the objectives. The Plan will not prevent implementation of any of the strategies.

The commitment to strategically protect large patches of well connected, high quality vegetation across the Strategic Assessment Area offers potential conservation benefits for the Regent Honeyeater. This process is consistent with one of the main strategies in the Recovery Plan to "improve the extent and quality of regent honeyeater habitat".

30.6.11 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 30-25 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The Plan has been developed to ensure that it is not inconsistent with any relevant TAPs. This analysis around consistency is presented in Chapter 15.

Table 30-25: Relevant Key Threatening Processes and associated Threat Abatement Plans for the Regent Honeyeater

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Competition and land degradation by rabbits	Threat abatement plan for competition and land degradation by rabbits (DoEE, 2016a)
Land clearance	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

30.7 *BOTAURUS POICILOPTILUS* (AUSTRALASIAN BITTERN)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Endangered
DESCRIPTION	*Botaurus poiciloptilus* (Australasian Bittern) is a large heron-like bird. It has mottled brown, dark brown to black feathers, a straw yellow bill and pale green to olive legs. The average male weighs 1.4 kg and the average female weighs 0.9 kg (TSSC, 2019a).
ECOLOGY	Breeding occurs from October to February. Females usually lay four to five olive-brown eggs. Nests are built on a bed of reeds in densely-vegetated wetlands, and placed about 30 cm above the water level. (TSSC, 2019a) Feeds mainly at night on fish, eels, frogs, freshwater crayfish and aquatic insects (Garnett, Szabo et al., 2011). The species is mainly solitary but has been seen in pairs or groups of up to 12 birds (TSSC, 2019a).
DISTRIBUTION AND HABITAT	The Australasian Bittern occurs in New Zealand, New Caledonia and Australia. In Australia the species occurs in south-eastern Australia: throughout Tasmania, south east of South Australia, Victoria, NSW (excluding the north west), and up to Yeppoon in Queensland. It also occurs in the south-west of Western Australia between Moora and Cape Arid (TSSC, 2019a). In NSW it occurs along the coast and has been recorded in the Murray-Darling Basin, in the floodplain wetlands of the Murray, Murrumbidgee, Lachlan, Macquarie and Gwydir Rivers. The species has been recorded in the Cumberland subregion. The area of occupancy in Australia is estimated to be 1,150 km^2 (TSSC, 2019a). The species inhabits freshwater or brackish swamps that are shallow and vegetated, with a preference for the presence of sedges, rushes, and reeds (Garnett, Szabo et al., 2011). The species is less often found in estuaries or tidal wetlands (TSSC, 2019a). The species moves between habitats as suitability changes and has been observed to use coastal wetlands during periods of drought and ephemeral wetlands when wet (TSSC, 2019a). All natural habitat where the species is known or likely to occur is considered habitat critical to the survival of the species (TSSC, 2019a).
POPULATIONS	The Australasian Bittern occurs as two sub-populations: one in south-eastern Australia and the other in south-western Australia (TSSC, 2019). The total Australian population is estimated at 1,000 mature individuals (Garnett, Szabo et al., 2011).
SOS SITES	This species has been assigned to the landscape species management stream because it is distributed across large areas and is subject to threatening processes that generally act at the landscape scale rather than at distinct, definable locations (OEH, 2018c).

RELEVANT PLANS AND POLICIES	Conservation Advice *Botaurus poiciloptilus* Australasian Bittern (TSSC, 2019a) Threat abatement plan for predation by the European red fox (DEWHA, 2008n) Threat abatement plan for predation by feral cats (DoE, 2015g)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for the Australian Bittern.

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	Yes	No	No	No	No

EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS** **Knowledge based map (KBM).** Habitat maps were generated using BioNet PCT associations, vegetation condition parameters (intact, thinned), 40 m buffer to hydrolines (based on preferred habitat comprising wetlands, often at the edges of pools or waterways, or from platforms or mats of vegetation over deep water) (TSSC, 2019a). No targeted surveys were undertaken as part of this project. **OUTSIDE THE NOMINATED AREAS** **Knowledge based map (KBM).** As above. No targeted surveys as part of this project were undertaken outside the nominated areas.
POPULATION MAPPING	**RECORD SELECTION** Records restricted to post 2007 to account for estimated 11-year lifespan of the species. **POPULATION DEFINITION** The south-eastern Australian subpopulation of the species is considered as one population for this assessment. All records within the Strategic Assessment Area are therefore considered part of the same population. **IMPORTANT POPULATION CRITERIA** All populations were considered to be important as the species is endangered.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in *conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.*

MAP	See Map 36.25 for a map of records and habitat across the Strategic Assessment Area
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 30-30 at the end of this species assessment for a breakdown of the occurrence of records and habitat for the Australasian Bittern in the Strategic Assessment Area. **Records** There are five records of the species within the Strategic Assessment Area: • Four occur at Pitt Town Lagoon in the north of the Strategic Assessment Area near to the Hawkesbury River (approximately 15 km from the nearest development area) • One occurs near Wianamatta (South Creek) in Oran Park (approximately 9 km from the nearest development area) **Potential habitat** The baseline mapping for the assessment has mapped 2,524 ha of potential habitat within the Strategic Assessment Area. Based on the limited number of records, this mapping is considered to be highly precautionary as it is based on all mapped streams with the appropriate PCTs. While some records occur in the Strategic Assessment Area, the area is not recognised as a key location for the species. In NSW the species primarily occurs along the coast and is frequently recorded in the Murray Darling Basin, notably in floodplain wetlands of the Murray, Murrumbidgee, Lachlan, Macquarie and Gwydir Rivers (TSSC, 2019a). Notable observations within proximity of the Strategic Assessment Area include Sydney Olympic Park approximately 9 km to the east of the Strategic Assessment Area, and Towra Point Wetlands approximately 20 km from the Strategic Assessment Area.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

30.7.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 180 ha of potential habitat within the nominated areas (not including excluded lands). Approximately 109 ha (61 per cent) of this has been avoided as part of the design of the urban capable lands and transport corridors (not including excluding lands). Of this:

- 11 ha was avoided for biodiversity purposes
- 99 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 30-31.

It is important to note that the avoidance calculations in Table 30-31, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 30-31 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

30.7.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 30.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

30.7.3 LOSS OF POTENTIAL HABITAT

Implementation of the Plan will not lead to direct impacts to known habitat. However, it will result in impacts to some potential habitat.

LOSS OF POTENTIAL HABITAT

Approximately 88 ha of potential habitat will be lost as a result of the implementation of the Plan (70 ha within the nominated areas and 18 ha within transport corridors outside the nominated areas). This habitat represents 3.5 per cent of mapped potential habitat across the Strategic Assessment Area. The majority of potential habitat (53 ha) to be impacted occurs within GPEC and is associated with the proposed alignment of the Outer Sydney Orbital within the vicinity of Wianamatta (South Creek).

The Conservation Advice notes that the major threat to the species from habitat loss relates to *the long-term diversion of water away from wetlands and floodplains to support irrigated agriculture and urban water supplies; and the permanent loss of wetlands through conversion to other purposes, such as agricultural and urban development* (TSSC, 2019a). Development under the Plan will not involve any of these types of impacts. The loss of potential habitat relates to clearing of vegetation mapped as potential habitat due to broad PCT associations or development that occurs within the 40 m buffer of hydrolines.

A summary of these impacts is provided in Table 30-32.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of the loss of potential foraging habitat is considered to be low. This is because:

- The likelihood of substantial impacts occurring to the species has been categorised as unlikely. There will be no impacts to areas known to support the species and only minor impacts to potential foraging habitat. The Strategic Assessment Area represents more marginal habitat for the species, which is more frequently recorded along the coast and within the Murray Darling Basin when in NSW. The potential habitat mapping is considered to be highly precautionary
- The consequence of any impacts to the species has been categorised as moderate. There will be loss of approximately 3.5 per cent of mapped potential habitat in the Strategic Assessment Area. There is low confidence that the species occurs in the impact areas

30.7.4 FRAGMENTATION OF HABITAT

Given the lack of records and wide-ranging nature of the species, it is considered unlikely that development within the nominated areas or transport corridors would lead to any fragmentation effects.

30.7.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the low risk of residual adverse impacts to the species, offsets were not considered necessary for the Australasian Bittern.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

30.7.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice for the Australasian Bittern identifies a range of threats to the species (TSSC, 2019a). Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Hydrological changes
- Predation by introduced vertebrates
- Weed invasion
- Inappropriate fire regimes

Transition from ponded rice to other farming systems, impacts from grazing animals and salinization of coastal wetlands are also identified in the conservation advice as key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the risk across the Strategic Assessment Area.

HYDROLOGICAL CHANGES

Habitat degradation from increased salinity, siltation and pollution is identified as a threat to the Australasian Bittern (TSSC, 2019a). This is a particular threat where important habitat areas are in the proximity of development and well connected hydrologically. The likelihood of adverse impacts to the species due to development under the Plan is low as mapped potential habitat in the Strategic Assessment Area within the vicinity of development lacks records and is not considered to be critical for the species.

The Plan also incorporates a range of measures to mitigate the risks associated with changes to hydrology and this further minimises the likelihood of impacts on the species. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5) and transport (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through:

- Development controls in the nominated areas in relation to:
  - Water cycle management. For example:
    - Water management measures must comply with council's requirements for detention, drainage and water sensitive urban design principles
    - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
  - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
  - Soil erosion and sedimentation. For example:
    - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
    - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom 2004) and submitted with each subdivision development application

- The implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the TfNSW Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology

While the threat to the species is already low, the package of measures in the Plan manages any residual risk to the species from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to habitat for the species

PREDATION BY INTRODUCED VERTEBRATES

Predation by introduced vertebrates such as foxes and cats is a key threat to the Australasian Bittern (noting that the extent of the impacts on this species is unknown) (DSEWPC, 2011a).

Cats and foxes are already well established in the Strategic Assessment Area and are unlikely to pose a novel threat to the species. However, the extent of proposed new urban development under the Plan means that the threat, particularly associated with cats, is likely to be exacerbated. It is likely that there will be an increase in the number of domestic cats in the local area, which, in turn, may lead to an increase in feral cat numbers. The main areas of concern relate to new urban development in Wilton and the southern section of GMAC, where the current density of houses is low.

While the actual impact on the Australasian Bittern is expected to be minimal due to their limited use of the Strategic Assessment Area, the Plan incorporates a range of measures to manage the risks. In summary, these include:

- A commitment (Commitment 17) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the SCAs. This includes a number of actions with the most relevant to the outcome for the species being:
  - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
  - Preparation of a Pest Animal Control Implementation Strategy
  - A process to enter into written agreements with delivery partners to implement the pest animal control program
  - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Development controls that will:
  - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
  - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
  - Require appropriate management and control of pest animals relevant to development sites
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing pests, consistent with the pest animal implementation strategy outlined in Commitment 16

WEED INVASION

Weed invasion and changes in abundance of certain plant species can reduce wetland productivity, which may impact on the quality of habitat for the Australasian Bittern (DSEWPC, 2011a).

Many weeds are already present within the Strategic Assessment Area and pose a threat to habitat for the Australasian Bittern. However, urban development and transport have the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or changing conditions to favour weeds.

The species is most susceptible to the threat of weeds from development under the Plan where new development occurs adjacent to habitat areas or connected waterways. However, the extent of impacts on the species is generally expected to be low given the limited use of the Strategic Assessment Area by the species and lack of records within proximity to development.

The Plan also incorporates a range of measures to manage the risk posed by weed invasion and this further minimises the likelihood of impacts on the species. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCAs. This includes a number of actions, of which the following are the most relevant to the outcome for the species:
    - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
    - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
    - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
    - Require proponents to undertake the following when applying for/undertaking development:
        - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
        - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
        - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes are identified as a key threat to the Australasian Bittern. Fire can reduce the quality of habitat features that are important to the species (DSEWPC, 2011a).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact habitat for the species. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant including:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy

  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from potential habitat. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the species from increased fire frequency as a result of development. This is because:

- Avoided lands supporting potential habitat will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat
- Fire management authorities will be engaged to ensure they understand the values relevant to the species and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to:

- The development of essential infrastructure within nominated areas but outside the urban capable lands
- Tunnels associated with transport projects

30.7.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

There are no records and limited potential habitat for the Australasian Bittern on avoided land in the nominated areas.

However, as outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to biodiversity through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

30.7.8 POTENTIAL IMPACTS FROM TUNNELS

Potential habitat for the Australasian Bittern occurs within the tunnel footprints for the Metro Rail Future Extension (4.6 ha) and the Outer Sydney Orbital (8.2 ha). These areas are not associated with records and the habitat mapping for the species is considered to be highly precautionary.

However, the Plan includes commitments to:

- Avoid any direct impacts to the areas where the species could occur
- Mitigate any potential indirect impacts (e.g. changes to hydrology, ground settling or subsidence) from the transport corridors as part of a future environmental impact assessment process

These commitments are expected to adequately address threats to the species from the construction and operation of the tunnels. See Section 36.6 in Chapter 36 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15

30.7.9 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DSEWPC, 2011a) identifies the following key issues that are likely to have the greatest influence on the long-term viability of the Australasian Bittern in relation to implementation of the Plan:

- Habitat loss
- Indirect impacts such as:
  - Reduced water quality
  - Predation by introduced vertebrates
  - Weed invasion
  - Inappropriate fire regimes

HABITAT LOSS

This assessment has identified the risk of residual adverse impacts to the Australasian Bittern from habitat loss as being low. Although development under the Plan will lead to the loss of 88 ha of mapped potential habitat, impacts on the species are likely to be minimal given:

- The areas being impacted are not known to support the species and the potential habitat mapping is very precautionary
- The importance of the Strategic Assessment Area more broadly is marginal. When in NSW, the species is more frequently recorded along the coast and within the Murray Darling Basin
- The loss of habitat does not involve the types of impacts or activities identified in the Conservation Advice as particularly problematic, which include *the long-term diversion of water away from wetlands and floodplains to support irrigated agriculture and urban water supplies; and the permanent loss of wetlands through conversion to other purposes, such as agricultural and urban development.* Instead, direct impacts under the Plan relate to clearing of vegetation mapped as potential habitat due to broad PCT associations, or development that occurs within the 40m buffer of hydrolines

As a result, habitat loss under the Plan is not expected to affect the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts associated with the identified threats will be managed and mitigated through the generic management strategies in the Plan.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

Development under the Plan will not affect areas known to support the Australasian Bittern but will lead to the loss of a small proportion of areas mapped as potential habitat. However, implementation of the Plan is not expected to adversely influence the long-term viability of the species for the following key reasons:

- Habitat known to support the species within the Strategic Assessment Areas occurs some distance from development and will not be affected by implementation of the Plan
- Areas of potential habitat that will be directly affected has been mapped using highly precautionary assumptions and impacts are not expected to affect the species' use of the Strategic Assessment Area
- Potential indirect impacts will be addressed through management measures in the Plan

30.7.10 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

30.7.11 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 30-29 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The Plan has been developed to ensure that it is not inconsistent with any relevant TAPs. This analysis around consistency is presented in Chapter 15.

Table 30-29: Relevant Key Threatening Processes and associated Threat Abatement Plans for Australasian Bittern

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP
Predation by European red fox	Threat abatement plan for predation by the European red fox (DEWHA, 2008n)
Predation by feral cats	Threat abatement plan for predation by feral cats (DoE, 2015g)

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

30.8 *CHALINOLOBUS DWYERI* (LARGE-EARED PIED BAT)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	*Chalinolobus dwyeri* (Large-eared Pied Bat) is a small to medium-sized insectivorous bat with shiny, black fur on its body. Has a total length of up to 10 cm and weighs 7-12 g (DoEE, 2018c).
ECOLOGY	It is a nocturnal species and forages for insects below the canopy and can travel several kilometres from roost sites. Breeding occurs in early winter and young are born in early summer. Females normally carry one or two pups and give birth once a year. The species has been recorded in groups of up to 50 breeding females at maternity roosts (DoEE, 2018). They have high site fidelity and visit the same maternity site over many years (OEH, 2018d).
DISTRIBUTION AND HABITAT	Records are poor for the species but occur from Shoalwater Bay in south Queensland to Ulladulla in south eastern NSW. In NSW it is found in areas of volcanic strata in the north east at Coolah Tops, Mt Kaputar and Warrumbungle National Park and in sandstone areas of the Sydney Basin and the western slopes and plains including Pilliga Nature Reserve (DERM, 2011). The area of occupancy is estimated to be 9,120 km^2 (DoEE, 2018). Inhabits well-timbered areas and low to mid-elevation dry open forests and woodland in close proximity to preferred roosting locations of sandstone caves, crevices in cliffs, old mine workings and disused mud nests of the Fairy Martin (*Petrochelidon ariel*). Requires very specific nursery roosts with deep roofs that allow juveniles to learn to fly and roof indentations, which are likely to capture the heat. The species is not associated with tree hollows. Habitat is associated with the following TECs: • Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest • Shale Sandstone Transition Forest • Brigalow (*Acacia harpophylla* dominant and co-dominant) • White Box-Yellow Box-Blakely's Red Gum Grassy Woodland and Derived Native Grassland • Weeping Myall – Coobah – Scrub Wilga Shrubland of the Hunter Valley • Temperate Highland Peat Swamps on Sandstone • Grey Box (*Eucalyptus microcarpa*) Grassy Woodlands and Derived Native Grasslands of South-eastern Australia • New England Peppermint (*Eucalyptus nova-anglica*) Grassy Woodlands. (DERM, 2011)

	The species Recovery Plan identifies the following as habitat critical to survival of the Large-eared Pied Bat (DERM, 2011): • Any maternity roosts • Sandstone cliffs and fertile wooded valley habitat within close proximity of each other
POPULATIONS	There is insufficient information to estimate total population. The species is thought to exist in a number of small populations, with colonies containing up to 50 individuals. Important populations in NSW exist in the sandstone escarpments of the Sydney basin and north west slopes of NSW (DERM, 2011).
SOS SITES	There are no SOS sites identified for the species because there is insufficient information available for effective management.
RELEVANT PLANS AND POLICIES	National recovery plan for the Large-eared Pied Bat *Chalinolobus dwyeri* (DERM, 2011)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species.
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=183

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	Yes	Yes	Yes	Yes

EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS**
	Knowledge based map (KBM). Habitat maps within the nominated areas for the Large-eared Pied Bat were generated using BioNet associations of intact and thinned vegetation conditions. Mapping was also restricted to sandstone areas and cliffs within 2 km of rocky areas containing caves, overhangs, escarpments, outcrops, or crevices, or within 2 km of old mines/tunnels. No targeted surveys as part of this project were undertaken for this species.
	OUTSIDE THE NOMINATED AREAS
	Knowledge based map (KBM). As above. No targeted surveys as part of this project were undertaken outside the nominated areas.
POPULATION MAPPING	**RECORD SELECTION**
	All BioNet records for the Strategic Assessment Area were included in the assessment.
	POPULATION DEFINITION

	The species is known to breed in very few locations across NSW and the distance bats move from the maternity roost to over wintering roosts has not been established, but is likely to be less than 100 km (DoEE, 2018c). As such all records within the Cumberland subregion are considered likely to be from the same breeding population
	IMPORTANT POPULATION CRITERIA
	The population of Large-eared Pied Bats was considered important within the Strategic Assessment Area because it is a population identified or inferred in a Commonwealth conservation advice, recovery plan, final determination, or other relevant policy document as being important.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 46.1 for a map of records and potential habitat across the Strategic Assessment Area.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 30-34 at the end of this species assessment for a breakdown of the occurrence of records and habitat for the Large-eared Pied Bat in the Strategic Assessment Area. **Records** The Large-eared Pied Bat has been recorded in the Strategic Assessment Area and surrounding region. There are 65 records for the species within the Strategic Assessment Area, with the majority of observations from the last 10 years. The records occur along the boundary of the Strategic Assessment Area in the south (where the largest cluster of records occurs within Wilton), east and west and are generally associated with areas of sandstone geology. These records are all considered to form part of a single population and which, more broadly, form part of the important population associated with the sandstone escarpments of the Sydney Basin. **Potential habitat** The baseline mapping for this assessment has mapped approximately 25,555 ha of potential habitat across the Strategic Assessment Area. The majority of the potential habitat occurs in the south of the Strategic Assessment Area and along the western and south-eastern edges, again in association with areas of sandstone. Habitat within the Strategic Assessment Area is likely to be used predominantly for foraging. Interrogation of the observation codes of records for the species indicate there are no known roost or breeding sites for the species within the Strategic Assessment Area. Anabat surveys for the species within a part of the northern section of Wilton did not confirm the presence of breeding habitat or breeding individuals. However, there are a number of suitable caves in the Appin and Wilton areas which may be used for roosting (Bruce Mullins, pers com). The habitat mapped within the Strategic Assessment Area forms part of a much larger area of the species' known distribution. Records occur from Nowra in the south, up the coast to Newcastle and inland to Kanangra-Boyd National Park and Wollemi National Park.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

30.8.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 3,250 ha of potential habitat for the Large-eared Pied Bat within the nominated areas (not including excluded lands). Approximately 2,937 ha (90 per cent) of this has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 2,236 ha avoided for biodiversity purposes
- 701 ha avoided for other purposes

The majority of avoidance occurs in GMAC (1,723 ha or 90 per cent) and Wilton (1,214 ha or 91 per cent).

A breakdown of avoidance across each nominated area is provided in Table 30-35.

It is important to note that the avoidance calculations in Table 30-35, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 30-35 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

30.8.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 30.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

30.8.3 LOSS OF POTENTIAL HABITAT

Implementation of the Plan will lead to a loss of potential habitat for the species. There will be no impacts to known roosting or breeding areas.

LOSS OF POTENTIAL HABITAT

Approximately 316 ha of potential Large-eared Pied Bat habitat will be lost, predominantly in Wilton and GMAC. This represents 1.2 per cent of potential habitat within the Strategic Assessment Area.

At a broader landscape level, direct impacts are proportionally smaller still, given the areas of foraging habitat within the Strategic Assessment Area forms a relatively small part of much larger and intact areas of habitat to the north and west of the Strategic Assessment Area and to the south of Sydney.

A summary of these impacts is provided in Table 30-36.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of the loss of potential foraging habitat is considered to be low. This is because:

- The likelihood of substantial impacts occurring to the species has been categorised as possible. There will be no impacts to known breeding or roosting areas, and moderate impacts to foraging habitat. However, impacts to foraging habitat relates to small sections on the fringes of habitat corridors. These corridors are associated with canopied vegetation along riparian corridors in an otherwise cleared landscape. The corridors themselves will be maintained which is important as the Recovery Plan notes that narrow connecting riparian strips in otherwise cleared habitat are sometimes quite heavily used. The species is wide-ranging and potential foraging habitat in the Strategic Assessment Area forms part of a much larger area of the species' known distribution

- The consequence of any impacts to the species has been categorised as moderate. There will be loss of approximately 1.2 per cent of mapped potential foraging habitat in the Strategic Assessment Area

30.8.4 FRAGMENTATION OF HABITAT

Loss of potential habitat relates to foraging habitat mainly within GMAC and Wilton and relates to small sections on the fringes of habitat corridors. Development will not increase the level of habitat fragmentation in these areas.

30.8.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the low risk of residual adverse impacts to the species, offsets were not considered necessary for the Large-eared Pied Bat.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

30.8.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Recovery Plan for the Large-eared Pied Bat identifies a range of threats to the species. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Disturbance of roosts from human recreational activities
- Fire in the proximity of roosts
- Predation by introduced predators

Mining of roosts, mine induced subsidence of cliff lines, habitat disturbance from livestock, and loss of genetic diversity are also identified as key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the risk across the Strategic Assessment Area.

DISTURBANCE OF ROOSTS FROM HUMAN RECREATIONAL ACTIVITIES

Disturbance of roosts from recreational activities such as bushwalking, caving and abseiling is identified as a threat to the Large-eared Pied Bat. Regular disturbance can lead to bats abandoning roosts or depleting essential fat reserves (DERM, 2011).

Areas considered most at risk from increased disturbance due to recreational activities are those that occur in close proximity to development within Wilton and GMAC. Roosting and maternity caves are most likely to be located within the sandstone areas adjacent to and surrounding the Strategic Assessment Area. Much of this land is protected for conservation or as part of Sydney's drinking water catchment and should have existing management frameworks to prevent inappropriate access and use.

The Plan incorporates a range of measures to mitigate the risks associated with recreational disturbance within the Strategic Assessment Area, including:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- A commitment (Commitment 7) to mitigate indirect and prescribed impacts from urban, infrastructure and major infrastructure (transport) development on Koalas. This is relevant to the species because a lot of the mapped habitat for the Large-eared Pied Bat is identified as important Koala habitat. Of particular relevance to habitat disturbance are associated actions around the use of exclusion fencing which will assist in controlling access to Koala habitat. These measures will help minimise inappropriate habitat disturbance to potential habitat within both Wilton and GMAC
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate access and use
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor issues such as illegal access and use
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan, combined with existing management of protected areas adjacent to the Strategic Assessment Area is expected to adequately manage the risk to the species from inappropriate recreational use.

FIRE IN THE PROXIMITY OF ROOSTS

Bushfires and prescribed burning are identified as a key threat to the Large-eared Pied Bat as they are potentially susceptible to direct mortality from heat and smoke if the fire is close to their relatively shallow cave roosts (DERM, 2011). Changes in foraging resources and prey species as a result of altered fire regimes may also impact the species (DERM, 2011).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact habitat for the species. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant including:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from potential foraging habitat.

> While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the species from increased fire frequency as a result of development. This is because:

- Avoided lands supporting potential habitat will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat
- Fire management authorities will be engaged to ensure they understand the values relevant to the species and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

PREDATION BY INTRODUCED PREDATORS

Predation by introduced predators such as cats, foxes and rats has been identified in the Recovery Plan as a possible, but unknown, threat to the Large-eared Pied Bat. Concerns relate to predation on individuals where they are forced to roost close to the ground (DERM, 2011).

Roosting within the Strategic Assessment Area is either absent or very limited. However, new urban development within GMAC and Wilton is in close proximity to areas of likely roosting outside the Strategic Assessment Area in surrounding sandstone areas. New urban development within these nominated areas is very likely to increase the number of domestic cats in the local area, which in turn, may lead to an increase in feral cat populations within adjacent areas of likely roosting habitat.

Existing land use within the nominated areas and surrounding region includes residential areas and farming, which means cats are unlikely to pose a novel threat to the species in the area. However, the extent of proposed new urban development under the Plan means the threat is likely to be exacerbated.

As outlined in Chapter 15, development controls will be implemented under the Plan to:

- Ensure that domestic animals are appropriately contained at urban/bushland interfaces
- Appropriately manage and control pest animals as relevant to the site

These measures are considered to adequately mitigate the threat to the species.

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to:

- The development of essential infrastructure within nominated areas but outside the urban capable lands
- Tunnels associated with transport projects

30.8.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

There are records of the Large-eared Pied Bat on avoided land in GMAC and potential habitat on avoided land within Wilton and GMAC. Therefore, the species may be subject to impacts from essential infrastructure. However, the species is mobile and wide-ranging, and the scale of impact is not expected to be significant.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to biodiversity through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

30.8.8 POTENTIAL IMPACTS FROM TUNNELS

Foraging habitat for the Large-eared Pied Bat occurs within the tunnel footprints for the Metro Rail Future Extension tunnel (24.0 ha). The area is unlikely to support breeding habitat (the site is not within 1 km of areas likely to contain caves, crevices and cliffs - see Map 17) and only a small amount of potential foraging habitat has the potential to be impacted.

However, the Plan includes commitments to:

- Avoid any direct impacts to the areas where the species could occur, including the Mater Dei BioBank site, as discussed in Chapter 36
- Mitigate any potential indirect impacts (e.g. changes to hydrology, ground settling or subsidence) from the transport corridors as part of a future environmental impact assessment process

These commitments are expected to adequately address threats to the species from the construction and operation of the tunnels. See Section 36.6 in Chapter 36 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15

30.8.9 IMPLICATIONS FOR LONG-TERM VIABILITY

The Recovery Plan for the Large-eared Pied Bat describes the species' reliance on very specific maternity roosts with physical characteristics that are uncommon in the landscape as an important limiting factor in the distribution of the species (DERM, 2011). The communal nature of the species when they roost and raise young, means that a reasonable proportion of a local population can be in one location and this makes them more vulnerable to impacts to these sites.

Implementation of the Plan will not directly affect any known roosting sites. Potential indirect impacts to roosting sites have been assessed and the generic management strategies in the Plan are considered adequate in addressing these risks. Altogether, impacts from development under the Plan are not expected to affect roosting or maternity sites and this substantially minimises the potential to adversely influence the species' long-term viability.

However, foraging habitat within proximity to roosting areas will be affected by development. These areas constitute habitat critical to survival, which suggests that any substantial impacts to these areas has the potential to affect the long-term viability of the species.

There are a number of factors relating to the impacts on these foraging areas which minimise the severity of impacts. These factors make it very unlikely that the species long-term viability will be affected by development under the Plan and include:

- Loss of foraging habitat represents a small proportion (1.2 per cent) of potential habitat within the Strategic Assessment Area. At a broader landscape level, these impacts are proportionally smaller still, given the much larger and intact areas of habitat to the north and west of the Strategic Assessment Area and to the south of Sydney
- Loss of potential foraging habitat predominantly occurs within GMAC and Wilton. The potential foraging habitat within these nominated areas is mostly associated with canopied vegetation along riparian corridors in an otherwise cleared landscape. The Recovery Plan notes that these types of corridors can be heavily used by the species. Impacts to this habitat will involve the loss of small sections on the fringes of the corridors. The corridors themselves will be retained, minimising any functional loss on potential foraging habitat. In fact, the planning controls that will establish environmental zoning (E2) on avoided lands are expected to improve the long-term outcome for these areas. This zoning will set out objectives that a consent authority must consider when assessing development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for managing the land and minimising degradation of habitat

In addition, the Plan will lead to the protection and management of large areas of vegetation within the SCA. Two of the reserves currently proposed by the Plan are suitably located to support foraging within proximity of potential sandstone roosting areas. They are:

- The Georges River Koala Reserve which is on the eastern side of the Strategic Assessment Area near GMAC where the Large-eared Pied Bat has been recorded. This will be implemented in two stages over the first 10 years of the Plan and will cover an area of approximately 1,892 ha
- The Gulguer Reserve investigation area which occurs on the western side of the Strategic Assessment Area where the Large-eared Pied Bat has been recorded. The Plan proposes to implement the reserve over the first 20 years of the Plan, and it will cover an area of approximately 1,800 ha

Altogether, it is considered very unlikely that implementation will adversely influence the long-term viability of the Large-eared Pied Bat.

30.8.10 CONSISTENCY WITH RECOVERY PLAN

In accordance with Section 146K of the EPBC Act, this section considers whether the implementation of the Plan is not inconsistent with the species' Recovery Plan. It considers two questions:

- Does the Plan prevent achievement of the objectives of the Recovery Plan
- Does the Plan prevent implementation of the Recovery Plan actions?

These questions are discussed below.

DOES THE PLAN PREVENT ACHIEVEMENT OF THE OBJECTIVES OF THE RECOVERY PLAN?

The overall objective of the Recovery Plan is to ensure the persistence of viable populations of the Large-eared Pied Bat throughout its geographic range (DERM, 2011). Specific objectives have been identified to support the overall objective, these are:

- Identify priority roost and maternity sites for protection
- Implement conservation and management strategies for priority sites
- Educate the community and industry to understand and participate in the conservation of the large-eared pied bat
- Research the large-eared pied bat to augment biological and ecological data to enable conservation management
- Determine the meta-population dynamics throughout the distribution of the large-eared pied bat

The outcome for the Large-eared Pied Bat under the Plan will not make it impossible to the achieve any of the objectives of the Recovery Plan.

DOES THE PLAN PREVENT IMPLEMENTATION OF THE RECOVERY PLAN ACTIONS?

The Recovery Plan identifies a set of actions in order to deliver on the objectives. The Plan will not prevent implementation of any of the actions.

The commitment to strategically protect large patches of well connected, high quality vegetation across the Strategic Assessment Area offers potential conservation benefits for the Large-eared Pied Bat. This process is consistent with one of the main actions in the Recovery Plan to "identify priority colonies and sites for conservation management and protection".

30.8.11 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 30-33 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For the Large-eared Pied Bat there are no relevant Threat Abatement Plans.

Table 30-33: Relevant Key Threatening Processes and associated Threat Abatement Plans for the Large-eared Pied Bat

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

30.9 *DASYURUS MACULATUS MACULATUS* (SPOT-TAILED QUOLL) – SE MAINLAND POPULATION

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Endangered
DESCRIPTION	*Dasyurus maculatus maculatus* (Spot-tailed Quoll) is a cat sized marsupial. It has reddish-brown fur with a cream-white stomach and irregular sized white spots covering its back, sides and tail. The large size and spotted tail are distinguishing features. (DELWP, 2016) Males grow to around 1.3 m long and weigh up to 7 kg, and females can grow to 85 cm and weigh up to 4 kg (DELWP, 2016).
ECOLOGY	The species is carnivorous and nocturnal. Main source of food is medium sized mammals including gliders, possums, small wallabies, rats and rabbits (OEH, 2018i). It also feeds on a variety of other animals including birds, reptiles, and invertebrates, and hunts on the ground and in trees (DELWP, 2016). Life expectancy in the wild is 3-5 years. Sexual maturity is reached at the age of 11-12 months and females generally produce a litter annually of (on average) five young. (DELWP, 2016) Mating occurs between late May and early August (DSEWPC, 2011b). Adults are solitary and can travel large distances such as 8 km a day and 19 km in a week. Female home ranges can be 88-1,515 ha and do not normally overlap. Male home ranges can be 359-5,512 ha, can overlap and include many female home ranges. They use several dens to rest in during the day and travel between them regularly (DELWP, 2016).
DISTRIBUTION AND HABITAT	Has a wide, patchy distribution in eastern Australia. Its distribution ranges from north-eastern Queensland to Tasmania. The species can be found in a variety of habitat types, including rainforest, open forest, woodland, coastal heath and inland riparian forest. It is mostly found in areas with rainfall of over 600 mm per year. Habitat critical to the survival has been identified in the species' Recovery Plan as large patches of forest with sufficient den sites and adequate densities of medium-sized mammalian prey (DELWP, 2016). Den sites have been recorded in tree hollows, rock crevices, hollow logs, hollow tree buttresses, clumps of vegetation, windrows, caves and boulder tumbles and under buildings. Maternal den sites include rock crevices, caves, boulder tumbles, hollow logs, hollow tree roots and burrows (DELWP, 2016).
POPULATIONS	Has 26 known important populations from Queensland to Victoria. In NSW records are generally confined to within 200 km of the coast and range from the Queensland border to Kosciuszko National Park. Locations include: Hunter Valley, Taree, Port Macquarie and Coffs Harbour through

	to the gorges and escarpments of the New England Tableland, south NSW, Hay and several disjunct populations between the Border Ranges and the Blue Mountains / Illawarra area. It is known to occur in the Cumberland subregion (OEH, 2018i).
SOS SITES	The following SOS sites for the species have been identified: • North Coast – proposed • Northern Tablelands • Jenolan-Kanangra • Wyangala Dam to Gillindich NR • Barren Grounds/Budderoo • Byadbo None of these sites occur within the Cumberland subregion.
RELEVANT PLANS AND POLICIES	National Recovery Plan for the Spotted-tailed Quoll *Dasyurus maculatus* (DELWP, 2016) Threat abatement plan for predation by feral cats (DoE, 2015g) Threat abatement plan for predation by the European red fox (DEWHA, 2008n)
SPECIES-SPECIFIC GUIDELINES	EPBC Act Policy Statement 3.4 Significant impact guidelines for *Dasyurus maculatus maculatus* (DEWHA, 2009c) - noting that this guideline relates only to proposed 1080 baiting programs and is not relevant to the activities under the Plan
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=75184

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	Yes	No	No	No	No
EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.				
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS**				
	Knowledge based map (KBM). Habitat maps for Spot-tailed Quoll were generated using BioNet PCT associations of intact and thinned vegetation in areas with greater than 600 mm rainfall. Patch size of greater than 1,000 ha was used in order to restrict habitat to areas of very large intact bushland remnants around, and connected to the edges of the Cumberland subregion. Under the BAM, the species was removed as a candidate species in in all nominated areas because there are no known breeding sites in the urban capable land.				
	OUTSIDE THE NOMINATED AREAS				
	Knowledge based map (KBM). As above. No targeted surveys as part of this project were undertaken outside the nominated areas.				

POPULATION MAPPING	**RECORD SELECTION** BioNet records from 1999 onwards were considered current for the assessment. **POPULATION DEFINITION** All records within an area covered by the average male home range (up to 5,512 ha) were considered a single population. **IMPORTANT POPULATION CRITERIA** All populations were considered to be important as the species is endangered.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 46.4 for a map of records and habitat across the Strategic Assessment Area.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 30-38 at the end of this species assessment for a breakdown of the occurrence of records and habitat for the Spot-tailed Quoll in the Strategic Assessment Area. **Records** Records of the Spot-tailed Quoll are widespread in the regions surrounding the Strategic Assessment Area, including from the Blue Mountains to the west, the northern beaches and central coast to the north and the Illawarra/Wollongong area to the south. Within the Strategic Assessment Area, records primarily occur around the edges where some level of landscape connectivity remains with the large areas of surrounding wilderness to the north and west of the Strategic Assessment Area and south of Sydney. Eight populations within or immediately adjacent to the Strategic Assessment Area have broadly been identified from the BioNet records, as follows: • Population #508 - in the north-east of the Strategic Assessment Area, approximately 20 km north of GPEC where there are three BioNet records • Population #200 - on the north-west boundary of the Strategic Assessment Area, almost 20 km north of GPEC near Bowen Mountain where there are three BioNet records • Population #495 - along the western boundary of the Strategic Assessment Area adjacent to and just north of GPEC where there are a large number of records along the Great Western Highway through to the Blue Mountains and following the Nepean River. One record associated with the Nepean River is in the Strategic Assessment Area • Population #509 - two post 1999 records within GPEC – one located in the Wianamatta Regional Park and one in the middle of an existing urban area in Cambridge Park (with a low level of accuracy) • Population #496 - in the west of the Strategic Assessment Area near Orangeville, where there are two BioNet records from 2004 • Population #498 - in the southern section of the Strategic Assessment Area, to the west of Wilton where there are two relatively recent BioNet records • Population #201 – south of Wilton where there are three BioNet records, all outside of the Strategic Assessment Area • Population #500 - east of the southern section of GMAC where there are four relatively recent BioNet records (one within the Strategic Assessment Area and the others adjacent) **Potential habitat** The baseline mapping for this assessment has mapped 32,527 ha of potential habitat within the Strategic Assessment Area. This habitat is predominantly associated with creek lines which the Spot-tailed Quoll may use for dispersal (Bruce Mullins, pers com).

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

30.9.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 3,756 ha of potential habitat for the Spot-tailed Quoll within the nominated areas (not including excluded lands). Approximately 3,110 ha (83 per cent) of this has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 2,337 ha was avoided for biodiversity purposes
- 773 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 30-39.

It is important to note that the avoidance calculations in Table 30-39, including 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 30-39 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

30.9.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred. Avoidance within the transport corridors will occur during the detailed design phase as each project is brought forward. The Plan includes a specific measure to support the Spot-tailed Quoll which is to: design the transport corridors to avoid and minimise impacts to fauna populations and habitat and connectivity, particularly along riparian corridors.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 30.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

30.9.3 LOSS OF POTENTIAL HABITAT

Implementation of the Plan will lead to the loss of potential habitat for the Spot-tail Quoll. A breakdown of impacts across the Strategic Assessment Area is given in Table 30-40.

The potential for fragmentation of habitat is also discussed below.

LOSS OF POTENTIAL HABITAT

Approximately 676 ha of potential habitat will be lost as a result of the implementation of the Plan, or 2 per cent of potential habitat mapped across the Strategic Assessment Area.

These direct impacts include potential habitat areas within the vicinity of:

- Population #509, where the Outer Sydney Orbital passes through the Wianamatta Regional Park within GPEC. The species primarily uses the much larger areas of intact habitat surrounding the Cumberland subregion. The habitat area within GPEC is not immediately connected to these areas and is unlikely to be as important due to the level of fragmentation associated with existing urban and rural development
- Populations #498 and #201, where urban development in Wilton will lead to the loss of isolated areas of potential habitat on the fringes of riparian corridors. The species may disperse along creek lines within the Strategic Assessment Area (Bruce Mullins, pers com). The corridors and associated vegetation have largely been avoided and the ecological function of each corridor within Wilton in terms of dispersal and connectivity will be maintained
- Population #500, where urban development in GMAC will lead to the loss of isolated areas of potential habitat on the fringes of riparian corridors. Again, the riparian corridors and associated vegetation that may be used for dispersal have largely been avoided and the ecological function of each corridor within GMAC will be maintained

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of the loss of potential habitat is considered to be low. This is because:

- The likelihood of substantial impacts occurring to the species has been categorised as possible. There will be moderate impacts to potential habitat. The majority of impacts occur along the edges of habitat corridors ensuring that the corridors themselves are maintained, and the species has access to a much larger network of intact habitat surrounding the Strategic Assessment Area
- The consequence of any impacts to the species has been categorised as minor. There will be loss of approximately 2 per cent of mapped potential habitat in the Strategic Assessment Area

30.9.4 FRAGMENTATION OF HABITAT

The majority of mapped potential habitat is associated with riparian corridors. Corridors such as these may be important landscape components for the species as they are more likely to contain the necessary den and prey resources (DELWP, 2016) and might be used within the Strategic Assessment Area for dispersal.

The urban capable land within the nominated areas has been specifically designed to avoid and minimise impacts to these corridors. Impacts that do occur are associated with small sections of fringing habitat. These corridors are currently unmanaged and vulnerable to edge effects. Under the Plan, planning controls will establish environmental zoning (E2) on these areas and this is expected to improve their long-term outcome. The zoning will set out objectives that a consent authority must consider when assessing development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for managing the land and minimising degradation of habitat.

The transport corridors have the potential to fragment habitat in the following locations:

- Potential habitat within Wianamatta Regional Park due to the development of the OSO. The species has been recorded in this area
- Fragmentation of small areas of potential habitat further south in GPEC, also due to the development of the OSO. There have been no historical records of the species using this area

The Plan includes a specific measure to design the transport corridors to avoid and minimise impacts to Spot-tailed Quoll populations and habitat and connectivity, particularly along riparian corridors. Designing creek crossings in these areas to maintain movement of the Spot-tail Quoll will significantly minimise any effects on the species. The area is also likely to be less important compared with the large areas of intact habitat surrounding the Strategic Assessment Area, due to the extent of existing urban and rural development within GPEC.

Altogether, direct impacts associated with development under the Plan are not expected to interfere with the movement of the Spot-tailed Quoll within the Strategic Assessment Area.

30.9.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the low risk of residual adverse impacts to the species, offsets were not considered necessary for the Spot-tailed Quoll.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

30.9.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Recovery Plan for the Spot-tailed Quoll identifies a range of threats to the species. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Competition and predation from introduced predators
- Road mortality
- Inappropriate fire regimes

Timber harvesting, poison baiting, deliberate killing, and poisoning by cane toads are also identified as key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the risk across the Strategic Assessment Area.

COMPETITION AND PREDATION FROM INTRODUCED PREDATORS

Competition and predation from introduced vertebrates such as cats and dogs is identified as a key threat to the Spot-tailed Quoll (DELWP, 2016).

Existing land use within the nominated areas and surrounding region (which includes residential and rural residential areas, and farming) means these issues are already present in the Strategic Assessment Area and are unlikely to pose a novel threat to the species.

However, the extent of proposed new urban development under the Plan means that the threat associated with cats and dogs is likely to be exacerbated. It is likely that there will be an increase in the number of domestic cats and dogs in the local area, which, in turn, may lead to an increase in feral cat and wild dog numbers. The main areas of concern relate to new urban development in Wilton and the southern section of GMAC, where the current density of houses is lower.

The Plan incorporates a range of measures to manage the risks associated with introduced predators. In summary, these include:

- A commitment (Commitment 17) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the SCAs. This includes a number of actions with the most relevant to the outcome for the species being:
    - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
    - Preparation of a Pest Animal Control Implementation Strategy
    - A process to enter into written agreements with delivery partners to implement the pest animal control program
    - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans

- Development controls that will:
  - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
  - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
  - Require appropriate management and control of pest animals relevant to development sites
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing pests, consistent with the pest animal implementation strategy outlined in Commitment 16
- A specific requirement in relation to Commitment 5 to contain domestic cats and dogs in new residential areas at the urban/bushland interface consistent with relevant Council guidelines.

These measures are considered to adequately address any potential increased threat from introduced predators due to implementation of the Plan.

ROAD MORTALITY

The Spot-tailed Quoll is susceptible to vehicle strike, and mortality on roads has been identified as a key threat to the species. The populations of Spot-tailed Quoll within and surrounding the Strategic Assessment Area are already exposed to a number of major roads, including from the Hume Highway, Wilton/Appin Road, Picton Road, Great Western Highway and Bells Line of Road.

Despite this exposure, none of the BioNet records for the area and surrounding region relate to vehicle strikes, which suggests that:

- The species is not regularly moving across existing roads to get from known habitat areas in the south into the more marginal habitat areas within the Strategic Assessment Area, or
- The species is dispersing along creek lines and passing under the roads where the crossings provide suitable conditions for an underpass (such as adequate vegetation cover), or
- Cases of roadkill are not being reported; although given the tendency for people to report Koala vehicle strikes within the area, this factor is unlikely to be the main contributor

Implementation of the Plan will lead to new roads and an increase in the volume of cars on these roads within and surrounding the nominated areas. The potential level of increased risk from these roads is difficult to predict. However, factors that reduce the potential risk include:

- The availability of much larger areas of intact vegetation outside of the Strategic Assessment Area, which is likely to reduce the species' need to cross roads in order to move into potential habitat areas within the Strategic Assessment Area
- The existing corridors of habitat within the nominated areas will be avoided and maintained. The only potential disruption relates to the development of the OSO within GPEC. However, the Plan includes a specific measure to design the transport corridors to avoid and minimise impacts to Spot-tailed Quoll populations and habitat and connectivity, particularly along riparian corridors. This measure should ensure safe passage for the Spot-tailed Quoll under creek crossings in this area

The Plan also incorporates a range of measures to manage the increased threat from road mortality. In summary, these include:

- Development controls that will:
  - Ensure that traffic calming measures are implemented in development areas not subject to Koala exclusion fencing, including speed limit restrictions for areas adjacent to land with biodiversity values, and installation of wildlife signposting and speed humps and audible surfacing in accordance with relevant standards
  - Require fauna-friendly road design structures to be installed and maintained in appropriate areas adjacent to fauna habitat, such as underpasses, fauna bridges and overpasses
- A commitment (Commitment 6) to mitigate indirect and prescribed impacts on threatened species from major infrastructure (transport) development on threatened species and their habitat. This includes mitigation measures to

specifically address impacts on the Spot-tailed Quoll during construction and operation of transport infrastructure as prescribed in Appendix E of the Plan

- A commitment (Commitment 7) to mitigate indirect and prescribed impacts from urban, infrastructure and major infrastructure (transport) development on Koalas. This is relevant to the species because a lot of the mapped habitat for the Spot-tailed Quoll is also identified as important Koala habitat. Of particular relevance to road mortality are actions around the use of exclusion fencing. These measures will help minimise the risk of road mortality within both Wilton and GMAC for the species.

These measures are considered to adequately address any potential increased threat from road mortality due to implementation of the Plan.

INAPPROPRIATE FIRE REGIMES

Bushfires and prescribed burning are identified as a key threat to the Spot-tailed Quoll as they can reduce the availability of prey and habitat features that provide protection from predation (DELWP, 2016).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact habitat for the species. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant including:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from potential foraging habitat. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the species from increased fire frequency as a result of development. This is because:

- Avoided lands supporting potential habitat will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat
- Fire management authorities will be engaged to ensure they understand the values relevant to the species and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to:

- The development of essential infrastructure within nominated areas but outside the urban capable lands
- Tunnels associated with transport projects

30.9.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

There is potential habitat on avoided land within Wilton and GMAC. The species may therefore be subject to impacts from essential infrastructure. However, the species is mobile and wide-ranging and the scale of impact is not expected to disrupt habitat use or movement.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to biodiversity through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15

30.9.8 IMPLICATIONS FOR LONG-TERM VIABILITY

The Recovery Plan identifies the major threatening processes relevant to the Spot-tailed Quoll and these should be considered most likely to affect the long-term viability of the species. They include:

- Habitat loss, modification and fragmentation
- Timber harvesting
- Poison baiting
- Competition and predation by introduced predators
- Deliberate killing
- Road mortality
- Bushfire and prescription burning
- Poisoning by cane toads
- Climate change

Of these threats, implementation of the Plan has the potential to lead to habitat loss, modification and fragmentation and exacerbate the threat from competition and predation by introduction predators, road mortality and bushfires.

HABITAT LOSS, MODIFICATION AND FRAGMENTATION

The Recovery Plan describes the aspects of the biology and ecology of the Spot-tailed Quoll that make the species particularly vulnerable to threatening processes. To summarise, Spot-tailed Quoll populations are limited to large, relatively intact patches of forest due to:

- Their generally solitary nature and large home ranges
- Their low population densities
- Their short lifespan and low reproductive output
- Juvenile dispersal being focussed on males, as females tend to remain near their birthplace. This limits the ability of the species to recolonise areas of fragmented habitat

The species is subsequently very sensitive to impacts that reduce, degrade and fragment their habitat (DELWP, 2016).

Development associated with implementation of the Plan will lead to the loss of areas of habitat for the Spot-tailed Quoll, including 656 ha of potential habitat. The risk of residual adverse impacts from this has been assessed as low for the following key reasons:

- Loss of habitat represents a small proportion (2 per cent) of potential habitat within the Strategic Assessment Area. At a broader landscape level, these impacts are proportionally smaller still, given the much larger and intact areas of habitat surrounding the Strategic Assessment Area
- Habitat surrounding the Strategic Assessment Area is vast and intact and therefore considered much more important to the viability of the species. Mapped potential habitat within the Strategic Assessment Area is predominately associated with creek lines within an otherwise cleared landscape. The species may use these creek lines for dispersal
- Where impacts to habitat occur within the nominated areas, they are associated with small sections of habitat that fringes the corridors. The integrity of the corridors themselves will be maintained. These corridors are currently unmanaged and vulnerable to edge effects. Under the Plan, planning controls will establish environmental zoning (E2) on these areas and this is expected to improve the long-term outcome for the biodiversity within the corridors. The zoning will set out objectives that a consent authority must consider when assessing development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for managing the land and minimising degradation of habitat. This is especially important within GMAC and Wilton where these corridors connect to the broader areas of habitat outside the Strategic Assessment Area
- The one exception to this is the potenital for impacts to a habitat corridor within GPEC associated with the OSO. However, there are a number of measures in the Plan to specifically address impats to habitat and movement for the Spot-tailed Quoll during detailed design of this infrastructure. This area of habitat is also considered more marginal due to the extent of existing urban and rural development and disconnection from the surrounding, intact habitat areas

In addition, the Plan will lead to the protection and management of large areas of vegetation within the SCA. Two of the reserves currently proposed by the Plan will protect habitat considered very likely to support the Spot-tailed Quoll, including:

- The Georges River Koala Reserve which is on the eastern side of the Strategic Assessment Area near GMAC where the Spot-tailed Quoll has been recorded. This will be implemented in two stages over the first 10 years of the Plan and will cover an area of approximately 1,892 ha
- The Gulguer Reserve investigation area which occurs on the western side of the Strategic Assessment Area and is connected to areas of habitat where the Spot-tailed Quoll has been recorded. The Plan proposes to implement the reserve over the first 20 years of the Plan and it will cover an area of approximately 1,800 ha

INDIRECT IMPACTS ASSOCIATED WITH INTRODUCED PREDATORS, ROAD MORTALITY AND BUSHFIRES

The potential indirect impacts associated with the identified threats will be managed and mitigated through generic management strategies and species-specific controls.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

Development under the Plan will lead to the loss of a small proportion of areas mapped as potential habitat for the Spot-tailed Quoll. Implementation of the Plan is not expected to adversely influence the long-term viability of the species due to the:

- Level of avoidance and minimisation of impacts to habitat corridors achieved through design of the urban capable lands within the nominated areas
- Marginal value of habitat within the Strategic Assessment Area which is generally fragmented and more degraded compared to the vast, surrounding areas of intact habitat
- The specific measures in the Plan to address potential impacts to dispersal ability from infrastructure design (namely the OSO) and road mortality

30.9.9 CONSISTENCY WITH RECOVERY PLAN

In accordance with Section 146K of the EPBC Act, this section considers whether the implementation of the Plan is not inconsistent with the species' Recovery Plan. It considers two questions:

- Does the Plan Prevent achievement of the objectives of the Recovery Plan?
- Does the Plan prevent implementation of the Recovery Plan actions?

These questions are discussed below.

DOES THE PLAN PREVENT ACHIEVEMENT OF THE OBJECTIVES OF THE RECOVERY PLAN?

The overall objective of the Recovery Plan is to reduce the rate of decline of the Spot-tailed Quoll, and ensure that viable populations remain throughout its current range in eastern Australia (DELWP, 2016). Specific objectives have been identified to support the overall objective. These fit broadly into three groups:

- Investigate and acquire information on distribution, status, and key aspects of the biology and ecology of the species to aid recovery
- Identify key threats and implement threat abatement management practices, those most relevant to the Plan include:
  - Reduce the rate of habitat loss and fragmentation on private land
  - Determine and manage the risk posed by introduced predators (in particular, cats)
  - Reduce the frequency of road mortality
- Increase community awareness of and involvement in the Recovery Plan

The outcome for the Spot-tailed Quoll under the Plan will not make it impossible to the achieve any of the objectives of the Recovery Plan.

DOES THE PLAN PREVENT IMPLEMENTATION OF THE RECOVERY PLAN ACTIONS?

The Recovery Plan identifies a set of actions to be implemented in order to deliver on the objectives. The Plan may support these actions, including:

- Target landholders in areas where Spotted-tailed Quolls are known to occur to protect and manage their land in a manner that is compatible with maintenance of Spotted-tailed Quoll habitat through voluntary conservation agreements
- Maintain and restore habitat corridors on unprotected freehold land

The Plan will not prevent implementation of any of the actions.

30.9.10 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 30-37 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The Plan has been developed to ensure that it is not inconsistent with any relevant TAPs. This analysis around consistency is presented in Chapter 15.

Table 30-37: Relevant Key Threatening Processes and associated Threat Abatement Plans for the Spot-tailed Quoll

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Predation by European red fox	Threat abatement plan for predation by the European red fox (DEWHA, 2008n)
Predation by feral cats	Threat abatement plan for predation by feral cats (DoE, 2015g)

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

30.10 *PTEROPUS POLIOCEPHALUS* (GREY-HEADED FLYING-FOX)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	*Pteropus poliocephalus* (Grey-headed Flying-fox [GHFF]) is the largest Australian bat with dark grey fur on the body and an orange/brown collar around the neck. The head is covered with light grey fur. It weighs 600-1,000 g and can grow up to 289 mm in length (DoEE, 2018c).
ECOLOGY	Mating occurs in early autumn, the larger roosting camps then break up and reform in late spring/early summer when food resources start to increase (DoEE, 2018c). Males and females separate in October when females usually give birth to a single young (DoEE, 2018c). The young are carried on their mothers' backs to foraging sites until they are around five weeks old, then left in maternal camps while their mothers forage until they become independent at around 12 weeks old. Following this, the males return to the camps for courting and to form bonds for the next breeding season (DoEE, 2018c). Blossom from *Eucalyptus* and related genera form a large part of the species diet (DoEE, 2018c). It also feeds on commercial fruit crops and on introduced tree species in urban areas (DoEE, 2018c). The species is highly mobile and migrates in response to food shortages (OEH, 2019b).
DISTRIBUTION AND HABITAT	The Grey-headed Flying-fox is usually found within 200 km of the eastern coast of Australia, from Rockhampton in Queensland to Melbourne in Victoria. It requires suitable habitat for both roosting and foraging. **Roosting habitat** The species roosts in groups of various sizes on exposed branches. Roost sites (known as camps) are generally located close to water, such as lakes, rivers, or the coast (DoEE, 2018c). Roost vegetation includes rainforest patches, stands of *Melaleuca*, mangroves and riparian vegetation (DoEE, 2018c). Roosting camps may contain tens of thousands of animals and are used for mating, and for giving birth and rearing young. Site fidelity to roosting camps is high; some have been used for over a century. The species can travel up to 50 km a night from roosting camps to forage but more often the distances are less than 20 km (DoEE, 2018c). **Foraging habitat** Grey-headed Flying-foxes feed on fruit and nectar from the canopy and use a range of vegetation communities, including rainforests, open forests, closed and open woodlands, *Melaleuca* swamps and *Banksia* woodlands (DoEE, 2018c).

	Winter and spring foraging resources are critical for the species. The draft recovery plan (DoEE, 2017a) identifies that the one of the key issues for the species recovery is the "protection and rehabilitation of foraging habitat and the expansion of forested areas that are productive during winter and spring". Important vegetation communities that provide winter and spring foraging resources are those that contain *Eucalyptus tereticornis*, *E. albens*, *E. crebra*, *E. fibrosa*, *E. melliodora*, *E. paniculata*, *E. pilularis*, *E. robusta*, *E. siderophloia*, *Banksia integrifolia*, *Castanospermum australe*, *Corymbia citriodora*, *C. eximia*, *C. maculata* (DoEE, 2017a).
POPULATIONS	There are no separate or distinct populations as there is constant genetic exchange and movement across the species' range. In 2005, the total population was estimated at 674,000 individuals (DoEE, 2018c). In 2008, thirty-nine camps used by Grey-headed Flying-foxes were known in the south-east region of NSW occurring mostly along the coastal lowlands and ranges (Eby & Law, 2008). A small number of the camps found in the Sydney Metropolitan area were occupied continuously. These were thought to have been established due to the increasing volumes of food in the gardens and streetscapes of Sydney. All camps associated with native vegetation were inhabited less consistently and were only occupied occasionally or rarely (Eby & Law, 2008).
SOS SITES	The species has been assigned to the landscape species management stream because it is distributed across large areas and is subject to threatening processes that generally act at the landscape scale rather than at distinct, definable locations (OEH, 2018g).
RELEVANT PLANS AND POLICIES	The SPRAT profile (DoEE, 2018c) for Grey-headed Flying-fox states that there is no: • Approved Conservation Advice for this species • Adopted or made Recovery Plan for this species • Threat Abatement Plan which has been identified as being relevant for this species However, there is a draft Recovery Plan for this species which was published for public comment by the Department of Environment and Energy in 2017. The Plan will be assessed with reference to the draft Recovery Plan.
SPECIES-SPECIFIC GUIDELINES	Referral guideline for management actions in grey-headed and spectacled flying-fox camps (DoE, 2015f)
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=186

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	ECOSYSTEM CREDIT SPECIES	CANDIDATE SPECIES CREDIT SPECIES			
		WILTON	GMAC	WSA	GPEC
	Yes	No	No	No	No
EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.				

HABITAT MAPPING

Two forms of habitat mapping are used in this analysis:

- A species distribution model developed for the Cumberland subregion for this project
- Foraging habitat mapping developed by Eby and Law (2008)

SPECIES DISTRIBUTION MODEL

Species distribution model (SDM). Potential habitat was mapped using an SDM. The SDM was developed using species records associated with camps. This condition was imposed because this species is known to forage widely, and therefore there was a risk that potential habitat would have been over-predicted by the model if all records had been included.

Consistent with the approach taken for other EPBC Category 1 species, impacts are calculated using the SDM.

During surveys for this assessment the species was recorded twice in GMAC and once in GPEC.

FORAGING HABITAT

Foraging habitat. Eby and Law (2008) mapped foraging habitat for the species across its range. As part of this work they ranked native vegetation according the nectar resources it provides. Habitat is ranked from a score of 1-4 where 1 is the highest nectar rank, and 4 is the lowest.

The mapping is used in the analysis for context and to enable a consideration of foraging resources outside the Cumberland Plain (which were not mapped by the SDM).

CAMP MAPPING

The National Flying Fox Monitoring Program provides monitoring data for camps across the range of the Grey-headed Flying-fox. Data is available about the number of individuals at camps from 2012 to 2019.

The importance of camps is categorised as follows:

CAMP CATEGORY	DESCRIPTION
Nationally important	Camps that have contained ≥ 10,000 GHFF in more than one year in the last 10 years, or have been occupied by more than 2,500 GHFF permanently or seasonally every year for the last 10 years (DoE, 2015f)
High priority	> 2,500 in at least 4 of last 8 surveys
Medium priority	Any records in the last 2 years
No GHFF in last 2 years	No records in the last 2 years
No GHFF since 2011	No records since 2011

POPULATION MAPPING

RECORD SELECTION

Based on other bat species, the life expectancy is likely to be between two and ten years. BioNet records have been taken from 2008 onwards.

POPULATION DEFINITION

The records of Grey-headed Flying-fox are considered to be part of a single population across their range (DoEE, 2017a)

IMPORTANT POPULATION CRITERIA

The population of Grey-headed Flying-foxes was considered important within the Strategic Assessment Area because it met the following criteria: a population identified or inferred in a Commonwealth conservation advice, recovery plan, final determination, or other relevant policy document as being important.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.32 for a map of records and habitat across the Strategic Assessment Area. See Map 36.33 for a map of Grey-headed Flying-fox camp sites and Eby and Law (2008) foraging habitat
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 30-42 and Table 30-43 at the end of this species assessment for a breakdown of the occurrence of Grey-headed Flying-fox records, habitat and camps in the Strategic Assessment Area. The Strategic Assessment Area supports foraging and roosting habitat for the species. **Foraging habitat** As outlined above, two types of mapping for foraging habitat are used in this assessment: • Baseline mapping for this assessment which was done through an SDM process • Eby and Law (2008) foraging habitat mapping The baseline mapping for the assessment mapped approximately 26,873 ha of potential and known foraging habitat within the Strategic Assessment Area (Map 36.32). Habitat is mapped in association with a range of woodland communities and generally occurs where native remnants are present. Foraging habitat within 20 km of camps is considered important due to the common distance the species can travel to feed. All potential habitat in the Strategic Assessment Area is within 20 km of a camp. Map 36.33 shows GHFF camps with a 20 km buffer in relation to the Eby and Law (2008) foraging habitat. This mapping extends beyond the boundary of the Strategic Assessment Area to provide context about the amount of habitat within the surrounding region. **Roosting habitat** The Strategic Assessment Area supports 11 Grey-headed Flying-fox camps. Categorisation of camps is discussed above in the approach to baseline data section. Of the 11 camps: • One is nationally important (Macquarie Fields). It occurs at Bingara Reserve in Macquarie Fields, and is located within the northern part of GMAC close to an existing urban area. Campbelltown City Council is in the process of developing a Management Plan for the camp. It is approximately 1.5 km from the nearest urban capable land • One is high priority (Picton), it occurs outside the nominated areas • Six are medium priority. Two of these (Campbelltown and Ropes Creek) occur within the nominated areas but outside the urban capable lands (GMAC and GPEC respectively), and another (Emu Plains) is close to the western boundary of GPEC • Three have had no records of GHFF since 2011 The nationally important camp and high priority camp have significant mapped foraging resources (highest nectar rank) within 20 km. Much of this occurs outside the Strategic Assessment Area and is unlikely to be impacted (e.g. defence land, protected land). In addition to these camps, there are 14 camps that occur within 20 km of the Strategic Assessment Area. Three of these are nationally important.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

30.10.1 NOMINATED AREAS

None of the three camps that occur within the nominated areas will be directly impacted. They include:

- Macquarie fields and Campbelltown in GMAC
- Ropes Creek in GPEC

The baseline mapping for this assessment has mapped 1,805 ha of potential habitat for the Grey-headed Flying-fox within the nominated areas (not including excluded lands). Approximately 1,231 ha (68 per cent) of this has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 749 ha was avoided for biodiversity purposes
- 482 ha was avoided for other purposes

Avoidance in WSA, GMAC and Wilton ranges between 57 per cent and 88 per cent. Avoidance is lower in GPEC, with 36 per cent of potential habitat avoided (117 ha avoided of 325 ha of potential habitat).

In addition, the Plan includes a specific mitigation measure (as part of Commitment 5) to retain large trees (≥50cm DBH) within urban capable lands during precinct planning where possible and avoid impacts to soil within the dripline of these trees during construction. This measure may provide additional avoidance of significant foraging trees for the Grey-headed Flying-fox within the nominated areas.

A breakdown of avoidance across each nominated area is provided in Table 30-44.

It is important to note that the avoidance calculations in Table 30-44, including for ‘avoidance for biodiversity purposes’, ‘avoidance for other reasons’, and ‘total avoidance’, have been calculated without including excluded lands as these lands are not covered by the Plan. Table 30-44 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

30.10.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred. It is important to note that there are no camps within the transport corridors.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 30.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

There will be no direct impacts to Grey-headed Flying-fox camps. However, implementation of the Plan will lead to the loss of potential foraging habitat. A breakdown of impacts across the Strategic Assessment Area is given in Table 30-45.

Given the wide-ranging nature of the species, it is considered unlikely that development within the nominated areas or transport corridors would lead to any fragmentation effects.

30.10.3 LOSS OF POTENTIAL HABITAT

LOSS OF POTENTIAL FORAGING HABITAT

Approximately 723 ha of potential foraging habitat will be lost as a result of implementation of the Plan, or 2.7 per cent of potential foraging habitat mapped across the Strategic Assessment Area.

While it is impossible to know the rate that habitat will be lost, it is clear that development will proceed in a staged way over the life of the Plan. If clearing was to occur progressively over the life of the Plan at an even rate, approximately 20 ha of potential foraging habitat would be lost each year. The rate and scale of clearing are considered unlikely to lead to dispersal from existing camp sites. Particularly within the context of the Plan's conservation program (see Section 30.10.4 below).

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of substantial impacts occurring to the species as a result of the loss of potential foraging habitat is considered to be low. As outlined in Section 30.3.5 which describes the risk assessment for wide-ranging species, "substantial" in this case is defined as impacts that could materially affect the species' use of the Strategic Assessment Area.

The risk rating of low was determined because:

- The likelihood of actual impacts occurring to the species has been categorised as possible. This is because:
  - There will be no impacts to known camps
  - The scale of impacts to foraging habitat is considered to be moderate. The species is highly mobile, feeds on fruit and nectar from a variety of vegetation communities and has access to large areas of intact vegetation surrounding the Strategic Assessment Area
- The consequence of any impacts to the species (if they did occur) has been categorised as minor as there will be loss of approximately 2.7 per cent of mapped potential foraging habitat in the Strategic Assessment Area

30.10.4 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the low risk of residual adverse impacts to the species, specific offsets were not considered necessary for the Grey-headed Flying-fox.

However, it is worth noting that the Plan's conservation program will provide substantial offsets for native vegetation. Much of which will provide potential foraging habitat for the species. Key components of the conservation program that will benefit Grey-headed Flying-fox include:

- Commitment 8 which will lead to the protection of at least 5,475 ha of native vegetation in the Cumberland subregion. At least 75 per cent of this target will be achieved by protecting existing native vegetation, and up to 25 per cent (or approximately 1,365 ha) will relate to ecological restoration
- A range of commitments that will help manage landscape threats across the Strategic Assessment Area. These will help maintain and improve the condition of foraging habitat for the species across the landscape over the life of the Plan and include commitments to manage weeds (Commitment 16), pest animals (Commitment 17), fire (Commitment 18), disease (Commitment 19), and support adaptation to climate change (Commitment 20)

Ecological restoration will be particularly beneficial to the species given the loss of potential foraging habitat. Ecological restoration is being prioritised early in implementation of the Plan which will help counteract the predicted progressive loss of potential foraging habitat over the life of the Plan. The NSW Government has committed $63 million in the first three years for a range of actions which include funding to plant 100,000 trees as part of ecological restoration of Koala habitat including within the Georges River Koala Reserve. These areas will provide benefits to the Grey-headed Flying-fox.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

30.10.5 RELEVANT POTENTIAL INDIRECT IMPACTS

The draft Recovery Plan for the Grey-headed Flying-fox identifies a range of threats to the species. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impact (identified as a threat) is considered relevant to implementation of the Plan: camp disturbance.

Climate change is also a relevant threat to each species. The extent to which the Plan has considered adaptation to climate change impacts is addressed in Chapter 41.

A range of other threats are identified in the draft recovery plan which are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the risks across the Strategic Assessment Area. They include: deliberate destruction associated with commercial horticulture; competition with Black Flying-foxes; electrocution on powerlines, entanglement in netting and on barbed-wire; and disease.

CAMP DISTURBANCE

The draft Recovery Plan notes that conflicts between people and flying fox camps is an ongoing problem. It typically occurs where camps are surrounded by urban and rural residential development, and people request relocation of the camp.

Inappropriate habitat disturbance within the Strategic Assessment Area may increase due to development within the nominated areas. Camps that are considered most at risk are those that occur in or close to the nominated areas.

There are three camps within or close to GMAC:

- Macquarie Fields – nationally important, surrounded by existing development, being managed by Campbelltown City Council
- Campbelltown – medium priority, near the Campbelltown town centre and surrounded by existing development
- Menangle – no records since 2011, adjacent to the Nepean River just to the west of GMAC

There are four camps within or close to GPEC:

- Ropes Creek – medium priority, surrounded by existing development
- Emu Plains – medium priority, close to the Nepean River to the west of GPEC, significant development and disturbed areas in the vicinity
- Penrith – no records since 2011, close to the Nepean River to the west of GPEC, significant development and disturbed areas in the vicinity
- Emu Plains (2007) - no records since 2011, close to the Nepean River to the west of GPEC, significant development and disturbed areas in the vicinity

There are no camps within or close to Wilton or WSA.

All of these camps are close to (or surrounded by) existing development and are not located adjacent to any of the proposed urban capable lands. It is considered unlikely that:

- Additional development within the nominated areas will substantially increase the risk of disturbance beyond what is currently occurring
- Implementation of the Plan will result in dispersal from existing camps

However, in order to ensure that any future camp disturbance is avoided, the Plan includes a precautionary requirement (as part of Commitment 5) to establish ecological setbacks in accordance with distances in the DCP to provide a buffer to adjacent development for any Grey-headed Flying-Fox camps. If it becomes relevant, this measure is considered adequate for protecting camps.

Nevertheless, the Plan does incorporate a range of measures to mitigate the risks associated with inappropriate habitat disturbance for the species. In relation to the Grey-headed Flying-fox these would be applicable to areas of potential foraging habitat in various locations. In summary, the measures include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance to vegetation
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas. This commitment is consistent with a number of actions in the draft recovery plan around educating the community about the species

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to:

- The development of essential infrastructure within nominated areas but outside the urban capable lands
- Tunnels associated with transport projects

30.10.6 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

There are records of the Grey-headed Flying-fox on avoided land in Wilton and GMAC and potential habitat on avoided land in all nominated areas. The species may be subject to impacts from essential infrastructure. However, the species is mobile and wide-ranging, and the scale of impact is not expected to be significant.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to biodiversity through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

30.10.7 POTENTIAL IMPACTS FROM TUNNELS

Foraging habitat for the species occurs within the tunnel footprints for both the Metro Rail Future Extension (61.7 ha) and the Outer Sydney Orbital (88.2 ha). There are no Grey-headed Flying-fox camps in these areas.

The Plan includes commitments to:

- Avoid and minimise impacts to the key areas of biodiversity within the tunnel footprints (Commitment 4). This would include the vast majority of potential foraging habitat for the Grey-headed Flying-fox
- Mitigate any potential indirect impacts (e.g. changes to hydrology, ground settling or subsidence) from the transport corridors as part of a future environmental impact assessment process

These commitments are expected to adequately address threats to the species from the construction and operation of the tunnels. See Section 36.6 in Chapter 36 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

30.10.8 IMPLICATIONS FOR LONG-TERM VIABILITY

The draft Recovery Plan identifies the following key issues that are likely to have the greatest influence on the long-term viability of the Grey-headed Flying-fox in relation to implementation of the Plan:

- Habitat loss
- Indirect impacts associated with camp disturbance

In addition, this section provides a brief discussion about the implications to the species of the 2019-20 bushfires.

HABITAT LOSS

Implementation of the Plan will not lead to impacts to any of the known camp sites for the species across the Strategic Assessment Area. In addition, there is a commitment to provide buffers around any camps if it becomes relevant during future planning.

However, the Plan authorises the clearing of 723 ha of potential foraging habitat which will be minimised in some locations by a commitment to retain large trees during precinct planning. The overall risk of substantial impacts occurring to the species as a result of habitat loss is low.

Habitat loss is not expected to adversely influence the long-term viability of the species because:

- The scale of clearing within the context of the available habitat both within and near to the Strategic Assessment Area is relatively minor. For example, there is currently 26,873 ha of mapped habitat in the Strategic Assessment Area
- Clearing is likely to occur progressively over the life of the Plan
- The Plan includes a range of commitments to protect and manage vegetation which will provide benefits to the species. These include a commitment to restore up to 1,365 ha of vegetation. It is also noted that restoring vegetation early in the life of the Plan is prioritised as part of an initial $63 million funding commitment
- The Plan includes a range of commitments to help manage landscape scale threats across the Strategic Assessment Area. These will provide a benefit to the species over the life of the Plan

The process of protecting land in the Strategic Assessment Area is likely to support actions from the draft recovery plan to increase the area of habitat for the species that is secured and managed for conservation.

INDIRECT IMPACTS

The potential indirect impacts associated with camp disturbance are not expected to substantially change from the current situation, and will not influence the long-term viability of the species.

IMPLICATIONS OF THE 2019-20 BUSHFIRES

As outlined in Part 1 of this report, the 2019-20 bushfires in NSW are unprecedented in their extent and intensity. As of 28 January 2020, the fires had burnt 5.3 million ha (6.7 per cent of NSW), including 2.7 million ha in national parks (37 per cent of the national park estate) and over 80 per cent of the Greater Blue Mountains World Heritage Area (EES, 2020).

The full impact of the fires will not be understood for some time (EES, 2020). This includes the potential impacts to the Grey-headed Flying-fox.

However, it should be noted that the initial analysis undertaken of the implications of the fires for this report (Part 1, Attachment A) did not identify Grey-headed Flying-fox as a species that may need additional commitments in the Plan. This is because it did not meet all of the following criteria (see Part 1 Attachment A for explanation):

- A high percentage (>10 per cent) of NSW records have been affected by fires of the 2019-2020 period, and
- The Cumberland subregion is already important for species persistence in NSW and/or has the potential to become more important for persistence because of the impacts of the fires to other areas of habitat, and
- The Plan has known or likely impacts to the species

CONCLUSION

There will be no direct impacts to known camps. There are large areas of potential habitat (26,873 ha) and impacts to this are relatively minor (723 ha) given the larger areas of intact habitat surrounding the Strategic Assessment Area.

Potential indirect impacts are addressed through a species-specific control defined in the Plan and implementation of the conservation program will protect large areas associated with potential habitat for the species.

Collectively these will ensure that the implementation of the Plan does not adversely influence the long-term viability of the Grey-headed Flying-fox.

30.10.9 CONSISTENCY WITH RECOVERY PLAN

There is no made or adopted recovery plan under the EPBC Act. However, there is a draft recovery plan that is addressed in this section.

In accordance with Section 146K of the EPBC Act, this section considers whether the implementation of the Plan is not inconsistent with the species' Recovery Plan. It considers two questions:

- Does the Plan prevent achievement of the objectives of the draft Recovery Plan?
- Does the Plan prevent implementation of the draft Recovery Plan actions?

These are discussed below.

DOES THE PLAN PREVENT ACHIEVEMENT OF THE OBJECTIVES OF THE DRAFT RECOVERY PLAN?

The overall objectives of the draft Recovery Plan are to:

- Improve the Grey-headed Flying-foxes national population trend by reducing the impact of threatening processes on Grey-headed Flying-foxes through habitat identification, protection, restoration and monitoring, and
- Assist communities and Grey-headed Flying-foxes to coexist through better education, stakeholder engagement, research, policy and continued support to fruit growers

In addition to the overall objectives, the draft Recovery Plan has a range of specific objectives, including:

- Identify, protect and enhance native foraging and roosting habitat for the Grey-headed Flying-fox
- Determine population trends in Grey-headed Flying-foxes so as to monitor the species' national distribution and conservation status

- Build community capacity to coexist with flying-foxes and minimise the impacts on urban settlements from existing camps without resorting to dispersal
- Increase public awareness and understanding of Grey-headed Flying-foxes and the recovery program
- Improve the management of Grey-headed Flying-fox camps in sensitive areas
- Assess and reduce the impact on Grey-headed Flying-foxes of electrocution on power lines, and entanglement in netting and on barbed-wire

The outcome for the Grey-headed Flying-fox under the Plan will not make it impossible to the achieve any of the objectives of the draft Recovery Plan.

Does the Plan prevent implementation of the draft Recovery Plan actions?

The draft Recovery Plan includes a number of actions to help achieve its objectives. The Plan will not prevent implementation of any of the actions.

30.10.10 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 30-41 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For the Grey-headed Flying-fox there are no relevant Threat Abatement Plans.

Table 30-41: Relevant Key Threatening Processes and associated Threat Abatement Plans for the Grey-headed Flying-fox

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

SPECIES AT VERY LOW RISK OF DIRECT IMPACTS

30.11 *HELEIOPORUS AUSTRALIACUS* (GIANT BURROWING FROG)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	*Heleioporus australiacus* (Giant Burrowing Frog) is a large, rotund frog that ranges from steely blue-grey to dark brown and black in colour with white/yellowish spots on its sides. It grows to approximately 10 cm in length. Tadpoles are plump, slow-moving and can grow up to 7.5 cm long. (DoE, 2014b)
ECOLOGY	The species feeds on ground-dwelling invertebrates including ants and spiders (DoEE, 2018c). Breeding occurs throughout the year with peaks in late summer or autumn. Individuals move into breeding habitat just before or just after heavy rain and can stay there for up to 10 days. Egg masses are foamy and can contain 500-800 eggs. They are laid in burrows or under vegetation in small pools. Tadpoles take 3-12 months to develop into frogs. The species spends most of their time (more than 95 per cent) in non-breeding habitats where they burrow below the soil surface or leaf litter. (DoE, 2014b)
DISTRIBUTION AND HABITAT	The species occurs in NSW and Victoria, along the coast and nearby ranges (DoE, 2014b). The species inhabits heath, woodland and open sclerophyll forest on a variety of soil types except those that are clay based. They are not restricted to watercourses but can be found in hanging swamps on sandstone shelves, by creeks, on sand or rock-based streams, dams, drainage ditches and culverts. (DoEE, 2018c). Breeding habitat tends to be in soaks or pools within first and second order streams. Breeding has also been recorded in ephemeral or permanent artificial drainage areas and culverts on roadsides (DoE, 2014b). Non-breeding habitat consist of areas up to 300 m from breeding sites. The species has rarely been recorded on cleared land (DoEE, 2018c).
POPULATIONS	Records possibly occur as two distinct populations. The northern population occurs from the Sydney Basin to Ulladulla with the southern population occurring from north of Narooma to Walhalla in Victoria. There are no population estimates for this species (DoE, 2014b).

SOS SITES	This species has been assigned to the landscape species management stream because it is distributed across large areas and is subject to threatening processes that generally act at the landscape scale rather than at distinct, definable locations (OEH, 2018f). No SOS sites for the species have been identified due to data deficiencies.
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Heleioporus australiacus* (giant burrowing frog) (DoE, 2014b) Threat abatement plan for predation by feral cats (DoE, 2015g) Threat abatement plan for predation by the European red fox (DEWHA, 2008n) Threat abatement plan for infection of amphibians with chytrid fungus resulting in chytridiomycosis (DoEE, 2016b)
SPECIES-SPECIFIC GUIDELINES	There are no species-specific guidelines for the Giant Burrowing Frog

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

<tr><td colspan="5">Knowledge based map (KBM). Habitat maps within the nominated areas for the Giant Burrowing Frog were generated using:
BioNet PCT associations of intact vegetation
Patch sizes of larger than 5 ha were to exclude small isolated patches of vegetation from the model
Areas within 300 m of 1st and 2nd order watercourses, excluding overlapping areas within 300 m from a 3rd (or higher) order watercourse
Rock units in ‘Hawkesbury Sandstone’ and ‘Minchinbury Sandstone’ and excluded soils in 'Blacktown', 'Glenorie', 'Luddenham', 'Picton', 'West Pennant Hills'
Targeted habitat assessments were undertaken for this species, the species was not recorded however suitable habitat was found to occur.</td></tr>
<tr><td colspan="5">OUTSIDE THE NOMINATED AREAS</td></tr>
<tr><td colspan="5">Knowledge based map (KBM). As above. No targeted surveys as part of this project were undertaken outside the nominated areas.</td></tr>
</table>

POPULATION MAPPING	**RECORD SELECTION** BioNet records were used from 2008 onwards based on the approximate 10 year life-span of the species (noting that this only excluded two records from the assessment – both with limited accuracy from 1974 and 1913). **POPULATION DEFINITION** Records within 300 m were considered to be a population. **IMPORTANT POPULATION CRITERIA** The populations of Giant Burrowing Frog were considered important within the Strategic Assessment Area because they met the following criteria: a population within a conservation reserve

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.29 for a map of records and habitat across the Strategic Assessment Area.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 30-47 at the end of this species assessment for a breakdown of the occurrence of records and habitat for the Giant Burrowing Frog in the Strategic Assessment Area. **Records** There are limited records for the Giant Burrowing Frog within the Strategic Assessment Area. This reflects the lack of suitable habitat across the Cumberland subregion generally and the relative extent of clearing compared with surrounding areas. The species occurs more commonly to the south-east of the Strategic Assessment Area between Campbelltown and Helensburgh, as well as to the north-west, north and north-east of the Strategic Assessment Area. Two populations from five records have been mapped within the Strategic Assessment Area – one in the Castlereagh area in the north, and a second in the Gulguer Nature Reserve in Greendale towards the western boundary of the Strategic Assessment Area. The population from the Castlereagh area is considered not important. It comprises a single record located within a largely cleared landscape containing large housing lots. The second population (comprising four records) is considered to be important on the basis of its occurrence within a protected area; the premise being that populations within protected areas have a greater chance of persistence, and therefore make a significant contribution to the conservation and recovery of the species. **Potential habitat** The baseline mapping for this assessment has mapped 4,075 ha of potential habitat within the Strategic Assessment Area. This primarily occurs in the south of the Strategic Assessment Area, with scattered patches in the west and along parts of the eastern boundary of the Strategic Assessment Area. Potential habitat within the Strategic Assessment Area occurs along the interface between broad areas of intact vegetation surrounding the Cumberland subregion and land that has been cleared for farming or houses within the Strategic Assessment Area. It is likely to be marginal when compared to available habitat in the region.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

30.11.1 NOMINATED AREAS

The baseline mapping for the assessment mapped 317.3 ha of potential habitat for the Giant Burrowing Frog within the nominated areas (not including excluded lands). Nearly all of this habitat has been avoided as part of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 223.7 ha was avoided for biodiversity purposes
- 93.0 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 30-48.

It is important to note that the avoidance calculations in Table 30-48, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 30-48 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

30.11.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 30.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

30.11.3 LOSS OF POTENTIAL HABITAT

Implementation of the Plan will result in very small impacts to potential habitat.

LOSS OF POTENTIAL HABITAT

Approximately 0.6 ha of potential Giant Burrowing Frog habitat will be lost as a result of the implementation of the Plan (within Wilton and GMAC). This habitat represents <0.1 per cent of potential habitat within the Strategic Assessment Area. No direct impacts will occur to locations where the species has been recorded.

A summary of these impacts is provided in Table 30-49.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of the loss of potential foraging habitat is considered to be very low. This is because:

- The likelihood of substantial impacts occurring to the species has been categorised as unlikely. There will be no direct impacts to known populations and small impacts to potential habitat. The species has not been recorded within the region associated with direct impacts and is unlikely to be found there. Impacts are to small and fragmented areas and avoid direct impacts to first and second order streams within the distribution of mapped potential habitat
- The consequence of any impacts to the species has been categorised as negligible. There will be loss of approximately <0.1 per cent of mapped potential foraging habitat in the Strategic Assessment Area

30.11.4 FRAGMENTATION OF HABITAT

Development within the nominated areas or transport corridors will not lead to fragmentation of potential habitat for the species.

30.11.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the very low risk of residual adverse impacts to the species, offsets were not considered necessary for the Giant Burrowing Frog.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

30.11.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice for the Giant Burrowing Frog identifies a range of threats to the species. Where these threats are relevant to the implementation of the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Changes to hydrology and water quality
- Inappropriate fire regimes
- Predation by foxes and cats
- Vehicle strike
- Infection with amphibian chytrid fungus

The Conservation Advice identifies a number of other key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the risk across the Strategic Assessment Area.

HYDROLOGICAL CHANGES

Hydrological changes caused by stormwater run-off, water extraction and sedimentation has been identified as a threat to the species (DoE, 2014b).

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for the species. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5) and transport (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through:

- Development controls in the nominated areas in relation to:
  - Water cycle management. For example:
    - Water management measures must comply with council’s requirements for detention, drainage and water sensitive urban design principles
    - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
  - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets

- Soil erosion and sedimentation. For example:
  - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
  - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom 2004) and submitted with each subdivision development application
- The implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the TfNSW Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the species from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts to habitat for the species
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to habitat for the species

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes are identified as a threat to the Giant Burrowing Frog (DoE, 2014b).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact habitat for the species. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant including:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from potential foraging habitat. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the species from increased fire frequency as a result of development. This is because:

- Avoided lands supporting potential habitat will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat

- Fire management authorities will be engaged to ensure they understand the values relevant to the species and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

PREDATION BY CATS

Predation by cats and other pest animals is recognised as a threat to the Giant Burrowing Frog, although the conservation advice states that the level of impact is unknown (DoE, 2014b). New urban development under the Plan is likely to increase the number of domestic cats in the local area, which in turn, may lead to an increase in feral cat populations.

The Plan incorporates a range of measures to manage the risks associated with cats. In summary, these include:

- A commitment (Commitment 17) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the SCAs. This includes a number of actions with the most relevant to the outcome for the species being:
    - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
    - Preparation of a Pest Animal Control Implementation Strategy
    - A process to enter into written agreements with delivery partners to implement the pest animal control program
    - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Development controls that will:
    - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
    - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
    - Require appropriate management and control of pest animals relevant to development sites
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing pests, consistent with the pest animal implementation strategy outlined in Commitment 16

VEHICLE STRIKE

Vehicle strike as a result of increased traffic frequency is an identified potential threat to the species (DoE, 2014b).

Expanding urban development within the nominated areas and development of transport corridors will increase the traffic within and surrounding these areas. However, the Giant Burrowing Frog is unlikely to be affected by this increase given the lack of historical records within proximity to development and the location of the known populations in areas that are unlikely to see any change in vehicle movements due to development under the Plan.

INFECTION WITH AMPHIBIAN CHYTRID FUNGUS

Amphibian chytrid fungus, which causes the infection known as chytridiomycosis, is identified as a key threat to the Giant Burrowing Frog (DoE, 2014b).

Chytrid fungus is already present in the Cumberland subregion, although there may be pockets of disease free areas that are inhospitable to the growth of the disease (for example, due to salinity levels or elevated concentrations of trace metals). The potential for dispersing chytridiomycosis in wild frog populations increases with urbanisation around streams. This comes from growing potential for human interaction, more water flow (urban run-off) and reduced optimal habitat.

The Plan incorporates a range of measures to manage the risks associated with this issue. In summary, these include:

- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
  - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
  - Entering into written agreements with delivery partners to implement priority disease control programs
- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures methods to protect the environment during construction, including best practice site hygiene protocols to minimise the spread of disease

The package of measures in the Plan is expected to adequately manage the risk associated with chytrid fungus because:

- It supports a landscape scale approach to the issue across the Cumberland subregion
- It will ensure appropriate controls during construction

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to the development of essential infrastructure within nominated areas but outside the urban capable lands.

It is noted that there is no mapped potential habitat, and no known records of the species, within either the OSO tunnel footprint or the Metro Rail Future Extension tunnel footprint. It is therefore considered unlikely that development within the tunnel footprints will negatively impact the Giant Burrowing Frog.

30.11.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

There are no known records of the Giant Burrowing Frog within avoided lands in any of the nominated areas. However, there is 316.7 ha of potential habitat mapped for the species within avoided lands within Wilton and GMAC, and therefore it is considered to be possible that the species may occur within avoided lands in these nominated areas.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15

30.11.8 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DoE, 2014b) identifies the following key issues relevant to implementation of the Plan that are likely to have the greatest influence on the long-term viability of the Giant Burrowing Frog:

- Habitat loss
- Indirect impacts such as:
  - Hydrological changes
  - Inappropriate fire regimes
  - Predation by cats
  - Vehicle strike
  - Infection with amphibian chytrid fungus

However, it is unlikely that any of these issues will be a problem within the Strategic Assessment Area. The key reasons for this are as follows:

- There are only two identified populations within the Strategic Assessment Area, one of which is important. The important population and associated habitat is separated by a distance of almost 6 km from the nearest urban capable land and is within an area already managed for conservation. The non-important population is based on one record located within a largely cleared landscape containing large housing lots
- While potential habitat in the south of the Strategic Assessment Area within Wilton and GMAC may be subject to indirect impacts, the species has not been recorded in this area and it is unlikely to be important to the viability of the populations in the region given the extent of adjacent wilderness known to support the species
- While there is a possibility that indirect impacts may affect the nearest records for the species to the east of the Strategic Assessment Area, potential impacts are likely to be minor and incremental given the distance from the nearest urban capable land (approximately 4 km) and the extent of existing development within the Campbelltown area

In addition, the Plan is very likely to lead to the protection and management of important areas for the species within the SCA. Two of the reserves currently proposed by the Plan are with known or have the potential to support the species. They are:

- The Gulguer Reserve investigation area which occurs on the western side of the Strategic Assessment Area where the Giant Burrowing frog has been recorded. The Plan proposes to implement the reserve over the first 20 years of the Plan and it will cover an area of approximately 1,800 ha
- The Georges River Koala Reserve which is on the eastern side of the Strategic Assessment Area near GMAC and which contains substantial areas of potential habitat. This will be implemented in two stages over the first 10 years of the Plan and will cover an area of approximately 1,892 ha

CONCLUSION

There is a very low risk of residual adverse impacts from habitat loss under the Plan and potential indirect impacts are managed and unlikely to affect the species.

Implementation of the Plan will not adversely influence the long-term viability of the Giant Burrowing Frog.

30.11.9 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

30.11.10 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in (DoE, 2014b) where they relate to:

- The potential direct impacts of the Plan, or

- The relevant indirect impacts

The Plan has been developed to ensure that it is not inconsistent with any relevant TAPs. This analysis around consistency is presented in Chapter 15.

Table 30-46: Relevant Key Threatening Processes and associated Threat Abatement Plans for the Giant Burrowing Frog

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Infection of amphibians with chytrid fungus resulting in chytridiomycosis	Threat abatement plan for infection of amphibians with chytrid fungus resulting in chytridiomycosis (DoEE, 2016b)
Land clearance	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP
Predation by European red fox	Threat abatement plan for predation by the European red fox (DEWHA, 2008n)
Predation by feral cats	Threat abatement plan for predation by feral cats (DoE, 2015g)

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

30.12 *LITORIA AUREA* (GREEN AND GOLDEN BELL FROG)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	*Litoria aurea* (Green and Golden Bell Frog) is a large dull olive to bright emerald-green frog with large irregular golden-bronze blotches on its back.
ECOLOGY	The Green and Golden Bell Frog has a diverse diet which includes invertebrates such as insect larvae, crickets, cockroaches, dragonflies, earthworms, flies, grasshoppers, mosquito wrigglers, isopods, freshwater crayfish and slugs (DEWHA, 2009b). Tadpoles feed on algal or bacterial scum growing on submerged rocks (DEWHA, 2009b). The species is active by day, although males call mostly at night. While they retain a close association with water bodies and appear to generally be faithful to a single water body for their general activities, records suggest that the species is highly mobile and can move some distance as part of migrations to and from breeding sites (Lemckert, 2019). Movements of up to 5 km may be common and the frog may disperse up to 10 km (DoEE, 2018c). Breeding occurs generally between September and February after heavy rains or storms and spawn is laid among aquatic vegetation (DEWHA, 2009b). The species has high fecundity and clutch sizes have been known to contain 2463-11,682 eggs (DEWHA, 2009b).
DISTRIBUTION AND HABITAT	Records of the Green and Golden Bell Frog are widely separated and isolated, occurring along coastal lowland areas of eastern NSW and Victoria ranging from Yuraygir National Park in the north to Lake Wellington in the south. In NSW, several records occur around Sydney and the species is known to occur in the Cumberland subregion. Nearly all current known populations of the Green and Golden Bell Frog are located with 10 km of the coast. This is most likely due to the fact that the species is susceptible to the amphibian chytrid fungus and the fungus is intolerant of salt. These locations therefore provide some refuge from the impacts of chytrid (Lemckert, 2019). Habitat comprises one or more water bodies, and associated terrestrial habitats with grassy areas and low vegetation (DEWHA, 2009b). The species uses water bodies that are still, shallow, temporary, unshaded, with aquatic plants and free of mosquito fish for breeding (DEWHA, 2009b). A range of water bodies are suitable for the species, as long as they are not fast flowing, including ponds, wetlands, farm dams, creek lines and irrigation channels (DEWHA, 2009b). Ephemeral water bodies are important habitat for the species as: • Flooding of these water bodies can trigger breeding • They can provide habitat stepping stones between otherwise disconnected areas

	• They are less likely to contain mosquito fish. In NSW, the species is known to occupy disturbed habitats such as abandoned mines and quarries (DEWHA, 2009b). Non-breeding habitat is usually closely associated with water bodies (often within 50 m) (Lemckert, 2019). These terrestrial habitats immediately adjacent to water bodies are used for foraging and shelter and preferably contain grassy areas and vegetation including a range of shelter sites such as logs, rocks or dense vegetation (DEWHA, 2009b). Shelter sites are used when the species is inactive and therefore vulnerable to predation. The species is more likely to be present, and habitat more likely to be important, where: • Multiple suitable breeding sites are within a close enough proximity for individuals to migrate between them • Multiple non-breeding water bodies are present in an area and within close enough proximity to allow migration between them (and breeding sites) with relative ease • The connectivity of breeding and non- breeding habitat contains vegetation and shelter that facilitates migration • There are other individuals occupying waterbodies in close proximity (Lemckert, 2019)
POPULATIONS	In 2008, 30 populations were known in NSW and records are clustered around the following areas: • Yuraygir National Park • Gosford • Greater Sydney • Kempsey-Port Macquarie • Hexham-Newcastle-Ravensworth-Mungo Brush • Illawarra-Batemans Bay • Eden-East Gippsland (DoE, 2014d) Most populations have fewer than 20 adults, however, a population in Captains Flat has around 100 adults and over 1,000 were recorded at Kooragang Island, Broughton Island and Homebush (DoEE, 2018c). A population is considered a separate population if it is located more than 10 km from a known or nearby population (DEWHA, 2009b).
SOS SITES	Eight SOS sites for the species have been identified: • Yuraygir National Park • Crescent Head • Broughton Island • Kooragang Island • Homebush/Sydney Olympic Park • Crookhaven • Molonglo Floodplain • Meroo The closest site to the Strategic Assessment Area is the Homebush/Sydney Olympic Park site.
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Litoria aurea* (Green and Golden Bell Frog) (DoE, 2014d) EPBC Act Policy Statement 3.19. Significant impact guidelines for the vulnerable green and golden bell frog (*Litoria aurea*) (DEWHA, 2009d) Threat abatement plan for predation by feral cats (DoE, 2015g) Threat abatement plan for predation by the European red fox (DEWHA, 2008n) Threat abatement plan for infection of amphibians with chytrid fungus resulting in chytridiomycosis (DoEE, 2016b)

SPECIES-SPECIFIC GUIDELINES	The EPBC Act Policy Statement 3.19 - Significant Impact Guidelines for the Vulnerable Green and Golden Bell Frog (*Litoria aurea*) (DEWHA, 2009d) provides guidance about how to determine whether a proposed action is likely to have a significant impact on the Green and Golden Bell Frog. The guidelines describe an action as having a significant impact on the Green and Golden Bell Frog if it directly or indirectly alters or interferes with the breeding or dispersal of the species. Specifically, a referral under the EPBC Act should be considered if the action results in: 1. The removal or degradation of aquatic or ephemeral habitat either where the Green and Golden Bell Frog has been recorded since 1995 or habitat that has been assessed as being suitable according to these guidelines. This can include impacts from chytrid and *Gambusia* originating off-site 2. The removal or degradation of terrestrial habitat within 200 m of habitat identified in threshold 1 3. Breaking the continuity of vegetation fringing ephemeral or permanent waterways or other vegetated corridors linking habitats meeting the criteria in threshold 1 Only one threshold needs to be met to be considered a significant impact.

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	Yes	Yes	Yes	Yes
EXPERT REPORT (BCAR PROCESS)	Yes (Lemckert, 2019). Available at Supporting Document C.				
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS**				
	Expert report polygons. Predicted polygons for the Green and Golden Bell Frog were provided for GMAC and GPEC only, as these are the only two nominated areas supporting extant populations of the species. The species polygons cover the locations of known records, the riparian corridor joining those records and a buffer of 1,000 m around the riparian corridor and records. This is the area deemed likely to be used for foraging, shelter, breeding and as migratory habitat as they move between water bodies and riparian corridors (Lemckert, 2019). Targeted habitat assessments were not undertaken as part of this project.				
	OUTSIDE THE NOMINATED AREAS				
	Species distribution model (SDM). Potential habitat outside the nominated areas was mapped using an SDM. The report for this process notes that there are important factors driving the species' distribution for which appropriate predictors were not available. For example, Chytridiomycosis is known to impact where the species occurs. In addition, the Green and Golden Bell Frog is known not to be restricted to areas surrounded by native vegetation and has been found in quarries,				

	constructed ponds, and small bodies of the water on the ground. Therefore, the resulting predictions should be used with some caution. No targeted surveys as part of this project were undertaken outside the nominated areas.
	MAPPING TO ADDRESS SIGNIFICANT IMPACT GUIDELINES
	Additional mapping was generated to enable an assessment of impacts against the criteria set out in EPBC Act Policy Statement 3.19 (DEWHA, 2009d). This mapping identifies: • Aquatic habitat based on the overlap between habitat identified through the expert polygon process and species distribution model with buffers applied to mapped drainage and water bodies (those defined by the Guidelines for riparian corridors on waterfront land (NOW, 2012)). The buffers were applied to both sides of the mapped drainage and were based on the Strahler stream order. A standard 40 m buffer was applied to water bodies • Terrestrial habitat, comprising potential habitat identified through the Expert report polygon process and species distribution model within 200 m of the aquatic habitat identified in (1)
POPULATION MAPPING	**RECORD SELECTION**
	All available BioNet records from 1995 onwards were included in the assessment, based on the guidance in the EPBC Act Policy Statement 3.19 (DEWHA, 2009d).
	POPULATION DEFINITION
	Populations were considered separate if records were more than 10 km apart OR where landscape features interrupted connectivity, based on the guidance in the EPBC Act Policy Statement 3.19 (DEWHA, 2009d).
	IMPORTANT POPULATION CRITERIA
	The populations of Green and Golden Bell Frog were considered important within the Strategic Assessment Area because they met the following criteria: a population identified or inferred in a Commonwealth conservation advice, plan, final determination, or other relevant policy document as being important

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.31 for a map of records and habitat across the Strategic Assessment Area.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 30-51 at the end of this species assessment for a breakdown of the occurrence of records and habitat for the Green and Golden Bell Frog in the Strategic Assessment Area. **Records** The Green and Golden Bell Frog has been recorded within the Strategic Assessment Area, although current records (from 1995 onwards) are limited. Four populations have been identified: • One population within GPEC associated with Ropes Creek • One population restricted to a small area around Blair Athol in GMAC. These records are of frogs that escaped a captive colony. No natural population has been identified, and while a population could potentially have established in that location, no records have been obtained after 2014 indicating that the population has disappeared (Lemckert, 2019) • One population identified at Gow Park in Mulgoa, approximately 2.4 km south of the nearest urban capable land within GPEC. This population was recorded in 1999 in a non-permanent creek • One population along the eastern boundary of the Strategic Assessment Area, approximately 17 km east of WSA

	There are a relatively large number of BioNet records for the Cumberland subregion. However, these are dominated by records from Sydney Olympic Park (outside of the Strategic Assessment Area) with over 95 per cent of the records located within the eastern third of the Cumberland subregion; again, primarily outside of the Strategic Assessment Area (Lemckert, 2019). The expert report for this species notes that the Green and Golden Bell Frog is unlikely to have been common across the majority of the Cumberland subregion, reflecting the fact that the region is over 10 km from the coast so chytrid fungus is more likely to be present (Lemckert, 2019). **Potential habitat** The baseline mapping for this assessment has mapped 5,501 ha of potential habitat within the Strategic Assessment Area. This habitat is concentrated towards the eastern most boundary of the Strategic Assessment Area, with some large areas identified north of GPEC and small, scattered areas along the western edge. Potential habitat within GPEC and GMAC is associated with the location of known records in these nominated areas. There is no potential habitat within Wilton and WSA. It is expected that survey effort has been sufficient to reasonably indicate likely presence across all four nominated areas (Lemckert, 2019).

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

30.12.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 25 ha of potential habitat for the Green and Golden Bell Frog within the nominated areas (not including excluded lands). Approximately 11 ha (46 per cent) of this has been avoided as part of the design of the urban capable lands and transport corridors. All of the avoidance occurred in GPEC and for biodiversity purposes.

A breakdown of avoidance across each nominated area is provided in Table 30-52.

It is important to note that the avoidance calculations in Table 30-52, including for ‘avoidance for biodiversity purposes’, ‘avoidance for other reasons’, and ‘total avoidance’, have been calculated without including excluded lands as these lands are not covered by the Plan. Table 30-52 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

30.12.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

However, the Plan includes a specific measure to support the Green and Golden Bell Frog: to design the transport corridors to avoid and minimise impacts to populations and habitat and connectivity, particularly along riparian corridors.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Offsets are provided for species that are considered to be at <u>medium</u> or <u>high</u> risk of residual adverse impacts. Offsets are not provided for species that are considered to be at <u>low</u> or <u>very low</u> risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

30.12.3 LOSS OF KNOWN AND POTENTIAL HABITAT

Implementation of the Plan will lead to impacts to potential habitat. The majority of these impacts relate to habitat within GPEC where the species has previously been recorded. A very small area of mapped potential habitat will be affected within transport corridors outside the nominated areas.

A breakdown of impacts across the Strategic Assessment Area is given in Table 30-53.

IMPACTS TO HABITAT WITHIN GPEC

The urban capable lands and transport corridors within GPEC intersect just over 13 ha of habitat within and adjacent to the Ropes Creek corridor. This habitat is known to have supported a population of the Green and Golden Bell Frog, with 6 BioNet records made between 1998 and 2012.

It has not been confirmed whether this population still exists. However, there are a series of other records for this population from nearby habitat associated with Ropes Creek (both current from 1995 onwards and a number of older records) and areas of suitable habitat remain along the corridor in the form of a high density of water bodies within undeveloped lands (Lemckert, 2019). It is likely that the population persists in the area. It is also noted that the clustering of records into several discrete areas that occurs along Ropes Creek is typical of the species. The species requires a series of supporting and interacting sub-populations (in this case based around water bodies) for long-term success (Lemckert, 2019).

The impacts include 1.7 ha of aquatic habitat and 7.1 ha of terrestrial habitat within 200 m of aquatic habitat. If confirmed present, this population would be important and the loss of associated water bodies, suitable nearby terrestrial habitat or habitat that provides connectivity value may be significant. To address this risk, there is a species-specific measure in the Plan to undertake targeted surveys within potential habitat along Ropes Creek and if confirmed present, to avoid, protect and enhance key habitat features identified within and adjacent to the Ropes Creek corridor.

The standard risk assessment method described in Section 30.3 was not seen as applicable to the Green and Golden Bell Frog due to the species-specific measure to undertake targeted surveys and protect all habitat if the species is confirmed to be present. This measure addresses any uncertainty relating to presence and will lead to a total avoidance outcome if confirmed. The mitigated risk to the species from loss of habitat in this area is necessarily very low.

IMPACTS TO HABITAT OUTSIDE THE NOMINATED AREAS

Two very small areas of mapped potential habitat (totalling 0.7 ha) will be intersected by transport corridors outside the nominated areas. There are no records associated with these areas. The risk to the species from these impacts is considered to be very low as:

- The lack of historical records within the two impacted areas and connected habitats provides a good indication that they are unlikely to support the species given the reasonable level of survey effort in the region
- The Plan includes a commitment (Commitment 6) to mitigate indirect and prescribed impacts on the Green and Golden Bell Frog from major infrastructure (transport) development. This will involve:
  - An assessment of the impacts on biodiversity and other environmental values based on detailed design
  - Implementing mitigation measures based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the TfNSW Biodiversity Guidelines
  - Identifying potential design options for major watercourse crossings to reduce disruption to connectivity and the risk of vehicle strikes
  - Undertaking ongoing monitoring of high-value environmental areas, and review and adjust mitigation measures (where practical) in response to monitoring outcomes

30.12.4 FRAGMENTATION OF HABITAT

Development under the Plan will not lead to any further fragmentation of Green and Golden Bell Frog populations. If presence of the population is confirmed within habitat associated with the Ropes Creek corridor, all relevant habitat will be avoided and protected.

30.12.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the very low risk of residual adverse impacts to the species, offsets were not considered necessary for the Green and Golden Bell Frog.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

30.12.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice for the Green and Golden Bell Frog identifies a range of threats to the species. Where these threats are relevant to the implementation of the Plan, the Plan includes management strategies to mitigate their impacts. They include:

- Changes to the structure and diversity of aquatic vegetation
- Changes to hydrology and water quality
- Intensification of public access to habitat
- Predation by foxes, cats, dogs and rats
- Inappropriate fire regimes
- Infection with amphibian chytrid fungus
- Road mortality

Predation of eggs and tadpoles, interaction with cane toads and grazing are also identified as potential threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the risk across the Strategic Assessment Area.

CHANGES TO THE STRUCTURE AND DIVERSITY OF AQUATIC VEGETATION

Changes to the structure and diversity of aquatic vegetation from weed invasion is a key threat to the Green and Golden Bell Frog. Weeds are already present within the Strategic Assessment Area. However, urban, transport and agricultural development has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

The species is most susceptible to the threat of weeds from development under the Plan where new urban growth or transport occurs adjacent to known populations or habitat, in particular adjacent to the OSO and close to North St Marys along Ropes Creek in GPEC.

The Plan incorporates a range of measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCAs. This includes a number of key actions:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans

   - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
   - Require proponents to undertake the following when applying for/undertaking development:
      - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
      - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
      - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
   - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

The package of measures in the Plan is expected to adequately manage the risk posed to the Green and Golden Bell Frog from invasive weeds. This is because:

- Avoided lands will be zoned appropriately to enable an adequate framework for management
- The Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy
- There will be a range of planning controls to minimise the potential spread of weeds during and after construction

CHANGES TO HYDROLOGY AND WATER QUALITY

A reduction in water quality and changes to hydrology are recognised as a principal threat to the species (DEWHA, 2009d). Key issues relate to changes to drainage patterns and stormwater runoff, soil erosion and sedimentation and increased pollutants.

Development under the Plan has the potential to alter water quality and hydrology in areas of known and potential habitat for the Green and Golden Bell Frog. The areas at risk include:

- The population associated with Ropes Creek where development of the Western Sydney Freight Line (transport corridor to the east of WSA) intersects an upstream section of the creek
- The population at Gow Park in Mulgoa, which is located downstream of development within WSA

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for the species. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5) and transport (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through:

- Development controls in the nominated areas in relation to:
   - Water cycle management. For example:
      - Water management measures must comply with council's requirements for detention, drainage and water sensitive urban design principles
      - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
   - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets

- Soil erosion and sedimentation. For example:
  - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
  - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom 2004) and submitted with each subdivision development application
- The implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the TfNSW Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the species from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts to habitat for the species
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to habitat for the species

INTENSIFICATION OF PUBLIC ACCESS TO HABITAT

Intensification of public access to habitat is identified as a threat to the species. However, populations of the Green and Golden Bell Frog adjacent to or within proximity of proposed development are already subject to this threat as they are located within highly urbanised areas. Implementation of the Plan is unlikely to change the current level of disturbance.

The Plan also incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for the species. In summary, these include:

- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate access and use by the public
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal activities
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas.
- A specific measure in relation to Commitment 5 to ensure key habitat features are protected and enhanced if the Green and Golden Bell Frog is confirmed present along Ropes Creek following targeted surveys

The package of measures in the Plan is expected to adequately manage the risk to the species from increased public access to habitat areas as a result of development. This is because:

- The Ropes Creek corridor will be protected and managed if the species is confirmed to occur there
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

PREDATION BY CATS AND OTHER PEST ANIMALS

Predation by cats and other pest animals is recognised as a threat to the Green and Golden Bell Frog. New urban development under the Plan is likely to increase the number of domestic cats in the local area. However, areas of habitat within proximity of proposed development already occur within highly urbanised areas. Any increase in the risk of predation from cats on populations of the Green and Golden Bell Frog as a result of the Plan is expected to be minimal.

The Plan also incorporates a range of measures to manage this issue across throughout the nominated areas. In summary, these include:

- A commitment (Commitment 17) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the SCAs. This includes a number of actions with the most relevant to the outcome for the species being:
  - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
  - Preparation of a Pest Animal Control Implementation Strategy
  - A process to enter into written agreements with delivery partners to implement the pest animal control program
  - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Development controls that will:
  - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
  - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
  - Require appropriate management and control of pest animals relevant to development sites
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing pests, consistent with the pest animal implementation strategy outlined in Commitment 16

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes are identified as a potential threat to the Green and Golden Bell Frog (DoE, 2014d).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact habitat for the species. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity across the Strategic Assessment Area. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant including:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from potential foraging habitat. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the species from increased fire frequency as a result of development. This is because:

- Avoided lands supporting potential habitat will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat
- Fire management authorities will be engaged to ensure they understand the values relevant to the species and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

INFECTION WITH AMPHIBIAN CHYTRID FUNGUS

Amphibian chytrid fungus, which causes the infection known as chytridiomycosis, is likely to impact on populations of the Green and Golden Bell Frog. The threat to the species from chytrid fungus is not well understood, with the risk of extinction from the disease categorised as low to moderate (DEWHA, 2009b; DoEE, 2016b). However, the suitability of habitat is influenced by the presence of chytrid fungus.

Chytrid fungus is already present in the Cumberland subregion, although there may be pockets of disease free areas that are inhospitable to the growth of the disease (for example, due to salinity levels or elevated concentrations of trace metals). The potential for dispersing chytridiomycosis in wild frog populations increases with urbanisation around streams. This comes from growing potential for human interaction, more water flow (urban run-off) and reduced optimal habitat. Increased risks associated with development under the Plan are minimal, however, as habitat areas are already highly urbanised.

The Plan also incorporates a range of measures to manage the risks associated with this issue. In summary, these include:

- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
  - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion (this measure specifically relates to chytrid fungus)
  - Entering into written agreements with delivery partners to implement priority disease control programs
- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures to protect the environment during construction, including best practice site hygiene protocols to minimise the spread of disease
- A specific measure in relation to Commitments 5 and 6 to incorporate best practice site hygiene protocols to manage the potential spread of chytrid fungus within construction environmental management plans, if the Green and Golden Bell Frog is confirmed present along Ropes Creek. This measure is consistent with the following priority action in the Conservation Advice (DoE, 2014d): “develop and implement suitable hygiene protocols to protect known sites from further outbreaks of chytrid fungus”

The package of measures in the Plan is expected to adequately manage the risk associated with chytrid fungus because:

- It supports a landscape scale approach to the issue across the Cumberland subregion
- It will ensure appropriate controls during construction, including a species specific measure for the Ropes Creek corridor

ROAD MORTALITY

Road mortality is identified as a potential threat to the Green and Golden Bell Frog (DoE, 2014d). This is not a novel threat to the species within the Strategic Assessment Area as roads have already been developed in proximity to habitat areas. However, implementation of the Plan will lead to new roads and an increase in the volume of cars on existing roads within and surrounding the nominated areas. The main areas of concern relate to:

- The development of the Outer Sydney Orbital downstream of habitat associated with the Ropes Creek corridor
- Development of the Western Sydney Freight Line (transport corridor to the east of WSA) which intersects a creek line upstream of Ropes Creek

The Plan incorporates a range of measures to manage the increased threat from road mortality. In summary, these include:

- Development controls that will require fauna-friendly road design structures to be installed and maintained in appropriate areas adjacent to fauna habitat, such as underpasses, fauna bridges and overpasses
- A commitment (Commitment 6) to mitigate indirect and prescribed impacts on threatened species from major infrastructure (transport) development on threatened species and their habitat. This includes an action to identify potential design options for major watercourse crossings to reduce disruption to connectivity and the risk of vehicle strikes, with specific reference to the Green and Golden Bell Frog

These measures are considered to adequately address any potential increased threat from road mortality due to implementation of the Plan.

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to the development of essential infrastructure within nominated areas but outside the urban capable lands.

There is no habitat for the Green and Golden Bell Frog within tunnel footprints and the species will not be impacted in these locations.

30.12.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

The species may be subject to impacts to potential habitat from essential infrastructure on avoided land within GPEC associated with the Ropes Creek corridor. However, the Plan includes a specific commitment to survey this area and if the species is found, avoid, protect and enhance key habitat features identified within and adjacent to the corridor.

In addition, as outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to biodiversity through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15

30.12.8 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DoE, 2014d) identifies the following key issues relevant to implementation of the Plan that are likely to have the greatest influence on the long-term viability of the Green and Golden Bell Frog:

- Habitat loss
- Indirect impacts including:
  - Changes to the structure and diversity of aquatic vegetation
  - Changes to hydrology and water quality
  - Intensification of public access to habitat
  - Predation by cats and other pest animals
  - Inappropriate fire regimes
  - Infection with amphibian chytrid fungus
  - Road mortality

HABITAT LOSS

The main issue relating to habitat loss for the Green and Golden Bell Frog occurs in GPEC where the urban capable lands and transport corridors intersect just over 13 ha of habitat within and adjacent to the Ropes Creek corridor. This habitat is known to have supported a population of the Green and Golden Bell Frog, with 6 BioNet records made between 1998 and 2012.

It has not been confirmed whether this population still exists. However, if it is present, it would be important and the loss of associated water bodies, suitable nearby terrestrial habitat or habitat that provides connectivity value may be significant. To address this risk, there is a species-specific measure in the Plan to undertake targeted surveys within potential habitat along Ropes Creek. If confirmed, key habitat features identified within and adjacent to the Ropes Creek corridor will be avoided, protected and enhanced. This habitat is not currently managed to protect the Green and Golden Bell Frog. An outcome that leads to its protection and ongoing management would therefore improve the long-term viability of the population. This would support a number of the priority actions in the Conservation Advice.

Any loss of potential habitat as a result of development is not expected to adversely affect the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts associated with development under the Plan will all be adequately managed and mitigated through a combination of species-specific and generic management strategies.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

This assessment has identified the potential for significant impacts to the Green and Golden Bell Frog as a result of development within GPEC. The Plan has responded with a number of specific measures to address these risks. These measures will ensure that the implementation of the Plan does not adversely influence the long-term viability of the species.

30.12.9 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

30.12.10 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 30-50 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The Plan has been developed to ensure that it is not inconsistent with any relevant TAPs. This analysis around consistency is presented in Chapter 15.

Table 30-50: Relevant Key Threatening Processes and associated Threat Abatement Plans for the Green and Golden Bell Frog

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Infection of amphibians with chytrid fungus resulting in chytridiomycosis	Threat abatement plan for infection of amphibians with chytrid fungus resulting in chytridiomycosis (DoEE, 2016b)
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP
Predation by European red fox	Threat abatement plan for predation by the European red fox (DEWHA, 2008n)
Predation by feral cats	Threat abatement plan for predation by feral cats (DoE, 2015g)

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

30.13 *PETAUROIDES VOLANS* (GREATER GLIDER)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	*Petauroides volans* (Greater Glider) is the largest gliding possum in Australia. It has thick fur which is dusky brown or dark to mottled grey on top and white or cream underneath. It can have a head and body length of 35-46 cm and 45-60 cm long tail. (TSSC, 2016e)
ECOLOGY	An arboreal nocturnal marsupial. Its diet consists of eucalypt leaves and sometimes flowers. It relies on trees with large hollows to shelter in during the day. Females reach sexual maturity in their second year and give birth to one offspring from March to June. They are estimated to live for 15 years. The home range is larger for males than for females and varies from 1-4 ha up to 16 ha in less productive forests and open woodlands. Male home ranges don't tend to overlap. They have low dispersal ability. (TSSC, 2016e)
DISTRIBUTION AND HABITAT	Restricted to eastern Australia, from the Windsor Tableland in north Queensland through to central Victoria. Isolated inland subpopulations have been found in western Townsville and the Einasleigh uplands. The species can be found in taller, montane, moist eucalypt forests containing old trees and large hollows. (TSSC, 2016e)
POPULATIONS	In 2014, the estimated population size was 100,000. The area of occupancy is estimated to be 16,164 km^2. Modelling suggests that the species requires at least 160 km^2 of native forest patches to maintain viable populations. (TSSC, 2016e)
SOS SITES	Key SOS management sites are being identified by EES, currently there are none.
RELEVANT PLANS AND POLICIES	Conservation Advice for *Petauroides volans* (Greater Glider) (TSSC, 2016e) Threat abatement plan for disease in natural ecosystems caused by *Phytophthora cinnamomi* (DoEE, 2018d)
SPECIES-SPECIFIC GUIDELINES	There are no species-specific guidelines for the Greater Glider.

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	No	No	No	No
EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.				
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS**				
	Knowledge based map (KBM). Habitat maps for the Greater Glider were generated using BioNet PCT associations of intact vegetation in areas with a patch size of greater than 25 ha. This patch size was chosen because smaller patch sizes were returning many areas of unsuitable habitat in the modelling.				
	OUTSIDE THE NOMINATED AREAS				
	Knowledge based map (KBM). As above.				
POPULATION MAPPING	**RECORD SELECTION**				
	BioNet records were restricted to post 2003 to account for the average 15 year lifespan of the species				
	POPULATION DEFINITION				
	The species occupies a relatively small home range with an average size of 1 to 3 ha and they have a low dispersal ability. Records separated by several kilometres and/or cleared developed areas were identified as separate populations.				
	IMPORTANT POPULATION CRITERIA				
	The populations of Greater Glider were considered important within the Strategic Assessment Area because they met the following criteria: a population within a conservation reserve				

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.30 for a map of records and habitat across the Strategic Assessment Area.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 30-55 at the end of this species assessment for a breakdown of the occurrence of records and habitat for the Greater Glider in the Strategic Assessment Area. **Records** Records for the Greater Glider are limited within the Strategic Assessment Area. There are thirteen known populations, of which four are considered important due to their location within a conservation reserve, including: • In the west of the Strategic Assessment Area, in Gulguer Nature Reserve. Approximately 5 km from the nearest transport corridor and WSA (important population #209) • In the south of the Strategic Assessment Area, between GMAC and Wilton. Records occur between 500 m and 2 km from urban capable lands (important population #207) • South west of Wilton towards the boundary of the Strategic Assessment Area. Near Couridjah, in the Thirlmere Lakes National Park (important population #210) • In the east of GMAC, on the boundary of the nominated area (important population #526) **Potential habitat** The baseline mapping for this assessment has mapped 25,763 ha of potential habitat within the Strategic Assessment Area. Due to the level of historical land clearing, potential habitat within the Strategic Assessment Area is more fragmented compared to surrounding areas of vegetation. The species is considered to be particularly sensitive to fragmentation, with a low dispersal ability and a requirement for large native patches of vegetation containing a high enough density of tree hollows. Potential habitat within the Strategic Assessment Area is therefore likely to be marginal compared to the much broader and intact areas of habitat to the north and west of the Strategic Assessment Area and to the south of Sydney.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

30.13.1 NOMINATED AREAS

The baseline mapping for the assessment mapped 2,400 ha of potential habitat for the Greater Glider within the nominated areas (not including excluded lands). Approximately 2,295 ha (96 per cent) of this has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 1,633 ha was avoided for biodiversity purposes
- 662 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 30-56.

It is important to note that the avoidance calculations in Table 30-56, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 30-56 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

30.13.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 30.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

30.13.3 LOSS OF POTENTIAL HABITAT

Implementation of the Plan will lead to loss and fragmentation of potential habitat. A breakdown of impacts across the Strategic Assessment Area is given in Table 30-57.

LOSS OF POTENTIAL HABITAT

Approximately 134 ha of potential Greater Glider habitat will be lost as a result of the implementation of the Plan (105 ha within the nominated areas and 29 ha within transport corridors outside the nominated areas). This habitat represents 0.5 per cent of potential habitat within the Strategic Assessment Area. There are no records of the species in these areas to be impacted.

The main impact areas include:

- GMAC: Loss of 48 ha of potential habitat on the edges of riparian corridors adjacent to the urban capable land
- GPEC: Loss of 31 ha where the OSO intersects Wianamatta Regional Park
- Wilton: Loss of 16 ha of potential habitat on the edges of riparian corridors adjacent to the urban capable land

There will also be impacts close to three locations where the species has been recorded that are not mapped as habitat within the nominated. Each record occurs in small, fragmented patches of vegetation adjacent to urban capable lands. They are:

- Population 528 in Wilton
- Population 585 in WSA
- Population 584 in GPEC

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of the loss of potential foraging habitat is considered to be very low. This is because:

- The likelihood of actual impacts occurring to the species has been categorised as possible. There will be impacts to potential habitat with a moderate confidence that the species occurs in the impact area. For example, in Wilton there will be some impacts to the edges of vegetation patches that are connected to an area with a known population (population 207). It is possible, although not certain that the species is present in some of the impact areas
- The consequence of any impacts to the species (if they did occur) has been categorised as negligible. There will be loss of approximately 0.5 per cent of mapped potential habitat in the Strategic Assessment Area

30.13.4 FRAGMENTATION OF HABITAT

FRAGMENTATION IMPACTS

The Plan will lead to fragmentation of potential habitat due to the development of the OSO within Wianamatta Regional Park.

RISK OF RESIDUAL ADVERSE IMPACTS

The risk of residual adverse impacts occurring to the species as a result of the loss of fragmentation is considered to be very low. This is because:

- The likelihood of fragmentation has been categorised as possible. This is because:
  - The likelihood that development presents a barrier to dispersal of the species is likely. The OSO transport corridor fragments habitat that could be used by the Greater Glider for dispersal
  - The type of fragmentation is impact to mapped habitat only. There are no records in the vicinity of the fragmentation
- The consequence of fragmentation has been categorised as negligible. This is because the area to be fragmented consists of a small area of potential habitat with no associated records

30.13.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the very low risk of residual adverse impacts to the species, offsets were not considered necessary for the Greater Glider.

However, it is worth noting that the Plan's conservation program is likely to provide substantial benefits for the species. In particular, the following reserves are likely to protect important populations:

- The Georges River Koala Reserve which occurs to the east of GMAC. It will cover up to 1,800 ha of land and include significant areas that are mapped as habitat for the Greater Glider
- The Gulguer Reserve Investigation Area which is on the western side of the Strategic Assessment Area. This area covers approximately 1,800 ha and has the potential to support the east-west connection between Burragorang State Conservation Area and Gulguer Nature Reserve (where population 209 has been recorded)

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

30.13.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice (and other key documents) for the Greater Glider identify a range of threats to the species (TSSC, 2016e). Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Too intense or frequent fires
- Habitat loss or degradation from *Phytophthora* root fungus

Timber production, entanglement in barbed wire fencing, hyper-predation by owls and competition from Sulphur-crested Cockatoos are also identified as key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the risk across the Strategic Assessment Area.

TOO INTENSE OR FREQUENT FIRES

Bushfires and prescribed burning are identified as key threats to the Greater Glider (TSSC, 2016e).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact habitat for the species or result in direct mortality. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant including:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
    - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from potential foraging habitat. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the species from increased fire frequency as a result of development. This is because:

- A landscape scale approach to fire management (including in reserves) will be applied with a focus on biodiversity values
- Avoided lands supporting potential habitat will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat
- Fire management authorities will be engaged to ensure they understand the values relevant to the species and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

HABITAT LOSS OR DEGRADATION FROM PHYTOPHTHORA ROOT FUNGUS

Potential habitat for the Greater Glider is threatened by exposure to *Phytophthora cinnamomi*, a soil-borne water mould which is fatal to many flora species.

Development under the Plan may increase the risk of the spread of infection/disease. This is primarily related to:

- Soil transportation on contaminated footwear, vehicles and machinery, and in residential garden establishment
- Increased site visitation rates
- Earthworks and activities conducted during construction
- Increased surface water runoff

The Plan incorporates a range of measures to manage the risks associated with diseases, pathogens and dieback. In summary, these include:

- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
  - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
  - Entering into written agreements with delivery partners to implement priority disease control programs
- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures methods to protect the environment during construction, including best practice site hygiene protocols to minimise spread of *Phytophthora* and Myrtle Rust
- A specific requirement in relation to Commitment 5 to incorporate best practice site hygiene protocols to manage the potential spread of pathogens, such as *Phytophthora* and Myrtle Rust

The package of measures in the Plan is expected to adequately manage the risk to potential habitat from diseases, pathogens and dieback because:

- It supports a landscape scale approach to the issue across the Cumberland subregion
- It will ensure appropriate controls during construction

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to:

- The development of essential infrastructure within nominated areas but outside the urban capable lands
- Tunnels associated with transport projects

30.13.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

There are records of the Greater Glider on avoided land in GPEC, WSA and GMAC and potential habitat on avoided land within all nominated areas. Therefore, the species may be subject to impacts from essential infrastructure. However, the species is mobile and the scale of impact is not expected to be significant.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to biodiversity through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

30.13.8 POTENTIAL IMPACTS FROM TUNNELS

Potential habitat for the Greater Glider occurs within the tunnel footprints for the Metro Rail Future Extension (31 ha) and the Outer Sydney Orbital (54 ha). These habitat areas are not associated with records.

However, the Plan includes commitments to:

- Avoid any direct impacts to the areas where the species could occur
- Mitigate any potential indirect impacts (e.g. changes to hydrology, ground settling or subsidence) from the transport corridors as part of a future environmental impact assessment process

These commitments are expected to adequately address threats to the species from the construction and operation of the tunnels. See Section 36.6 in Chapter 36 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

30.13.9 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DoE, 2015d) identifies the following key issues that are likely to have the greatest influence on the long-term viability of the Greater Glider in relation to implementation of the Plan:

- Habitat loss
- Indirect impacts such as:
  - Too intense or frequent fires
  - Habitat loss or degradation from *Phytophthora* root fungus

HABITAT LOSS AND FRAGMENTATION

The risk of residual adverse impacts to the species from habitat loss and fragmentation is <u>very low</u>. While the Plan authorises the clearing of 134 ha of potential habitat (0.5 per cent of potential habitat within the Strategic Assessment Area), this is considered unlikely to have a significant effect on the species because:

- There are no direct impacts to areas with known records of the species or important populations
- The majority of direct impacts occur on the edges of habitat corridors and to areas that are already highly fragmented
- The areas of foraging habitat within the Strategic Assessment Area are connected to a much larger network of intact habitat to the north, west and south. In this regional context, implementation of the Plan impacts a very small proportion of the habitat available to the species

In addition, the conservation program is likely to provide significant benefits to the species within the Strategic Assessment Area.

Habitat loss and fragmentation are not expected to adversely influence the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts associated with too intense or frequent fires, and habitat loss or degradation from *Phytophthora* root rot fungus will be managed and mitigated through the generic and species-specific management strategies in the Plan.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

There are large areas of potential habitat (25,763 ha) and impacts to this are relatively minor (134 ha) given the larger areas of intact habitat surrounding the Strategic Assessment Area.

Potential indirect impacts are addressed through general management strategies and species-specific controls defined in the Plan and implementation of the conservation program will protect large areas associated with potential habitat for the species.

Collectively these will ensure that the implementation of the Plan does not adversely influence the long-term viability of the Greater Glider.

30.13.10 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

30.13.11 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 30-54 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The Plan has been developed to ensure that it is not inconsistent with any relevant TAPs. This analysis around consistency is presented in Chapter 15.

Table 30-54: Relevant Key Threatening Processes and associated Threat Abatement Plans for the Greater Glider

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Dieback caused by the root-rot fungus (*Phytophthora cinnamomi*)	Threat abatement plan for disease in natural ecosystems caused by *Phytophthora cinnamomi* (DoEE, 2018d)
Land clearance	There is no relevant TAP
Loss of climatic habitat caused by anthropogenic emissions of greenhouse gasses	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

30.14 *POMMERHELIX DURALENSIS* (DURAL LAND SNAIL)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Endangered
DESCRIPTION	*Pommerhelix duralensis* (Dural Land Snail) is a medium sized snail with a dark brown to black semi-translucent, almost spherical shaped, shell. Adults grow approximately 10-23 mm in height and 14-23 mm in width. (DoE, 2015d)
ECOLOGY	Individuals are solitary. The species is nocturnal and typically active approximately one hour after dusk until dawn. Migration and dispersal are limited, overnight straight-line distances are less than one metre. Reproduction rates are low with about 32 eggs per season. Offspring mortality is high at 90 per cent in the first year. Life expectancy is approximately five years. Main food source is native fungi. The ranges of individuals are adjacent to each other but do not overlap significantly (DoE, 2015d).
DISTRIBUTION AND HABITAT	Endemic to NSW. Until recently, known records occurred predominantly along the north-east fringes of the Cumberland subregion on shale-sandstone transitional landscape, where the distribution is dependent on the shale availability (DoE, 2015d). Within the last year, new records for the species have been found near Silverdale and St Helens Park, which significantly increase the known southern range of the species. Inhabits forested areas with good native cover and woody debris. It favours sheltering under rocks or inside curled-up bark (OEH, 2019b). It is thought to be intolerant of highly disturbed and weedy habitats (DoE, 2015d). The species is found within the following EPBC listed TECs: • Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest • Turpentine-Ironbark Forest in the Sydney Basin Bioregion • Shale Sandstone Transition Forest of the Sydney Basin Bioregion The species' habitat is severely fragmented, almost all links between the species' shale transition habitat and adjoining Cumberland Plain have been lost through land clearance. (DoE, 2015d) Shale-influenced habitats along the north west fringes of the Cumberland Plain are considered important for the species (DoE, 2015d).
POPULATIONS	Long term population trends are unknown. A number of populations are now isolated into remnants under five hectares in size (DoE, 2015d).
SOS SITES	No SOS sites for the species have been identified due to data deficiencies.

RELEVANT PLANS AND POLICIES	Conservation advice for *Pommerhelix duralensis* (Dural Land Snail) (DoE, 2015d)
SPECIES-SPECIFIC GUIDELINES	There are no species-specific guidelines.
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=85268

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	No	No	No	No

EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.
	ACROSS THE STRATEGIC ASSESSMENT AREA
HABITAT MAPPING	**Species distribution model (SDM).** An SDM for the species was prepared across the Cumberland subregion. Given the species was determined not to be a candidate species credit species in the nominated areas, any mapped habitat within the nominated areas was removed. The report for this process, published in 2018 (Supporting Document F), used known information and records about the species to model the distribution of habitat for the Dural Land Snail. However (as outlined in the following section), additional records of the Dural Land Snail have recently been discovered which significantly extend the known southern range of the species. It is therefore recognised that the SDM was produced without knowledge of the full current extent of the species' records. The report for this process mapped some areas of habitat in the locality of the new southern records of the species. Based on available records at the time, analysis within the report suggests that the model for the species overestimated the available habitat for the species, due to an absence of known records in those localities. However, the recent discovery of new records now suggests that the habitat mapped in these areas is likely to constitute real habitat. It is further recognised that additional habitat may be present for this species within the southern portion of the Strategic Assessment Area, and that future research may provide greater clarity regarding the extent of occurrence and habitat preferences for the Dural Land Snail.
	RECORD SELECTION
POPULATION MAPPING	Species records were compiled from BioNet and surveys undertaken for the project. Records were downloaded for the purposes of this assessment in September 2019, and assessments of species have been conducted primarily based on this dataset. However, it is noted (based on a review of the BioNet Atlas in July 2020) that there are new records in BioNet which significantly expand the known range of the species when compared to the original downloaded records.

	The Conservation Advice notes that the Dural Land Snail is morphologically similar to, and can be mistaken for, other species within the *Pommerhelix* and *Meridolum* genera which occur adjacent to the range of the Dural Land Snail. Expert review may therefore be required to confirm the authenticity of the new southern records. However, for the purposes of this report, it is assumed on a precautionary basis that the new species records have been correctly identified as the Dural Land Snail, and the records have been assessed accordingly. At the time of writing, it was too late to include the additional populations into the population database generated for this report, and as such these populations have not been assigned population numbers or included in the maps associated with this report, nor are they considered in impact statistics. However, these records have still been considered when assessing impacts to the species within the written body of this report. This assessment therefore includes consideration of all available BioNet records as of July 2020.
	POPULATION DEFINITION
	Biological populations were defined using the records dataset and available information about the nature of the species. Records have been grouped into populations based on geographic restrictions and connectivity between patches of suitable vegetation.
	IMPORTANT POPULATION CRITERIA
	Populations of the Dural Land Snail were then categorised as important or not-important based on the methodology set out in Section 11.5.3 of Chapter 11. All populations were considered to be important as the species is endangered.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.28 for a map of records and habitat across the Strategic Assessment Area. Note that the map of records for the Dural Land Snail represents records within the database prepared for this report (compiled September 2019). Additional records for this species are now available on BioNet and have also been considered within this report.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 30-59 at the end of this species assessment for a breakdown of the occurrence of records and habitat for the Dural Land Snail in the Strategic Assessment Area. **Records** *Records within the population database for this report (compiled September 2019)* The majority of known records of the Dural Land Snail occur in the north and north east of the Cumberland subregion, ranging between Parramatta and Macquarie Park in the south, through to South Maroota and Sackville in the north. Within this dataset, all records except one is outside the Strategic Assessment Area. The record is located along the northern boundary of the Strategic Assessment Area, near Tennyson. *New records identified on BioNet as of July 2020* Within the Strategic Assessment Area, four new records are present, which significantly expand the known range of the species. These are as follows: • Two records to the north of GPEC, one at Agnes Banks and one to the east of Wianamatta Nature Reserve • One record between Silverdale township and the Gulguer Nature Reserve • One record directly adjacent to the boundary of GMAC, near the Georges River at St Helens Park. It is noted that this record occurs within the footprint of the proposed Georges River Koala Reserve

	The new records at Silverdale and St Helens Park are the southernmost known records of the Dural Land Snail. **Potential habitat** The baseline mapping for this assessment has mapped 25,503 ha of potential habitat within the Strategic Assessment Area. The majority of mapped potential habitat occurs in the north of the Strategic Assessment Area, with scattered patches along the Western fringes and across the centre.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

30.14.1 NOMINATED AREAS

There is no mapped habitat for the species within the nominated areas.

30.14.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 30.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

30.14.3 LOSS OF POTENTIAL HABITAT

Implementation of the Plan will not lead to direct impacts to records or populations. However, it will lead to the loss of some potential habitat within the transport corridors. A breakdown of impacts across the Strategic Assessment Area is given in Table 30-60.

LOSS OF POTENTIAL HABITAT

Approximately 46 ha of potential habitat will be directly impacted. This loss is associated with the transport corridors outside the nominated areas, including development of the M7/Ropes Crossing Link Road at the north-east corner of GPEC, and development of the OSO to the west and south of WSA. It is noted that there are no known records of the species in the vicinity of impacted habitat.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of the loss of potential foraging habitat is considered to be very low. This is because:

- The likelihood of actual impacts occurring to the species has been categorised as possible. There will be moderate impacts to potential foraging habitat

- The consequence of any impacts to the species (if they did occur) has been categorised as minor. There will be loss of approximately 0.2 per cent of mapped potential foraging habitat in the Strategic Assessment Area, however, there are very few records close to and within areas that will be impacted

30.14.4 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the very low risk of residual adverse impacts to the species, offsets were not considered necessary for the Dural Land Snail.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

30.14.5 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice (DoE, 2015d) for the Dural Land Snail (and other key documents) identifies a range of threats to the species. Where these threats are relevant to the implementation of the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Inappropriate fire regimes and habitat modification for bushfire asset protection
- Disturbance due to weed control activities, including slashing and burning activities

Predation, habitat modification, low fecundity and high mortality, use of garden pesticides to control snails and slugs, and competition with the common garden snail are also identified as key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the risk across the Strategic Assessment Area.

INAPPROPRIATE FIRE REGIMES AND HABITAT MODIFICATION FOR BUSHFIRE ASSET PROTECTION

Inappropriate fire regimes and habitat modification for bushfire asset protection are identified as key threats to the Dural Land Snail (DoE, 2015d).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact habitat for the species. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant including:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans

- The introduction of planning controls that will:
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
    - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from potential foraging habitat. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

It is further noted that one of the new BioNet records for the Dural Land Snail occurs within the footprint of the proposed Georges River Koala Reserve (Commitment 10). The establishment of the Koala Reserve is a major focus of the Plan and will be managed for conservation purposes, which will include fire management measures to protect the biodiversity values of the reserve.

The package of measures in the Plan is expected to adequately manage the risk to the species from increased fire frequency as a result of development. This is because:

- A known record at the southernmost extent of the species will be protected through establishment and management of the Georges River Koala Reserve (Commitment 10) which will undertake fire management practices to protect biodiversity values
- Avoided lands supporting potential habitat will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat
- Fire management authorities will be engaged to ensure they understand the values relevant to the species and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

DISTURBANCE DUE TO WEED CONTROL ACTIVITIES INCLUDING SLASHING AND BURNING ACTIVITIES

Disturbance due to weed control activities is identified as a key threat to the Dural Land Snail (DoE, 2015d). In particular, the species is threatened by weed control which involves mechanical damage to the understorey, and by the burning of composted weed materials (as the snail is attracted to the compost piles which subsequently are burnt).

There is no potential habitat for the Dural Land Snail within the nominated areas. Therefore, the main risk areas for this species include known populations and mapped potential habitat outside of the nominated areas. The majority of habitat for the species occurs within the northern portion of the Strategic Assessment Area.

The Plan includes a commitment (Commitment 16) to manage priority weeds in strategic locations within the Cumberland subregion. Action 3 associated with this commitment is as follows: prepare a Weed Control Implementation Strategy to establish a coordinated weed control program, that:

- Identifies priority weed species and priority locations for weed control to maximise benefits to biodiversity in the SCA
- Identifies the training, extension and resource needs to address threats
- Provides guidance on weed control methods
- Identifies roles, responsibilities, delivery partners and other stakeholders, including Bushcare and Landcare groups, and Local Aboriginal Land Councils
- Provides guidance on funding decisions under the weed control program

Through provision of training, extension and resources, and through providing guidance on appropriate weed control measures at key sites throughout the Cumberland subregion, it is considered that the Plan will enable implementation of appropriate weed control measures which will not result in damage to biodiversity values. This measure is considered to provide protection to the Dural Land Snail from inappropriate weed control methods.

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to tunnels associated with transport projects

30.14.6 POTENTIAL IMPACTS FROM TUNNELS

Potential habitat for the Dural Land Snail occurs within the tunnel footprints for the Metro Rail Future Extension (20.0 ha) and the Outer Sydney Orbital (60.3 ha). However, whilst habitat has been mapped for this species in this locality, it is noted that there are no known records of the species in the vicinity of the tunnel footprints. The Plan includes commitments to:

- Avoid any direct impacts to the areas where the species could occur, including the Mater Dei BioBank site, as discussed in Chapter 36
- Mitigate any potential indirect impacts (e.g. changes to hydrology, ground settling or subsidence) from the transport corridors as part of a future environmental impact assessment process

These commitments are expected to adequately address threats to the species from the construction and operation of the tunnels. See Section 36.6 in Chapter 36 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15

30.14.7 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice for the Dural Land Snail (DoE, 2015d) identifies the following key issues that are likely to have the greatest influence on the long-term viability of the species in relation to implementation of the Plan:

- Habitat loss
- Indirect impacts such as:
  - Inappropriate fire regimes and habitat modification for bushfire asset protection
  - Disturbance due to weed control activities, including slashing and burning activities

HABITAT LOSS AND FRAGMENTATION

As outlined above, implementation of the Plan will lead to loss of potential habitat within transport corridors. While the Plan facilitates the clearing of 45.8 ha of potential habitat, this is only a small proportion (0.2 per cent) of potential habitat within the Strategic Assessment Area. It is noted that the Plan will not impact shale-influenced habitats along the northwest fringes of the Cumberland subregion which are considered to be important for the species' survival (DoE, 2015d).

Based on the application of the risk assessment method, the overall risk of residual adverse impacts associated with these direct impacts is very low. Impacts will only occur within foraging habitat, and no known records of the species will be impacted.

The Plan includes a broader set of commitments and actions which are likely to benefit the species, which includes commitments to protect land within the SCAs which contain approximately 3,480.9 ha of potential habitat for the Dural Land Snail. It is also noted that the southernmost known record of the Dural Land Snail occurs within the footprint of the proposed Georges River Koala Reserve, which will be protected and managed for conservation under Commitment 10 of the Plan.

On balance, direct impacts associated with implementation of the Plan are not expected to threaten the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts associated with inappropriate fire regimes and habitat modification for bushfire asset protection and disturbance due to weed control activities, including slashing and burning activities have been analysed and determined to be adequately managed and mitigated through the generic management strategies in the Plan.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

The limited scale of direct impacts to the species habitat and the management measures in the Plan to address potential indirect impacts will ensure that the implementation of the Plan does not adversely influence the long-term viability of the species.

30.14.8 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

30.14.9 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in (DoE, 2015d) where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For the Dural Land Snail, there are no relevant Threat Abatement Plans.

Table 30-58: Relevant Key Threatening Processes and associated Threat Abatement Plans for the Dural Land Snail

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence and direct impacts. Cross references to the tables are provided throughout the text above.

30.15 *ROSTRATULA AUSTRALIS* (AUSTRALIAN PAINTED SNIPE)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Endangered, marine
DESCRIPTION	*Rostratula australis* (Australian Painted Snipe) is a medium sized stocky wading bird with blue-green legs and a long orange-pink bill. It has a brown head, nape and chest with comma shaped white markings around the eyes, white belly and a white harness shape marking from its breast to back. Its plumage is barred olive green and black (DSEWPC, 2013).
ECOLOGY	The species breeds all year round depending on available suitable wetland conditions. It has been known to lay up to four clutches of 2 to 6 eggs per year. Females mostly breed every two years. (DoEE, 2018c). The species feeds on vegetation, seeds and invertebrates such as insects, worms, molluscs and crustaceans. It is mostly active at dawn, dusk and throughout the night (DoEE, 2018c; Garnett, Szabo et al., 2011). It is generally seen singly or in pairs. Movement patterns are not well understood, the species may be dispersive or migratory (DoEE, 2018c).
DISTRIBUTION AND HABITAT	The species is only found in Australia and mainly occurs in the Murray Darling Basin. It is widespread across Australia (DoEE, 2018c; DSEWPC, 2013). It is associated with the following EPBC Act listed TECs: • Seasonal Herbaceous Wetlands (Freshwater) of the Temperate Lowland Plains • Upland Wetlands of the New England Tablelands The species inhabits ephemeral and permanent shallow freshwater wetlands, occasionally brackish wetlands. It favours a dense cover of grass and reeds. Important areas for the species include the Murray Darling Basin, Queensland Channel Country, Fitzroy Basin of Central Queensland, south eastern South Australia and adjacent parts of Victoria. (DSEWPC, 2013)
POPULATIONS	The species occurs as a single sub-population and estimated at between 100 and 1,500 individuals (Garnett, Szabo et al., 2011).
SOS SITES	One SOS site has been identified for the species: Far West NSW It does not occur within the Cumberland IBRA subregion.
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Rostratula australis* (Australian painted snipe) (DSEWPC, 2013) Threat abatement plan for predation by feral cats (DoE, 2015g)

	Threat abatement plan for predation by the European red fox (DEWHA, 2008n)
SPECIES-SPECIFIC GUIDELINES	There are no species-specific guidelines for the Australian Painted Snipe.
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=77037

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	Yes	No	No	No	No

EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS**
	Knowledge based map (KBM). Habitat maps were generated using vegetation classes derived from BioNet PCT associations, vegetation condition parameters (intact), 40 m buffer to waterways (based on preferred habitat comprising freshwater wetlands). No targeted surveys were undertaken as part of this project.
	OUTSIDE THE NOMINATED AREAS
	Knowledge based map (KBM). As above. No targeted surveys as part of this project were undertaken outside the nominated areas.
POPULATION MAPPING	**RECORD SELECTION**
	Records restricted to post 2002 to account for estimated 16 year lifespan of the species.
	POPULATION DEFINITION
	Biological populations of were defined using the records dataset and available information about the nature of the species. All records within the Cumberland subregion are representative of a portion of the east coast population and therefore records in the Strategic Assessment Area have been grouped as one single population.
	IMPORTANT POPULATION CRITERIA
	Populations of the Australian Painted Snipe were then categorised as important or not-important based on the methodology set out in Section 11.5.3 of Chapter 11. All populations were considered to be important as the species is endangered.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.26 for a map of records and habitat across the Strategic Assessment Area.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 30-62 at the end of this species assessment for a breakdown of the occurrence of records and habitat for the Australian Painted Snipe in the Strategic Assessment Area. **Records** There are two records for the Australian Painted Snipe within the Strategic Assessment Area in the last sixteen years: • One is within GPEC from an unnamed water body outside of the urban capable land near to Wianamatta (South Creek) • The other is from the north of the Strategic Assessment Area in the floodplain of the Hawkesbury River While two records occur in the Strategic Assessment Area, the area is not recognised as a key location for the species and the nominated areas include only one record (within GPEC). The only other recent record in the Cumberland subregion (outside the Strategic Assessment Area) is from the former wastewater ponds associated with the old Riverstone Meatworks in the Marsden Park North Precinct of the North West Growth Centre (approximately 5.6 km from the nearest development area). **Potential habitat** The baseline mapping for this assessment has mapped 2,231 ha of potential habitat within the Strategic Assessment Area. This mapping is considered to be highly precautionary as it is based on all mapped waterways with the appropriate PCTs.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

30.15.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 106 ha of potential habitat for the Australian Painted Snipe within the nominated areas (not including excluded lands). Approximately 72 ha (68 per cent) of this has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 14 ha was avoided for biodiversity purposes
- 57 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 30-63.

It is important to note that the avoidance calculations in Table 30-63, including for ‘avoidance for biodiversity purposes’, ‘avoidance for other reasons’, and ‘total avoidance’, have been calculated without including excluded lands as these lands are not covered by the Plan. Table 30-63 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

30.15.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 30.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

30.15.3 LOSS OF POTENTIAL HABITAT

Implementation of the Plan will lead to impacts to some potential habitat. Given the wide-ranging nature of the species, it is considered unlikely that development within the nominated areas or transport corridors would lead to any fragmentation effects.

LOSS OF POTENTIAL HABITAT

Approximately 40 ha of potential habitat will be lost as a result of the implementation of the Plan. This habitat represents 1.8 per cent of mapped potential habitat across the Strategic Assessment Area. The majority of impacts to potential habitat occur in WSA (17 ha) and GPEC (10 ha), consisting of multiple small potential habitat areas.

A summary of these impacts is provided in Table 30-64.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of the loss of potential foraging habitat is considered to be very low. This is because:

- The likelihood of actual impacts occurring to the species has been categorised as unlikely. There will be minor impacts to potential foraging habitat and it is considered unlikely for the species to be present in these areas. The Strategic Assessment Area is not recognised as a key location for the species and the mapping is considered to be highly precautionary
- The consequence of any impacts to the species (if they did occur) has been categorised as minor. There will be loss of approximately 1.8 per cent of mapped potential habitat in the Strategic Assessment Area and very few records close to or within impacted areas

30.15.4 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the very low risk of residual adverse impacts to the species, offsets were not considered necessary for the Australian Painted Snipe.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

30.15.5 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice for the Australian Painted Snipe identifies a range of threats to the species. Where these threats are relevant to the implementation of the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Loss or degradation of wetlands
- Predation by feral animals
- Vegetation changes caused by introduced plants
- Inappropriate fire regimes

Grazing, coastal port and infrastructure development, and shale oil mining are also identified as key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the risk across the Strategic Assessment Area.

LOSS OR DEGRADATION OF WETLANDS

Loss and degradation of wetlands through drainage and diversion of water is identified as a threat to the Australian Painted Snipe (DSEWPC, 2013). This is a particular threat where important habitat areas are in the proximity of development and well connected hydrologically. The majority of habitat in the Strategic Assessment Area within the vicinity of development lacks records and is not considered to be critical for the species.

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for the species. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5) and transport (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through:

- Development controls in the nominated areas in relation to:
  - Water cycle management. For example:
    - Water management measures must comply with council's requirements for detention, drainage and water sensitive urban design principles
    - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
  - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
  - Soil erosion and sedimentation. For example:
    - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
    - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom 2004) and submitted with each subdivision development application
- The implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the TfNSW Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the species from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts to habitat for the species
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to habitat for the species

The commitments and actions under the Plan are consistent with the following regional priority action in the conservation advice (DSEWPC, 2013): "manage any changes to hydrology that may result in changes to water table levels, run-off, salinity, algal blooms, sedimentation or pollution".

PREDATION BY FERAL ANIMALS

Predation by feral animals such as foxes and cats is identified as a potential threat to the Australian Painted Snipe, however, the Conservation Advice states that there is no evidence for this (DSEWPC, 2013).

Existing land use within the nominated areas and surrounding region (which includes residential and rural residential areas, and farming) means these issues are already present in the Strategic Assessment Area and are unlikely to pose a novel threat to the species.

However, the extent of proposed new urban development under the Plan means that the threat associated with cats is likely to be exacerbated. It is likely that there will be an increase in the number of domestic cats in the local area, which, in turn, may lead to an increase in feral cat numbers. The main areas of concern relate to new urban development in Wilton and the southern section of GMAC, where the current density of houses is low.

In relation to the residual risks associated with invasive fauna, the Plan incorporates a range of measures to manage the risks. In summary, these include:

- A commitment (Commitment 17) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the SCAs. This includes a number of actions with the most relevant to the outcome for the species being:
  - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
  - Preparation of a Pest Animal Control Implementation Strategy
  - A process to enter into written agreements with delivery partners to implement the pest animal control program
  - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Development controls that will:
  - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
  - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
  - Require appropriate management and control of pest animals relevant to development sites
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing pests, consistent with the pest animal implementation strategy outlined in Commitment 16

VEGETATION CHANGES CAUSED BY INTRODUCED PLANTS

Vegetation changes caused by introduced plants is identified as a threat to the Australian Painted Snipe (DSEWPC, 2013).

Many weeds are already present within the Strategic Assessment Area and pose a threat to habitat for the Australian Painted Snipe. However, urban development and transport have the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or changing conditions to favour weeds.

The species is most susceptible to the threat of weeds from development under the Plan where new urban development occurs adjacent to habitat areas and introduces edge effects.

The Plan incorporates a range of measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCAs. This includes a number of actions, of which the following are the most relevant to the outcome for the species:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program

  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

The package of measures in the Plan is expected to adequately manage the risk posed to the species from weed invasion. This is because:

- The Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy
- There will be a range of planning controls to minimise the potential spread of weeds during and after construction

INAPPROPRIATE FIRE REGIMES

Altered fire regimes are identified as a potential threat to the Australian Painted Snipe, however, the conservation advice states that the impacts are unknown (DSEWPC, 2013).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact habitat for the species. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant including:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas

  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from potential foraging habitat. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the species from increased fire frequency as a result of development. This is because:

- Avoided lands supporting potential habitat will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat
- Fire management authorities will be engaged to ensure they understand the values relevant to the species and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

The commitments and actions under the Plan are consistent with the following regional priority action in the conservation advice (DSEWPC, 2013) to: "develop and implement a suitable fire management strategy for the habitat of the Australian Painted Snipe".

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to:

- The development of essential infrastructure within nominated areas but outside the urban capable lands
- Tunnels associated with transport projects

30.15.6 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

There are no records and limited potential habitat for the Australian Painted Snipe on avoided land in the nominated areas.

However, as outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to biodiversity through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

30.15.7 POTENTIAL IMPACTS FROM TUNNELS

Foraging habitat for the Australian Painted Snipe occurs within the tunnel footprints for the Metro Rail Future Extension (6.8 ha) and the Outer Sydney Orbital (5.7 ha). These areas are not associated with records and the habitat mapping for the species is considered to be highly precautionary

However, the Plan includes commitments to:

- Avoid any direct impacts to the areas where the species could occur
- Mitigate any potential indirect impacts (e.g. changes to hydrology, ground settling or subsidence) from the transport corridors as part of a future environmental impact assessment process

These commitments are expected to adequately address threats to the species from the construction and operation of the tunnels. See Section 36.6 in Chapter 36 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

30.15.8 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DSEWPC, 2013) identifies the following key issues that are likely to have the greatest influence on the long-term viability of Australian Painted Snipe in relation to implementation of the Plan:

- Habitat loss
- Indirect impacts such as:
  - Loss or degradation of wetlands
  - Predation by introduced vertebrates
  - Vegetation changes caused by introduced plants
  - Inappropriate fire regimes

HABITAT LOSS AND FRAGMENTATION

The risk of residual adverse impacts to the species from habitat loss is very low. Although the Plan authorises the clearing of 40 ha of potential habitat, this is only a small proportion (1.8 per cent) of potential habitat within the Strategic Assessment Area.

There are no specific commitments for the Australia Painted Snipe included in the Plan. This reflects the low level of risk to the species.

However, the Plan includes broader commitments and actions that are likely to benefit the species. In particular:

- The SCAs contain approximately 231 ha of mapped potential habitat for the species. Although the final extent of potential habitat that will be secured in these areas is unclear, the opportunity to secure large, well connected and high quality vegetation that provides potential habitat makes it likely that the conservation program will deliver benefits for this species
- Implementation of the conservation program will protect 5 ha of PCTs associated with habitat for the species

The process of protecting land in the Strategic Assessment Area is likely to support a management priority from the conservation advice to increase the area of habitat for the species that is secured and managed for conservation.

As a result, habitat loss under the Plan is not expected to influence the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts associated with the identified threats will be managed and mitigated through the generic management strategies in the Plan.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

There will be no direct impacts to known populations. There are large areas of potential habitat (2,231 ha) and impacts to this are relatively minor (40 ha).

Potential indirect impacts are addressed through management measures in the Plan.

Collectively these will ensure that the implementation of the Plan does not adversely influence the long-term viability of the Australian Painted Snipe.

30.15.9 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

30.15.10 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 30-61 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The consistency of the Plan with relevant Threat Abatement Plans is discussed in detail in Chapter 15. The Plan is not inconsistent with any of the Threat Abatement Plans.

Table 30-61: Relevant Key Threatening Processes and associated Threat Abatement Plans for the Australian Painted Snipe

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP
Predation by European red fox	Threat abatement plan for predation by the European red fox (DEWHA, 2008n)
Predation by feral cats	Threat abatement plan for predation by feral cats (DoE, 2015g)

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

SPECIES AT NO RISK OF DIRECT IMPACTS

30.16 *HIRUNDAPUS CAUDACUTUS* (WHITE-THROATED NEEDLETAIL)

This species assessment provides an impact assessment for the White-throated Needletail. The species is also a listed migratory species and assessed in Chapter 32 which should be read in conjunction with the assessment in this section.

This assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable, migratory **NB:** *An assessment of this species as a migratory species is provided in Chapter 32*
DESCRIPTION	*Hirundapus caudacutus* (White-throated Needletail) is a large swift, weighing up to 120 g. It has a thickset body up to around 20cm in length and long pointed wings. Plumage is generally olive green on the head and neck, grey and brown on the wings and body, with a white patch under the tail. (TSSC, 2019b)
ECOLOGY	There is limited information about the ecology of the White-throated Needletail. The species has two subspecies of which only one (*Hirundapus caudacutus caudacutus*) occurs in Australia. This subspecies is migratory. It breeds in northeast Asia (from central Siberia through to Northern China, Sakhalin and Japan) and migrates to Australia for the non-breeding season. The species typically arrives in northern Australia between September and early November before dispersing south along both sides of the Great Dividing Range. The species typically departs Australia between mid-March and April. (TSSC, 2019b) In Australia, the species has been recorded eating a wide range of insects. It is mostly aerial but has been recorded roosting. The species is typically gregarious and has been recorded in large flocks of hundreds or thousands of birds, including mixed flocks with Fork-tailed Swift (*Apus pacificus*) and Fairy Martins (*Hirundo ariel*). (DoEE, 2018c)
DISTRIBUTION AND HABITAT	In Australia, the species is widespread across eastern and south-eastern Australia. It has been recorded between Queensland and the south-east of South Australia in coastal regions and inland as far as the western side of the Great Dividing Range (DoEE, 2018c). The species is almost always observed in flight and has been recorded over a wide range of habitats at altitudes between 1 m above ground up to below cloud level (TSSC, 2019b). It is most commonly recorded above wooded areas and less commonly above treeless areas, but has been recorded above urban areas, farmland, coastal areas, and islands well out to sea (DoEE, 2018c). There are limited records of the species roosting in Australia, but it seems to prefer trees in forests and woodlands with dense foliage or hollows (TSSC, 2019b).

POPULATIONS	The White-throated Needletail occurs as a single, mobile population. The total population that migrates to Australia is unknown, but is estimated at 10,000 individuals (DoE, 2015e).
SOS SITES	No SOS Sites have been identified.
RELEVANT PLANS AND POLICIES	Conservation Advice *Hirundapus caudacutus* (White-throated Needletail) (TSSC, 2019b)
SPECIES-SPECIFIC GUIDELINES	Referral guideline for 14 birds listed as migratory species under the EPBC Act (DoE, 2015e)
SPRAT LINK	https://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=682

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	No	No	No	No
EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.				
HABITAT MAPPING	Due to the aerial nature of the species and the limited information about its ecology, it was not possible to produce meaningful habitat mapping. The species appears to prefer certain geographic and meteorological conditions, rather than relying on particular kinds of vegetation or habitat features.				
POPULATION MAPPING	**RECORD SELECTION**				
	Records of the species were collated from Birdlife Australia, the Atlas of Living Australia, and BioNet Atlas. These records reflect observations as well as organised surveys. The analysis used a conservative estimate of individuals based on the total recorded sightings of the species per year across the Cumberland subregion.				
	POPULATION DEFINITION				
	As outlined above, there is a single population of the species. All records within the Strategic Assessment Area are therefore considered part of the same population.				
	IMPORTANT POPULATION CRITERIA				
	The population is an important population.				

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	There are numerous records of the White-throated Needletail within the Strategic Assessment Area. See the record data below which shows the ten years with the highest records of the species since 1980. Records occur from spring to early autumn and the species has been recorded in ecologically significant numbers (based on the definition in the *Referral guideline for 14 birds listed as migratory species under the EPBC Act* (DoE, 2015e) with over 2,000 records in 2016-17 and 2012-13, and at least 350 records every year since the 2009-10 austral summer. Records are more frequent over urban areas in the north and east of the Strategic Assessment Area. This may reflect the increased population of birdwatchers in this area, rather than any preference for this area by the species. It is likely that the species is also regularly present above less disturbed areas but is not recorded.

Ranked year of highest number of records (number of individuals/year)									
First	**Second**	**Third**	**Fourth**	**Fifth**	**Sixth**	**Seventh**	**Eighth**	**Ninth**	**Tenth**
2,576 (2016-17)	2,208 (2012-13)	1,472 (2017-18)	884 (2015-16)	739 (2014-15)	676 (2011-12)	644 (2013-14)	593 (2010-11)	356 (2009-10)	233 (1986-87)

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of habitat has not been calculated for this species as it was not to possible prepare meaningful habitat mapping.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts. Due to the nature of the data for this species, a risk assessment using the methodology set out in Section 30.3 was not undertaken.

30.16.1 LOSS OF POTENTIAL HABITAT

Potential impacts associated with implementation of the Plan are discussed in relation to foraging and roosting habitat.

LOSS OF POTENTIAL FORAGING HABITAT

The species has been observed foraging over a wide range of habitats. The Atlas of Living Australia, Birdlife Australia and BioNet Atlas contain numerous records in or above heavily modified and urban environments. The species is aerial while foraging and is often observed in areas of updraughts (e.g. above cliffs, ridges, and dunes, in the smoke of bushfires, in whirlwinds, or along the edges of low pressure systems) (DoEE, 2018c).

It is unlikely that modification of habitat from implementation of the Plan will substantially alter the species' use of the Strategic Assessment Area. There are no anticipated impacts to foraging habitat from the Plan.

LOSS OF POTENTIAL ROOSTING HABITAT

There are limited records of the White-throated Needletail roosting and it was previously thought that the species was exclusively aerial in Australia. Records now suggest that the species can roost in tall trees and may prefer roosting sites on ridgelines. There is some evidence that the species uses traditional roosting sites although there are no records of these sites in the Cumberland subregion.

The risk to the species from the impact of the Plan on roosting habitat is low. The species is wide-ranging and not known to roost within the Strategic Assessment Area. The Plan will conserve large areas of high-quality woodland, which will ensure species has continued access to potential roosting sites within the Cumberland subregion.

30.16.2 FRAGMENTATION OF HABITAT

Given the wide-ranging nature of the species, it is considered unlikely that development within the nominated areas or transport corridors would lead to any fragmentation effects.

30.16.3 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given there is no risk of residual adverse impacts to the species, offsets were not considered necessary for the White-throated Needletail.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

30.16.4 RELEVANT POTENTIAL INDIRECT IMPACTS

Direct mortality (wind turbines and overhead wires) and poisoning (organochlorides) are identified as key threats to the White-throated Needletail in the Conservation Advice. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to substantially exacerbate the risks across the Strategic Assessment Area.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

30.16.5 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (TSSC, 2019b) identifies threats to the White-throated Needletail within Australia. However, these threats in the context of the Strategic Assessment Area are unlikely to influence the long-term viability of the species.

30.16.6 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

30.16.7 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Given the lack of direct and indirect impacts, there are no relevant Key Threatening Processes (KTPs) or associated Threat Abatement Plans (TAPs).

30.17 *HOPLOCEPHALUS BUNGAROIDES* (BROAD-HEADED SNAKE)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	*Hoplocephalus bungaroides* (Broad-headed Snake) is black with yellow spots forming narrow irregular cross-bands on its back, and a grey-black belly. It has a flattened head and can grow to 60-150 cm long. (DoE, 2014c)
ECOLOGY	The species is active at dusk and is an ambush predator, spending long periods of time (up to four weeks) in the same place, preying on small reptiles and mammals. Female snakes mature at six years old and males at five years old. Females reproduce every other year. Mating occurs from autumn to spring and females give birth to 4-12 live young between January and April. The average home range of the species in woodland is 3.43 ha. Male home ranges do not overlap, and individuals show a preference for sites they have previously used. (DoEE, 2018c)
DISTRIBUTION AND HABITAT	Records are restricted to the sandstone ranges in the Sydney Basin, within a 200 km radius of Sydney. There are four main areas of occurrence: • Blue Mountains • Southern Sydney • An area outside of the Cumberland Plain, to the north-west • The Nowra hinterland (DoE, 2014c) Adults shelter in rocky outcrops during autumn, winter and early spring, then move to adjacent sclerophyll woodland during late spring and summer. In woodland areas, the species can be found in large trees, with multiple hollows and in dead trees. Individual snakes use between one and nine trees. Pregnant females and juveniles remain in rocky habitat, using cooler, shaded rocks and crevices (DoEE, 2018c). They can spend long periods of inactivity (up to 48 days) in a single hollow (DoEE, 2018c).
POPULATIONS	There are no current population estimates.
SOS SITES	The following SOS sites for the species have been identified: • Woronora Plateau • Morton National Park

	• Royal National Park None of these sites occur within the Cumberland IBRA subregion.
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Hoplocephalus bungaroides* (Broad-headed Snake) (DoE, 2014c) Threat abatement plan for competition and land degradation by unmanaged goats (DEWHA, 2008m) Threat abatement plan for predation by feral cats (DoE, 2015g) Threat abatement plan for predation by the European red fox (DEWHA, 2008n)
SPECIES-SPECIFIC GUIDELINES	There are no species-specific guidelines for the Broad-headed Snake.
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=1182

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	Yes	No	No	No	No
EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.				

HABITAT MAPPING	**WITHIN THE NOMINATED AREAS**
	Knowledge based map (KBM). Habitat maps for the Broad-headed Snake were generated using BioNet PCT associations of intact vegetation. Patch sizes of larger than 5 ha were used to exclude small isolated patches of vegetation from the model.
	OUTSIDE THE NOMINATED AREAS
	Knowledge based map (KBM). As above.
POPULATION MAPPING	**RECORD SELECTION**
	Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset.
	POPULATION DEFINITION
	Biological populations were defined using the records dataset and available information about the nature of the species. There is only one record of this species within the Strategic Assessment Area, which has been identified as a single population.
	IMPORTANT POPULATION CRITERIA

	Populations of the Broad-headed Snake were then categorised as important or not-important based on the methodology set out in Section 11.5.3 of Chapter 11. No important populations have been identified for this species (all non-important).

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.27 for a map of records and habitat across the Strategic Assessment Area. It is important to note that the records for this species are sensitive and have been denatured for representation on the map.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 30-66 at the end of this species assessment for a breakdown of the occurrence of records and habitat for the Broad-headed Snake in the Strategic Assessment Area. **Records** There is a single current record of the Broad-headed Snake within the Strategic Assessment Area, reflecting the largely unsuitable habitat across most of the area. The record is dated from 2014 located in the southern section of the Strategic Assessment Area, near Buxton. The species is known from surrounding areas, with numerous records located in the broad areas of intact vegetation: • To the south of Sydney, south east of the Strategic Assessment Area • In the Blue Mountains to the north west of the Strategic Assessment Area **Potential habitat** The baseline mapping for this assessment has mapped 6,735 ha of potential Broad-headed Snake habitat within the Strategic Assessment Area. This is primarily associated with the vegetation along riparian corridors that occur over sandstone geology in the very south of the Strategic Assessment Area and along the eastern boundary. Some potential habitat has been mapped within Wilton and the southern parts of GMAC. Mapped potential habitat may support the species. However, it is likely to be less important than surrounding areas given the small number of records within the Strategic Assessment Area. There are large areas of more suitable, intact habitat adjacent to the Strategic Assessment Area, while potential habitat within the Strategic Assessment Area is limited and at the interface between bushland and cleared farmland or urban areas.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

30.17.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 699 ha of potential habitat for the Broad-headed Snake within the nominated areas (not including excluded lands). All of this habitat has been avoided as part of the urban capable lands and transport corridors (not including excluded land). Of this:

- 303 ha was avoided for biodiversity purposes
- 396 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 30-67.

It is important to note that the avoidance calculations in Table 30-67, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 30-67 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

30.17.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 30.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

There will be no direct impacts to the species as a result of implementation of the Plan and offsets are not considered necessary.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

30.17.3 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice for the Broad-headed Snake identifies a range of threats to the species (DoE, 2014c). Where these threats are relevant to the implementation of the Plan, the Plan includes management strategies to mitigate their impacts. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Bush rock removal
- Inappropriate fire regimes
- Predation by cats
- Road mortality

Development of ridgetops, pine plantation development, illegal collection, vehicle strike and disturbance by feral goats are also identified as key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the risk across the Strategic Assessment Area.

Potential indirect impacts are considered relevant to populations of the Broad-headed Snake to the south of Sydney, south east of the Strategic Assessment Area.

BUSH ROCK REMOVAL

Bush rock removal has been identified as a threat to the Broad-headed Snake as rocks are used as retreat sites by the species (DoEE, 2018c). Bush rock 'collectors' are known to favour the same type and size of rocks as the Broad-Headed Snake, their gecko prey and the spiders preyed on by geckos (DoEE, 2018c).

Development in GMAC and Wilton may lead to an increase in human activity and landscaping of gardens which could increase this threat in accessible areas of the surrounding bushland where the species is known to occur. The risk areas primarily relate to the Dharawal National Park (noting that large areas of bushland near to Wilton and the southern half of GMAC are designated as 'Special Areas' within Sydney's drinking water catchment and access is restricted).

The Dharawal National Park Plan of Management acknowledges the threat of bush rock removal to the Broad-headed Snake and undertakes to protect exfoliating rock from all avoidance disturbance (NSW NPWS, New South Wales et al., 2006).

These measures are considered to adequately mitigate the level of risk to the Broad-headed Snake.

INAPPROPRIATE FIRE REGIMES

Bushfires are identified as a threat to the Broad-headed Snake as they can reduce the availability of hollows or prey, and may endanger snakes sheltering in hollows (DoEE, 2018c).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact habitat for the species. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant including:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from potential foraging habitat. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the species from increased fire frequency as a result of development. This is because:

- Avoided lands supporting potential habitat will be zoned appropriately to enable an adequate framework for management

- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat
- Fire management authorities will be engaged to ensure they understand the values relevant to the species and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

PREDATION BY CATS

Cats are a potential predator of Broad-headed Snakes (DoEE, 2018c).

Existing land use within the nominated areas and surrounding region (which includes residential and rural residential areas, and farming) means these issues are already present in the Strategic Assessment Area and are unlikely to pose a novel threat to the species.

However, the extent of proposed new urban development under the Plan means that the threat associated with cats is likely to be exacerbated. It is likely that there will be an increase in the number of domestic cats in the local area, which, in turn, may lead to an increase in feral cat numbers. The main areas of concern relate to new urban development in Wilton and the southern section of GMAC, where the current density of houses is low.

In relation to the residual risks associated with invasive fauna, the Plan incorporates a range of measures to manage the risks. In summary, these include:

- A commitment (Commitment 17) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the SCAs. This includes a number of actions with the most relevant to the outcome for the species being:
    - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
    - Preparation of a Pest Animal Control Implementation Strategy
    - A process to enter into written agreements with delivery partners to implement the pest animal control program
    - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Development controls that will:
    - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
    - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
    - Require appropriate management and control of pest animals relevant to development sites
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing pests, consistent with the pest animal implementation strategy outlined in Commitment 16
- A specific requirement to support other species in the region to contain domestic cats in new residential areas at the urban/bushland interface which is likely to be of benefit to the Broad-headed Snake
- Existing pest management within the Dharawal, Heathcote and Royal National Parks

The package of measures in the Plan is expected to adequately mitigate the level of risk to the Broad-headed Snake

ROAD MORTALITY

The Broad-headed Snake is susceptible to vehicle strike, and mortality on roads has been identified as a potential threat to the species (DoE, 2014c). Implementation of the Plan will lead to new roads and an increase in the volume of cars on existing roads within and surrounding Wilton and GMAC.

The development of new roads will not intersect any potential habitat for the Broad-headed Snake and is unlikely to increase the level of threat to the species. Increased traffic on existing roads outside of the Strategic Assessment Area may present more of a risk to the species. For instance, along the Hume Highway, Picton Road and Appin Road. It is noted that this will represent an incremental change to an existing threat rather than a novel one, and while it is difficult to predict, any potential increase in road mortality along these existing roads as a direct result of development under the Plan is expected to minor in this context.

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to the development of essential infrastructure within nominated areas but outside the urban capable lands.

It is noted that there is no mapped potential habitat, and no known records of the species, within either the OSO tunnel footprint or the Metro Rail Future Extension tunnel footprint. It is therefore considered unlikely that development within the tunnel footprints will negatively impact the Broad-headed Snake.

30.17.4 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

There are no known records of the Broad-headed Snake within avoided lands in any of the nominated areas. However, there is 699 ha of potential habitat mapped for the species within avoided lands within Wilton and GMAC, and therefore it is considered to be possible that the species may occur within avoided lands in these nominated areas.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15

30.17.5 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DoE, 2014c) identifies the following key issues that are likely to have the greatest influence on the long-term viability of the Broad-headed Snake in relation to implementation of the Plan:

- Indirect impacts, such as:
  - Bush rock removal
  - Inappropriate fire regimes

- Predation by cats
- Road mortality

INDIRECT IMPACTS

The potential indirect impacts associated with bush rock removal, inappropriate fire regimes, predation by cats and road mortality will be managed and mitigated through generic management strategies in the Plan.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

There will be no direct impacts to the species as a result of implementation of the Plan.

Potential indirect impacts are addressed through general management strategies

Collectively these will ensure that the implementation of the Plan does not adversely influence the long-term viability of the Broad-headed Snake.

30.17.6 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

30.17.7 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 30-65 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The consistency of the Plan with relevant Threat Abatement Plans is discussed in detail in Chapter 15. The Plan is not inconsistent with any of the Threat Abatement Plans.

Table 30-65: Relevant Key Threatening Processes and associated Threat Abatement Plans for the Broad-headed Snake

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Predation by feral cats	Threat abatement plan for predation by feral cats (DoE, 2015g)

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

Table 30-66: Occurrence of the Broad-headed Snake in the Strategic Assessment Area

	SAA TOTAL	WITHIN PROTECTED LANDS

30.18 *MACQUARIA AUSTRALASICA* (MACQUARIE PERCH)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Endangered
DESCRIPTION	*Macquaria australasica* (Macquarie Perch) is a moderately sized, elongated oval shaped, freshwater fish. Mature adults are either black-grey, blue-grey, or olive-brown on the dorsal side and off-white on the ventral side (DoE, 2013b).
ECOLOGY	The Macquarie Perch is a nocturnal species. Males reach maturity at two years of age and females at three years of age. Spawning occurs immediately upstream of stretches of shallow running water over gravel beds from the middle of spring to early summer (DoE, 2013b). Feeds on insects and larvae. Some fish use the same river each year for spawning (DoEE, 2018c).
DISTRIBUTION AND HABITAT	Distribution extends from southern NSW, through the ACT, to northern Victoria (DoE, 2013b). Current NSW populations exist in catchments of the Hawkesbury-Nepean river system and the Georges River, the upper reaches of the Lachlan and Murrumbidgee Rivers, Mongarlowe River, and Queanbeyan River. In Victoria populations occur in the upper reaches of the Mitta Mitta River, Ovens River, Broken River, Campaspe River, Goulburn River, Yarra River, and in Lake Eildon. (DoEE, 2018c) A riverine schooling species typically found in the cool upper reaches of rivers. It has a preference for clear water and deep, rocky holes with vegetation, overhanging banks and debris providing coverage (DoE, 2013b; DoEE, 2018c).
POPULATIONS	Populations are often small and geographically separated (DoE, 2013b). There is currently no estimate of total population.
SOS SITES	Not applicable. This species is listed under the NSW *Fisheries Management Act 1994* and is not addressed under the SOS program.
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Macquaria australasica* (Macquarie Perch) (DoE, 2013b) National Recovery Plan for the Macquarie Perch (*Macquaria australasica*) (DoEE & DPI, 2018)
SPECIES-SPECIFIC GUIDELINES	There are no species-specific guidelines for the Macquarie Perch.
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=66632

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	ECOSYSTEM CREDIT SPECIES	CANDIDATE SPECIES CREDIT SPECIES			
		WILTON	GMAC	WSA	GPEC
	No	No	No	No	No

EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.
HABITAT MAPPING	**WITHIN AND OUTSIDE THE NOMINATED AREAS** **Knowledge based map (KBM)**. Habitat mapping for the Macquarie Perch was generated by mapping: • The waterways identified in the recovery plan (DoEE & DPI, 2018) that occur within and close to the Strategic Assessment Area that support: o Self-sustaining native populations, or o Translocated and stocked populations • Any additional waterways within the Strategic Assessment Area that support records of the species since 2000
POPULATION MAPPING	**RECORD SELECTION** All BioNet records since 2000 have been included in the assessment. **POPULATION DEFINITION** Populations in distinct rivers and streams are considered separate populations. **IMPORTANT POPULATION CRITERIA** All populations were considered to be important as the species is endangered.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 46.2 for a map of records and habitat across the Strategic Assessment Area.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	The species' recovery plan identifies a number of self-sustaining native populations of the Macquarie Perch in stretches of river within and near to the Strategic Assessment Area as follows: • The Grose River, north west of the Strategic Assessment Area boundary, in the Blue Mountains National Park, near Yarramundi. It is approximately 11 km from the northern boundary of GPEC

	• Erskine Creek, west of the Strategic Assessment Area boundary, in the Blue Mountains National Park, near Warragamba. It is approximately 9.7 km from GPEC in the Hawkesbury-Nepean catchment • The Warragamba dam to the west of the Strategic Assessment Area boundary • The upper reaches of the Nepean River to the south of the Strategic Assessment Area • Cordeaux River, where there is a single BioNet record approximately 600 m south of Wilton • Cataract River (below Cataract Dam) which flows from the south east to the north west in between Wilton and GMAC up to the Nepean river • The Georges River, which follows the eastern boundary of GMAC from Gilead to Appin. it is between 130 m and 1.6 km from the GMAC urban capable land in the Georges/Cooks catchment There are also a number of waterways that have BioNet records that are not identified in the recovery plan. They are: • Little Wheeny Creek, near kurrajong in the north west. This record is located approximately 20 km from the closest urban capable land in GPEC • Glenbrook Creek, where there is a single BioNet record approximately 7.6 km west of GPEC • Nattai and Little Rivers which occur to the south west of the Strategic Assessment Area

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

All riparian corridors and waterways that are potential habitat for the species were avoided as part of the planning process within the nominated areas. No potential habitat occurs within proposed transport corridors.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts. Direct impacts are assessed in relation to impacts to mapped habitat.

Due to the nature of the data for this species, a risk assessment using the methodology set out in Section 30.3 was not undertaken.

There will be no direct impacts to known populations or areas of potential habitat for the Macquarie Perch as a result of the Plan and offsets are not considered necessary.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

30.18.1 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice and Recovery Plan for Macquarie Perch identify a range of threats to the species. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Hydrological changes
- Habitat degradation caused by bushfires
- Recreational fishing

Competition and predation from introduced fish species (including carp, gambusia, redfin perch and trout), barriers to fish movement, introduced diseases, and cold water pollution are also identified as key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the risk across the Strategic Assessment Area.

HYDROLOGICAL CHANGES

Hydrological changes, including river siltation, as a result of the removal of riparian vegetation, land use changes and construction activities is identified as a key threat to the Macquarie Perch (DoEE, 2018c; DoEE & DPI, 2018). Increased sediment loads can fill in deep holes and cover gravel beds, which are important spawning habitats, and can affect the composition of the benthic fauna, which form the majority of the species' diet (DoEE, 2018c).

There is no possibility of hydrological changes in the majority of waterways that occur within and near to the Strategic Assessment Area as they are not hydrologically connected to areas of development. However, there are two areas that have some limited potential to be affected. They are:

- The population and habitat along the Georges River which is within the same catchment as a very small section of the urban capable land in GMAC. There is minimal risk of hydrological changes within this section of the River as a result of development. However, measures are included in the Plan to protect water ways and water quality (see below)
- The population/s and habitat along the Cordeaux River and upper reaches of the Nepean River which have the potential to be affected by hydrological changes as a result of development as they are within the same catchment as the majority of Wilton

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for the species. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5) and transport (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through:

- Development controls in the nominated areas in relation to:
  - Water cycle management. For example:
    - Water management measures must comply with council's requirements for detention, drainage and water sensitive urban design principles
    - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
  - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
  - Soil erosion and sedimentation. For example:
    - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
    - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom 2004) and submitted with each subdivision development application
- The implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the TfNSW Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology

These measures are considered to adequately mitigate the level of risk to the Macquarie Perch.

HABITAT DEGRADATION CAUSED BY BUSHFIRES

Bushfires are identified as a threat to the Macquarie Perch as they can increase water temperatures, increase pH, reduce the foliage cover of streams, and increase the sediment load of rivers (DoEE, 2018c; DoEE & DPI, 2018).

Increased human activity within the nominated areas increases the risk of fire within adjacent areas of potential Macquarie Perch habitat. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant including:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from potential foraging habitat. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

These measures are considered to adequately mitigate the level of risk to the Macquarie Perch.

RECREATIONAL FISHING

Recreational fishing is identified as a threat to the Macquarie Perch. Urban development may lead to increased recreational fishing within nearby areas known to support the species. Fishing Macquarie Perch is prohibited in Australia and comes with heavy penalties for harming, possessing, buying or selling them or for damaging their habitat (DoEE & DPI, 2018; NSW DPI, 2017). Despite this, a potential increase in the rate of recreational fishing presents a greater risk to the populations within proximity of the nominated areas.

The Plan incorporates the following specific management measures (as part of Commitment 5) to address this issue: consult with relevant resource managers to consider:

- Prohibiting recreational fishing along the stretches of habitat associated with Erskine Creek, Glenbrook Creek, Georges River and Cordeaux River known to support the species
- Installing signs/interpretive displays at appropriate sites used to access fishing locations at Erskine Creek, Glenbrook Creek, Georges River and Cordeaux River to assist with identification and awareness of threats

These measures are expected to adequately mitigate the level of risk to the Macquarie Perch.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

30.18.2 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DoE, 2013b) and Recovery Plan (DoEE & DPI, 2018) identify the key issues that are likely to have the greatest influence on the long-term viability of the Macquarie Perch in relation to implementation of the Plan. They are indirect impacts associated with:

- Hydrological changes
- Habitat degradation caused by bushfires
- Recreational fishing

Direct impacts are not relevant to this species

INDIRECT IMPACTS

The potential indirect impacts associated with hydrological changes, habitat degradation caused by bushfires, and recreational fishing will be managed and mitigated through a number of commitments and actions in the Plan (see Chapter 15 for details). Indirect impacts will not adversely influence the long-term viability of the species.

IMPLICATIONS OF THE 2019-20 BUSHFIRES

As outlined in Part 1 of this report, the 2019-20 bushfires in NSW are unprecedented in their extent and intensity. As of 28 January 2020, the fires had burnt 5.3 million ha (6.7 per cent of NSW), including 2.7 million ha in national parks (37 per cent of the national park estate) and over 80 per cent of the Greater Blue Mountains World Heritage Area (EES, 2020).

The full impact of the fires will not be understood for some time (EES, 2020). This includes the potential impacts to the Macquarie Perch. However, it appears that fish populations in some waterways outside the Strategic Assessment Area may have been severely affected.

It should be noted that the initial analysis undertaken of the implications of the fires for this report (Part 1, Attachment A) did not identify Macquarie Perch as a species that may need additional commitments in the Plan. This is because it did not meet all of the following criteria (see Part 1 Attachment A for explanation):

- A high percentage (>10 per cent) of NSW records have been affected by fires of the 2019-2020 period, and
- The Cumberland subregion is already important for species persistence in NSW and/or has the potential to become more important for persistence because of the impacts of the fires to other areas of habitat, and
- The Plan has known or likely impacts to the species

CONCLUSION

The Plan will not lead to direct impacts to this species, while the management strategies for indirect impacts will ensure that the implementation of the Plan does not adversely influence the long-term viability of the species.

30.18.3 CONSISTENCY WITH RECOVERY PLAN

In accordance with Section 146K of the EPBC Act, this section considers whether the implementation of the Plan is not inconsistent with the species' Recovery Plan. It considers two questions:

- Does the Plan prevent achievement of the objectives of the Recovery Plan?
- Does the Plan prevent implementation of the Recovery Plan actions?

These are discussed below.

DOES THE PLAN PREVENT ACHIEVEMENT OF THE OBJECTIVES OF THE RECOVERY PLAN?

The overall objective of the Recovery Plan is to: ensure the recovery and ongoing viability of Macquarie perch populations throughout the species' range (including historically translocated populations in Cataract Reservoir and the Mongarlowe and Yarra rivers).

The Recovery Plan also includes a range of strategies to achieve the objective. These are:

- Conserve existing Macquarie perch (including historically translocated populations in Cataract Reservoir and the Mongarlowe and Yarra rivers);
- Protect and restore Macquarie perch habitat;
- Understand and address threats to Macquarie perch populations and habitats;
- Establish additional Macquarie perch populations within the species' natural range;
- Improve understanding of the biology and ecology of the Macquarie perch and its distribution and abundance; and
- Increase participation by community groups in Macquarie perch conservation.

The outcome for the Macquarie Perch under the Plan will not make it impossible to the achieve the objective or implement the strategies of the Recovery Plan.

DOES THE PLAN PREVENT IMPLEMENTATION OF THE RECOVERY PLAN ACTIONS?

The Recovery Plan includes a number of actions to help achieve its objective. The Plan will not prevent implementation of any of the actions.

30.18.4 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 30-68 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For Macquarie Perch, there are no relevant Threat Abatement Plans.

Table 30-68: Relevant Key Threatening Processes and associated Threat Abatement Plans for the Macquarie Perch

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP

30.19 THREATENED MIGRATORY SHOREBIRDS

This section provides an impact analysis for the five migratory shorebirds that are also listed as threatened. It draws on the detailed analysis in Section 32.2 of Chapter 32 which addresses the 21 listed migratory shorebirds that have been recorded in the Cumberland subregion. Chapter 32 should be read in conjunction with the assessments in this section.

The five species are:

- *Calidris canutus* (Red Knot)
- *Calidris ferruginea* (Curlew Sandpiper)
- *Charadrius leschenaultii* (Greater Sand Plover)
- *Limosa lapponica bauera* (Bar-tailed Godwit)
- *Numenius madagascariensis* (Eastern Curlew)

They are addressed in the same section because they:

- Share similar habitat requirements
- Are assessed using the same baseline data
- Are very similar in terms of potential impacts

The assessment of the five species in this section analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- The approach to baseline data for migratory shorebirds
- A background to each species including its occurrence in the Strategic Assessment Area
- Avoidance of impacts
- Direct impacts and offsets
- Potential indirect impacts and mitigation
- Potential additional impacts from essential infrastructure and tunnels
- Likely effects of implementation of the Planon the long-term viability for each species

30.19.1 THE APPROACH TO BASELINE DATA FOR MIGRATORY SHOREBIRDS

The approach to developing baseline data for migratory shorebirds is described in detail in Section 32.2.2 of Chapter 32. It is summarised here.

The baseline data includes:

- Compilation of available records for shorebird species
- Habitat mapping (including the identification of important habitat) across the Cumberland subregion

None of the species were candidate species under the BCAR process.

COMPILATION OF RECORDS

Records were compiled from the Birdlife Australia Database and the OEH BioNet Database. This is considered to be the most complete data for shorebirds in the Cumberland subregion.

APPROACH TO HABITAT MAPPING WITHIN THE CUMBERLAND SUBREGION

Given the similarity in habitat requirements between migratory shorebirds, habitat was mapped for all species through a single process which identified habitat sites across the Cumberland subregion.

The habitat mapping was undertaken broadly in accordance with the approach outlined in the *Industry guidelines for avoiding, assessing and mitigating impacts on EPBC Act listed migratory shorebird species* (DoEE, 2017b) (referred to as the Guidelines from this point). However, the method applied was more precautionary than required under the Guidelines to ensure that no important habitat sites were missed (see ‘limitations in the baseline data’ below).

See Section 32.2.1 for an explanation of the Guidelines and how they treat habitat for migratory shorebirds.

The process involved the following steps:

Step 1: Analysis of records across the Cumberland subregion

Records were compiled and examined across the whole of the Cumberland subregion. The initial step considered the subregion as a single habitat unit to determine which species exceeded the thresholds outlined in the Guidelines for important habitat across the whole area (i.e. which species occur in numbers greater than the threshold when records are summed across the whole subregion).

Step 2: Identification of important migratory shorebird habitat sites

The spatial distribution of records was then assessed to identify the individual wetland and waterbody (or wetland mosaic) where the thresholds were exceeded at a site level. Each wetland that was identified as important for migratory shorebirds had its boundary marked and a 250 m buffer applied. This buffer distance is consistent with the Guidelines which suggest buffer distances ranging from 165 to 255 m to mitigate against disturbance (DoEE, 2017b).

For ephemeral wetlands the threshold was considered across every year where records were held.

For permanent wetlands, the guidelines suggest considering the last five years. The approach taken for this assessment was to look at records for the last 20 years for sites that were thought to be permanent. This acknowledges the uncertainty in determining if habitat sites are permanent or ephemeral across the Strategic Assessment Area.

Step 3: Identification of potential migratory shorebird habitat

The remaining potential migratory shorebird habitat in the subregion was determined based on the presence of suitable wetlands throughout the landscape that exceed 1.5 ha in area. This 1.5 ha threshold was used as a proxy for the minimum disturbance distance for shorebirds of 150 m.

Wetland mapping layers were interrogated from the Directory of Important Wetlands (DoEE, 2018b) and the LPI topographical data Hydro Area layer (LPI, 2016) to identify areas of potential habitat.

LIMITATIONS IN THE BASELINE DATA

The data used in the habitat mapping is the best available across the Cumberland subregion. It incorporates:

- Historical records from both BioNet and Birdlife Australia
- Wetland and waterbody mapping from DAWE and LPI

However, there has not been a systematic survey for migratory shorebirds across the subregion and it is likely that shorebirds visit a number of sites where there are no records.

To address uncertainty in the data a precautionary approach was taken. This involved:

- Considering the whole of the Cumberland subregion to determine what species occurred in numbers greater than the important habitat thresholds when their records were summed for all sites
- Mapping potential habitat using wetland and waterway mapping

OVERVIEW OF SHOREBIRD HABITAT

A total of 11 important sites occur for migratory shorebirds across the subregion (see Table 30-69 and Map 49). None of these sites will be directly impacted by development under the Plan.

Table 30-69: Summary of migratory shorebird habitat sites

Habitat type	Number of sites	Total area of habitat (ha)
Important habitat within the Strategic Assessment Area	5	182.3
Important habitat within the broader Cumberland subregion	6	54.5

The important habitat sites can be broadly placed into five groups based on their location:

- Sites in the Strategic Assessment Area:
  - Sites 7, 9, 17 and 21 all occur near to the Hawkesbury River in the north of the Strategic Assessment Area
  - Site 19 occurs in the Mt Annan Botanic Gardens to the west of GMAC
- Sites outside the Strategic Assessment Area in the broader Cumberland subregion:
  - Sites 1 and 11 occur in the Marsden Park North Precinct of the existing North West Growth Area
  - Sites 3, 13 and 15 all occur within the vicinity of Sydney Olympic Park
  - Site 5 occurs outside in the suburb of Panania

It is important to note that important migratory shorebird habitat has been mapped for use in BAM assessments. No important migratory shorebird habitat has been identified within the Strategic Assessment Area.

A number of sites are subject to existing management (e.g. as a nature reserve). A profile for each site is provided in Section 32.2.3 of Chapter 32.

30.19.2 BACKGROUND TO EACH SPECIES INCLUDING ITS OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

CALIDRIS CANUTUS (RED KNOT)

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Endangered, marine, migratory ***NB:** An assessment of this species as a migratory species is provided in Chapter 32*
DESCRIPTION	*Calidris canutus* (Red Knot) is a small to medium migratory shorebird. It has a length of 23-25 cm, a wingspan of 45-54 cm, a short neck, a short straight bill, short legs, and wings that extend beyond its tail (TSSC, 2016b).
ECOLOGY	There are six recognised subspecies of the Red Knot, of which three have been recorded in Australia: • *Calidris canutus piersmai* regularly occurs in Australia, almost exclusively in the north west • *C. c. rogersi* regularly occurs in Australia, mostly in the east • *C. c. canutus* occurs as a vagrant The species breeds at a range of locations around the Arctic. It is thought that the vast majority of the population migrates to Australia in the non-breeding season. Individuals typically arrive in Australia from late August. The species returns to the northern hemisphere between February and May. (TSSC, 2016b)
DISTRIBUTION AND HABITAT	In Australia, the species mainly inhabits coastal environments and saline wetlands near the coast. The Red Knot is rarely observed in or around freshwater swamps or inland aquatic habitats. The species: • Forages in soft substrate near the edge of intertidal mudflats or sandflats exposed by low time, or in nearby lakes, sewage ponds and floodwaters • Roosts on sandy beaches, spits, and islets; mudflats; or shallow saline ponds. The species prefers roosting habitat in open areas away from potential cover for predators (TSSC, 2016b)
POPULATIONS	The species occurs as a single population in Australia. An estimated 135,000 individuals are present in Australia during the austral summer.
SOS SITES	No SOS Sites have been identified.

RELEVANT PLANS AND POLICIES	Conservation Advice. *Calidris canutus*. Red Knot (TSSC, 2016b)
SPECIES-SPECIFIC GUIDELINES	Industry guidelines for avoiding, assessing and mitigating impacts on EPBC Act listed migratory shorebird species (DoEE, 2017b) Wildlife Conservation Plan for Migratory Shorebirds (DoEE, 2015)
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=855

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area and provides a qualitative description of where records and habitat occur.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	The Red Knot has been recorded at one important habitat site, the Mason Park Wetlands (Site 3). This site is outside the Strategic Assessment Area on the eastern edge of the Cumberland subregion, close to Sydney Olympic Park. The species has not been recorded in the Cumberland subregion in numbers above the 0.1 per cent threshold for important habitat (as defined in the migratory shorebird Guidelines) when the subregion is considered a single habitat unit.

CALIDRIS FERRUGINEA (CURLEW SANDPIPER)

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Critically endangered, migratory ***NB:*** *An assessment of this species as a migratory species is provided in Chapter 32*
DESCRIPTION	*Calidris ferruginea* (Curlew Sandpiper) is a small, slim migratory bird with long legs and a long black bill (TSSC, 2015a).
ECOLOGY	The species breeds in the Russian Arctic before migrating to the southern hemisphere. A relatively small proportion of the species (thought to be less than 13 per cent) migrates to Australia for the for the austral summer. Most immature birds do not return to the northern hemisphere for two years following their first arrival in Australia.
DISTRIBUTION AND HABITAT	In Australia, the species occurs along the coast but is also widespread inland (although in lower and variable numbers). The species uses a range of freshwater and brackish coastal and estuarine areas and inland waterbodies, where it: • Forages on mudflats and in nearby shallow water, and occasionally low, sparse vegetation • Roosts in open areas with damp substrates, especially on shingle, shell or sand beaches, spits and islets (TSSC, 2015a)
POPULATIONS	The species occurs as a single population in Australia.
SOS SITES	Five SOS Sites have been identified for the Curlew Sandpiper: • Clarence River Estuary • Hunter Estuary and Port Stephens • Manning River Estuary • Richmond River Estuary • Shoalhaven Estuary

	They are all outside the Strategic Assessment Area. The closest SOS Site is in the Shoalhaven Estuary, north of Jervis Bay.
RELEVANT PLANS AND POLICIES	Conservation Advice. *Calidris ferruginea*. Curlew Sandpiper (TSSC, 2015a)
SPECIES-SPECIFIC GUIDELINES	Industry guidelines for avoiding, assessing and mitigating impacts on EPBC Act listed migratory shorebird species (DoEE, 2017b) Wildlife Conservation Plan for Migratory Shorebirds (DoEE, 2015)
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=856

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area and provides a qualitative description of where records and habitat occur.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	The Curlew Sandpiper has been recorded in small numbers in a range of wetlands and waterbodies across the Strategic Assessment Area. These include:
	• Six sites which are identified as important habitat for migratory shorebirds:
	  o Site 1 – which is comprised of ponds at the old Riverstone Meatworks. It occurs outside the Strategic Assessment Area (in the Marsden Park North Precinct of the North West Growth Centre)
	  o Sites 3 and 13 – which both occur within the vicinity of Sydney Olympic Park outside the Strategic Assessment Area on the eastern edge of the Cumberland subregion
	  o Site 7 – which is Bushell's Lagoon in the north of the Strategic Assessment Area (to the north of the Hawkesbury River)
	  o Site 9 – which is Pitt Town Lagoon in the north of the Strategic Assessment Area (to the east of the Hawkesbury River)
	  o Site 21 – which is McGraths Hill Wetland in the north of the Strategic Assessment Area (to the south of the Hawkesbury River)
	• A small number of other sites close to the Hawkesbury River and in proximity to Sites 7, 9 and 21
	• One record within GPEC outside urban capable land
	The number of records from these sites is low. Considered as a single habitat unit, the Cumberland subregion has not exceeded 0.1 per cent of the total flyway population for this species in a single year.

CHARADRIUS LESCHENAULTII (GREATER SAND PLOVER)

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable, migratory, marine ***NB:** An assessment of this species as a migratory species is provided in Chapter 32*
DESCRIPTION	*Charadrius leschenaultii* (Greater Sand Plover) is a medium sized brown and white plover. It is similar in appearance to the Lesser Sand-plover although distinctly bigger (TSSC, 2016c).
ECOLOGY	The Greater Sand Plover is a migratory shorebird. The species breeds in China, Mongolia and nearby parts of Russia. During the non-breeding season, the species migrates south, with records

	from Australia and the south Pacific across the coast of the Indian Ocean to the eastern and southern coasts of Africa and the south eastern shores of the Mediterranean. (TSSC, 2016c) Only the subspecies *C. l. leschenaultia* occurs in Australia. Almost three quarters of the subspecies is present in Australia during the austral summer. Birds typically arrive between mid-July and November and leave in late February. Most immature birds remain in Australia during the breeding season. (TSSC, 2016c)
DISTRIBUTION AND HABITAT	During the austral summer the species is widespread but more common in northern Australia. It is found in coastal areas in every Australian state. In NSW, the species is common north of the Northern Rivers region, with occasional records south to around Shoalhaven Heads. (TSSC, 2016c) While in Australia the species is almost entirely coastal. It inhabits sheltered beaches, intertidal mudflats, sandbanks, salt marshes, estuaries, coral reefs, rocky islands or platforms, tidal lagoons and dunes near the coast. They typically forage in wet sand or mud, and roost on sand-spits or high on banks near beaches. (TSSC, 2016c)
POPULATIONS	The species occurs as a single (important) population in Australia.
SOS SITES	Five SOS Sites have been identified for the Curlew Sandpiper. They are all outside the Strategic Assessment Area. The closest SOS Site is in the Shoalhaven Estuary, north of Jervis Bay.
RELEVANT PLANS AND POLICIES	Conservation Advice. *Charadrius leschenaultia*. Greater sand plover (TSSC, 2016c)
SPECIES-SPECIFIC GUIDELINES	Industry guidelines for avoiding, assessing and mitigating impacts on EPBC Act listed migratory shorebird species (DoEE, 2017b) Wildlife Conservation Plan for Migratory Shorebirds (DoEE, 2015)
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=877

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area and provides a qualitative description of where records and habitat occur.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	The Greater Sand Plover has been recorded at one important habitat site, the Mason Park Wetlands (Site 3). This site is outside the Strategic Assessment Area on the eastern edge of the Cumberland subregion, close to Sydney Olympic Park. The species has not been recorded in the Cumberland subregion in numbers above the 0.1 per cent threshold for important habitat when the subregion is considered a single habitat unit.

LIMOSA LAPPONICA BAUERA (BAR-TAILED GODWIT)

SPECIES BACKGROUND

This section describes the occurrence of the species in the Strategic Assessment Area and provides a qualitative description of where records and habitat occur.

EPBC ACT LISTING	Vulnerable, migratory ***NB:*** *An assessment of this species as a migratory species is provided in Chapter 32*
DESCRIPTION	*Limosa lapponica bauera* (Bar-tailed Godwit) is a large migratory bird with a long neck and very long upturned bill. It has dark barring on the lower white rump, upper tail and lining of the underwing (TSSC, 2016g).
ECOLOGY	Two subspecies of *L. lapponica* regularly occur in Australia:

	• In the non-breeding season, *L. l. baueri* (listed as migratory and vulnerable) occurs along the north and east coasts of Australia (TSSC, 2016g) • *L. l. menzbieri* (listed as migratory and critically endangered) occurs predominately in Western Australia (TSSC, 2016h) and is not considered likely to occur in the Cumberland subregion This assessment considers impacts to *L. lapponica baueri*. The subspecies breeds in northern Siberia and Alaska before migrating through the Yellow Sea to Australia and New Zealand. Immature birds often remain in Australia for one or two austral winters before returning to their breeding grounds in the Northern Hemisphere. The Bar-tailed Godwit has one of the longest non-stop migratory routes recorded for any bird. This makes the species sensitive to changes in intertidal habitats used for feeding to create fuel stores prior to migration.
DISTRIBUTION AND HABITAT	In Australia, the species: • Mainly occurs along the north and east coasts • Typically forages in coastal habitats such as large intertidal sandflats, banks, mudflats, estuaries, inlets, harbours, coastal lagoons and bays • Typically roosts on sandy beaches, sandbars, spits and in near-coastal saltmarsh The Bar-tailed Godwit is thought to have high site fidelity in the non-breeding season (TSSC, 2016g).
POPULATIONS	The species occurs as a single (important) population in Australia.
SOS SITES	No SOS Sites have been identified.
RELEVANT PLANS AND POLICIES	Conservation Advice. *Limosa lapponica baueri*. Bar-tailed godwit (western Alaskan) (TSSC, 2016g)
SPECIES-SPECIFIC GUIDELINES	Industry guidelines for avoiding, assessing and mitigating impacts on EPBC Act listed migratory shorebird species (DoEE, 2017b) Wildlife Conservation Plan for Migratory Shorebirds (DoEE, 2015)
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=86380

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area and provides a qualitative description of where records and habitat occur.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	The species has been recorded in the Cumberland subregion in numbers above the 0.1 per cent threshold for important habitat when the subregion is considered a single habitat unit. However, it does not exceed the threshold at any individual site. It has been recorded at three of the important habitat sites: • Site 9 – which is Pitt Town Lagoon in the north of the Strategic Assessment Area (to the east of the Hawkesbury River) • Sites 13 and 15 – which both occur in Sydney Olympic Park outside the Strategic Assessment Area on the eastern edge of the Cumberland subregion There are no records within the nominated areas or transport corridors.

NUMENIUS MADAGASCARIENSIS (EASTERN CURLEW)

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Critically endangered, migratory ***NB:*** *An assessment of this species as a migratory species is provided in Chapter 32*

DESCRIPTION	*Numenius madagascariensis* (Eastern Curlew) is the largest migratory shorebird in the world. It has a long neck and legs, and a very long downcurved bill (TSSC, 2015b).
ECOLOGY	The species breeds in Russia, Mongolia and north-eastern China. It is thought that approximately 73 per cent of the population migrates to Australia in the non-breeding season. Individuals arrive in Australia as early as July, with the majority of birds arriving in mid-to-late August. Migration north typically starts in late February and continues until March or April. Immature individuals may spend as many as three austral winters in Australia before returning to the Northern Hemisphere to breed. (TSSC, 2015b)
DISTRIBUTION AND HABITAT	In Australia, the species: • Is typically distributed across coastal areas and is rarely found inland • Typically forages in sheltered intertidal sandflats or mudflats that are either open or vegetated with seagrass, or near mangroves, saltflats or saltmarshes • Typically roosts during high tide periods on sandy spits, sandbars and islets, either on sand near the high-water mark or among coastal vegetation • Is rarely found on near-coastal lakes or in grassy areas (TSSC, 2015b)
POPULATIONS	The species occurs as a single population in Australia.
SOS SITES	No SOS Sites have been identified.
RELEVANT PLANS AND POLICIES	Conservation Advice. *Numenius madagascariensis*. Eastern Curlew (TSSC, 2015b)
SPECIES-SPECIFIC GUIDELINES	Industry guidelines for avoiding, assessing and mitigating impacts on EPBC Act listed migratory shorebird species (DoEE, 2017b) Wildlife Conservation Plan for Migratory Shorebirds (DoEE, 2015)
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=847

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area and provides a qualitative description of where records and habitat occur.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	The Eastern Curlew has been recorded at one important habitat site, Wanngal Wetland (Site 13). This site is outside the Strategic Assessment Area on the eastern edge of the Cumberland subregion. It is part of the Newington Nature Reserve within Sydney Olympic Park. The species has not been recorded in the Cumberland subregion in numbers above the 0.1 per cent threshold for important habitat when the subregion is considered a single habitat unit.

30.19.3 AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

No important habitat for any of the five species occurs within the nominated areas or transport corridors. Avoidance of impacts was therefore not necessary.

30.19.4 DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

There are no direct impacts to important habitat for any of the five species. Offsets were therefore not considered necessary.

30.19.5 POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the five species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile or conservation advice, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

The Conservation Advices identify a common range of threats to each of the five species along their migratory pathways and in Australia. Threats along their migratory pathways (i.e. outside Australia) are not considered further.

Threats in Australia include:

- Ongoing human disturbance
- Habitat loss and degradation from pollution
- Changes to the water regime
- Invasive plants

Climate change is also a relevant threat to each species. The extent to which the Plan has considered adaptation to climate change impacts is addressed in Chapter 41.

Section 32.2.4 in Chapter 32 provides a detailed analysis of the potential for these threats to occur as indirect impacts to migratory shorebirds as a result of implementation of the Plan. This analysis (which should be read in conjunction with this assessment) concludes that the risks to important habitat from these threats are considered to be negligible across the Strategic Assessment Area. In summary, this is because none of the important habitat sites are:

- In close proximity to the nominated areas or transport corridors
- Hydrologically well connected (e.g. downstream) to development areas

It is relevant to note that even though implementation of the Plan is considered unlikely to indirectly impact migratory shorebird habitat, the Plan includes a range of measures that may provide a benefit to these areas. These measures include landscape scale approaches to:

- Conserving and managing land
- Managing fire
- Managing weeds
- Managing pest animals

30.19.6 POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to each species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

No important habitat for any of the five species occurs within the nominated areas or transport corridors. Potential additional impacts from essential infrastructure and tunnels are therefore not relevant.

30.19.7 LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY FOR EACH SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the five species. The analysis has regard for the guidance in the Conservation Advices (there are no Recovery Plan for the species), and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also identifies any relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

As outlined above, implementation of the Plan will not lead to any direct or indirect impacts to important habitat for any of the species. This will ensure that the implementation of the Plan does not adversely influence their long-term viability.

CONSISTENCY WITH RECOVERY PLANS

There are no recovery plans for the species.

KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Given the lack of direct and indirect impacts, there are no relevant Key Threatening Processes (KTPs) or associated Threat Abatement Plans (TAPs).

31 Threatened Ecological Communities impact assessment

31.1 INTRODUCTION

There are eight Category 1 Threatened Ecological Communities (TECs) and one ecological community nominated for listing in the Finalised Priority Assessment List (FPAL) that are assessed in this Chapter. These ecological communities were identified as needing detailed assessment (see Part 3 for the approach, and Chapter 28 for the results) as they are reliant on the Cumberland subregion and have some potential to be impacted directly, indirectly or cumulatively.

The Chapter is structured around the level of direct impacts likely to occur to each TEC (see Table 31-1). TECs subject to the largest direct impacts are discussed first, with TECs at lower levels of direct impact discussed subsequently. The ecological community nominated for listing is assessed last.

The overall assessment approach for TECs is presented below in Section 31.2. To support the TEC assessment three additional pieces of technical analysis were undertaken. These were:

- A patch size analysis to calculate the number and sizes of patches of each TEC across the Strategic Assessment Area. See Section 31.3 for a description of the approach with the results presented in each TEC assessment
- A viability analysis to identify the patches of each TEC within the Strategic Assessment Area that are more likely to be viable in the longer-term. The methodology for the viability analysis is presented below in Section 31.4 with the results presented in each TEC assessment
- A trend analysis undertaken by RMIT University (A Gordon & Peterson, 2019) that examined the extent and condition of a component (PCT 849) of Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest. The trend analysis examined the potential impacts of development and offsetting under various scenarios on PCT 849 over the life of the Plan. A report for the trend analysis is provided at Supporting Document D. A summary of the approach and results is provided in Section 31.6 as part of the assessment of Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest

The analysis in this chapter concludes that the avoidance, mitigation and offset measures in the Plan will ensure that the long-term viability of the TECs and the nominated ecological community will not be adversely influenced.

Table 31-1: Ecological communities assessed in this chapter categorised according to the scale of direct impacts

Direct impacts to TECs	Number of TECs	TEC names
TECs subject to direct impacts	4	• Shale Sandstone Transition Forest of the Sydney Basin Bioregion • Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest • Cooks River/Castlereagh Ironbark Forest of the Sydney Basin Bioregion • Coastal Swamp Oak (*Casuarina glauca*) Forest of New South Wales and South East Queensland ecological community
TECs not directly impacted	4	• Castlereagh Scribbly Gum and Agnes Banks Woodlands of the Sydney Basin Bioregion • Elderslie Banksia Scrub Forest in the Sydney Basin Bioregion • Turpentine-Ironbark Forest of the Sydney Basin Bioregion • Western Sydney Dry Rainforest and Moist Woodland on Shale
Nominated ecological community	1	• Coastal Floodplain Eucalypt Forest of Eastern Australia (nominated for listing under the EPBC Act)

31.2 TEC ASSESSMENT APPROACH

The assessments for TECs follow a standard format. However, the content is tailored for the specific context of each TEC.

There are nine sections to the assessments. They are described below and include:

- TEC background
- Approach to baseline data
- Occurrence in the Strategic Assessment Area
- Avoidance of impacts
- Direct impacts and offsets
- Potential indirect impacts and mitigation
- Potential additional impacts from essential infrastructure and tunnels
- Likely effects of implementation of the Plan on the long-term viability of the TEC
- Data tables

To assist the reader, standard explanatory text about the purpose and content of each section is provided throughout the assessments in *blue italics text*. The text is repeated for each TEC. It enables the reader to quickly understand the content of each section and where in the broader report more detailed information is available about a particular issue.

31.2.1 TEC BACKGROUND

Sets out the basic information about the TEC. It provides a description of the TEC, and an overview of the listing definition and its distribution. These provide context for the impact assessment. At the end of the section are links to key documents that provide additional background information.

31.2.2 APPROACH TO BASELINE DATA

Provides an overview of the approach to baseline data for the TEC. It:

- Provides a summary of the approach to vegetation mapping for the strategic assessment which forms the baseline for the TEC mapping
- Outlines the vegetation condition states used in the mapping
- Identifies the NSW Plant Community Types (PCTs) that are associated with the TEC
- Summarises the approach to mapping the EPBC TEC at the scale of the Strategic Assessment Area
- Summarises the approach to the patch size analysis for the ecological community
- Summarises the approach to identifying areas of likely higher long-term viability for the TEC in the Strategic Assessment Area

Please refer to Section 11.3 (in Chapter 11) for details about the methods for mapping native vegetation, and Section 11.4.3 for details about the mapping methods for EPBC TECs.

31.2.3 OCCURRENCE IN THE STRATEGIC ASESSMENT AREA

Describes the occurrence of the TEC in the Strategic Assessment Area. It includes reference to a map of the TEC which can be viewed as a separate file (layered PDF). The map provides critical context for the assessment and should be viewed in conjunction with the text presented in the assessments. This section also provides a qualitative description of where the TEC occurs.

31.2.4 AVOIDANCE OF IMPACTS

Provides an overview of the area of the TEC that was avoided through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan.

The definition of what constitutes avoidance has been adopted from the BCAR process. Under the BAM, avoidance refers to land that is suitable for development and included in the area proposed for development or biodiversity certification, but has been avoided because of its biodiversity value. This is referred to as avoided for 'biodiversity purposes' in this assessment.

Land not impacted because it is not suitable for development or biodiversity certification, or land that has been excluded from the area proposed for development is not considered to have been avoided under the BAM. This land is referred to as avoidance for 'other purposes' and includes:

- Riparian corridors consistent with the *Water Management Act 2000*:
  - Strahler stream order 2 - buffer 20 m either side
  - Strahler stream order 3 - buffer 30 m either side
  - Strahler stream order 4 and above - buffer 40 m either side
- State protected land (>18 degrees slope, considered too steep for urban development)

Some land within the nominated areas was not considered for inclusion in the area proposed for development and has therefore been identified as 'excluded' land. These lands include:

- Existing protected land, including reserves and established offset sites
- Council owned land which is zoned for environmental conservation, environmental management or recreation
- Commonwealth land, such as Defence Establishment Orchard Hills
- Lands within the nominated areas already assessed as part of another development approval (Bingara Gorge), or lands progressing through an alternate assessment (Mount Gilead, Menangle Park, Sydney Metro Stage 1)
- Lands already developed (existing urban areas, urban land zones and roads)

A further, detailed explanation of the avoidance process and terminology is provided in Chapter 14.

31.2.5 DIRECT IMPACTS AND OFFSETS

Provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts. Direct impacts are assessed in relation to the loss of the mapped TEC.

Direct impacts were determined based on an intersect of the urban capable lands and transport corridors with the baseline mapping generated for each TEC. It has been assumed that total permanent clearing will occur within the urban capable lands and transport corridors for the purposes of the assessment. However, it is important to note that in reality:

- Further avoidance will be undertaken within the transport corridors (see Chapter 7)
- Direct impacts will occur progressively over the life of the Plan, which reduces the severity of impacts

The analysis considers direct impacts within the context of the information provided through the patch size analysis and viability analysis (i.e. which patches are considered most likely to be viable in the long term).

The Plan provides offsets for TECs that are impacted directly. The rationale and process for setting offset targets for TECs is set out in Section 8.5.2 of Chapter 8, and explained in detail in the Conservation Priorities Method that supports the Plan.

31.2.6 POTENTIAL INDIRECT IMPACTS AND MITIGATION

Identifies and discusses the potential indirect impacts to each TEC that may occur as a result of development under the Plan. They were identified as being relevant to the TEC if:

- The indirect impact is identified as a threat in a relevant profile or conservation advice, and
- The threat is present in the Cumberland subregion, and
- The Plan has the potential to exacerbate the threat

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

Where relevant to each TEC, indirect impacts are discussed in relation to the following categories which encapsulate the various ways threats to TECs are discussed in Conservation and Listing Advices:

- Inappropriate fire regimes
- Weed invasion

- Inappropriate habitat disturbance
- Changes to hydrology
- Diseases, pathogens and dieback
- Invasive fauna

31.2.7 POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

Considers the potential additional impacts to TECs due to essential infrastructure projects that are needed to support development within the nominated areas. These might include projects such as water and electricity utilities, communications facilities, stormwater management systems, and waste or resource management systems. The assessment covers projects that may need to be located outside urban capable lands and on areas that are identified as avoided lands within the nominated areas.

This section also assesses the likelihood of potential additional impacts to TECs due to the tunnel sections of the transport corridors. The impacts of tunnels were assessed separately to the rest of the transport corridors as only small areas of the footprints will be disturbed and it is not possible to determine at this stage the nature and extent of those impacts.

Please refer to the following chapters for details about these development types:

- Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels
- Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)

31.2.8 LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE TEC

Considers the likely effects of implementation of the Plan on the long-term viability of the TEC. This assessment has regard for the guidance in the Conservation Advice for each TEC (none of the TECs have EPBC Recovery Plans), and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation.

Where applicable, this section also discusses the consistency of the Plan with any relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

31.2.9 DATA TABLES

Sets out the data tables for occurrence, avoidance and direct impacts for each TEC.

31.3 PATCH SIZE ANALYSIS

A patch size analysis was undertaken for each TEC. This process used the mapping undertaken for the strategic assessment to identify and calculate the size of each patch of the TEC. This information was then used to calculate:

- The total number of patches of each TEC
- The distribution of patch sizes across three categories:
  - 0.5-5 ha
  - 5-20 ha
  - >20 ha

31.4 ASSESSMENT OF VIABILITY FOR TECS

For TECs, the consideration of likely effects on long-term viability took into account an analysis undertaken as part of the strategic assessment to identify areas of likely higher long-term viability in the Strategic Assessment Area.

31.4.1 PURPOSE

The purpose of the analysis was to identify the patches of the TEC within the Strategic Assessment Area that are more likely to be viable in the longer-term to inform the evaluation of the overall outcome of the Plan for the TEC. Viability is defined in a qualitative sense as the "probability of long-term survival of TEC patches".

31.4.2 APPROACH

The approach involved reviewing Conservation Advices for each TEC to identify the factors that influence the long-term viability or conservation significance of a patch of the TEC. This review found that Conservation Advices generally identify a similar set of factors that influence long-term viability. Key factors included:

- Larger patches are generally more viable than smaller patches
- Better condition patches are generally more viable than poorer condition patches
- Connected patches are generally more viable than poorer connected patches
- Patches with a lower edge/area ratio are generally more viable than patches with a higher edge/area ratio

While the Conservation Advices identified several more factors as being important for viability or conservation significance, spatial data at the scale of the Strategic Assessment Area was not available on TECs to include these factors in the analysis.

A single rule-set was developed for all TECs to identify patches more likely to be of higher viability. To meet this requirement, patches needed to:

- Have a minimum patch size of 20 ha
- Be in intact condition
- Be well connected to other patches of native vegetation (this was defined as having greater than 30 per cent native vegetation cover in surrounding 550 m and 1750 m buffers)
- Have a good edge to area ratio (this was defined as "an edge to area ratio of the patch of native vegetation is smaller than an equivalent 100 m wide patch of the same size")

It is important to note that patches of the TEC that do not meet this rule-set are not necessarily of lower conservation value. Small patches are often of high conservation significance, particularly in over-cleared landscapes such as the Cumberland subregion, and if managed appropriately, can persist in the long-term (Wintle et al, 2019). The purpose of this analysis was to distinguish between different patches of the TEC based on guidance in Conservation Advices to enable a more meaningful evaluation of impacts and overall outcomes of the Plan based on available data.

31.4.3 RESULTS

The results of the TEC viability analysis are presented throughout this chapter for each TEC assessment.

TECS SUBJECT TO DIRECT IMPACTS

31.5 SHALE SANDSTONE TRANSITION FOREST OF THE SYDNEY BASIN BIOREGION

This assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan on the TEC in accordance with the EPBC Terms of Reference. It sets out:

- *TEC background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the TEC*
- *Data tables*

THREATENED ECOLOGICAL COMMUNITY BACKGROUND

This section sets out the basic information about the TEC. It provides a description of the TEC, and an overview of the listing definition and its distribution. These provide context for the impact assessment. At the end of the section are links to key documents that provide additional background information.

EPBC ACT LISTING	Critically Endangered
DESCRIPTION	The TEC is a forest or open woodland with an overstorey dominated by various Eucalypt species and an understorey comprising sclerophyll shrubs, grasses and herbs. It occurs primarily on soils derived from shale substrates and is also found on weathered sandstone substrates. The TEC occurs in the transition zone between the Wianamatta Group shale that underlies the Cumberland Plain and the sandstone-dominated Hawkesbury Group of the surrounding subregions. The canopy is usually a mix of two or more of the following native tree species: Grey Gum (*Eucalyptus punctata*), Narrow-leaved Ironbark (*E. crebra*), Broad-leaved Ironbark (*E. fibrosa* subsp. *fibrosa*), Forest Red Gum (*E. tereticornis* subsp. *tereticornis*), Red Mahogany (*E. resinifera* subsp. *resinifera*), one or more stringybarks (*E. eugenioides* or *E. globoidea*), and Narrow-leaved Apple (*Angophora bakeri*). The mid-layer is commonly dominated by eucalypt species and Black She-oak (*Allocasuarina littoralis*). If a shrub layer is present, it is typically well-developed, diverse and dominated by *Bursaria spinosa* (blackthorn) in areas with low sandstone influence. The ground layer is diverse and dominated by grasses, graminoids and herbs. (DoE, 2014h) The following PCTs are associated with the TEC: • 792 Deane's Gum - Mountain Grey Gum - Turpentine tall moist forest on shale, Sydney Basin Bioregion • 1281 Turpentine - Grey Ironbark open forest on shale in the lower Blue Mountains, Sydney Basin Bioregion • 1395 Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion A range of fauna species occur in the TEC, including reptiles, amphibians, birds, micro-bats, and marsupials. Most of these fauna species are not restricted to the TEC and also occur in, and are likely to rely on, adjacent wetlands, grasslands, woodlands and forests. The TEC is equivalent to the NSW BC Act listed TEC Shale Sandstone Transition Forest where key diagnostic and condition thresholds are met (DoE, 2014h).

EPBC DEFINITION	Only patches of the TEC that meet minimum size and condition thresholds are considered part of the TEC under the EPBC Act. Thresholds relate to factors such as patch size, understorey native vegetation cover, number of tree hollows, or whether the patch is contiguous with other native vegetation patches. Details of the thresholds are provided in the Conservation Advice (DoE, 2014h).
DISTRIBUTION	The TEC is confined to the Sydney Basin bioregion, on the edge of the Cumberland subregion and the adjacent Hornsby, Woronora, and Lower Blue Mountains Plateau. The TEC primarily occurs at elevations below 200 m (but may occur up to 350 m in the Blue Mountains and 600 m in the Southern Highlands) with mean annual rainfall of 800 - 1100 mm. The TEC generally occurs on soils that are primarily derived from shale substrates with some influence from weathered sandstone substrates. It is also strongly associated with the Mittagong Formation (DoE, 2014h).
SOS SITES	The TEC has been categorised under the 'widespread' management stream for TECs under the SOS program. Management of this category of TECs focuses on planning and regulatory processes, policy and programs, and private land conservation and reservation of land. Currently no management sites have been identified for this TEC.
RELEVANT PLANS AND POLICIES	Approved Conservation Advice (including listing advice) for Shale Sandstone Transition Forest of the Sydney Basin Bioregion (EC25R) (DoE, 2014h) Key Threatening Processes relevant to the TEC are identified in Section 2.1 of the Conservation Advice There is no adopted or made Commonwealth Recovery Plan for the TEC Threat Abatement Plans relevant to the TEC are identified in Table 31-2

APPROACH TO BASELINE DATA

This section provides an overview of the approach to baseline data for the TEC. It:

- *Provides a summary of the approach to vegetation mapping for the strategic assessment which forms the baseline for the TEC mapping*
- *Outlines the vegetation condition states used in the mapping*
- *Identifies the NSW Plant Community Types (PCTs) that are associated with the TEC*
- *Summarises the approach to mapping the EPBC TEC*
- *Summarises the approach to the patch size analysis for the ecological community*
- *Summarises the approach to identifying areas of likely higher long-term viability in the Strategic Assessment Area*

Please refer to Section 11.3 (in Chapter 11) for details about the methods for mapping native vegetation, and Section 11.4.3 for details about the mapping methods for EPBC TECs.

APPROACH TO VEGETATION MAPPING	Native vegetation was mapped at two levels for the strategic assessment. Within the nominated areas, native vegetation was mapped using a method consistent with the BAM. This involved using a combination of API, existing desktop mapping, previous surveys and studies, rapid assessment ground-truthing, and field surveys (including floristic plot surveys). This process resulted in detailed maps of PCTs categorised by condition. Outside the nominated areas, native vegetation was mapped using the best available data integrated into a single dataset. Vegetation condition states were also applied across the broader area. It should be noted that comprehensive on-ground surveys across all native vegetation within the nominated areas was not possible and no surveys were undertaken outside the nominated areas. This means that a set of assumptions around the available data was required to translate the site

	based condition thresholds for the EPBC TEC so that it could be mapped at the scale of the Strategic Assessment Area. These assumptions are summarised below and explained in detail in Section 11.4.3 of Chapter 11.
VEGETATION CONDITION STATES	Vegetation condition was mapped using the following five condition states. These states generally range from better (intact) to worse (urban native/exotic) condition and are: • **Intact:** This condition state was assigned to areas of wooded vegetation community, including regrowth, that displays a range of structural layers and habitat features (e.g. tree hollows and large trees, fallen timber, leaf litter) with a largely unmodified canopy density and a range of age classes and species present • **Thinned:** This condition state was assigned to native vegetation in various states of modification, including: o Wooded vegetation with a partly-cleared canopy and a more open structure compared to the intact PCT o Wooded vegetation that has been under scrubbed • **Scattered trees:** This condition state includes a single tree or small group of trees surrounded by native or exotic pasture or areas of cultivation. Other structural components of the vegetation have typically been removed • **Grasslands:** Grasslands included two separate state zones – exotic grassland and native grasslands • **Urban native/exotic:** This condition type was assigned to areas of vegetation within urban areas that consisted of street trees, urban parks and other patches of planted vegetation that could provide habitat for native species
ASSOCIATED PCTs	The following PCTs are associated with the TEC: • 792 Deane's Gum - Mountain Grey Gum - Turpentine tall moist forest on shale, Sydney Basin Bioregion • 1281 Turpentine - Grey Ironbark open forest on shale in the lower Blue Mountains, Sydney Basin Bioregion • 1395 Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion
MAPPING APPROACH	Mapping of the TEC across the Strategic Assessment Area used the following criteria which are based on applying the condition thresholds at a landscape scale to the available data: • Patch size ≥ 0.5 ha, AND • > 50% of the perennial understorey vegetation cover is made up of native species (based on field verification), • Rainfall 800-1100 mm pa, AND • Growing on Shale or sandstone soil substrates OR • Patch size ≥ 2 ha, AND • > 50% of the perennial understorey vegetation cover is made up of native species (based on field verification), AND • Rainfall 800-1100 mm pa, AND • Growing on Shale or sandstone soil substrates OR • Patch size ≥ 0.5 ha, AND • ≥ 30% perennial understorey vegetation made up of natives, AND • The patch has at least one tree with hollows per ha or at least one large tree (≥ 80 cm dbh) per ha (based on field verification), OR, the patch is contiguous with a native vegetation remnant ≥1 ha • Rainfall 800-1100 mm pa, AND • Growing on Shale or sandstone soil substrates

	OR • Patch size ≥ 0.5 ha, AND • ≥ 50% perennial understorey vegetation made up of natives (based on field verification), AND • Rainfall 800-1100 mm pa, AND • Growing on Shale or sandstone soil substrates
PATCH SIZE ANALYSIS	As outlined in Section 31.3, a patch size analysis for the ecological community was undertaken to identify the number and size of patches across the Strategic Assessment Area.
VIABILITY ASSESSMENT	As outlined in Section 31.4, an analysis was undertaken to identify areas of likely higher long-term viability for the TEC in the Strategic Assessment Area The purpose of the analysis was to identify the patches of the TEC within the Strategic Assessment Area that are more likely to be viable in the longer-term to inform the evaluation of the overall outcome of the Plan for the TEC. Viability is defined in a qualitative sense as the "probability of long-term survival of TEC patches". The approach involved reviewing Conservation Advices for each TEC to identify the factors that influence the long-term viability or conservation significance of a patch of the TEC. This review found that Conservation Advices generally identify a similar set of factors that influence long-term viability. Key factors included: • Larger patches are generally more viable than smaller patches • Better condition patches are generally more viable than poorer condition patches • Connected patches are generally more viable than poorer connected patches • Patches with a lower edge/area ratio are generally more viable than patches with a higher edge/area ratio

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the TEC in the Strategic Assessment Area. It includes reference to a map which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where the TEC occurs.

MAP	See Map 48.6 for a map of the TEC across the Strategic Assessment Area.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	The baseline mapping for this assessment mapped approximately 8,214 ha of the TEC within the Strategic Assessment Area (see Table 31-3 for further details). Of this, approximately 5,899 ha has been identified as higher viability through the viability analysis. The TEC occurs in the following main locations within the Strategic Assessment Area: • In the north west, around North Richmond • In the mid-west, near Silverdale, Oakdale and Werombi • In the south, around Wilton and the southern part of GMAC It occurs in the following nominated areas: • Wilton – 1,006.5 ha total, 522.7 ha of this identified as higher viability • GMAC – 1,719.6 ha total, 1,127.4 ha of this identified as higher viability • GPEC – 1.7 ha total, 0 ha of this identified as higher viability It does not occur in WSA or the transport corridors outside the nominated areas. The Conservation Advice does not specifically identify any sites in the Strategic Assessment Area that are important to the TEC. The Conservation Advice states that all areas that meet the minimum condition thresholds as defined in the advice (categories A to D) are considered habitat critical to the survival of the TEC. These are generally: • Patch size (≥ 0.5 ha) with ≥ 30% native understory • Well-connected patches ≥ 1 ha in area or the patch has at least one tree with hollows or at least one large locally indigenous tree (> 80 cm dbh)

	The Conservation Advice also identifies several factors affecting the value of a patch, including: • A larger size and/or a high area to boundary ratio • Part of a larger remnant of native vegetation or linking other remnants • Evidence of recruitment of key plant species/range of age cohorts • High native species richness • Presence of threatened species • Low level of weeds and pest animals The TEC is highly fragmented across the Strategic Assessment Area, comprising 817 patches with an average patch size of 10 ha.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of the TEC that was avoided through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

31.5.1 NOMINATED AREAS

The baseline mapping for this assessment mapped 2,138 ha of the TEC within the nominated areas (not including excluded lands). Approximately 1,947 ha (91 per cent) has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 1,691 ha was avoided for biodiversity purposes
- 255 ha was avoided for other purposes

An additional 589.6 ha occurs on excluded lands.

A breakdown of avoidance across each nominated area is provided in Table 31-4.

It is important to note that the avoidance calculations in Table 31-4, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 31-4 shows the amounts of habitat within excluded lands for context only.

31.5.2 TRANSPORT

Avoidance results are only reported for urban development within the nominated areas, as detailed design of the footprint within the Transport Corridors has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts. It considers:

- *Predicted impacts within urban capable lands and transport corridors*
- *Potential issues associated with fragmentation*
- *Potential additional impacts from essential infrastructure (within nominated areas but outside the urban capable lands) and tunnels associated with transport projects*

Offsets are provided for any TECs that are subject to direct impacts. The rationale and process for setting offset targets for TECs is set out in Section 8.5.2 of Chapter 8, and explained in detail in the Conservation Priorities Method that supports the Plan.

Implementation of the Plan will lead to direct impacts to the TEC (see Section 31.5.3 for discussion) but will not generally increase fragmentation (see Section 31.5.4 for discussion).

31.5.3 DIRECT IMPACTS TO THE TEC

Implementation of the Plan will lead to a loss of a total of 191.8 ha of the TEC within Wilton and GMAC. There will be no direct impacts within WSA, GPEC or transport corridors outside the nominated areas. These impacts represent approximately 2.3 per cent of the remaining TEC in the Strategic Assessment Area and 7 per cent of the TEC in the nominated areas. A breakdown of direct impacts is provided in Table 31-5.

The majority of the TEC that will be impacted within Wilton and southern GMAC:

- Is in thinned condition (135.7 ha), with only 22.5 per cent of direct impacts occurring to patches in intact condition
- Comprises small patches (less than 5 ha) (approximately 62 per cent)
- Is not mapped as higher viability, with only 33.7 ha of higher viability TEC being directly impacted

The most notable direct impacts to the TEC occur in Wilton and southern GMAC due to urban development. The threat to the TEC in these locations is reduced because:

- Impacts generally occur only to the edges of patches of the TEC that remain connected to larger patches of native vegetation associated with the gullies and gorges of Wilton and GMAC, and will not generally fragment or isolate patches of the TEC
- Potential habitat corridors along waterways that may be used by species associated with the TEC will be maintained
- The impact in the context of the amount remaining in the Strategic Assessment Area is relatively minor

31.5.4 FRAGMENTATION OF THE TEC

As outlined above, impacts largely occur to the edges of patches within Wilton and GMAC and will not result in a loss of connectivity (and therefore will not lead to fragmentation). Areas of the TEC that will not be impacted within these two nominated areas generally provide important habitat for Koalas and often form part of primary and secondary corridors for the species. As outlined in Chapter 30, a significant focus of the Plan is protecting these Koala corridors and maintaining connectivity for Koalas. These processes have helped avoid any notable fragmentation to the TEC.

31.5.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

To compensate for the predicted direct impacts to the TEC, the Plan includes a commitment (Commitment 8.1) to secure 715 ha of the TEC as part of the conservation program. This would:

- Lead to the protection and management of an additional 8.7 per cent of the ecological community within the Strategic Assessment Area
- Increase the level of protection and management of the ecological community by approximately 98.1 per cent on top of what is currently secured in the Strategic Assessment Area

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the TEC that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the TEC if:

- *The indirect impact is identified as a threat in a relevant profile or conservation advice, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

31.5.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice (DoE, 2014h) identifies a range of threats to the TEC. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential indirect impacts (identified as threats in the Conservation Advice) are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Inappropriate habitat disturbance
- Changes to hydrology
- Diseases, pathogens and dieback
- Invasive fauna

Climate change is also a relevant threat to the ecological community. The extent to which the Plan has considered adaptation to climate change impacts is addressed in Chapter 41.

Impacts from inappropriate grazing regimes, soil salinisation, and mining were also identified in the Conservation Advice as key threats. However, none of these are considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate these risks across the Strategic Assessment Area.

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes can affect the structure and species composition of the TEC (DoE, 2014h). This can be caused by:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact the TEC. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development. For the TEC this includes areas in and around Wilton and the southern part of GMAC where significant areas of the TEC are present.

The key factors that influence the appropriateness of a fire regime are fire frequency, intensity and season of occurrence (DECCW, 2011). The Conservation Advice (DoE, 2014h) and the Cumberland Plain Recovery Plan (DECCW, 2011) provide information on fire regimes suitable for the TEC.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant to the outcome for the TEC being:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the Strategic Conservation Areas (SCAs) that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas

- Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from the TEC. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes.

Also relevant for the TEC is the fact that it largely overlaps with Koala habitat which is a key focus of the Plan in terms of protection and management. Significant areas of Koala habitat will be managed which will include the application of the fire management strategy and a set of measures to control access to bushland which will help minimise risks around arson and accidental fires.

The package of measures in the Plan is expected to adequately manage the risk to the TEC from altered fire regimes as a result of development. This is because:

- Avoided lands where large areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting the TEC
- Fire management authorities will be engaged to ensure they understand the requirements of the TEC and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas
- The measures in the Plan for Koalas in terms of protecting and managing habitat, and constraining access to bushland will help protect the TEC

The commitments and actions under the Plan are consistent with a number of high priority actions in the Conservation Advice (DoE, 2014h). For example:

- To "integrate fire…management regimes"
- To "implement appropriate fire management regimes that take into account results from research"

WEED INVASION

The TEC is threatened with invasion of weeds. Weeds can displace native plants and reduce the diversity and regenerative capacity of the TEC (DoE, 2014h). Weed incursion in the TEC is associated with agricultural activities as well as urban development.

Key weeds that can occur in the TEC include: African Olive (*Olea europaea* subsp. *cuspidata*), Fireweed (*Senecio madagascariensis*), Spear Thistle (*Cirsium vulgare*), Cat's Ear (*Hypochaeris radicata*), Pigeon Grass (*Setaria gracilis*), Plantain (*Plantago lanceolata*), Paddy's Lucerne (*Sida rhombifolia*), Bridal Creeper (*Myrsiphyllum asparagoides*), Sow Thistle (*Sonchus oleraceus*), and Broad-leafed and Small-leaf Privet (*Ligustrum lucidum* and *L. Sinense*) in wetter areas.

The most serious threats to the TEC are from Bridal Creeper and African Olive as they are highly competitive and difficult to manage (DoE, 2014h).

These weeds are already present within the Strategic Assessment Area and pose a threat to the TEC. However, urban development and transport have the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or changing conditions to favour weeds.

The TEC is most susceptible to the threat of weeds from development under the Plan where new urban development occurs adjacent to the TEC and introduces edge effects. Key risk areas include:

- In north and north west of Wilton, where the urban capable land impacts the edges of patches of the TEC connected to gorges and gullies on the edge of the nominated area
- In the southern part of GMAC, where the urban capable land impacts the edges of patches of the TEC connected to gorges and gullies on the edge and middle of the nominated area

The Plan incorporates a range of measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Areas. This includes a number of actions, of which the following are the most relevant to the outcome for the TEC:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

Importantly for the TEC, weeds will be actively managed within the 715 ha to be added to conservation as part of the offset program.

The package of measures in the Plan is expected to adequately manage the risk posed to the TEC from weed invasion. This is because:

- Avoided lands where large areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- The Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy. This includes the land to be protected under the conservation program for the TEC
- There will be a range of planning controls to minimise the potential spread of weeds during and after construction

These controls are consistent with a number of threat abatement actions in the Conservation Advice about the management of invasive species.

INAPPROPRIATE HABITAT DISTURBANCE

Inappropriate habitat disturbance is identified in the Conservation Advice (DoE, 2014h) as a threat to the TEC. This relates to a wide range of different mechanisms for disturbance including:

- Inappropriate mowing, slashing or scrubbing of the understorey for reasons such as bushfire fuel reduction, grazing and perceived aesthetics
- Dumping of rubbish and garden waste which can directly impact areas of the TEC as well as facilitate increases in weeds (see above) and pollutants

- Inappropriate recreational activities such as ad hoc track building and trail bike use which can directly impact areas of the TEC and facilitate processes such as erosion
- Removal of wood which changes the structure and habitat features of the TEC
- Inadvertent disturbance during construction which has the potential to directly impact the TEC outside approved development areas

Each of these mechanisms have the potential to alter the structure and floristic composition of the TEC.

Inappropriate habitat disturbance within the Strategic Assessment Area may increase due to development within the nominated areas. Occurrences of the TEC considered most at risk are those that occur in close proximity to development within Wilton and GMAC.

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for the TEC. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- A commitment (Commitment 7) to mitigate indirect and prescribed impacts from urban, infrastructure and major infrastructure (transport) development on Koalas. This is relevant to the TEC because the vast majority of the TEC is identified as important Koala habitat. Of particular relevance to habitat disturbance are associated actions around the use of exclusion fencing which will assist in controlling access to Koala habitat. These measures will help minimise inappropriate habitat disturbance to the TEC within both Wilton and GMAC
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations (including the 715 ha for the TEC)
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas. This commitment is consistent with a number of actions in the Conservation Advice around educating the community about the TEC

The package of measures in the Plan is expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development. This is because:

- Avoided lands where large areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- The measures in the Plan for Koalas in terms of protecting and managing habitat, and constraining access to bushland will help protect the TEC
- A program of education for the community will be run to help them understand the biodiversity values they live near

CHANGES TO HYDROLOGY

The creation of hard surfaces associated with urban development and transport results in changes to the hydrology of surrounding areas. The main threat to the TEC associated with altered hydrology is increased runoff into patches of the

TEC carrying high nutrient and sediment loads, as well as weed seeds or propagules. This can both encourage weed invasion and cause erosion (DoE, 2014h).

The TEC is most susceptible to the threat of increased runoff from development under the Plan where new urban or transport development occurs adjacent (and upstream or upslope) to the TEC. Key risk areas are:

- In north and north west of Wilton
- In the southern part of GMAC

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for the TEC. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5) and transport (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through:

- Development controls in the nominated areas in relation to:
  - Water cycle management. For example:
    - Water management measures must comply with council's requirements for detention, drainage and water sensitive urban design principles
    - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
  - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
  - Soil erosion and sedimentation. For example:
    - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
    - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom 2004) and submitted with each subdivision development application
- The implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the RMS Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the TEC from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts to the TEC
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to the TEC

The commitments and actions under the Plan are consistent with the following high priority action in the Conservation Advice (DoE, 2014h): "Manage any changes to hydrology or disruptions to water flows that may result in changes to water table levels and/or increased run-off, salinity, sedimentation or pollution".

DISEASES, PATHOGENS AND DIEBACK

TECs are potentially susceptible to a range of diseases, pathogens and dieback which can substantially affect their long term viability. Recognised threats include myrtle rust and dieback caused by the root-rot fungus *Phytophthora cinnamomi*.

Development under the Plan may increase the risk of the spread of infection/disease. This is primarily related to:

- Soil transportation on contaminated footwear, vehicles and machinery, and in residential garden establishment
- Increased site visitation rates
- Earthworks and activities conducted during construction
- Increased surface water runoff

The Plan incorporates a range of measures to manage the risks associated with diseases, pathogens and dieback. In summary, these include:

- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
  - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
  - Entering into written agreements with delivery partners to implement priority disease control programs
- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures methods to protect the environment during construction, including best practice site hygiene protocols to minimise spread of *Phytophthora* and Myrtle Rust

The package of measures in the Plan is expected to adequately manage the risk to the TEC from diseases, pathogens and dieback because:

- It supports a landscape scale approach to the issue across the Cumberland subregion
- It will ensure appropriate controls during construction

The commitments and actions under the Plan are consistent with a number of high priority actions in the Conservation Advice (DoE, 2014h). For example:

- To "manage any other known, potential or emerging threats such as rural tree dieback"
- To "use appropriate hygiene to minimise the introduction or spread of plant diseases and weeds at susceptible sites"

INVASIVE FAUNA

The Conservation Advice (DoE, 2014h) identifies introduced animals and aggressive native species as a threat to the TEC. These species include:

- Domestic species such as cats and dogs which are related to urban development
- Pest species such as foxes, rats, house mice and rabbits which are primarily related to agricultural development
- Aggressive bird species which compete for resources including the introduced Indian myna, and native species such as the sulphur-crested cockatoo

Collectively, these animals can lead to declines in biodiversity through:

- Predation
- Damage to vegetation and soils
- Competition for resources

Existing land use within the nominated areas and surrounding region (which includes residential and rural residential areas, and farming) means that these issues are already present in the Strategic Assessment Area and are unlikely to pose a novel threat to the TEC.

However, the extent of proposed new urban development under the Plan means that the threats associated with cats and dogs are likely to be exacerbated. It is likely that there will be an increase in the number of domestic cats and dogs in the local area, which, in turn, may lead to an increase in feral cat and wild dog numbers. The main areas of concern relate to new urban development in Wilton and the southern section of GMAC, where the current density of houses is low.

Agricultural development within Wilton and GMAC is not part of the Plan. As a result a substantial increase in pest species (other than feral cats or wild dogs) is not expected to occur as a result of implementation of the Plan.

In relation to aggressive bird species, the two main drivers for increasing the threat within the TEC are:

- Fragmentation of habitat which creates greater edge effects and facilitates access by aggressive bird species. As outlined above in the analysis of direct impacts, the Plan is considered unlikely to lead to any notable fragmentation to the TEC and as such is not considered an issue

- Habitat disturbance through inappropriate land management which can change the structure of the TEC and facilitate access by aggressive bird species. As outlined above in relation to inappropriate habitat disturbance, the Plan includes a package of measures which are expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development

In relation to the residual risks associated with invasive fauna, the Plan incorporates a range of measures to manage the risks. In summary, these include:

- A commitment (Commitment 17) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the Strategic Conservation Areas. This includes a number of actions with the most relevant to the outcome for the TEC being:
  - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
  - Preparation of a Pest Animal Control Implementation Strategy
  - A process to enter into written agreements with delivery partners to implement the pest animal control program
  - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Development controls that will:
  - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
  - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
  - Require appropriate management and control of pest animals relevant to development sites
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing pests, consistent with the pest animal implementation strategy outlined in Commitment 16

The commitments and actions under the Plan are consistent with the following high priority action in the Conservation Advice (DoE, 2014h): "Control introduced pest animals, including domestic pets, to allow natural regeneration and to manage threats, especially to threatened species".

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the TEC from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts due to urban development analysed above, there is the potential for impacts to the TEC to occur due to development of essential infrastructure within nominated areas but outside the urban capable lands.

The TEC does not occur within the vicinity of the tunnel footprints for transport and is therefore not at risk of additional impacts from tunnels.

31.5.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

The TEC occurs on avoided land within Wilton (753.7 ha) and GMAC (1,192.8 ha), but not WSA or GPEC. It is possible that some of the areas on avoided land within Wilton and GMAC will be impacted by essential infrastructure. Impacts to the TEC are probable as the majority of the TEC occurs within lands avoided for biodiversity purposes between urban capable lands and on the edge of GMAC bordering with Wilton.

To limit the potential impacts to the TEC from essential infrastructure, the guidelines for essential infrastructure development include the following requirements: "Limit the total cumulative direct impacts within avoided lands to Shale Sandstone Transition Forest in the Sydney Basin Bioregion over the life of the Plan to no more than 20 ha in Wilton and 20 ha in GMAC".

As outlined in Chapter 37, any proposed essential infrastructure developments on avoided lands in the nominated areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine if the TEC was present
- Measures to avoid impacts to the listed TEC through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

The maximum additional impact to the TEC from essential infrastructure will be 40 ha. It is likely that the actual impacts will be less due to the proposed avoidance processes. In addition, any impacts that do occur will be adequately mitigated and offset through the application of the BAM. See Section 37.6 in Chapter 37 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE TEC

This section considers the likely effects of implementation of the Plan on the long-term viability of the TEC. The analysis has regard for the guidance in the Conservation Advice (there is no Recovery Plan for the TEC), and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also identifies any relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

31.5.8 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DoE, 2014h) identifies the following key issues that are likely to have the greatest influence on the long-term viability of the TEC in relation to implementation of the Plan. They are:

- Habitat loss and fragmentation
- Indirect impacts including:
  - Inappropriate fire regimes
  - Weed invasion
  - Inappropriate habitat disturbance
  - Changes to hydrology
  - Diseases, pathogens and dieback
  - Invasive fauna

HABITAT LOSS AND FRAGMENTATION

As outlined above, implementation of the Plan may lead to the loss of 191.8 ha of the TEC within the urban capable lands within the nominated areas, and potentially an additional 40 ha within avoided lands due to essential infrastructure. However, it is not considered likely that this will threaten the long-term viability of the TEC because:

- The majority of the remaining areas of higher viability TEC in the nominated areas have been avoided and are not impacted by the Plan, including:
  - 1,141 ha avoided for biodiversity purposes
  - 205 ha avoided for other purposes
- The majority of impacts are to lower viability areas of the TEC:
  - 0.6 per cent of higher viability TEC in the Strategic Assessment Area
  - 2.0 per cent of higher viability TEC in the nominated areas
- The impacts are unlikely to increase the level of fragmentation

- The offsets proposed by the Plan (715 ha of the TEC) will provide a substantial addition to the level of protection of the TEC and will support a key high priority action in the Conservation Advice to increase the area of larger, high quality patches of TEC that is secured and managed for conservation

It is worth noting that two of the reserves proposed by the Plan contain substantial areas of the TEC. They are:

- The Georges River Koala Reserve which is on the eastern side of the Strategic Assessment Area near GMAC. This will be implemented in two stages over the first 10 years of the Plan and contains approximately 375 ha of the TEC
- The Gulguer Reserve investigation area which occurs on the western side of the Strategic Assessment Area. The Plan proposes to implement the reserve over the first 20 years of the Plan. The area contains approximately 600 ha of the TEC

INDIRECT IMPACTS

The potential indirect impacts associated with inappropriate fire regimes, weed invasion, inappropriate habitat disturbance, changes to hydrology, diseases, pathogens and dieback, and invasive fauna will be managed and mitigated through a number of commitments and actions in the Plan.

Indirect impacts are not expected to influence the long-term viability of the TEC.

CONCLUSION

The nature of the impacts to the TEC combined with the commitments to protect 715 ha of the TEC and manage indirect impacts will ensure that the implementation of the Plan does not adversely influence the long-term viability of the TEC.

31.5.9 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the TEC.

31.5.10 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 31-2 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The Plan is not inconsistent with any of the relevant TAPs. Please refer to Section 15.9 of Chapter 15 for a detailed discussion of each TAP and the relationship of the Plan.

Table 31-2: Key Threatening Processes and relevant Threat Abatement Plans for Shale Sandstone Transition Forest of the Sydney Basin Bioregion

KEY THREATENING PROCESS	RELEVANT THREAT ABATEMENT PLAN
Aggressive exclusion of birds from potential woodland and forest habitat by over-abundant noisy miners (*Manorina melanocephala*)	There is no relevant TAP
Dieback caused by the root-rot fungus (*Phytophthora cinnamomi)*	There is no relevant TAP
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Predation by feral cats	Threat abatement plan for predation by feral cats (DoE, 2015g)

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

31.6 CUMBERLAND PLAIN SHALE WOODLANDS AND SHALE-GRAVEL TRANSITION FOREST

This assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan on the TEC in accordance with the EPBC Terms of Reference. It sets out:

- *TEC background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the TEC*
- *Data tables*

THREATENED ECOLOGICAL COMMUNITY BACKGROUND

This section sets out the basic information about the TEC. It provides a description of the TEC, and an overview of the listing definition and its distribution. These provide context for the impact assessment. At the end of the section are links to key documents that provide additional background information.

EPBC ACT LISTING	Critically Endangered
DESCRIPTION	The TEC is a temperate eucalypt woodland which is endemic to the shale hills and plains of the Sydney Basin bioregion and is mostly found within the Cumberland subregion. The TEC ranges from grassy woodland to forest, with the understorey ranging from mostly grassy to mostly shrubby. Occasional stands of this TEC are dense, particularly in shale-gravel transition areas. The TEC may have an upper tree layer, lower tree layer, shrub layer and a ground layer, although one or more layers may be sparse or absent. It must have an upper tree layer present, in addition to either a ground or shrub layer, to meet the EPBC definition of the TEC. The upper tree canopy is often dominated by *Eucalyptus moluccana*, *E. tereticornis*, *E. fibrosa*, *E. crebra* or other canopy species that may be locally dominant in some areas. The lower tree layer may include *Acacia* species, *Melaleuca* species, *Exocarpos* and young eucalypts. Shrub layers may be present and are often dominated by *Bursaria spinosa*, with a number of other species present. Ground layers comprise perennial native grasses, graminoids and non-woody plants. A range of fauna species occur in the TEC, including reptiles, amphibians, birds, micro-bats, and marsupials. Most of these fauna species are not restricted to the TEC and also occur in, and are likely to rely on, other native vegetation in the Cumberland subregion. The TEC correlates to two NSW BC Act listed TECs (Cumberland Plain Woodland, and Shale Gravel Transition Forest) where key diagnostic and condition thresholds are met. (DEWHA, 2009a)
EPBC DEFINITION	Only patches of the TEC that meet minimum size and condition thresholds are considered part of the TEC under the EPBC Act. Thresholds relate to factors such as projected foliage cover percentage, patch size, understorey native vegetation cover, number of tree hollows, or whether the patch is contiguous with other native vegetation patches. Details of the thresholds are provided in the listing advice (TSSC, 2009).

DISTRIBUTION	The TEC is confined to the Sydney Basin bioregion and mostly restricted to the Cumberland subregion. The TEC is scattered across the subregion. The TEC primarily occurs in a coastal valley rain shadow, with mean annual rainfall of 700 to 900 mm (TSSC, 2009) and may occur in some elevated areas with higher (orogenic) rainfall. It occurs on flat to undulating or hilly terrain, up to 350 m or slightly higher, and is mostly found on clay soils derived from the Wianamatta Group geological unit (DEWHA, 2009a).
SOS SITES	The two TECs listed under the BC Act that correlate to the TEC are being managed under the Saving our Species program. The management programs for these TECs are still being developed. Currently, no management sites have been identified for this TEC.
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest (DEWHA, 2009a) Listing Advice for Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest (TSSC, 2009) Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest Policy Statement 3.31 (DEWHA, 2010) There is no adopted or made Commonwealth Recovery Plan for the TEC. The TEC is included in the Cumberland Plain Recovery Plan (NSW) (DECCW, 2011) Key Threatening Processes and Threat Abatement Plans relevant to the TEC are identified in Table 31-6.

APPROACH TO BASELINE DATA

This section provides an overview of the approach to baseline data for the TEC. It:

- *Provides a summary of the approach to vegetation mapping for the strategic assessment which forms the baseline for the TEC mapping*
- *Outlines the vegetation condition states used in the mapping*
- *Identifies the NSW Plant Community Types (PCTs) that are associated with the TEC*
- *Summarises the approach to mapping the EPBC TEC*
- *Summarises the approach to the patch size analysis for the ecological community*
- *Summarises the approach to identifying areas of likely higher long-term viability in the Strategic Assessment Area*

Please refer to Section 11.3 (in Chapter 11) for details about the methods for mapping native vegetation, and Section 11.4.3 for details about the mapping methods for EPBC TECs.

APPROACH TO VEGETATION MAPPING	Native vegetation was mapped at two levels for the strategic assessment. Within the nominated areas, native vegetation was mapped using a method consistent with the BAM. This involved using a combination of API, existing desktop mapping, previous surveys and studies, rapid assessment ground-truthing, and field surveys (including floristic plot surveys). This process resulted in detailed maps of PCTs categorised by condition. Outside the nominated areas, native vegetation was mapped using the best available data integrated into a single dataset. Vegetation condition states were also applied across the broader area. It should be noted that comprehensive on-ground surveys across all native vegetation within the nominated areas was not possible and no surveys were undertaken outside the nominated areas. This means that a set of assumptions around the available data was required to translate the site based condition thresholds for the EPBC TEC so that it could be mapped at the scale of the Strategic Assessment Area. These assumptions are summarised below and explained in detail in Section 11.4.3 of Chapter 11.

VEGETATION CONDITION STATES	Vegetation condition was mapped using the following five condition states. These states generally range from better (intact) to worse (urban native/exotic) condition and are:
	• **Intact:** This condition state was assigned to areas of wooded vegetation community, including regrowth, that displays a range of structural layers and habitat features (e.g. tree hollows and large trees, fallen timber, leaf litter) with a largely unmodified canopy density and a range of age classes and species present
	• **Thinned:** This condition state was assigned to native vegetation in various states of modification, including:
	  o Wooded vegetation with a partly-cleared canopy and a more open structure compared to the intact PCT
	  o Wooded vegetation that has been under scrubbed
	• **Scattered trees:** This condition state includes a single tree or small group of trees surrounded by native or exotic pasture or areas of cultivation. Other structural components of the vegetation have typically been removed
	• **Grasslands:** Grasslands included two separate state zones – exotic grassland and native grasslands
	• **Urban native/exotic:** This condition type was assigned to areas of vegetation within urban areas that consisted of street trees, urban parks and other patches of planted vegetation that could provide habitat for native species

ASSOCIATED PCTs	The following PCTs are associated with the TEC: • 724 Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion • 849 Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion • 850 Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion
MAPPING APPROACH	Mapping of the TEC across the Strategic Assessment Area used the following criteria which are based on applying the condition thresholds at a landscape scale to the available data: • Patch size ≥ 0.5 ha, AND • > 10% canopy cover • > 50% perennial understorey vegetation made up of natives (based on field verification), AND • Generally below 350 m elevation, AND • Growing on clay soils derived from Wianamatta OR • Patch size ≥ 5 ha, AND • > 10% canopy cover • > 30% perennial understorey made up of natives (based on field verification), AND • Generally below 350 m elevation, AND • Growing on clay soils derived from Wianamatta OR • Patch size ≥ 0.5 ha, AND • > 30% perennial understorey vegetation made up of natives, AND • The patch is contiguous with a native vegetation remnant ≥ 0.5 ha, AND • Generally below 350 m elevation, AND • Growing on clay soils derived from Wianamatta

	OR • Patch size ≥ 0.5 ha, AND • > 30% perennial understorey vegetation made up of natives, AND • The patch has at least one tree with hollows per ha or at least one large tree (≥80 cm) per ha (based on field verification), AND • Generally below 350 m elevation, AND • Growing on clay soils derived from Wianamatta
PATCH SIZE ANALYSIS	As outlined in Section 31.3, a patch size analysis for the ecological community was undertaken to identify the number and size of patches across the Strategic Assessment Area.
VIABILITY ASSESSMENT	As outlined in Section 31.4, an analysis was undertaken to identify areas of likely higher long-term viability for the TEC in the Strategic Assessment Area The purpose of the analysis was to identify the patches of the TEC within the Strategic Assessment Area that are more likely to be viable in the longer-term to inform the evaluation of the overall outcome of the Plan for the TEC. Viability is defined in a qualitative sense as the "probability of long-term survival of TEC patches". The approach involved reviewing Conservation Advices for each TEC to identify the factors that influence the long-term viability or conservation significance of a patch of the TEC. This review found that Conservation Advices generally identify a similar set of factors that influence long-term viability. Key factors included: • Larger patches are generally more viable than smaller patches • Better condition patches are generally more viable than poorer condition patches • Connected patches are generally more viable than poorer connected patches • Patches with a lower edge/area ratio are generally more viable than patches with a higher edge/area ratio

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the TEC in the Strategic Assessment Area. It includes reference to a map which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where the TEC occurs.

MAP	See Map 48.4 for a map of the TEC across the Strategic Assessment Area.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	The baseline mapping for this assessment has mapped approximately 9,737 ha of the TEC within the Strategic Assessment Area (see Table 31-7 for further details). Of this, approximately 4,310 ha has been identified as higher viability through the viability analysis. The TEC occurs in the following main locations in the Strategic Assessment Area: • Scheyville National Park (474 ha) • Orchard Hills (426.6 ha) • Holsworthy (patch size 238 ha) • Wianamatta Regional Park (185 ha) • Cobbitty (145 ha) • Agnes Banks (138 ha) • Bringelly (137 ha) It occurs in the following nominated areas: • Wilton – 11.5 ha including 1.2 ha that is higher viability • GMAC – 92.0 ha including 8.1 ha that is higher viability • WSA – 85.9 ha including 0.1 ha that is higher viability • GPEC – 1,014.3 ha including 314.0 ha that is higher viability

	43.8 ha also occurs in transport corridors outside the nominated areas. Of this, 5.8 ha is higher viability. The Listing Advice (TSSC, 2009) does not specifically identify any sites in the Strategic Assessment Area that are important to the TEC. It states that all patches meeting the minimum condition thresholds as defined in the advice are considered habitat critical to the survival of the TEC. These are generally: • Patches ≥ 0.5 ha with a predominately native understory • Patches that are well-connected to other large (≥ 5 ha) native vegetation remnants in the landscape • Patches that have large mature trees (≥ 80 cm dbh) or trees with hollows The Listing Advice also identifies several factors affecting the value of a patch, including: • A larger size and/or a high area to boundary ratio • Part of a larger remnant of native vegetation or linking other remnants • Evidence of recruitment of key plant species/range of age cohorts • Low level of weeds and pest animals • High native species richness, particularly in the ground layer • Presence of threatened species The TEC is highly fragmented across the Strategic Assessment Area, comprising over 1,900 patches with an average patch size of 4.9 ha. A total of six patches are greater than 100 ha, and 26 patches are greater than 50 ha in size. A number of patches are connected to areas of other vegetation types, which improves vegetation connectivity and provides some buffer from potential impacts associated with edge effects that would otherwise be expected with such a scattered distribution.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of the TEC that was avoided through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

31.6.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 204 ha of the TEC within the nominated areas (not including excluded lands). Approximately 94 ha (46 per cent) has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 74 ha was avoided for biodiversity purposes
- 19 ha was avoided for other purposes

An additional 999 ha occurs on excluded lands.

A breakdown of avoidance across each nominated area is provided in Table 31-8.

It is important to note that the avoidance calculations in Table 31-8, including for ‘avoidance for biodiversity purposes’, ‘avoidance for other reasons’, and ‘total avoidance’, have been calculated without including excluded lands as these lands are not covered by the Plan. Table 31-8 shows the amounts of habitat within excluded lands for context only.

31.6.2 TRANSPORT

Avoidance results are only reported for urban development within the nominated areas, as detailed design of the footprint within the Transport Corridors has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts. It considers:

- *Predicted impacts within urban capable lands and transport corridors*
- *Potential issues associated with fragmentation*
- *Potential additional impacts from essential infrastructure (within nominated areas but outside the urban capable lands) and tunnels associated with transport projects*

Offsets are provided for any TECs that are subject to direct impacts. The rationale and process for setting offset targets for TECs is set out in Section 8.5.2 of Chapter 8, and explained in detail in the Conservation Priorities Method that supports the Plan.

Implementation of the Plan will lead to direct impacts to the TEC (see Section 31.6.3 for discussion) but will not generally increase fragmentation (see Section 31.6.4 for discussion).

31.6.3 DIRECT IMPACTS TO THE TEC

Implementation of the Plan will lead to a loss of a total of 154.7 ha of the TEC within the nominated areas and transport corridors. This loss represents approximately 1.6 per cent of the remaining TEC in the Strategic Assessment Area and 12.9 per cent of the TEC in the nominated areas. A breakdown of direct impacts is provided in Table 31-9.

The majority of the TEC impacted:

- Is in thinned condition (128.1 ha), with only 14.6 per cent of direct impacts occurring to patches in intact condition
- Comprises small patches (0.5-5 ha)
- Is not mapped as higher viability, with only 12.1 ha of higher viability TEC being impacted

The most notable direct impacts to the TEC occur in the following locations:

- Within GPEC, which will result in the loss of several small (0.5-5 ha) generally isolated patches of the TEC and reduces the size of a few larger patches. Less than 0.1 ha of these impacted areas is mapped as higher viability
- The loss of an area of partially connected patches associated with a riparian corridor in the southern portion of WSA near Luddenham and Bringelly. Less than 0.1 ha of these impacted areas is mapped as higher viability
- At Cobbitty due to the OSO and Shanes Park due to the M7 link

The threat to the TEC in these locations is reduced because:

- The Plan mainly impacts patches of the TEC that are generally isolated and exposed to edge effects
- The amount of impact in the context of the amount remaining in the Strategic Assessment Area is relatively minor
- Impacts account for less than 0.3 per cent of mapped higher viability TEC across the Strategic Assessment Area

31.6.4 FRAGMENTATION OF THE TEC

As outlined above, impacts largely occur to small, isolated patches or to the edge of patches and are not expected to further fragment the TEC.

31.6.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

To compensate for the predicted direct impacts to the TEC, the Plan includes a commitment to secure 575 ha of the TEC as part of the conservation program. This would:

- Lead to the protection and management of an additional 5.9 per cent of the ecological community within the Strategic Assessment Area
- Increase the level of protection and management of the ecological community by approximately 28.5 per cent on top of what is currently secured in the Strategic Assessment Area

These offsets also help address an identified threat in the Conservation Advice around the low level of protection of the TEC in reserves.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the TEC that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the TEC if:

- *The indirect impact is identified as a threat in a relevant profile or conservation advice, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

31.6.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice (DEWHA, 2009a) identifies a range of threats to the TEC. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential indirect impacts (identified as threats in the Conservation Advice) are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Inappropriate habitat disturbance

In addition to the threats identified in the Conservation Advice, the following potential indirect impacts are considered relevant to the TEC:

- Changes to hydrology
- Diseases, pathogens and dieback
- Invasive fauna

Climate change is also a relevant threat to the ecological community. The extent to which the Plan has considered adaptation to climate change impacts is addressed in Chapter 41.

Impacts from inappropriate grazing regimes were also identified in the Conservation Advice as a key threat. However, this is not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate this risks across the Strategic Assessment Area.

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes can affect the structure and species composition of the TEC. This can be caused by:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

Altered fire regimes can affect the structure and species composition of the TEC, particularly the understorey layers. Fire intervals of 4 to 12 years are likely to maintain most understorey species within the TEC. Fire intervals which are too short are associated with reduced native plant diversity (NSW Scientific Committee, 2009).

An absence of fire for extended periods of time can also result in proliferation of Blackthorn (*Bursaria spinosa*). Dense occurrences occur when fire has been absent from the TEC for a number of decades. Blackthorn has been recorded in densities of up to 1,000 plants per ha in unburnt patches of this TEC, leading to the decline of ground layer species. High densities of Blackthorn currently occur in many TEC remnants (TSSC, 2009).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact the TEC. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development. For the TEC this includes areas in and around GPEC, WSA and GMAC, and to a lesser degree in Wilton where the TEC is much less extensive.

The key factors that influence the appropriateness of a fire regime are fire frequency, intensity and season of occurrence (DECCW, 2011).

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant to the outcome for the TEC being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy for the Strategic Conservation Areas that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
    - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from the TEC. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the TEC from altered fire regimes as a result of development. This is because:

- Avoided lands where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting the TEC
- Fire management authorities will be engaged to ensure they understand the requirements of the TEC and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas

WEED INVASION

The TEC is threatened with invasion of weeds. Weeds can displace native plants and reduce the diversity and regenerative capacity of the TEC. The most serious threats to the TEC include African Olive (O*lea europa* subsp. *cuspidata*), Bridal Creeper (*Asparagus asparagoides*) and a range of exotic grasses (DEWHA, 2009a).

These weeds are already present within the Strategic Assessment Area and pose a threat to the TEC. However, urban development and transport have the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or changing conditions to favour weeds.

The TEC is most susceptible to the threat of weeds from development under the Plan where new urban development occurs adjacent to the TEC and introduces edge effects. Key risk areas include in and around GPEC, WSA and GMAC, and to a lesser degree in Wilton where the TEC is much less extensive.

The Plan incorporates a range of measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Areas. This includes a number of actions, of which the following are the most relevant to the outcome for the TEC:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

Importantly for the TEC, weeds will be actively managed within the 575 ha to be added to conservation as part of the offset program.

The package of measures in the Plan is expected to adequately manage the risk posed to the TEC from weed invasion. This is because:

- Avoided lands where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- The Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy. This includes the land to be protected under the conservation program for the TEC
- There will be a range of planning controls to minimise the potential spread of weeds during and after construction

These controls are consistent with a number of threat abatement actions in the Conservation Advice about the management of invasive weeds.

INAPPROPRIATE HABITAT DISTURBANCE

Inappropriate habitat disturbance is identified in the Conservation Advice as a threat to the TEC. This relates to a wide range of different mechanisms for disturbance including:

- Inappropriate mowing, slashing or scrubbing of the understorey for reasons such as bushfire fuel reduction, grazing and perceived aesthetics
- Dumping of rubbish and garden waste which can directly impact areas of the TEC as well as facilitate increases in weeds (see above) and pollutants
- Inappropriate recreational activities such as ad hoc track building and trail bike use which can directly impact areas of the TEC and facilitate processes such as erosion
- Removal of wood which changes the structure and habitat features of the TEC
- Inadvertent disturbance during construction which has the potential to directly impact the TEC outside approved development areas

Each of these mechanisms have the potential to alter the structure and floristic composition of the TEC.

Inappropriate habitat disturbance within the Strategic Assessment Area may increase due to development within the nominated areas. Occurrences of the TEC considered most at risk are those in and around GPEC, WSA and GMAC, and to a lesser degree in Wilton where the TEC is much less extensive.

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for the TEC. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations (including the 575 ha for the TEC)
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan is expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development. This is because:

- Avoided lands where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

CHANGES TO HYDROLOGY

The creation of hard surfaces associated with urban development and transport results in changes to the hydrology of surrounding areas. The main threat to the TEC associated with altered hydrology is increased runoff into patches of the TEC carrying high nutrient and sediment loads, as well as weed seeds or propagules. This can both encourage weed invasion and cause erosion.

The TEC is most susceptible to the threat of increased runoff from development under the Plan where new urban or transport development occurs adjacent (and upstream or upslope) to the TEC. Key risk areas include in and around GPEC, WSA and GMAC, and to a lesser degree in Wilton where the TEC is much less extensive.

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for the TEC. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5) and transport (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through:

- Development controls in the nominated areas in relation to:
  - Water cycle management. For example:
    - Water management measures must comply with council's requirements for detention, drainage and water sensitive urban design principles
    - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
  - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
  - Soil erosion and sedimentation. For example:
    - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
    - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom 2004) and submitted with each subdivision development application
- The implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the RMS Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the TEC from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts to the TEC
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to the TEC

DISEASES, PATHOGENS AND DIEBACK

TECs are potentially susceptible to a range of diseases, pathogens and dieback which can substantially affect their long term viability. Recognised threats include myrtle rust and dieback caused by the root-rot fungus *Phytophthora cinnamomi*.

Development under the Plan may increase the risk of the spread of infection/disease. This is primarily related to:

- Soil transportation on contaminated footwear, vehicles and machinery, and in residential garden establishment
- Increased site visitation rates
- Earthworks and activities conducted during construction
- Increased surface water runoff

The Plan incorporates a range of measures to manage the risks associated with diseases, pathogens and dieback. In summary, these include:

- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
  - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
  - Entering into written agreements with delivery partners to implement priority disease control programs
- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures methods to protect the environment during construction, including best practice site hygiene protocols to minimise spread of *Phytophthora* and Myrtle Rust

The package of measures in the Plan is expected to adequately manage the risk to the TEC from diseases, pathogens and dieback because:

- It supports a landscape scale approach to the issue across the Cumberland subregion
- It will ensure appropriate controls during construction

INVASIVE FAUNA

TECs can be threatened by introduced animals and aggressive native species. These species include:

- Domestic species such as cats and dogs which are related to urban development
- Pest species such as foxes, rats, house mice and rabbits which are primarily related to agricultural development
- Aggressive bird species which compete for resources including the introduced Indian myna, and native species such as the sulphur-crested cockatoo

Collectively, these animals can lead to declines in biodiversity through:

- Predation
- Damage to vegetation and soils
- Competition for resources

Existing land use within the nominated areas and surrounding region (which includes residential and rural residential areas, and farming) means that these issues are already present in the Strategic Assessment Area and are unlikely to pose a novel threat to the TEC.

However, the extent of proposed new urban development under the Plan means that the threats associated with cats and dogs are likely to be exacerbated. It is likely that there will be an increase in the number of domestic cats and dogs in the local area, which, in turn, may lead to an increase in feral cat and wild dog numbers.

In relation to aggressive bird species, the two main drivers for increasing the threat within the TEC are:

- Fragmentation of habitat which creates greater edge effects and facilitates access by aggressive bird species. As outlined above in the analysis of direct impacts, the Plan is considered unlikely to lead to any notable fragmentation to the TEC and as such is not considered an issue
- Habitat disturbance through inappropriate land management which can change the structure of the TEC and facilitate access by aggressive bird species. As outlined above in relation to inappropriate habitat disturbance, the Plan includes a package of measures which are expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development

In relation to the residual risks associated with invasive fauna, the Plan incorporates a range of measures to manage the risks. In summary, these include:

- A commitment (Commitment 17) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the Strategic Conservation Areas. This includes a number of actions with the most relevant to the outcome for the TEC being:
  - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
  - Preparation of a Pest Animal Control Implementation Strategy
  - A process to enter into written agreements with delivery partners to implement the pest animal control program
  - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Development controls that will:
  - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
  - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
  - Require appropriate management and control of pest animals relevant to development sites

- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing pests, consistent with the pest animal implementation strategy outlined in Commitment 16

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the TEC from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the TEC to occur due to:

- Development of essential infrastructure within nominated areas but outside the urban capable lands (see Section 31.6.7 for discussion)
- Development of tunnels within the transport corridors (see Section 31.6.8 for discussion)

31.6.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

The TEC occurs on avoided land within GMAC (22.5 ha), WSA (20.1 ha) and GPEC (51.1 ha). It is possible that some of these areas will be impacted by essential infrastructure as the majority of the avoided TEC occurs on lands avoided for biodiversity purposes (74.4 ha). Impacts are more likely where the TEC occurs on avoided lands between urban capable lands.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine if the TEC was present
- Measures to avoid impacts to the listed TEC through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the TEC will occur as a results of essential infrastructure as every effort should be made to avoid and minimise impacts. Any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

31.1.1 POTENTIAL IMPACTS FROM TUNNELS

The TEC occurs within the tunnel footprints for the Metro Rail Future Extension (39.6 ha) and the Outer Sydney Orbital (58.4 ha). The Plan includes commitments to:

- Avoid any direct impacts associated with tunnels to the areas where the TEC occurs
- Mitigate any potential indirect impacts (e.g. changes to hydrology, ground settling or subsidence) from the transport corridors as part of a future environmental impact assessment process

These commitments are expected to adequately address threats to the TEC from the construction and operation of the tunnels. See Section 36.6 in Chapter 36 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE TEC

This section considers the likely effects of implementation of the Plan on the long-term viability of the TEC. The analysis has regard for the guidance in the Conservation Advice (there is no Recovery Plan for the TEC), and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above. It also discusses the results of the trend analysis that was undertaken to understand how one of the PCTs that comprise the TEC (PCT 849) is likely to fare over the life of the Plan.

Where applicable, this section also identifies any relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

31.6.8 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DEWHA, 2009a) and other relevant TEC documents identify the following key issues that are likely to have the greatest influence on the long-term viability of the TEC in relation to implementation of the Plan. They are:

- Habitat loss and fragmentation
- Indirect impacts including:
  - Inappropriate fire regimes
  - Weed invasion
  - Inappropriate habitat disturbance
  - Changes to hydrology
  - Diseases, pathogens and dieback
  - Invasive fauna

HABITAT LOSS AND FRAGMENTATION

As outlined above, implementation of the Plan may lead to the loss of 154.7 ha of the TEC. However, it is not considered likely that this will threaten the long-term viability of the TEC because:

- The scale of impacts are relatively minor when considering the mapped extent of the TEC across the Strategic Assessment Area (less than 1.6 per cent)
- The majority of impacts are to lower viability areas of the TEC:
  - Less than 0.3 per cent of higher viability TEC in the Strategic Assessment Area
  - Approximately 3.7 per cent of higher viability TEC in the nominated areas
- The impacts are unlikely to increase the level of fragmentation
- The offsets proposed by the Plan (575 ha of the TEC) will provide a substantial addition to the level of protection of the TEC and address a key threat identified in the Conservation Advice around its current low level of protection

It is worth noting that two of the reserves proposed by the Plan contain substantial areas of the TEC. They are:

- The Georges River Koala Reserve which is on the eastern side of the Strategic Assessment Area near GMAC. This will be implemented in two stages over the first 10 years of the Plan and contains approximately 60 ha of the TEC
- The Gulguer Reserve investigation area which occurs on the western side of the Strategic Assessment Area. The Plan proposes to implement the reserve over the first 20 years of the Plan. The area contains approximately 200 ha of the TEC

Trend analysis

This conclusion is supported by the trend analysis that was undertaken by RMIT University (A Gordon & Peterson, 2019) that examined the predicted extent and condition of PCT 849 over the life of the Plan under various scenarios. PCT 849 is one of several PCTs that make up the EPBC listed TEC and the results of the analysis provide valuable information about the long-term viability of the TEC as a whole.

The trend analysis examined the potential impacts of development and offsetting under various scenarios on PCT 849 in the Cumberland subregion over the life of the Plan. This is an important analysis because the typical impact assessment approach considers impacts and offsets largely in a static sense (i.e. they are unable to consider quantitative trends in biodiversity values because of the complexity involved). The trend analysis provided the opportunity to model how a key part of the TEC would fare over time and included consideration of the baseline pressures on vegetation. It was informed by expert elicitation with a range of well-regarded experts in the vegetation of the Cumberland subregion and is a robust analysis.

The scenarios analysed through the project are largely consistent with commitments in the Plan. Key findings were:

- Existing landscape scale threats across the Cumberland subregion (e.g. weeds) are significant and will result in an approximate 5.8 per cent decline in the extent and condition of the PCT over the life of the Plan unless additional areas are managed. These threats will operate with or without the Plan
- The proposed impacts of development under the Plan that were modelled in the analysis (noting that further avoidance has occurred since that time) will lead to approximately the same magnitude of losses (~5.8 per cent) to the PCT that will occur due to existing landscape threats
- High intensity management (as occurs in reserves and biodiversity stewardship sites) and early offsetting will provide the greatest benefits to the outcomes of the PCT over the life of the Plan
- Securing approximately 1,605 ha of offsets for PCT 849 (it is important to note that the actual target in the Plan is 2,325 ha which is substantially greater than the amount modelled in the trend analysis) will compensate for the impacts of development where earlier offsetting and higher intensity management is preferenced by improving the extent and condition of the PCT over the life of the Plan. This was measured by considering the extent and condition of the PCT over time. This approach also has the potential to contribute significantly to addressing the predicted declines across the subregion due to existing landscape scale threats

This last point is a critical one. Not only will the offsets in the Plan compensate for the impacts, but they have the potential to address the predicted declines in the PCT that are occurring across the Strategic Assessment Area due to current threats.

Supporting Document D provides further details regarding the methodology and results of the trend analysis.

Strategic priority

The Conservation Advice sets out a strategic priority for the TEC which is to take “an appropriate broad scale landscape approach” to ensure the TEC is “given adequate consideration in decision making”. This is one of the key premises behind the Plan which is taking a landscape scale approach to both development planning and conservation.

Two key points raised in the Conservation Advice about the strategic priority are:

- “The program should therefore identify those remnants that are most important for long-term conservation and recovery of the community. Consideration should be given to position inside and out of planned urban growth areas, proximity of smaller remnants to larger native vegetation remnants, conserving habitat values (e.g. large trees with hollows) and functionality as corridors or 'stepping stones' for fauna and flora”
- “Whilst the connectivity of remnants that meet the Description and Condition Thresholds in the listing advice for the national ecological community is a high priority, reconnection to lower-quality remnants, other ecological communities or native plantings should also be considered in order to optimise biodiversity outcomes across the landscape”

Both the avoidance processes used to define the urban capable lands (see Chapter 14) and the conservation program have specifically addressed these points. Key areas of the TEC have been avoided in the design of the urban capable lands, and the conservation program is applying a process to identify:

- Remnants that are the most important for long-term conservation
- Corridors and connectivity for biodiversity
- Areas that are suitable for restoration including lower-quality remnants of the TEC and derived grasslands

INDIRECT IMPACTS

The potential indirect impacts associated with inappropriate fire regimes, weed invasion, inappropriate habitat disturbance, changes to hydrology, diseases, pathogens and dieback, and invasive fauna will be managed and mitigated through a number of commitments and actions in the Plan.

Indirect impacts are not expected to influence the long-term viability of the TEC.

Conclusion

The nature of the impacts to the TEC combined with the commitments to protect 575 ha of the TEC and manage indirect impacts will ensure that the implementation of the Plan does not adversely influence the long-term viability of the TEC.

31.6.9 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the TEC.

31.6.10 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 31-6 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The Plan is not inconsistent with any of the relevant TAPs. Please refer to Section 15.9 of Chapter 15 for a detailed discussion of each TAP and the relationship of the Plan.

Table 31-6: Key Threatening Processes and relevant Threat Abatement Plans for Cumberland Plain Shale Woodlands and Shale-gravel Transition Forest

KEY THREATENING PROCESS	RELEVANT THREAT ABATEMENT PLAN
Dieback caused by the root-rot fungus (*Phytophthora cinnamomi*)	Threat abatement plan for disease in natural ecosystems caused by *Phytophthora cinnamomi* (DoEE, 2018d)
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP
Predation by feral cats	Threat abatement plan for predation by feral cats (DoE, 2015g)

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

31.7 COOKS RIVER/CASTLEREAGH IRONBARK FOREST OF THE SYDNEY BASIN BIOREGION

This assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan on the TEC in accordance with the EPBC Terms of Reference. It sets out:

- *TEC background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the TEC*
- *Data tables*

THREATENED ECOLOGICAL COMMUNITY BACKGROUND

This section sets out the basic information about the TEC. It provides a description of the TEC, and an overview of the listing definition and its distribution. These provide context for the impact assessment. At the end of the section are links to key documents that provide additional background information.

EPBC ACT LISTING	Critically Endangered
DESCRIPTION	The TEC is a dry sclerophyll open forest to low woodland community with an overstorey dominated by *Eucalyptus fibrosa* and *Melaleuca decora*. *Eucalyptus longifolia* is also often present. The midstorey is usually moderate to dense, commonly including *Melaleuca nodosa* and *Lissanthe strigosa*, and to a lesser extent *Melaleuca decora.* The ground layer is variable and generally sparse with a mix of grasses and other graminoids, forbs, and low shrubs. The TEC can intergrade into Shale-Gravel Transition Forest (where the alluvium is shallow), Castlereagh Swamp Woodland (in moist depressions) and Castlereagh Scribbly Gum Woodland (on sandier soils). The following PCT is associated with the TEC: 725 Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin bioregion. A range of fauna species occur in the TEC, including reptiles, amphibians, birds, micro-bats, and marsupials. Most of these fauna species are not restricted to the TEC and also occur in, and are likely to rely on, other native vegetation in the Cumberland subregion. Most plant species in the TEC are able to regenerate from lignotubers and buds beneath the bark as well as seeds stored in the soil (OEH, 2019d). The TEC is equivalent to the NSW BC Act listed TEC Cooks River/Castlereagh Ironbark Forest where key diagnostic and condition thresholds are met. The EPBC conditions include a treeless, shrubby state that is not included in the NSW-listed TEC. (DoE, 2015)
EPBC DEFINITION	Only patches of the TEC that meet minimum size and condition thresholds are considered part of the TEC under the EPBC Act. Thresholds relate to factors such as patch size, understorey native vegetation cover, number of tree hollows, or whether the patch is contiguous with other native vegetation patches. Details of the thresholds are provided in the Conservation Advice (DoE, 2015).
DISTRIBUTION	The TEC is confined to the Sydney Basin bioregion and mostly restricted to the Cumberland subregion.

	The majority of the TEC is found in larger patches in the north-west part of the subregion in the Castlereagh area between Penrith and Richmond. Other significant patches occur in the Kemps Creek and Holsworthy areas. Smaller patches of the TEC occur in the eastern part of the subregion, such as the upper Cooks River valley. The TEC primarily occurs in elevations below 100 m with mean annual rainfall of 800-1000 mm. It generally occurs on clay soils derived from Tertiary alluvium and on Wianamatta Shale soils found next to Tertiary alluvium. In the eastern areas of its distribution, the TEC can be found on soils with a sandstone influence. (DoE, 2015c)
SOS SITES	The TEC has been categorised under the 'widespread' management stream for TECs under the SOS program. Management of this category of TECs focuses on planning and regulatory processes, policy and programs, and private land conservation and reservation of land. Currently no management sites have been identified for this TEC.
RELEVANT PLANS AND POLICIES	Approved Conservation Advice (including listing advice) for Cooks River/Castlereagh Ironbark Forest of the Sydney Basin Bioregion (DoE, 2015c) Key Threatening Processes relevant to the TEC are identified in the Conservation Advice There is no adopted or made Commonwealth Recovery Plan for the TEC. The TEC is included in the Cumberland Plain Recovery Plan (NSW) (DECCW, 2011) Threat Abatement Plans relevant to the TEC are identified in Table 31-14

APPROACH TO BASELINE DATA

This section provides an overview of the approach to baseline data for the TEC. It:

- *Provides a summary of the approach to vegetation mapping for the strategic assessment which forms the baseline for the TEC mapping*
- *Outlines the vegetation condition states used in the mapping*
- *Identifies the NSW Plant Community Types (PCTs) that are associated with the TEC*
- *Summarises the approach to mapping the EPBC TEC*
- *Summarises the approach to the patch size analysis for the ecological community*
- *Summarises the approach to identifying areas of likely higher long-term viability in the Strategic Assessment Area*

Please refer to Section 11.3 (in Chapter 11) for details about the methods for mapping native vegetation, and Section 11.4.3 for details about the mapping methods for EPBC TECs.

APPROACH TO VEGETATION MAPPING	Native vegetation was mapped at two levels for the strategic assessment. Within the nominated areas, native vegetation was mapped using a method consistent with the BAM. This involved using a combination of API, existing desktop mapping, previous surveys and studies, rapid assessment ground-truthing, and field surveys (including floristic plot surveys). This process resulted in detailed maps of PCTs categorised by condition. Outside the nominated areas, native vegetation was mapped using the best available data integrated into a single dataset. Vegetation condition states were also applied across the broader area. It should be noted that comprehensive on-ground surveys across all native vegetation within the nominated areas was not possible and no surveys were undertaken outside the nominated areas. This means that a set of assumptions around the available data was required to translate the site based condition thresholds for the EPBC TEC so that it could be mapped at the scale of the Strategic Assessment Area. These assumptions are summarised below and explained in detail in Section 11.4.3 of Chapter 11.

VEGETATION CONDITION STATES	Vegetation condition was mapped using the following five condition states. These states generally range from better (intact) to worse (urban native/exotic) condition and are: • **Intact:** This condition state was assigned to areas of wooded vegetation community, including regrowth, that displays a range of structural layers and habitat features (e.g. tree hollows and large trees, fallen timber, leaf litter) with a largely unmodified canopy density and a range of age classes and species present • **Thinned:** This condition state was assigned to native vegetation in various states of modification, including: o Wooded vegetation with a partly-cleared canopy and a more open structure compared to the intact PCT o Wooded vegetation that has been under scrubbed • **Scattered trees:** This condition state includes a single tree or small group of trees surrounded by native or exotic pasture or areas of cultivation. Other structural components of the vegetation have typically been removed • **Grasslands:** Grasslands included two separate state zones – exotic grassland and native grasslands • **Urban native/exotic:** This condition type was assigned to areas of vegetation within urban areas that consisted of street trees, urban parks and other patches of planted vegetation that could provide habitat for native species
ASSOCIATED PCTs	The following PCT is associated with the TEC: • 725 Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin bioregion.
MAPPING APPROACH	Mapping of the TEC across the Strategic Assessment Area used the following criteria which are based on applying the condition thresholds at a landscape scale to the available data: • Patch size ≥ 0.5 ha (Patch size > 0.1 ha in areas east of Riverstone), AND • ≥ 30% of perennial understorey vegetation cover is native (field verification), AND • Below 100 m elevation, AND • Rainfall 800-1000 mm per year, AND • Growing on Clay rich soils derived from tertiary alluvium and on Wianamatta derived shale soils found next to tertiary alluvium, AND • Patch is contiguous with native vegetation remnant >1ha, OR the patch has at least one tree with hollows or at least one large locally indigenous tree (>80 cm) (based on field verification) OR • Patch size ≥ 0.5 ha (Patch size > 0.1 ha in areas east of Riverstone), AND • ≥ 50% of perennial understorey vegetation cover is native (based on field verification), AND • Below 100 m elevation, AND • Rainfall 800-1000 mm per year, AND • Growing on clay rich soils derived from tertiary alluvium and on Wianamatta derived shale soils found next to tertiary alluvium
PATCH SIZE ANALYSIS	As outlined in Section 31.3, a patch size analysis for the ecological community was undertaken to identify the number and size of patches across the Strategic Assessment Area.

VIABILITY ASSESSMENT	As outlined in Section 31.4, an analysis was undertaken to identify areas of likely higher long-term viability for the TEC in the Strategic Assessment Area The purpose of the analysis was to identify the patches of the TEC within the Strategic Assessment Area that are more likely to be viable in the longer-term to inform the evaluation of the overall outcome of the Plan for the TEC. Viability is defined in a qualitative sense as the "probability of long-term survival of TEC patches". The approach involved reviewing Conservation Advices for each TEC to identify the factors that influence the long-term viability or conservation significance of a patch of the TEC. This review found that Conservation Advices generally identify a similar set of factors that influence long-term viability. Key factors included: • Larger patches are generally more viable than smaller patches • Better condition patches are generally more viable than poorer condition patches • Connected patches are generally more viable than poorer connected patches • Patches with a lower edge/area ratio are generally more viable than patches with a higher edge/area ratio

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the TEC in the Strategic Assessment Area. It includes reference to a map which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where the TEC occurs.

MAP	See Map 48.3 for a map of the TEC across the Strategic Assessment Area.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	The baseline mapping for this assessment has mapped approximately 791 ha of the TEC within the Strategic Assessment Area (see Table 31-11 for further details). Of this, approximately 592 ha has been identified as higher viability through the viability analysis. The TEC occurs in the following main locations within the Strategic Assessment Area: • Northern part of the Strategic Assessment Area between Windsor Downs, Llandilo and Agnes Banks associated with larger remnants of native vegetation in this locality • Northern part of GPEC within Wianamatta Regional Park and near Ropes Crossing • Southern part of WSA near Kemps Creek It occurs in the following nominated areas: • WSA – 33.6 ha. None of this is mapped as higher viability • GPEC – 96.8 ha including 39.2 ha that is higher viability The Conservation Advice does not specifically identify any sites in the Strategic Assessment Area that are important to the TEC. It states that all patches that meet the minimum condition categories as defined in the advice are considered habitat critical to the survival of the TEC. The Conservation Advice also identifies several factors affecting the value of a patch, including: • A larger size and/or a high area to boundary ratio • Part of a larger remnant of native vegetation or linking other remnants • Evidence of recruitment of key plant species/range of age cohorts • High native species richness • Presence of threatened species • Low level of weeds and pest animals The TEC is highly fragmented across the Strategic Assessment Area, comprising approximately 153 patches most of which (120) are less than 5 ha. Only seven patches are greater than 20 ha. However, the TEC intergrades into other native vegetation types, and many patches of the TEC are surrounded by or connected to larger areas of native vegetation, providing a buffer to edge effects.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of the TEC that was avoided through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

31.7.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 52 ha of the TEC within the nominated areas (not including excluded lands). Approximately 26 ha (50 per cent) was avoided as part of the urban capable lands and transport corridors (not including excluded lands). All of this was avoided for biodiversity purposes.

An additional 78 ha occurs on excluded lands.

A breakdown of avoidance across each nominated area is provided in Table 31-12.

It is important to note that the avoidance calculations in Table 31-12, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 31-12 shows the amounts of habitat within excluded lands for context only.

31.7.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred. Avoidance within the transport corridors will occur during the detailed design phase as each project is brought forward.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts. It considers:

- *Predicted impacts within urban capable lands and transport corridors*
- *Potential issues associated with fragmentation*
- *Potential additional impacts from essential infrastructure (within nominated areas but outside the urban capable lands) and tunnels associated with transport projects*

Offsets are provided for any TECs that are subject to direct impacts. The rationale and process for setting offset targets for TECs is set out in Section 8.5.2 of Chapter 8, and explained in detail in the Conservation Priorities Method that supports the Plan.

Implementation of the Plan will lead to direct impacts to the TEC (see Section 31.7.3 for discussion) and increase fragmentation in one location (see Section 31.7.4 for discussion).

31.7.3 DIRECT IMPACTS TO THE TEC

Implementation of the Plan will lead to loss of a total of 26.3 ha of the TEC within GPEC and WSA. This loss represents approximately 3 per cent of the remaining TEC in the Strategic Assessment Area and 20 per cent of the TEC in the nominated areas. A breakdown of direct impacts is provided in Table 31-13.

The majority of the TEC impacted within GPEC and WSA:

- Is in thinned condition (13 ha)
- Comprises small patches (less than 5 ha) (14 out of the 17 impacted patches)
- Is not mapped as higher viability. Impacts will occur to 10.8 ha of higher viability TEC

The majority of the loss of the TEC (15 ha) is due to the Outer Sydney Orbital in the northern part of GPEC.

The most notable direct impacts to the TEC occur to patches impacted by the Outer Sydney Orbital in the northern part of GPEC within Wianamatta Regional Park (19.3 ha). Impacts in this location will occur to patches that:

- Are of moderate size (> 5 ha)
- Are mostly in intact condition and that are known to contain several threatened flora species (see Chapter 29), which (consistent with the Conservation Advice) makes them of higher conservation value
- Form part of a larger, well-connected patch of native vegetation associated with the Wianamatta Regional Park

However, the Plan includes a specific commitment (Commitment 3) to avoid and minimise impacts to the TEC due to the construction of the Outer Sydney Orbital within the Wianamatta Regional Park.

Impacts in WSA (7.0 ha) will occur to a number of small patches that are predominately in thinned condition.

31.1.2 FRAGMENTATION OF THE TEC

The Conservation Advice identifies fragmentation as a key threat to the TEC (DoE, 2015).

Fragmentation of the TEC will occur due to the direct impacts from the Outer Sydney Orbital in Wianamatta Regional Park (GPEC). In this area, the Outer Sydney Orbital will intersect the middle of several patches of the TEC that form part of a larger, well-connected patch of native vegetation to the west and Ropes Creek riparian corridor to the south. The TEC is also marginally connected to a larger patch of the TEC to the east at Ropes Crossing.

Fragmentation of the TEC may increase the susceptibility of the TEC to weed invasion and other edge effects and has the potential to reduce its long-term viability in this location.

Fragmentation is not expected to occur to the TEC in WSA.

31.7.4 OFFSETS FOR RESIDUAL DIRECT IMPACTS

To compensate for the predicted direct impacts to the TEC, the Plan includes a commitment to secure 105 ha of the TEC as part of the conservation program. This would:

- Lead to the protection and management of an additional 13.3 per cent of the TEC within the Strategic Assessment Area
- Increase the level of protection and management of the ecological community by approximately 25 per cent on top of what is currently secured in the Strategic Assessment Area

These offsets are consistent with the following two high priority actions in the Conservation Advice:

- “Protect and conserve patches of this ecological community…”
- “Promote formal conservation arrangements, management agreements and covenants on private land. For crown and private land, promote inclusion in reserve tenure”

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the TEC that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the TEC if:

- *The indirect impact is identified as a threat in a relevant profile or conservation advice, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

31.7.5 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice identifies a range of threats to the TEC. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential indirect impacts (identified as threats in the Conservation Advice) are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Inappropriate habitat disturbance
- Changes to hydrology
- Diseases, pathogens and dieback
- Invasive fauna

To help address these potential indirect impacts, the Plan includes a requirement to undertake mitigation in accordance with the *Best Practice Guidelines: Cooks River/Castlereagh Ironbark Forest* (DECC, 2008a) within and adjacent to the TEC. These are discussed further below in relation to specific indirect impacts.

Climate change is also a relevant threat to the ecological community. The extent to which the Plan has considered adaptation to climate change impacts is addressed in Chapter 41.

Impacts from dryland salinity due to historical clearing and uncontrolled grazing were also identified in the Conservation Advice as key threats. However, none of these are considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate these risks across the Strategic Assessment Area.

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes can affect the structure and species composition of the TEC (DoE, 2015c). This can be caused by:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

Altered fire regimes, particularly increased fire frequency due to arson, can affect the structure and species composition of the TEC by altering the mid and ground layers. This is despite most plant species in the TEC being able to regenerate after fire from lignotubers and buds beneath the bark, as well as seeds stored in the soil (OEH, 2019d). While most impacts to the TEC are associated with increased fire, in some areas the TEC is threatened due to a lack of fire (DoE, 2015c).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact the TEC. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development. For the TEC this includes areas in the north of GPEC, and the south east of WSA.

The key factors that influence the appropriateness of a fire regime are fire frequency, intensity and season of occurrence (DECCW, 2011).

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant to the outcome for the TEC being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy for the Strategic Conservation Areas that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy

  - o Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - o Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - o Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from the TEC. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes
- A specific requirement in relation to two commitments (Commitments 5 and 6) to apply the best practice guidelines for managing the TEC (DECC, 2008a). This includes specifics around fire management and is consistent with a high priority action in the Conservation Advice

The package of measures in the Plan is expected to adequately manage the risk to the TEC from altered fire regimes as a result of development. This is because:

- Avoided lands in WSA where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting the TEC
- Fire management authorities will be engaged to ensure they understand the requirements of the TEC and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas
- The fire management requirements for the TEC specified in the best practice guidelines will be applied

These controls are consistent with a number of priority conservation actions in the Conservation Advice about the management of fire.

WEED INVASION

The TEC is threatened with invasion and competition by weeds. It typically occurs on soils that are richer in nutrients compared to other soil types in the Sydney Basin bioregion, which means it is particularly susceptible to threats from weeds (DECC, 2008a).

The most serious threats are:

- Mid-storey weeds:
  - o Green cestrum (*Cestrum parqui*), which is dispersed by birds and water
  - o Mickey mouse bush (*Ochna serrulata*), which is dispersed by birds and dumped garden waste. This weed can establish in undisturbed bushland
- Ground-layer weeds: Ground Asparagus (*Asparagus aethiopicus*), dispersed by birds and dumped garden waste. This weed affects availability of nutrients and water
- Grassy weeds:
  - o Panic veldt grass (*Ehrharta erecta*), which is dispersed by water, birds, contaminated soil and dumped garden waste
  - o Kikuyu (*Cenchrus clandestinus*), which is dispersed by dumped garden waste
  - o Common couch (*Cynodon dactylon*), which can escape from pastures and lawns
- Vines: Bridal creeper (*Asparagus asparagoides*)

These weeds are already present within the Strategic Assessment Area and pose a threat to the TEC. However, urban and transport development within the northern half of the Strategic Assessment Area has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or changing conditions to favour weeds.

The TEC is most susceptible to the threat of weeds from development under the Plan where new urban development or transport corridors occur adjacent to the TEC and/or fragments patches of the TEC into smaller patches and introduces edge effects. Key risk areas include:

- Northern part of GPEC where the Outer Sydney Orbital corridor fragments TEC patches
- South-eastern part of WSA where urban development occurs immediately adjacent to several connected TEC patches

The Plan incorporates a range of measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Areas. This includes a number of actions, of which the following are the most relevant to the outcome for the TEC:
    - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
    - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
    - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
    - Require proponents to undertake the following when applying for/undertaking development:
        - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
        - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
        - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas
- A specific requirement in relation to two commitments (Commitments 5 and 6) to apply the best practice guidelines for managing the TEC (DECC, 2008a). This includes specifics around weed management and is consistent with a high priority action in the Conservation Advice

Importantly for the TEC, weeds will be actively managed within the 105 ha to be added to conservation as part of the offset program.

The package of measures in the Plan is expected to adequately manage the risk posed to the TEC from weed invasion. This is because:

- Avoided lands where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- The Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy. This includes the land to be protected under the conservation program for the TEC
- There will be a range of planning controls to minimise the potential spread of weeds during and after construction
- The weed management requirements for the TEC specified in the best practice guidelines will be applied

These controls are consistent with a number of priority conservation actions in the Conservation Advice about the management of weeds.

INAPPROPRIATE HABITAT DISTURBANCE

Inappropriate habitat disturbance is identified in the Conservation Advice as a threat to the TEC. This relates to a wide range of different mechanisms for disturbance including:

- Inappropriate mowing, slashing or scrubbing of the understorey for reasons such as bushfire fuel reduction, grazing and perceived aesthetics
- Dumping of rubbish and garden waste which can directly impact areas of the TEC as well as facilitate increases in weeds (see above) and pollutants
- Inappropriate recreational activities such as ad hoc track building and trail bike use which can directly impact areas of the TEC and facilitate processes such as erosion
- Removal of wood which changes the structure and habitat features of the TEC
- Inadvertent disturbance during construction which has the potential to directly impact the TEC outside approved development areas

Each of these mechanisms have the potential to alter the structure and floristic composition of the TEC.

Inappropriate habitat disturbance within the Strategic Assessment Area may increase due to development within the nominated areas. Occurrences of the TEC considered most at risk are those to the north of GPEC, and the south-east of WSA.

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for the TEC. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations (including the 105 ha for the TEC)
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan is expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development. This is because:

- Avoided lands where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

These controls are consistent with a number of priority conservation actions in the Conservation Advice about the management of disturbance.

CHANGES TO HYDROLOGY

The creation of hard surfaces associated with urban development and transport results in changes to the hydrology of surrounding areas. The main threat to the TEC associated with altered hydrology is increased runoff into patches of the TEC carrying high nutrient and sediment loads, as well as weed seeds or propagules. This can both encourage weed invasion and cause erosion.

The TEC is most susceptible to the threat of increased runoff from development under the Plan where new urban or transport development occurs adjacent (and upstream or upslope) to the TEC. Key risk areas are those in the north of GPEC and the south east of WSA.

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for the TEC. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5) and transport (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through:

- Development controls in the nominated areas in relation to:
  - Water cycle management. For example:
    - Water management measures must comply with council's requirements for detention, drainage and water sensitive urban design principles
    - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
  - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
  - Soil erosion and sedimentation. For example:
    - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
    - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom 2004) and submitted with each subdivision development application
- The implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the RMS Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the TEC from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts to the TEC
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to the TEC

DISEASES, PATHOGENS AND DIEBACK

TECs are potentially susceptible to a range of diseases, pathogens and dieback which can substantially affect their long term viability. Recognised threats include myrtle rust and dieback caused by the root-rot fungus *Phytophthora cinnamomi*.

Development under the Plan may increase the risk of the spread of infection/disease. This is primarily related to:

- Soil transportation on contaminated footwear, vehicles and machinery, and in residential garden establishment
- Increased site visitation rates
- Earthworks and activities conducted during construction
- Increased surface water runoff

The Plan incorporates a range of measures to manage the risks associated with diseases, pathogens and dieback. In summary, these include:

- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
    - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
    - Entering into written agreements with delivery partners to implement priority disease control programs
- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures methods to protect the environment during construction, including best practice site hygiene protocols to minimise spread of *Phytophthora* and Myrtle Rust

The package of measures in the Plan is expected to adequately manage the risk to the TEC from diseases, pathogens and dieback because:

- It supports a landscape scale approach to the issue across the Cumberland subregion
- It will ensure appropriate controls during construction

INVASIVE FAUNA

TECs can be threatened by introduced animals and aggressive native species. These species include:

- Domestic species such as cats and dogs which are related to urban development
- Pest species such as foxes, rats, house mice and rabbits which are primarily related to agricultural development
- Aggressive bird species which compete for resources including the introduced Indian myna, and native species such as the sulphur-crested cockatoo

Collectively, these animals can lead to declines in biodiversity through:

- Predation
- Damage to vegetation and soils
- Competition for resources

Existing land use within the nominated areas and surrounding region (which includes residential and rural residential areas, and farming) means that these issues are already present in the Strategic Assessment Area and are unlikely to pose a novel threat to the TEC.

However, the extent of proposed new urban development under the Plan means that the threats associated with cats and dogs are likely to be exacerbated. It is likely that there will be an increase in the number of domestic cats and dogs in the local area, which, in turn, may lead to an increase in feral cat and wild dog numbers.

In relation to aggressive bird species, the two main drivers for increasing the threat within the TEC are:

- Fragmentation of habitat which creates greater edge effects and facilitates access by aggressive bird species. As outlined above in the analysis of direct impacts, fragmentation is likely to occur in the vicinity of the Wianamatta Regional Park but not in other areas of the TEC
- Habitat disturbance through inappropriate land management which can change the structure of the TEC and facilitate access by aggressive bird species. As outlined above in relation to inappropriate habitat disturbance, the Plan includes a package of measures which are expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development

In relation to the residual risks associated with invasive fauna, the Plan incorporates a range of measures to manage the risks. In summary, these include:

- A commitment (Commitment 17) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the Strategic Conservation Areas. This includes a number of actions with the most relevant to the outcome for the TEC being:
    - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan

- Preparation of a Pest Animal Control Implementation Strategy
- A process to enter into written agreements with delivery partners to implement the pest animal control program
- Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans

- Development controls that will:
  - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
  - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
  - Require appropriate management and control of pest animals relevant to development sites
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing pests, consistent with the pest animal implementation strategy outlined in Commitment 16

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the TEC from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the TEC to occur due to development of essential infrastructure within the avoided lands of WSA.

The TEC does not occur within the vicinity of the tunnel footprints for transport and is therefore not at risk of additional impacts from tunnels.

31.7.6 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

Areas of the TEC occur within the avoided lands of WSA. Of the 26.1 ha, 19.4 ha is in good (intact) condition and 6.7 ha is in moderate (thinned) condition. It is possible that some of these areas will be impacted by essential infrastructure where it occurs between urban capable lands.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine if the TEC was present
- Measures to avoid impacts to the listed TEC through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the TEC will occur as a results of essential infrastructure as every effort should be made to avoid and minimise impacts. Any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE TEC

This section considers the likely effects of implementation of the Plan on the long-term viability of the TEC. The analysis has regard for the guidance in the Conservation Advice (there is no Recovery Plan for the TEC), and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also identifies any relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

31.7.7 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DoE, 2015c) identifies the following key issues that are likely to have the greatest influence on the long-term viability of the TEC:

- Habitat loss and fragmentation
- Indirect impacts including:
  - Inappropriate fire regimes
  - Weed invasion
  - Inappropriate habitat disturbance
  - Changes to hydrology
  - Diseases, pathogens and dieback
  - Invasive fauna

Habitat loss and fragmentation

As outlined above, implementation of the Plan may lead to the loss of 26.3 ha of the TEC (7.0 ha in WSA and 19.3 ha in GPEC). This equates to 3.3 per cent of the remaining TEC in the Strategic Assessment Area.

The impacts in WSA are not expected to threaten the long-term viability of the TEC because:

- Impacts are to a number of smaller already fragmented patches
- Of the 7.0 ha to be impacted, only 0.2 ha is in intact condition and none of it is mapped as higher viability
- The impacts are unlikely to increase the level of fragmentation of the TEC

The impacts in GPEC are more complex in relation to the implications for the long-term viability of the TEC. This is because:

- The impacts from the Outer Sydney Orbital will lead to fragmentation within the Wianamatta Regional Park
- Of the 19.3 ha to be impacted, 10.8 ha is mapped as higher viability. This represents 1.8 per cent of the higher viability TEC in the Strategic Assessment Area (592 ha)

It is noted that the Plan commits (Commitment 3) to avoid and minimise impacts to the TEC due to the construction of the Outer Sydney Orbital in GPEC. It will be critical that this process avoids and minimise impacts as far as possible to reduce the scale of impacts. As part of this process, Transport for NSW will report to the Department on avoidance achieved within the transport corridors. The Department will use this information to track impacts and adjust offset requirements through the Plan's reconciliation accounting process. This process provides an incentive for Transport for NSW to avoid impacts to this TEC and reduce offset requirements.

To address the overall residual risks associated with direct impacts the Plan commits to protecting 105 ha of the TEC. This will provide a substantial contribution to the area of the TEC that is protected within the Strategic Assessment Area (an additional 13.3 per cent), and supports a number of high priority actions in the Conservation Advice.

As part of this commitment, the Plan is also prioritising restoration of up to 25 per cent of the offset target for the TEC. Restoration provides the potential for substantial improvements in the long-term viability of the TEC by:

- Adding to the known extent of TEC by rehabilitating degraded areas of vegetation that do not currently meet the EPBC listing criteria
- Improving the resilience of patches of the TEC where restoration occurs in strategic locations (e.g. by increasing the size of an existing patch, or connecting existing patches)

Given the extent of impacts from the Outer Sydney Orbital, the timing of offsetting will be critical for the TEC. Offsets should be provided early during the implementation of the Plan and ideally be in place before the construction of the Outer Sydney Orbital. If this were to occur, the long-term viability of the TEC will not be adversely affected.

INDIRECT IMPACTS

The potential indirect impacts associated with inappropriate fire regimes, weed invasion, inappropriate habitat disturbance, changes to hydrology, diseases, pathogens and dieback, and invasive fauna will be managed and mitigated through a number of commitments and actions in the Plan.

Indirect impacts are not expected to influence the long-term viability of the TEC.

CONCLUSION

Implementation of the Plan is not expected to adversely influence the long-term viability of the TEC where offsetting occurs early and restoration of the TEC is successful.

31.7.8 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the TEC.

31.7.9 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 31-10 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The Plan is not inconsistent with any of the relevant TAPs. Please refer to Section 15.9 of Chapter 15 for a detailed discussion of each TAP and the relationship of the Plan.

Table 31-10: Key Threatening Processes and relevant Threat Abatement Plans for Cooks River/Castlereagh Ironbark Forest

KEY THREATENING PROCESS	RELEVANT THREAT ABATEMENT PLAN
Dieback caused by the root-rot fungus (*Phytophthora cinnamomi*)	Threat abatement plan for disease in natural ecosystems caused by *Phytophthora cinnamomi* (DoEE, 2018d)
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP
Predation by feral cats	Threat abatement plan for predation by feral cats (DoE, 2015g)

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

31.8 COASTAL SWAMP OAK (*CASUARINA GLAUCA*) FOREST OF NSW AND SOUTH EAST QUEENSLAND

This assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan on the TEC in accordance with the EPBC Terms of Reference. It sets out:

- *TEC background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the TEC*
- *Data tables*

THREATENED ECOLOGICAL COMMUNITY BACKGROUND

This section sets out the basic information about the TEC. It provides a description of the TEC, and an overview of the listing definition and its distribution. These provide context for the impact assessment. At the end of the section are links to key documents that provide additional background information.

EPBC ACT LISTING	Endangered
DESCRIPTION	The TEC varies from open forest to low woodlands, depending on landscape location and disturbance history, with an overstorey dominated by *Casuarina glauca* (swamp oak, swamp she-oak). *Eucalyptus* species may also be present. *Melaleuca* species may also occur in the overstorey, midstorey or as emergent in freshwater patches of the TEC. The midstorey is not always present in occurrences of the TEC. Instead, a sub-canopy of smaller trees may often be present. This sub-canopy typically consists of juvenile canopy species. The climbing plant species that is most commonly found in the TEC is *Parsonsia straminea*. The ground layer is typically a contiguous to semi-contiguous layer of forbs, ferns, sedges, grasses and plant litter. The composition of this ground layer is influenced by groundwater salinity. The following PCT is associated with the TEC: 1800 Swamp Oak open forest on river flats of the Cumberland Plain and Hunter valley. A range of fauna species occur in the TEC, including reptiles, amphibians, birds, micro-bats, and marsupials. Most of these fauna species are not restricted to the TEC and also occur in, and are likely to rely on, adjacent wetlands, grasslands, woodlands and forests. The TEC is equivalent to the NSW BC Act listed TEC Swamp Oak Floodplain Forest where key diagnostic and condition thresholds are met. (DoEE, 2018a)
EPBC DEFINITION	Only patches of the TEC that meet minimum size and condition thresholds are considered part of the TEC under the EPBC Act. Thresholds relate to factors such as patch size, understorey native vegetation cover, number of tree hollows, or whether the patch is contiguous with other native vegetation patches. Details of the thresholds are provided in the Conservation Advice (DoEE, 2018a)
DISTRIBUTION	The TEC has a broad extent of occurrence along the east coast of Australia from Curtis Island in Queensland to Bermagui in NSW. However, its area of occupancy is limited. It occurs within the subregion from Cranebrook in the north to Bow Bowing in the south. The TEC primarily occurs in coastal catchments at elevations of less than 50 m, typically within 30 km of the coast. It generally occurs on unconsolidated sediments including alluvium deposits.

	The soils are hydrosols that are grey-black clay-loam and/or sandy loam soils and are saturated with water for long periods of time. It can also occur on peaty soils. (DoEE, 2018a)
SOS SITES	The TEC has been categorised under the 'widespread' management stream for TECs under the SOS program. Management of this category of TECs focuses on planning and regulatory processes, policy and programs, and private land conservation and reservation of land. A priority management site for the TEC has been proposed at Eurobodalla on the NSW south coast (OEH, 2018j).
RELEVANT PLANS AND POLICIES	Conservation Advice (including listing advice) for Coastal Swamp Oak *(Casuarina glauca)* Forest of New South Wales and South East Queensland ecological community (DoEE, 2018a). Key Threatening Processes relevant to the TEC are identified in Table 8 of the Conservation Advice. There is no Recovery Plan for the TEC. Threat Abatement Plans relevant to the TEC are identified in Chapter 15.

APPROACH TO BASELINE DATA

This section provides an overview of the approach to baseline data for the TEC. It:

- *Provides a summary of the approach to vegetation mapping for the strategic assessment which forms the baseline for the TEC mapping*
- *Outlines the vegetation condition states used in the mapping*
- *Identifies the NSW Plant Community Types (PCTs) that are associated with the TEC*
- *Summarises the approach to mapping the EPBC TEC*
- *Summarises the approach to the patch size analysis for the ecological community*
- *Summarises the approach to identifying areas of likely higher long-term viability in the Strategic Assessment Area*

Please refer to Section 11.3 (in Chapter 11) for details about the methods for mapping native vegetation, and Section 11.4.3 for details about the mapping methods for EPBC TECs.

APPROACH TO VEGETATION MAPPING	Native vegetation was mapped at two levels for the strategic assessment. Within the nominated areas, native vegetation was mapped using a method consistent with the BAM. This involved using a combination of API, existing desktop mapping, previous surveys and studies, rapid assessment ground-truthing, and field surveys (including floristic plot surveys). This process resulted in detailed maps of PCTs categorised by condition. Outside the nominated areas, native vegetation was mapped using the best available data integrated into a single dataset. Vegetation condition states were also applied across the broader area. It should be noted that comprehensive on-ground surveys across all native vegetation within the nominated areas was not possible and no surveys were undertaken outside the nominated areas. This means that a set of assumptions around the available data was required to translate the site based condition thresholds for the EPBC TEC so that it could be mapped at the scale of the Strategic Assessment Area. These assumptions are summarised below and explained in detail in Section 11.4.3 of Chapter 11. It is also important to note that limited mapping exists for PCT 1800 outside of the nominated areas as the PCT has historically been included in mapping for other PCTs. It is expected that more PCT 1800 exists outside of the nominated areas than identified in the best available data.
VEGETATION CONDITION STATES	Vegetation condition was mapped using the following five condition states. These states generally range from better (intact) to worse (urban native/exotic) condition and are:

	• **Intact:** This condition state was assigned to areas of wooded vegetation community, including regrowth, that displays a range of structural layers and habitat features (e.g. tree hollows and large trees, fallen timber, leaf litter) with a largely unmodified canopy density and a range of age classes and species present • **Thinned:** This condition state was assigned to native vegetation in various states of modification, including: o Wooded vegetation with a partly-cleared canopy and a more open structure compared to the intact PCT o Wooded vegetation that has been under scrubbed • **Scattered trees:** This condition state includes a single tree or small group of trees surrounded by native or exotic pasture or areas of cultivation. Other structural components of the vegetation have typically been removed • **Grasslands:** Grasslands included two separate state zones – exotic grassland and native grasslands • **Urban native/exotic:** This condition type was assigned to areas of vegetation within urban areas that consisted of street trees, urban parks and other patches of planted vegetation that could provide habitat for native species
ASSOCIATED PCTs	The following PCT is associated with the TEC: • 1800 Swamp Oak open forest on river flats of the Cumberland Plain and Hunter valley
MAPPING APPROACH	Mapping of the TEC across the Strategic Assessment Area used the following criteria which are based on applying the condition thresholds at a landscape scale to the available data: • Patch size ≥ 5 ha, OR • Patch size at least 2 ha and < 5 ha, OR • Patch is at least 0.5 ha and < 2 ha and is connected to a larger area of native vegetation of at least 5 ha, AND • Non-native species comprise < 20% of total understorey vegetation cover OR • Patch size ≥ 5 ha, OR • Patch size at least 2 ha and < 5 ha, OR • Patch is at least 0.5 ha and < 2 ha and is connected to a larger area of native vegetation of at least 5 ha, AND • Non-native species comprise < 50% of total understorey vegetation cover OR • Patch size ≥ 5 ha, OR • Patch size at least 2 ha and < 5 ha, OR • Patch is at least 0.5 ha and < 2 ha and is connected to a larger area of native vegetation of at least 5 ha, AND • Non-native species comprise < 80% of total understorey vegetation cover
PATCH SIZE ANALYSIS	As outlined in Section 31.3, a patch size analysis for the ecological community was undertaken to identify the number and size of patches across the Strategic Assessment Area.
VIABILITY ASSESSMENT	As outlined in Section 31.4, an analysis was undertaken to identify areas of likely higher long-term viability for the TEC in the Strategic Assessment Area The purpose of the analysis was to identify the patches of the TEC within the Strategic Assessment Area that are more likely to be viable in the longer-term to inform the evaluation of the overall outcome of the Plan for the TEC. Viability is defined in a qualitative sense as the "probability of long-term survival of TEC patches". The approach involved reviewing Conservation Advices for each TEC to identify the factors that influence the long-term viability or conservation significance of a patch of the TEC. This review found that Conservation Advices generally identify a similar set of factors that influence long-term viability. Key factors included:

	• Larger patches are generally more viable than smaller patches • Better condition patches are generally more viable than poorer condition patches • Connected patches are generally more viable than poorer connected patches • Patches with a lower edge/area ratio are generally more viable than patches with a higher edge/area ratio

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the TEC in the Strategic Assessment Area. It includes reference to a map which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where the TEC occurs.

MAP	See Map 48.2 for a map of the TEC across the Strategic Assessment Area.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	The baseline mapping for this assessment has mapped approximately 272 ha of the TEC within the Strategic Assessment Area (see Table 31-15 for further details). None of the TEC is identified as higher viability. This is because none of the mapped TEC occurs in intact condition which is one of the criteria that must be met to be mapped as higher viability. The TEC occurs mainly along waterways and is scattered within and outside the nominated areas in the northern half of the Strategic Assessment Area. The TEC occurs in GPEC, WSA and GMAC. The Conservation Advice does not specifically identify any sites in the Strategic Assessment Area that are important to the TEC. The Conservation Advice states that all patches of a reasonable size and in the highest condition categories as defined in the advice (categories A and B) are considered habitat critical to the survival of the TEC. These are generally: • Large (≥ 5 ha) or moderate patches (≥ 2 ha and < 5 ha) with a predominately native understory • Well-connected smaller patches (< 2 ha and ≥ 0.5 ha) with a predominately native understory The Conservation Advice also identifies several factors affecting the value of a patch, including: • A larger size and/or a high area to boundary ratio • Part of a larger remnant of native vegetation or linking other remnants • Patches in catchments or tidal areas with minimal modification to natural hydrology • Evidence of recruitment of key plant species/range of age cohorts • High native species richness • Presence of threatened species • Low level of weeds and pest animals The TEC is highly fragmented across the Strategic Assessment Area, comprising 109 patches with an average patch size of 2.5 ha. The TEC mostly occurs as long and narrow patches along riparian corridors surrounded by either urban development or farming.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of the TEC that was avoided through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

31.8.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped approximately 34 ha of the TEC within the nominated areas (not including excluded lands). Approximately 32 ha (96 per cent) has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 5 ha was avoided for biodiversity purposes

- 28 ha was avoided for other purposes

An additional 64 ha occurs on excluded lands.

A breakdown of avoidance across each nominated area is provided in Table 31-16.

It is important to note that the avoidance calculations in Table 31-16, including for ‘avoidance for biodiversity purposes’, ‘avoidance for other reasons’, and ‘total avoidance’, have been calculated without including excluded lands as these lands are not covered by the Plan. Table 31-16 shows the amounts of habitat within excluded lands for context only.

31.8.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts. It considers:

- *Predicted impacts within urban capable lands and transport corridors*
- *Potential issues associated with fragmentation*
- *Potential additional impacts from essential infrastructure (within nominated areas but outside the urban capable lands) and tunnels associated with transport projects*

Offsets are provided for any TECs that are subject to direct impacts. The rationale and process for setting offset targets for TECs is set out in Section 8.5.2 of Chapter 8, and explained in detail in the Conservation Priorities Method that supports the Plan.

Implementation of the Plan will lead to direct impacts to the TEC (see Section 31.8.3 for discussion) but will not generally increase fragmentation (see Section 31.8.4 for discussion).

31.8.3 DIRECT IMPACTS TO THE TEC

Implementation of the Plan will lead to the loss of 1.8 ha of the TEC predominantly within transport corridors in WSA. This loss represents less than 1 per cent of the remaining TEC in the Strategic Assessment Area and 1.8 per cent of the TEC in the nominated areas. A breakdown of direct impacts is provided in Table 31-17.

The majority of the TEC impacted within WSA:

- Is in thinned condition (1.7 ha)
- Comprises small patches (less than 5 ha) (6 of 7 impacted patches)

The majority of the loss in WSA is from transport within the nominated area. The threat to the TEC in relation to the TEC is reduced because:

- Only small areas of the TEC will be impacted
- Impacts are to patches in thinned or scattered condition. There are no impacts to intact patches
- Impacts generally occur to the edges of patches that are isolated and not well connected to native vegetation

31.1.3 FRAGMENTATION OF THE TEC

As outlined above, impacts largely occur to the edges of patches and will not result in a loss of connectivity and therefore will not lead to fragmentation.

31.8.4 OFFSETS FOR RESIDUAL DIRECT IMPACTS

To compensate for the predicted direct impacts to the TEC, the Plan includes a commitment to secure 5 ha of the TEC as part of the conservation program. This would:

- Lead to the protection and management of an additional 1.8 per cent of the ecological community within the Strategic Assessment Area
- Increase the level of protection and management of the ecological community by approximately 25.1 per cent on top of what is currently secured in the Strategic Assessment Area

These offsets are consistent with a number of high priority actions in the Conservation Advice to protect the TEC.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the TEC that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the TEC if:

- *The indirect impact is identified as a threat in a relevant profile or conservation advice, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

31.8.5 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice identifies a range of threats to the TEC. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential indirect impacts (identified as threats in the Conservation Advice) are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Inappropriate habitat disturbance
- Changes to hydrology
- Invasive fauna

In addition to the threats identified in the Conservation Advice, the following potential indirect impacts are considered relevant to the TEC:

- Diseases, pathogens and dieback

Climate change is also a relevant threat to the ecological community. The extent to which the Plan has considered adaptation to climate change impacts is addressed in Chapter 41.

Impacts from agricultural activities, including grazing were also identified in the Conservation Advice as key threats. However, none of these are considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate these risks across the Strategic Assessment Area.

INAPPROPRIATE FIRE REGIMES

The TEC occurs in fire adapted landscapes and may be affected by fires that are too frequent or not frequent enough. However, the impact of inappropriate fire regimes are not well understood (DoEE, 2018a). Inappropriate fire regimes can be caused by:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact the TEC. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development. For the TEC this includes areas in GPEC, WSA, and the northern part of GMAC.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant to the outcome for the TEC being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy for the Strategic Conservation Areas that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
    - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from the TEC. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the TEC from altered fire regimes as a result of development. This is because:

- Avoided lands where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting the TEC
- Fire management authorities will be engaged to ensure they understand the requirements of the TEC and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas

These controls are consistent with a number of priority actions in the Conservation Advice about the management of fire.

WEED INVASION

The TEC is threatened with invasion and competition by weeds. Weed incursions in this TEC are caused by (DoEE, 2018a):

- Physical disturbance to vegetation within the community (the predominant cause of weed incursions), such as through landfill, waste dumping and soil disturbance
- Encroachment of garden plants
- Altered hydrology and polluted runoff from urban and agricultural areas which alters conditions within the TEC to favour weed growth
- Grazing from feral animals
- Inappropriate fire regimes

Key weeds include Bridal Creeper (*Asparagus asparagoides*), Bitou Bush (*Chrysanthemoides monilifera*), Camphor Laurel (*Cinnamomum camphora*), Umbrella Tree (*Schefflera actinophylla*), Privets (*Ligustrum* spp.), Winter Senna (*Senna pendula*), invasive grasses (*Pennisetum* spp. and *Stenotaphrum secundatum*), and Lantana (*Lantana camara*). The TEC is also threatened by aquatic weeds such as Water Hyacinth (*Eichhornia crassipes*), *Ludwigia* spp. and Salvinia (*Salvinia molesta*) (DoEE, 2018a).

Urban and transport development within the Strategic Assessment Area has the potential to increase the spread of weeds by providing more opportunities for weed dispersal or changing conditions to favour weeds. However, all mapped areas of this TEC within the Strategic Assessment Area are considered to have significant edge effects and occur in close proximity to urban development or farming and are already significantly exposed to weed incursion.

The TEC is most susceptible to the threat of weeds from development under the Plan where new urban development or transport corridors occur adjacent to the TEC and/or fragments patches of the TEC into smaller patches and introduces edge effects. Key risk areas include parts of GPEC, WSA, and the northern part of GMAC:

The Plan incorporates a range of measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Areas. This includes a number of actions, of which the following are the most relevant to the outcome for the TEC:
    - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
    - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
    - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
    - Require proponents to undertake the following when applying for/undertaking development:
        - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
        - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
        - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

The package of measures in the Plan is expected to adequately manage the risk posed to the TEC from weed invasion. This is because:

- Avoided lands where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- The Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy. This includes the land to be protected under the conservation program for the TEC
- There will be a range of planning controls to minimise the potential spread of weeds during and after construction

These controls are consistent with a number of priority conservation actions in the Conservation Advice about the management of weeds.

INAPPROPRIATE HABITAT DISTURBANCE

Inappropriate habitat disturbance is identified in the Conservation Advice as a threat to the TEC, with impacts resulting from recreational activity identified as a particular issue. As discussed for the other TECs in this Chapter, inappropriate habitat disturbance may also occur through other mechanisms such as:

- Dumping of rubbish and garden waste which can directly impact areas of the TEC as well as facilitate increases in weeds (see above) and pollutants
- Inadvertent disturbance during construction which has the potential to directly impact the TEC outside approved development areas

Inappropriate habitat disturbance within the Strategic Assessment Area may increase due to development within the nominated areas. Occurrences of the TEC considered most at risk are those that occur in GPEC, WSA, and the northern part of GMAC.

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for the TEC. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan is expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development. This is because:

- Avoided lands where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

These controls are consistent with a number of priority conservation actions in the Conservation Advice about the management of disturbance.

CHANGES TO HYDROLOGY

The creation of hard surfaces associated with urban development and transport results in changes to the hydrology of surrounding areas. The main threats to the TEC are associated with reduced water quality, sedimentation and eutrophication (DoEE, 2018a).

The TEC is most susceptible to the threat of increased runoff from development under the Plan where new urban or transport development occurs adjacent (and upstream or upslope) to the TEC. Key risk areas are those that occur in GPEC, WSA, and the northern part of GMAC.

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for the TEC. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5) and transport (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through:

- Development controls in the nominated areas in relation to:
  - Water cycle management. For example:
    - Water management measures must comply with council's requirements for detention, drainage and water sensitive urban design principles
    - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
  - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
  - Soil erosion and sedimentation. For example:
    - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
    - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom 2004) and submitted with each subdivision development application
- The implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the RMS Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the TEC from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts to the TEC
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to the TEC

These controls are consistent with a number of priority conservation actions in the Conservation Advice about hydrology.

INVASIVE FAUNA

TECs can be threatened by introduced animals and aggressive native species. These species include:

- Domestic species such as cats and dogs which are related to urban development
- Pest species such as feral pigs, foxes, rats, house mice and rabbits which are primarily related to agricultural development
- Aggressive bird species which compete for resources including the Noisy Miner

Collectively, these animals can lead to declines in biodiversity through:

- Predation
- Damage to vegetation and soils
- Competition for resources

Existing land use within the nominated areas and surrounding region (which includes residential and rural residential areas, and farming) means that the majority of these issues are already present in the Strategic Assessment Area and are unlikely to pose a novel threat to the TEC.

However, the extent of proposed new urban development under the Plan means that (in particular) the threats associated with cats and dogs are likely to be exacerbated. It is likely that there will be an increase in the number of domestic cats and dogs in the local area, which, in turn, may lead to an increase in feral cat and wild dog numbers.

In relation to aggressive bird species, the two main drivers for increasing the threat within the TEC are:

- Fragmentation of habitat which creates greater edge effects and facilitates access by aggressive bird species. As outlined above in the analysis of direct impacts, fragmentation is not considered likely to occur
- Habitat disturbance through inappropriate land management which can change the structure of the TEC and facilitate access by aggressive bird species. As outlined above in relation to inappropriate habitat disturbance, the Plan includes a package of measures which are expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development

In relation to the residual risks associated with invasive fauna, the Plan incorporates a range of measures to manage the risks. In summary, these include:

- A commitment (Commitment 17) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the Strategic Conservation Areas. This includes a number of actions with the most relevant to the outcome for the TEC being:
  - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
  - Preparation of a Pest Animal Control Implementation Strategy
  - A process to enter into written agreements with delivery partners to implement the pest animal control program
  - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Development controls that will:
  - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
  - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
  - Require appropriate management and control of pest animals relevant to development sites
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing pests, consistent with the pest animal implementation strategy outlined in Commitment 16

These controls are consistent with a number of priority conservation actions in the Conservation Advice about the management of invasive fauna.

DISEASES, PATHOGENS AND DIEBACK

TECs are potentially susceptible to a range of diseases, pathogens and dieback which can substantially affect their long term viability. Recognised threats include myrtle rust and dieback caused by the root-rot fungus *Phytophthora cinnamomi*.

Development under the Plan may increase the risk of the spread of infection/disease. This is primarily related to:

- Soil transportation on contaminated footwear, vehicles and machinery, and in residential garden establishment
- Increased site visitation rates
- Earthworks and activities conducted during construction
- Increased surface water runoff

The Plan incorporates a range of measures to manage the risks associated with diseases, pathogens and dieback. In summary, these include:

- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:

- Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
- Entering into written agreements with delivery partners to implement priority disease control programs

- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures methods to protect the environment during construction, including best practice site hygiene protocols to minimise spread of *Phytophthora* and Myrtle Rust

The package of measures in the Plan is expected to adequately manage the risk to the TEC from diseases, pathogens and dieback because:

- It supports a landscape scale approach to the issue across the Cumberland subregion
- It will ensure appropriate controls during construction

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the TEC from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the TEC to occur due to development of essential infrastructure within the avoided lands of WSA.

The TEC does not occur within the vicinity of the tunnel footprints for transport and is therefore not at risk of additional impacts from tunnels.

31.8.6 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

Areas of the TEC occur within the avoided lands of WSA (29.1 ha) and GPEC (3.3 ha). Impacts to the TEC are possible where it occurs within land avoided for biodiversity purposes (~4.6 ha). The likelihood of impact is reduced where the TEC occurs in riparian corridors (~27.9 ha).

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine if the TEC was present
- Measures to avoid impacts to the listed TEC through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the TEC will occur as a results of essential infrastructure as every effort should be made to avoid and minimise impacts. Any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE TEC

This section considers the likely effects of implementation of the Plan on the long-term viability of the TEC. The analysis has regard for the guidance in the Conservation Advice (there is no Recovery Plan for the TEC), and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also identifies any relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

31.8.7 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DoEE, 2018a) identifies the following key issues that are likely to have the greatest influence on the long-term viability of the TEC in relation to implementation of the Plan. They are:

- Habitat loss and fragmentation
- Indirect impacts including:
  - Inappropriate fire regimes
  - Weed invasion
  - Inappropriate habitat disturbance
  - Changes to hydrology
  - Invasive fauna

HABITAT LOSS AND FRAGMENTATION

As outlined above, implementation of the Plan may lead to the loss of 1.8 ha of the TEC. However, it is not considered likely that this will threaten the long-term viability of the TEC because:

- The scale of impacts are minor when considering the mapped extent of the TEC across the Strategic Assessment Area (less than 0.7 per cent) and more broadly within the context of the entire range of the TEC
- There is no mapped higher viability TEC in the Strategic Assessment Area and all impacts occur to thinned or scattered condition vegetation
- There will be no fragmentation
- The offsets proposed by the Plan (5 ha of the TEC) will increase the level of protection of the TEC and address a number of actions in the Conservation Advice about improving the area of the TEC that is protected and managed

INDIRECT IMPACTS

The potential indirect impacts associated with inappropriate fire regimes, weed invasion, inappropriate habitat disturbance, changes to hydrology, and invasive fauna will be managed and mitigated through a number of commitments and actions in the Plan.

Indirect impacts are not expected to influence the long-term viability of the TEC.

CONCLUSION

The nature of the impacts to the TEC combined with the commitments to protect 5 ha of the TEC and manage indirect impacts will ensure that the implementation of the Plan does not adversely influence the long-term viability of the TEC.

31.8.8 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the TEC.

31.8.9 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 31-14 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The Plan is not inconsistent with any of the relevant TAPs. Please refer to Section 15.9 of Chapter 15 for a detailed discussion of each TAP and the relationship of the Plan.

Table 31-14: Key Threatening Processes and relevant Threat Abatement Plans for Coastal Swamp Oak (*Casuarina Glauca*) Forest of NSW and South East Queensland

KEY THREATENING PROCESS	RELEVANT THREAT ABATEMENT PLAN
Aggressive exclusion of birds from potential woodland and forest habitat by over-abundant noisy miners (*Manorina melanocephala*)	There is no relevant TAP
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP
Predation by feral cats	Threat abatement plan for predation by feral cats (DoE, 2015g)
Psittacine Circoviral (beak and feather) Disease affecting endangered psittacine species	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

TECS NOT DIRECTLY IMPACTED

31.9 CASTLEREAGH SCRIBBLY GUM AND AGNES BANKS WOODLANDS OF THE SYDNEY BASIN BIOREGION

This assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan on the TEC in accordance with the EPBC Terms of Reference. It sets out:

- *TEC background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the TEC*
- *Data tables*

THREATENED ECOLOGICAL COMMUNITY BACKGROUND

This section sets out the basic information about the TEC. It provides a description of the TEC, and an overview of the listing definition and its distribution. These provide context for the impact assessment. At the end of the section are links to key documents that provide additional background information.

EPBC ACT LISTING	Endangered
DESCRIPTION	The TEC is a low woodland community with an overstorey dominated by *Angophora bakeri*, *Eucalyptus racemosa*, *E. parramattensis* subsp. *parramattensis*. *Melaleuca decora* and *Eucalyptus fibrosa* may also be present and prominent (DoE, 2015b). The midstorey is a shrub layer that commonly includes *Banksia* and *Melaleuca* species and to a lesser extent *Leptospermum trinervium*, *Dillwynia sericea*, *Monotoca scoparia*, *Platysace ericoides*, *Persoonia nutans*, *Pimelea linifolia* subsp. *linifolia* and *Hakea sericea*. The ground layer consists of a mix of grasses, other graminoids and forbs (DoE, 2015b). The TEC can intergrade into Cooks River/Castlereagh Ironbark Forest (on gravel-clay soils), Castlereagh Swamp Woodland (in moist depressions) and Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest (on clay soils) (DoE, 2015b). The following PCTs are associated with the TEC: • 883 Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion • 958 Narrow-leaved Apple - Hard-leaved Scribbly Gum heathy woodland on sand at Agnes Banks, Sydney Basin Bioregion A range of fauna species occur in the TEC, including reptiles, amphibians, birds, micro-bats, marsupials and invertebrates. Most of these species are not restricted to the TEC and also occur in, and are likely to rely on, other native vegetation in the Cumberland subregion (DoE, 2015b). Most plant species in the TEC are able to regenerate from lignotubers and buds beneath the bark as well as seeds stored in the soil (OEH, 2010). The TEC is equivalent to two NSW BC Act listed TECs (Castlereagh Scribbly Gum Woodland and Agnes Banks Woodland) where key diagnostic and condition thresholds are met (DoE, 2015b).

EPBC DEFINITION	Only patches of the TEC that meet minimum size and condition thresholds are considered part of the TEC under the EPBC Act. Thresholds relate to factors such as patch size, understorey native vegetation cover, number of tree hollows, or whether the patch is contiguous with other native vegetation patches. Details of the thresholds are provided in the Conservation Advice (DoE, 2015b).
DISTRIBUTION	The TEC is confined to the Sydney Basin bioregion and occurs across the Cumberland subregion, and on the margins of Sydney Cataract, Wollemi and Burragorang subregions. The majority of the TEC is found in larger patches in the north-west part of the Cumberland subregion in the Castlereagh area between Richmond and Llandilo. Other significant patches occur in the Holsworthy area with smaller occurrences at Tahmoor, Kemps Creek and Longneck Lagoon. The TEC primarily occurs in elevations below 80 m with mean annual rainfall of 700-900 mm. It generally occurs on Tertiary sands and gravels of the Hawkesbury-Nepean river system. At Agnes Banks, the TEC primarily occurs aeolian sands overlying Tertiary alluvium. (DoE, 2015b)
SOS SITES	Part of this TEC (PCT 883) has been categorised under the 'widespread' management stream for TECs under the SOS program. Management of this category of TECs focuses on planning and regulatory processes, policy and programs, and private land conservation and reservation of land. Currently no management sites have been identified for this TEC. The Agnes Banks component of the TEC (PCT 958) is in the 'range-restricted' category and has a cluster of management sites near to and including Agnes Banks Nature Reserve.
RELEVANT PLANS AND POLICIES	Approved Conservation Advice (including listing advice) for Castlereagh Scribbly Gum and Agnes Banks Woodlands of the Sydney Basin Bioregion (DoE, 2015b) Key Threatening Processes relevant to the TEC are identified in Appendix D of the Conservation Advice There is no adopted or made Commonwealth Recovery Plan for the TEC. The TEC is included in the Cumberland Plain Recovery Plan (NSW) (DECCW, 2011)

APPROACH TO BASELINE DATA

This section provides an overview of the approach to baseline data for the TEC. It:

- *Provides a summary of the approach to vegetation mapping for the strategic assessment which forms the baseline for the TEC mapping*
- *Outlines the vegetation condition states used in the mapping*
- *Identifies the NSW Plant Community Types (PCTs) that are associated with the TEC*
- *Summarises the approach to mapping the EPBC TEC*
- *Summarises the approach to the patch size analysis for the ecological community*
- *Summarises the approach to identifying areas of likely higher long-term viability in the Strategic Assessment Area*

Please refer to Section 11.3 (in Chapter 11) for details about the methods for mapping native vegetation, and Section 11.4.3 for details about the mapping methods for EPBC TECs.

APPROACH TO VEGETATION MAPPING	Native vegetation was mapped at two levels for the strategic assessment. Within the nominated areas, native vegetation was mapped using a method consistent with the BAM. This involved using a combination of API, existing desktop mapping, previous surveys and studies, rapid assessment ground-truthing, and field surveys (including floristic plot surveys). This process resulted in detailed maps of PCTs categorised by condition. Outside the nominated areas, native vegetation was mapped using the best available data integrated into a single dataset. Vegetation condition states were also applied across the broader area.

	It should be noted that comprehensive on-ground surveys across all native vegetation within the nominated areas was not possible and no surveys were undertaken outside the nominated areas. This means that a set of assumptions around the available data was required to translate the site based condition thresholds for the EPBC TEC so that it could be mapped at the scale of the Strategic Assessment Area. These assumptions are summarised below and explained in detail in Section 11.4.3 of Chapter 11.
VEGETATION CONDITION STATES	Vegetation condition was mapped using the following five condition states. These states generally range from better (intact) to worse (urban native/exotic) condition and are: • **Intact:** This condition state was assigned to areas of wooded vegetation community, including regrowth, that displays a range of structural layers and habitat features (e.g. tree hollows and large trees, fallen timber, leaf litter) with a largely unmodified canopy density and a range of age classes and species present • **Thinned:** This condition state was assigned to native vegetation in various states of modification, including: o Wooded vegetation with a partly-cleared canopy and a more open structure compared to the intact PCT o Wooded vegetation that has been under scrubbed • **Scattered trees:** This condition state includes a single tree or small group of trees surrounded by native or exotic pasture or areas of cultivation. Other structural components of the vegetation have typically been removed • **Grasslands:** Grasslands included two separate state zones – exotic grassland and native grasslands • **Urban native/exotic:** This condition type was assigned to areas of vegetation within urban areas that consisted of street trees, urban parks and other patches of planted vegetation that could provide habitat for native species
ASSOCIATED PCTs	The following PCTs are associated with the TEC: • 883 Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion • 958 Narrow-leaved Apple - Hard-leaved Scribbly Gum heathy woodland on sand at Agnes Banks, Sydney Basin Bioregion
MAPPING APPROACH	Mapping of the TEC across the Strategic Assessment Area used the following criteria which are based on applying the condition thresholds at a landscape scale to the available data: • Patch size ≥ 0.5 ha, AND • ≥ 30% (< 50%) of the perennial understorey vegetation cover is made up of native species (based on field verification), AND • The patch is contiguous with a native vegetation remnant >1 ha in area, AND • Growing on tertiary sands and gravels of the Hawkesbury-Nepean river system OR • Patch size ≥ 0.5 ha, AND • ≥ 70% of the perennial understorey vegetation cover is made up of native species, AND • Elevations below 80 m, AND • Growing on tertiary sands and gravels of the Hawkesbury-Nepean river system OR • Patch size is ≥ 2 ha, AND • ≥ 50% of the perennial understorey vegetation cover is made up of native species (based on field verification)
PATCH SIZE ANALYSIS	As outlined in Section 31.3, a patch size analysis for the ecological community was undertaken to identify the number and size of patches across the Strategic Assessment Area.

VIABILITY ASSESSMENT	As outlined in Section 31.4, an analysis was undertaken to identify areas of likely higher long-term viability for the TEC in the Strategic Assessment Area The purpose of the analysis was to identify the patches of the TEC within the Strategic Assessment Area that are more likely to be viable in the longer-term to inform the evaluation of the overall outcome of the Plan for the TEC. Viability is defined in a qualitative sense as the "probability of long-term survival of TEC patches". The approach involved reviewing Conservation Advices for each TEC to identify the factors that influence the long-term viability or conservation significance of a patch of the TEC. This review found that Conservation Advices generally identify a similar set of factors that influence long-term viability. Key factors included: • Larger patches are generally more viable than smaller patches • Better condition patches are generally more viable than poorer condition patches • Connected patches are generally more viable than poorer connected patches • Patches with a lower edge/area ratio are generally more viable than patches with a higher edge/area ratio

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the TEC in the Strategic Assessment Area. It includes reference to a map which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where the TEC occurs.

MAP	See Map 48.1 for a map of the TEC across the Strategic Assessment Area.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	The baseline mapping for this assessment has mapped approximately 2,769 ha of the TEC within the Strategic Assessment Area (see Table 31-19 for further details). Of this, 2,606 ha has been identified as higher viability through the viability analysis. The TEC occurs in the following main locations within the Strategic Assessment Area: • The vast majority occurs outside the nominated areas north of GPEC between Castlereagh and Windsor Downs where it is connected with larger remnants of native vegetation • Two smaller patches occur to the south of WSA near Kemps Creek • Several patches occur outside the nominated areas around Holsworthy and Pitt Town It does not occur in any of the nominated areas or transport corridors. The Conservation Advice does not specifically identify any sites in the Strategic Assessment Area that are important to the TEC. It states that all patches that meet the minimum (moderate class) condition thresholds as defined in the advice (categories A and B) are considered habitat critical to the survival of the TEC. These are generally: • Patch sizes ≥ 0.5 ha with ≥ 30% native understorey and patches that are well-connected to a native vegetation remnant of ≥ 1 ha in area • Patch sizes ≥ 0.5 ha with ≥ 50% native understorey The Conservation Advice also identifies several factors affecting the value of a patch, including: • A larger size and/or large area to boundary ratio • Part of a larger remnant of native vegetation or linking other remnants • Evidence of recruitment of key plant species/range of age cohorts • Good faunal habitat • High native species richness • Presence of threatened species • Low level of weeds and pest animals

	The TEC is highly fragmented across the Strategic Assessment Area, comprising approximately 145 patches with an average patch size of approximately 19 ha. Because the TEC intergrades into other vegetation types, many patches of the TEC are surrounded by larger areas of native vegetation, which provides some buffer from potential impacts associated with edge effects.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of the TEC that was avoided through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

None of the TEC was mapped within the nominated areas or transport corridors. Avoidance of the TEC was therefore not necessary.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts. It considers:

- *Predicted impacts within urban capable lands and transport corridors*
- *Potential issues associated with fragmentation*
- *Potential additional impacts from essential infrastructure (within nominated areas but outside the urban capable lands) and tunnels associated with transport projects*

Offsets are provided for any TECs that are subject to direct impacts. The rationale and process for setting offset targets for TECs is set out in Section 8.5.2 of Chapter 8, and explained in detail in the Conservation Priorities Method that supports the Plan.

Implementation of the Plan will not lead to direct impacts or fragmentation of the TEC. As a result the Plan does not provide offsets for the TEC.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the TEC that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the TEC if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

31.9.1 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice identifies a range of threats to the TEC. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential indirect impacts (identified as threats in the Conservation Advice) are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion

- Inappropriate habitat disturbance
- Diseases, pathogens and dieback
- Invasive fauna

Climate change is a relevant threat to the ecological community. The extent to which the Plan has considered adaptation to climate change impacts is addressed in Chapter 41.

A number of other threats were identified in the Conservation Advice. However, none of these are considered likely to impact the TEC. They are:

- Changes to hydrology. The distance of the TEC away from urban and transport development areas means that changes in hydrology is not a relevant indirect impact
- Grazing. Implementation of the Plan will not exacerbate this risk across the Strategic Assessment Area

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes can affect the structure and species composition of the TEC by altering the mid and ground layers. Low seedling recruitment has been observed in the TEC, which is thought to be associated with extended dry periods and too frequent fire. Many plant species in the TEC can survive for decades as seeds stored in the soil, bulbs, corms, rhizomes, rootstocks or lignotubers (DoE, 2015b).

While most impacts to the TEC are associated with increased fire, in some areas the TEC is threatened due to a lack of fire because of its proximity to residential areas. This generally occurs where the TEC has not been burnt for over 30 years (DoE, 2015b).

Inappropriate fire regimes can be caused by:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

While it is noted that the TEC does not occur in any of the nominated areas, increased human activity across the Strategic Assessment Area may increase the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact the TEC. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. For the TEC, the closest areas are to the north of GPEC (Londonderry area) and to the south of WSA (near Kemps Creek).

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, the relevant measures for this TEC include a commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant to the outcome for the TEC being:

- Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
- Preparation of a fire management strategy for the Strategic Conservation Areas that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
- A process to work with delivery partners to implement the fire management strategy
- Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans

The measures in the Plan are expected to adequately manage the risk to the TEC from altered fire regimes as a result of development. This is because fire management authorities will be engaged to ensure they understand the requirements of the TEC and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas.

These controls are consistent with a high priority conservation action in the Conservation Advice to “Undertake appropriate fire management practices…”.

WEED INVASION

The TEC is threatened with invasion and competition by weeds. Weed incursion in the TEC is associated with agricultural activities as well as urban development. The most serious threats are: Cootamundra wattle (*Acacia baileyana*), Flat weed (*Hypochaeris radicata*), African love grass (*Eragrostis curvula*), Kikuyu (*Cenchrus clandestinus*) and several other grasses and vines (DoE, 2015b).

These weeds are already present within the Strategic Assessment Area and pose a threat to the TEC. However, the development has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or changing conditions to favour weeds.

While it is noted that the TEC does not occur in any of the nominated areas, the TEC may be susceptible to the landscape threat of weeds driven by new urban development.

The Plan incorporates a range of measures to manage the risk posed by weed invasion to biodiversity. In summary, the relevant measures for this TEC include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Areas. This includes a number of actions, of which the following are the most relevant to the outcome for the TEC:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16

The package of measures in the Plan is expected to adequately manage the risk posed to the TEC from weed invasion. This is because the Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy. This includes the land to be protected under the conservation program for the TEC.

These controls are consistent with a number of priority conservation actions in the Conservation Advice about the management of weeds.

INAPPROPRIATE HABITAT DISTURBANCE

Inappropriate habitat disturbance is identified in the Conservation Advice as a threat to the TEC. This relates to a wide range of different mechanisms for disturbance including:

- Inappropriate mowing, slashing or scrubbing of the understorey for reasons such as bushfire fuel reduction, grazing and perceived aesthetics
- Dumping of rubbish and garden waste which can directly impact areas of the TEC as well as facilitate increases in weeds (see above) and pollutants
- Inappropriate recreational activities such as ad hoc track building and trail bike use which can directly impact areas of the TEC and facilitate processes such as erosion
- Removal of wood which changes the structure and habitat features of the TEC

Each of these mechanisms have the potential to alter the structure and floristic composition of the TEC.

Inappropriate habitat disturbance within the Strategic Assessment Area may increase due to development within the nominated areas.

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for the TEC. In summary, these include:

- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan is expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development. This is because:

- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

DISEASES, PATHOGENS AND DIEBACK

TECs are potentially susceptible to a range of diseases, pathogens and dieback which can substantially affect their long term viability. Recognised threats include myrtle rust and dieback caused by the root-rot fungus *Phytophthora cinnamomi*.

Development under the Plan may increase the risk of the spread of infection/disease. This is primarily related to:

- Soil transportation on contaminated footwear, vehicles and machinery, and in residential garden establishment
- Increased site visitation rates
- Earthworks and activities conducted during construction
- Increased surface water runoff

While many of these disease pathways are not relevant to the TEC given the distance it occurs from the nominated areas, the Plan incorporates a range of measures to manage the risks associated with diseases, pathogens and dieback. In summary, these include:

- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
  - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
  - Entering into written agreements with delivery partners to implement priority disease control programs
- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures methods to protect the environment during construction, including best practice site hygiene protocols to minimise spread of *Phytophthora* and Myrtle Rust

The package of measures in the Plan is expected to adequately manage the risk to the TEC from diseases, pathogens and dieback because:

- It supports a landscape scale approach to the issue across the Cumberland subregion
- It will ensure appropriate controls during construction

INVASIVE FAUNA

TECs can be threatened by introduced animals and aggressive native species. These species include:

- Domestic species such as cats and dogs which are related to urban development
- Pest species such as foxes, rats, house mice and rabbits which are primarily related to agricultural development
- Aggressive bird species which compete for resources including the introduced Indian myna, and native species such as the sulphur-crested cockatoo

Collectively, these animals can lead to declines in biodiversity through:

- Predation
- Damage to vegetation and soils
- Competition for resources

Existing land use within the nominated areas and surrounding region (which includes residential and rural residential areas, and farming) means that these issues are already present in the Strategic Assessment Area and are unlikely to pose a novel threat to the TEC.

However, the extent of proposed new urban development under the Plan means that the threats associated with cats and dogs are likely to be exacerbated. It is likely that there will be an increase in the number of domestic cats and dogs in the local area, which, in turn, may lead to an increase in feral cat and wild dog numbers.

In relation to aggressive bird species, the two main drivers for increasing the threat within the TEC are:

- Fragmentation of habitat which creates greater edge effects and facilitates access by aggressive bird species. As outlined above there will be no direct impacts due to implementation of the Plan and no fragmentation of the TEC
- Habitat disturbance through inappropriate land management which can change the structure of the TEC and facilitate access by aggressive bird species. As outlined above in relation to inappropriate habitat disturbance, the Plan includes a package of measures which are expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development

In relation to the residual risks associated with invasive fauna, the Plan incorporates a range of measures to manage the risks. In summary, these include:

- A commitment (Commitment 17) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the Strategic Conservation Areas. This includes a number of actions with the most relevant to the outcome for the TEC being:
  - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
  - Preparation of a Pest Animal Control Implementation Strategy
  - A process to enter into written agreements with delivery partners to implement the pest animal control program
  - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Development controls that will:
  - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
  - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
  - Require appropriate management and control of pest animals relevant to development sites
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing pests, consistent with the pest animal implementation strategy outlined in Commitment 16

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the TEC from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

Given the TEC does not occur within the nominated areas or transport corridors, there is no risk of additional impacts from essential infrastructure or tunnels.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE TEC

This section considers the likely effects of implementation of the Plan on the long-term viability of the TEC. The analysis has regard for the guidance in the Conservation Advice (there is no Recovery Plan for the TEC), and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also identifies any relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

31.9.2 IMPLICATIONS FOR LONG-TERM VIABILITY

As outlined above, implementation of the Plan will not lead to any direct impacts to the TEC and potential indirect impacts will be managed. This will ensure that the implementation of the Plan does not adversely influence the long-term viability of the TEC.

31.9.3 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the TEC.

31.9.4 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 31-18 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The Plan is not inconsistent with any of the relevant TAPs. Please refer to Section 15.9 of Chapter 15 for a detailed discussion of each TAP and the relationship of the Plan.

Table 31-18: Key Threatening Processes and relevant Threat Abatement Plans for Castlereagh Scribbly Gum and Agnes Banks Woodlands of the Sydney Basin Bioregion

KEY THREATENING PROCESS	RELEVANT THREAT ABATEMENT PLAN
Dieback caused by the root-rot fungus (*Phytophthora cinnamomi*)	Threat abatement plan for disease in natural ecosystems caused by *Phytophthora cinnamomi* (DoEE, 2018d)
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP
Predation by feral cats	Threat abatement plan for predation by feral cats (DoE, 2015g)

DATA TABLES

This section sets out the data table for occurrence. Cross references to the table are provided throughout the text above.

Table 31-19: Occurrence of Castlereagh Scribbly Gum and Agnes Banks Woodlands in the Strategic Assessment Area

	SAA TOTAL	WITHIN PROTECTED LANDS
TOTAL TEC MAPPING (ha)	**2,769.3**	**491.8**
Intact	2,658.3	488.7
Thinned	111.1	3.0
Scattered Trees	0.0	0.0
Higher Viability TEC	2,605.7	456.8

31.10 ELDERSLIE BANKSIA SCRUB FOREST IN THE SYDNEY BASIN BIOREGION

This assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan on the TEC in accordance with the EPBC Terms of Reference. It sets out:

- *TEC background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the TEC*
- *Data tables*

THREATENED ECOLOGICAL COMMUNITY BACKGROUND

This section sets out the basic information about the TEC. It provides a description of the TEC, and an overview of the listing definition and its distribution. These provide context for the impact assessment. At the end of the section are links to key documents that provide additional background information.

EPBC ACT LISTING	Critically Endangered
DESCRIPTION	The TEC is a type of scrubby forest or woodland limited to sandy substrates associated with deep Tertiary sand deposits on the Nepean River floodplain (DAWE, 2020). The canopy may include *Banksia intergrifolia* subsp. *intergrifolia* (Coast Banksia), *Angophora subvelutina*, *Eucalyptus botryoides* x *E. saligna* and other *Eucalyptus* species, with a subcanopy of Coast Banksia, or *Melaleuca decora* and *M. linariifolia* in wetter areas (DAWE, 2020). The midstorey is a shrub layer that commonly includes *Acacia* species, *Aotus ericoides*, *Brachyloma daphnoides*, *Dillwynia glaberrima*, and *Persoonia linearis* (DAWE, 2020). In some areas, the TEC has elements associated with dry rainforest and riverflat forest, including *Clematis* species, *Clerodendrum tomentosum*, *Duboisia myoporoides*, *Kunzea ambigua* and *Platysace lanceolate*. The ground layer consists of a mix of ferns, graminoids and forbs. A range of fauna species may occur in the TEC, including amphibians, reptiles, birds and mammals. However, as a result of historical modifications to the structure of the TEC and a loss of important habitat features, remnants of the TEC are likely to be of value only to the more disturbance-tolerant or highly mobile species (DAWE, 2020). The TEC is equivalent to the BC Act listed TEC of the same name, which is equivalent to PCT 774. It also includes areas that intergrade with surrounding forest described in NSW as either River Flat Eucalypt Forest (PCT 835), Moist Shale Woodland (PCT 830) or Cumberland Plain Woodland (PCT 849 or 850), provided that the key diagnostic characteristics are met (DAWE, 2020).
EPBC DEFINITION	Condition thresholds have not been applied to this TEC because of the very small size of patches and extent of the TEC remaining. All remaining patches are considered to comprise the TEC and are critical to the survival of the community, including degraded patches (DAWE, 2020).
DISTRIBUTION	The TEC is restricted to the Cumberland subregion within the Sydney Basin bioregion. It is only known from the Camden LGA. Known patches are small and occur in an extensively cleared and mined Tertiary sand deposit at Spring Farm, near Elderslie (DAWE, 2020). The TEC primarily occurs in elevations of 60-100 m with mean annual rainfall of approximately 750 mm (DAWE, 2020).
SOS SITES	Currently one management site has been identified for this TEC: Spring Farm in Camden

RELEVANT PLANS AND POLICIES	Conservation Advice for the Elderslie Banksia Scrub Forest in the Sydney Basin Bioregion (DAWE, 2020). Key Threatening Processes relevant to the TEC are identified in Appendix C of the Conservation Advice. There is no adopted or made Commonwealth Recovery Plan for the TEC.
SPRAT LINK	https://www.environment.gov.au/cgi-bin/sprat/public/publicshowcommunity.pl?id=145

APPROACH TO BASELINE DATA

This section provides an overview of the approach to baseline data for the TEC. It:

- *Provides a summary of the approach to vegetation mapping for the strategic assessment which forms the baseline for the TEC mapping*
- *Outlines the vegetation condition states used in the mapping*
- *Identifies the NSW Plant Community Types (PCTs) that are associated with the TEC*
- *Summarises the approach to mapping the EPBC TEC*
- *Summarises the approach to the patch size analysis for the ecological community*
- *Summarises the approach to identifying areas of likely higher long-term viability in the Strategic Assessment Area*

Please refer to Section 11.3 (in Chapter 11) for details about the methods for mapping native vegetation, and Section 11.4.3 for details about the mapping methods for EPBC TECs.

APPROACH TO VEGETATION MAPPING	Native vegetation was mapped at two levels for the strategic assessment. Within the nominated areas, native vegetation was mapped using a method consistent with the BAM. This involved using a combination of API, existing desktop mapping, previous surveys and studies, rapid assessment ground-truthing, and field surveys (including floristic plot surveys). This process resulted in detailed maps of PCTs categorised by condition. Outside the nominated areas, native vegetation was mapped using the best available data integrated into a single dataset. Vegetation condition states were also applied across the broader area. It should be noted that comprehensive on-ground surveys across all native vegetation within the nominated areas was not possible and no surveys were undertaken outside the nominated areas. This means that a set of assumptions around the available data was required to translate the site based condition thresholds for the EPBC TEC so that it could be mapped at the scale of the Strategic Assessment Area. These assumptions are summarised below and explained in detail in Section 11.4.3 of Chapter 11.
VEGETATION CONDITION STATES	Vegetation condition was mapped using the following five condition states. These states generally range from better (intact) to worse (urban native/exotic) condition and are: • **Intact:** This condition state was assigned to areas of wooded vegetation community, including regrowth, that displays a range of structural layers and habitat features (e.g. tree hollows and large trees, fallen timber, leaf litter) with a largely unmodified canopy density and a range of age classes and species present • **Thinned:** This condition state was assigned to native vegetation in various states of modification, including: o Wooded vegetation with a partly-cleared canopy and a more open structure compared to the intact PCT o Wooded vegetation that has been under scrubbed • **Scattered trees:** This condition state includes a single tree or small group of trees surrounded by native or exotic pasture or areas of cultivation. Other structural components of the vegetation have typically been removed

	• **Grasslands:** Grasslands included two separate state zones – exotic grassland and native grasslands • **Urban native/exotic:** This condition type was assigned to areas of vegetation within urban areas that consisted of street trees, urban parks and other patches of planted vegetation that could provide habitat for native species
ASSOCIATED PCTs	The TEC is equivalent to Elderslie Banksia Scrub Forest listed under the BC Act, which is equivalent to PCT 774 (Coast Banksia scrub on sand in the Elderslie area). Note that the TEC also includes areas that intergrade with surrounding River Flat Eucalypt Forest (PCT 835), Moist Shale Woodland (PCT 830) or Cumberland Plain Woodland (PCT 849 or 850), provided that the key diagnostic characteristics are met (DAWE, 2020).
MAPPING APPROACH	PCT 774 was used to map the TEC. Note that as no condition thresholds have been applied to the TEC under the Conservation Advice, all patches of PCT 774 would comprise the EPBC TEC provided that the key diagnostic characteristics are met
PATCH SIZE ANALYSIS	As outlined in Section 31.3, a patch size analysis for the ecological community was undertaken to identify the number and size of patches across the Strategic Assessment Area.
VIABILITY ASSESSMENT	A viability assessment wasn't undertaken due to the late listing of this TEC. In addition, the TEC is very restricted within the subregion and all remaining patches are considered critical to its survival.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the TEC in the Strategic Assessment Area. It includes reference to a map which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where the TEC occurs.

MAP	See Map 48.9 for a map of the TEC across the Strategic Assessment Area.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	The baseline mapping for this assessment has mapped approximately 11.4 ha of the TEC within the Strategic Assessment Area (see Table 31-19 for further details). The TEC occurs in the one location within the Strategic Assessment Area – in Spring Farm, north of the Nepean River and south-east of Camden. The TEC does not occur in any of the nominated areas or transport corridors. The closest urban capable land occurs in GMAC approximately 3 km to the east. The OSO tunnel occurs approximately 4.5 km to the west, and the Metro Rail Future Extension tunnel occurs approximately 1.8 km to the north-east. The Conservation Advice states that, due to the very small size of patches and extent of the TEC remaining, all remaining patches are considered habitat critical to the survival of the TEC. The TEC is fragmented and comprises seven patches with an average patch size of approximately 1.6 ha. Because the TEC intergrades into other vegetation types, some patches of the TEC are surrounded by larger areas of native vegetation, which provides some buffer from potential impacts associated with edge effects.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of the TEC that was avoided through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

None of the TEC was mapped within the nominated areas or transport corridors. Avoidance of the TEC was therefore not necessary.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts. It considers:

- *Predicted impacts within urban capable lands and transport corridors*
- *Potential issues associated with fragmentation*
- *Potential additional impacts from essential infrastructure (within nominated areas but outside the urban capable lands) and tunnels associated with transport projects*

Offsets are provided for any TECs that are subject to direct impacts. The rationale and process for setting offset targets for TECs is set out in Section 8.5.2 of Chapter 8, and explained in detail in the Conservation Priorities Method that supports the Plan.

Implementation of the Plan will not lead to direct impacts or fragmentation of the TEC. As a result the Plan does not provide offsets for the TEC.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the TEC that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the TEC if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

31.10.1 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice identifies a range of threats to the TEC. As outlined in Chapter 15 (Section 15.5 and Attachment A), consideration was given to the potential relevance of these threats as indirect impacts that may result from implementation of the Plan.

Given the limited extent of the TEC in the Strategic Assessment Area, the distance that it occurs from the nominated areas and transport corridors, and its location within and immediately adjacent to existing urban areas, it is considered unlikely that implementation of the Plan would exacerbate most of the identified threats and would therefore not generally result in indirect impacts on the TEC. However, there is some potential for the OSO and Metro Rail Future Extension tunnels to cause hydrological impacts that may affect the TEC.

CHANGES TO HYDROLOGY

The Conservation Advice identifies changes to hydrology as a threat to the TEC. The main hydrology-related threat identified in the advice is increased runoff into patches of the TEC from surrounding urban development, carrying high nutrient and sediment loads, as well as weed seeds or propagules. This can both encourage weed invasion and cause erosion (DAWE, 2020). The Plan is unlikely to exacerbate this threat to the TEC.

However, the OSO and Metro Rail Future Extension tunnels have the potential to cause groundwater level drawdown into the tunnel void and water quality impacts from the disposal of poor quality groundwater and surface water drainage from the tunnels during operation. While the tunnels occur some distance from the TEC, there is potential for this to affect groundwater flows in the area, which may affect the TEC. The Conservation Advice identifies that groundwater discharge may be the cause of the some of the wetter areas within the TEC (DAWE, 2020).

The Metro Rail Future Extension tunnel is also near the top of the sub-catchment of Spring Creek. The Conservation Advice identifies that remnants of the TEC occur along Spring Creek, and further pollution of this waterway risks additional contamination of its riparian soils (DAWE, 2020).

The Plan includes a commitment to mitigate indirect and prescribed impacts from the transport corridors (Commitment 6). This commitment will be delivered through NSW environmental assessment and approval processes. As described in Part 2, each transport project will be subject to future strategic planning and detailed design and a process of environmental assessment and approval. For the transport corridors outside the nominated areas (where biodiversity impacts have not been assessed under the BC Act - see Part 1), including the OSO and Metro Rail Future Extension tunnels, this process will involve assessment under both:

- State Significant Infrastructure approval process (or equivalent)
- BC Act and BAM (or equivalent)

The process under the BC Act and BAM will address the potential indirect impacts of the tunnels on biodiversity values and the State Significant Infrastructure approval process (or equivalent) will assess the other environmental impacts and matters that need to be considered prior to construction and operation of the transport project. These processes will include an assessment of risks to the environment and the identification of mitigation measures to manage these risks from impacts related to hydrology and water quality, including groundwater drawdown.

This commitment and process to assess and mitigate the indirect impacts of the tunnels through a future environmental assessment and approval processes is considered adequate to address any risk of hydrology impacts to the TEC.

Climate change is a relevant threat to the ecological community. The extent to which the Plan has considered adaptation to climate change impacts is addressed in Chapter 41.

It is also worth noting that the Plan includes a range of landscape scale measures that will protect biodiversity (e.g. protection of large areas of land, fire management strategy, weed control implementation strategy, and pest animal control implementation strategy). These measures will benefit all biodiversity in the Cumberland subregion and may potentially relate to this TEC.

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the TEC from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

Given the TEC does not occur within the nominated areas or transport corridors, there is no risk of additional impacts from essential infrastructure. The OSO and Metro Rail Future Extension tunnels have the potential to cause hydrological impacts. This is discussed above.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE TEC

This section considers the likely effects of implementation of the Plan on the long-term viability of the TEC. The analysis has regard for the guidance in the Conservation Advice (there is no Recovery Plan for the TEC), and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also identifies any relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

31.10.2 IMPLICATIONS FOR LONG-TERM VIABILITY

As outlined above, implementation of the Plan will not lead to any direct impacts to the TEC and potential indirect impacts associated with the OSO and Metro Rail Future Extension tunnels are considered to be adequately managed. This will ensure that the implementation of the Plan does not adversely influence the long-term viability of the TEC.

31.10.3 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the TEC.

31.10.4 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Given the lack of direct impacts and limited indirect impacts, there are no relevant Key Threatening Processes (KTPs) or associated Threat Abatement Plans (TAPs).

DATA TABLES

This section sets out the data table for occurrence. Cross references to the table are provided throughout the text above.

Table 31-20: Occurrence of Elderslie Banksia Scrub Forest in the Strategic Assessment Area

	SAA TOTAL	WITHIN PROTECTED LANDS
TOTAL TEC MAPPING (ha)	**11.4**	**2.5**

Higher Viability TEC	N/A	N/A

31.11 TURPENTINE-IRONBARK FOREST OF THE SYDNEY BASIN BIOREGION

This assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan on the TEC in accordance with the EPBC Terms of Reference. It sets out:

- *TEC background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the TEC*
- *Data tables*

THREATENED ECOLOGICAL COMMUNITY BACKGROUND

This section sets out the basic information about the TEC. It provides a description of the TEC, and an overview of the listing definition and its distribution. These provide context for the impact assessment. At the end of the section are links to key documents that provide additional background information.

EPBC ACT LISTING	Critically Endangered
DESCRIPTION	The TEC is an open forest with a canopy of eucalypts and other trees that can reach 30 m tall. The midstorey comprises shrubs and small trees with a ground layer of herbs and grasses. The canopy is normally dominated by Turpentine (*Syncarpia glomulifera*) and a variety of eucalypt species. The midstorey may include small trees such as Sweet Pittosporum (*Pittosporum undulatum*), Native peach (*Trema aspera*) and Parramatta Wattle (*Acacia parramattensis*), and a shrub layer with Elderberry Panax (*Polyscias sambucifolia*), Mock Olive (*Notelaea longifolia*), and Prickly Beard-heath (*Leucopogon juniperinus*) amongst others. The ground layer may include Forest Hedgehog-grass (*Echinopogon ovatus*), Weeping Grass (*Microlaena stipoides*) and Kangaroo Grass (*Themeda triandra*).(DoE, 2014g)(DoE, 2014g)(DoE, 2014d)(DoE, 2014a)(DoE, 2014g)(DoE, 2014a) The occurrence of the TEC is transitional between Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest in drier areas, and Blue Gum High Forest in higher rainfall areas. The following PCTs are associated with the TEC: • 792 Deane's Gum - Mountain Grey Gum - Turpentine tall moist forest on shale, Sydney Basin Bioregion • 1183 Smooth-barked Apple - Sydney Peppermint - Turpentine heathy open forest on plateaux areas of the Sydney Basin Bioregion • 1281 Turpentine - Grey Ironbark open forest on shale in the lower Blue Mountains, Sydney Basin Bioregion • 1284 Turpentine - Smooth-barked Apple moist shrubby forest of the lower Blue Mountains, Sydney Basin Bioregion A range of fauna species occur in the TEC, including small mammals, birds, reptiles, amphibians and a large range of invertebrates. Most of these fauna species are not restricted to the TEC and also occur in, and are likely to rely on, other native vegetation in the Cumberland subregion. The TEC is equivalent to two NSW BC Act listed TECs – Sydney Turpentine-Ironbark Forest, and Blue Mountains Shale Cap Forest – where key diagnostic and condition thresholds are met. (DoE, 2014g)

EPBC DEFINITION	Only patches of the TEC that meet minimum size and condition thresholds are considered part of the TEC under the EPBC Act. Thresholds relate to factors such as patch size, understorey native vegetation cover, number of tree hollows, or whether the patch is contiguous with other native vegetation patches. Details of the thresholds are provided in the Conservation Advice (DoE, 2014g).
DISTRIBUTION	The TEC is confined to the Sydney Basin bioregion and mostly restricted to the Cumberland subregion and immediate surrounds. It has a scattered distribution to the west of Richmond, Penrith and Picton and in the north east of the subregion. The TEC primarily occurs in the Cumberland subregion and up to 750 m on shale caps of the Woronora, Blue Mountains and Hornsby Plateaux, with mean annual rainfall of 800 - 1100 mm per year. It generally occurs on fertile clay soils derived from Wianamatta shale, and clay of shale lenses within Hawkesbury Sandstone (DoE, 2014g).
SOS SITES	The TEC has been categorised under the 'widespread' management stream for TECs under the SOS program. Management of this category of TECs focuses on planning and regulatory processes, policy and programs, and private land conservation and reservation of land. Currently no management sites have been identified for this TEC.
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for Turpentine–Ironbark Forest in the Sydney Basin Bioregion (DoE, 2014g) Key Threatening Processes relevant to the TEC are identified in Page 4 of the Conservation Advice There is no Recovery Plan for the TEC
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicshowcommunity.pl?id=38

APPROACH TO BASELINE DATA

This section provides an overview of the approach to baseline data for the TEC. It:

- *Provides a summary of the approach to vegetation mapping for the strategic assessment which forms the baseline for the TEC mapping*
- *Outlines the vegetation condition states used in the mapping*
- *Identifies the NSW Plant Community Types (PCTs) that are associated with the TEC*
- *Summarises the approach to mapping the EPBC TEC*
- *Summarises the approach to the patch size analysis for the ecological community*
- *Summarises the approach to identifying areas of likely higher long-term viability in the Strategic Assessment Area*

Please refer to Section 11.3 (in Chapter 11) for details about the methods for mapping native vegetation, and Section 11.4.3 for details about the mapping methods for EPBC TECs.

APPROACH TO VEGETATION MAPPING	Native vegetation was mapped at two levels for the strategic assessment. Within the nominated areas, native vegetation was mapped using a method consistent with the BAM. This involved using a combination of API, existing desktop mapping, previous surveys and studies, rapid assessment ground-truthing, and field surveys (including floristic plot surveys). This process resulted in detailed maps of PCTs categorised by condition. Outside the nominated areas, native vegetation was mapped using the best available data integrated into a single dataset. Vegetation condition states were also applied across the broader area. It should be noted that comprehensive on-ground surveys across all native vegetation within the nominated areas was not possible and no surveys were undertaken outside the nominated areas. This means that a set of assumptions around the available data was required to translate the site based condition thresholds for the EPBC TEC so that it could be mapped at the scale of the Strategic Assessment Area. These assumptions are summarised below and explained in detail in Section 11.4.3 of Chapter 11.

VEGETATION CONDITION STATES	Vegetation condition was mapped using the following five condition states. These states generally range from better (intact) to worse (urban native/exotic) condition and are:
	• **Intact:** This condition state was assigned to areas of wooded vegetation community, including regrowth, that displays a range of structural layers and habitat features (e.g. tree hollows and large trees, fallen timber, leaf litter) with a largely unmodified canopy density and a range of age classes and species present
	• **Thinned:** This condition state was assigned to native vegetation in various states of modification, including:
	  o Wooded vegetation with a partly-cleared canopy and a more open structure compared to the intact PCT
	  o Wooded vegetation that has been under scrubbed
	• **Scattered trees:** This condition state includes a single tree or small group of trees surrounded by native or exotic pasture or areas of cultivation. Other structural components of the vegetation have typically been removed
	• **Grasslands:** Grasslands included two separate state zones – exotic grassland and native grasslands
	• **Urban native/exotic:** This condition type was assigned to areas of vegetation within urban areas that consisted of street trees, urban parks and other patches of planted vegetation that could provide habitat for native species

ASSOCIATED PCTs	The following PCTs are associated with the TEC: • 792 Deane's Gum - Mountain Grey Gum - Turpentine tall moist forest on shale, Sydney Basin Bioregion • 1183 Smooth-barked Apple - Sydney Peppermint - Turpentine heathy open forest on plateaux areas of the Sydney Basin Bioregion • 1281 Turpentine - Grey Ironbark open forest on shale in the lower Blue Mountains, Sydney Basin Bioregion • 1284 Turpentine - Smooth-barked Apple moist shrubby forest of the lower Blue Mountains, Sydney Basin Bioregion
MAPPING APPROACH	Mapping of the TEC across the Strategic Assessment Area used the following criteria which are based applying the condition thresholds at a landscape scale to the available data: • Condition class (A or B, low and moderate), AND • Patch > 1 ha, AND • Tree canopy cover > 10% (field verification) OR • Condition class (A or B, low and moderate), AND • Patch > 1 ha, AND • Tree canopy cover < 10% (field verification), AND • Part of a remnant of native vegetation > 5 ha
PATCH SIZE ANALYSIS	As outlined in Section 31.3, a patch size analysis for the ecological community was undertaken to identify the number and size of patches across the Strategic Assessment Area.
VIABILITY ASSESSMENT	As outlined in Section 31.4, an analysis was undertaken to identify areas of likely higher long-term viability for the TEC in the Strategic Assessment Area The purpose of the analysis was to identify the patches of the TEC within the Strategic Assessment Area that are more likely to be viable in the longer-term to inform the evaluation of the overall outcome of the Plan for the TEC. Viability is defined in a qualitative sense as the "probability of long-term survival of TEC patches". The approach involved reviewing Conservation Advices for each TEC to identify the factors that influence the long-term viability or conservation significance of a patch of the TEC. This review found that Conservation Advices generally identify a similar set of factors that influence long-term viability. Key factors included:

	• Larger patches are generally more viable than smaller patches • Better condition patches are generally more viable than poorer condition patches • Connected patches are generally more viable than poorer connected patches • Patches with a lower edge/area ratio are generally more viable than patches with a higher edge/area ratio

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the TEC in the Strategic Assessment Area. It includes reference to a map which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where the TEC occurs.

MAP	See Map 48.7 for a map of the TEC across the Strategic Assessment Area.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	The baseline mapping for this assessment has mapped approximately 44 ha of the TEC within the Strategic Assessment Area (see Table 31-21 for further details). Of this, approximately 6 ha has been identified as higher viability through the viability analysis. The TEC occurs in the following main locations within the Strategic Assessment Area: • In the north-west, next to the Blue Mountains National Park, 16.4 km from GPEC • In the southeast, near Minto Heights: o 1 km from the boundary of GMAC o 5.2 km from the GMAC urban capable footprint There are no mapped occurrences of the TEC within the nominated areas or transport corridors. The Conservation Advice does not specifically identify any sites in the Strategic Assessment Area that are important to the TEC. The Conservation Advice states that all patches meeting the condition thresholds in the listing advice are eligible to be considered under the EPBC Act for actions that may require referral. These are generally: • Patches > 1 ha with tree canopy cover of > 10% • Patches > 1 ha with tree canopy < 10% only if they are part of a remnant of native vegetation ≥ 5 ha in area The TEC is fragmented across the Strategic Assessment Area, comprising 13 patches with an average patch size of 3.4 ha.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of the TEC that was avoided through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

None of the TEC was mapped within the nominated areas or transport corridors. Avoidance of the TEC was therefore not necessary.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts. It considers:

- *Predicted impacts within urban capable lands and transport corridors*
- *Potential issues associated with fragmentation*

- *Potential additional impacts from essential infrastructure (within nominated areas but outside the urban capable lands) and tunnels associated with transport projects*

Offsets are provided for any TECs that are subject to direct impacts. The rationale and process for setting offset targets for TECs is set out in Section 8.5.2 of Chapter 8, and explained in detail in the Conservation Priorities Method that supports the Plan.

Implementation of the Plan will not lead to direct impacts or fragmentation of the TEC. As a result the Plan does not provide offsets for the TEC.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the TEC that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the TEC if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

31.11.1 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice identifies a range of threats to the TEC. As outlined in Chapter 15 (Section 15.5 and Attachment A), consideration was given to the potential relevance of these threats as indirect impacts that may result from implementation of the Plan.

Given the limited extent of the TEC in the Strategic Assessment Area and the distance that it occurs from the nominated areas, it was considered unlikely that implementation of the Plan would exacerbate any of the identified threats and would therefore not result in any indirect impacts.

Climate change is a relevant threat to the ecological community. The extent to which the Plan has considered adaptation to climate change impacts is addressed in Chapter 41.

It is worth noting that the Plan includes a range of landscape scale measures that will protect biodiversity (e.g. protection of large areas of land, fire management strategy, weed control implementation strategy, and pest animal control implementation strategy). These measures will benefit all biodiversity in the Cumberland subregion and may potentially relate to this TEC.

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the TEC from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

Given the TEC does not occur within the nominated areas or transport corridors, there is no risk of additional impacts from essential infrastructure or tunnels.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE TEC

This section considers the likely effects of implementation of the Plan on the long-term viability of the TEC. The analysis has regard for the guidance in the Conservation Advice (there is no Recovery Plan for the TEC), and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also identifies any relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

31.11.2 IMPLICATIONS FOR LONG-TERM VIABILITY

As outlined above, implementation of the Plan will not lead to any direct or indirect impacts to the TEC. This will ensure that the implementation of the Plan does not adversely influence the long-term viability of the TEC.

31.11.3 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the TEC.

31.11.4 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Given the lack of direct and indirect impacts, there are no relevant Key Threatening Processes (KTPs) or associated Threat Abatement Plans (TAPs).

DATA TABLES

This section sets out the data table for occurrence. Cross references to the table are provided throughout the text above.

Table 31-21: Occurrence of Turpentine–Ironbark Forest in the Sydney Basin Bioregion in the Strategic Assessment Area

	SAA TOTAL	WITHIN PROTECTED LANDS

31.12 WESTERN SYDNEY DRY RAINFOREST AND MOIST WOODLAND ON SHALE

This assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan on the TEC in accordance with the EPBC Terms of Reference. It sets out:

- *TEC background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the TEC*
- *Data tables*

THREATENED ECOLOGICAL COMMUNITY BACKGROUND

This section sets out the basic information about the TEC. It provides a description of the TEC, and an overview of the listing definition and its distribution. These provide context for the impact assessment. At the end of the section are links to key documents that provide additional background information.

EPBC ACT LISTING	Critically Endangered
DESCRIPTION	The TEC varies from low closed rainforest on lower slopes and in gullies, to more open, moist woodland on upper slopes and in disturbed sites. The rainforest form of this TEC is dominated by non-eucalypts including Prickly-leaved Paperbark (*Melaleuca styphelioides*), Hickory Wattle (*Acacia implexa*), Native Quince (*Alectryon subcinereus*) and White Euodia (*Melicope micrococca*). The woodland form has a more open canopy dominated by eucalypts, including Forest Red Gum (*Eucalyptus tereticornis*) and Coastal Grey Box (*E. moluccana*). The lower layers of the TEC may include shrubs of varying density, and a sparse groundcover of grasses, herbs and forbs. Vines and scramblers may also be present. This TEC is also characterised by a number of moisture-dependent plants such as ferns and broad-leaved shrubs. The following PCTs are associated with the TEC: • 830 Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion • 877 Grey Myrtle dry rainforest of the Sydney Basin Bioregion and South East Corner Bioregion Vine thickets within this TEC provide good habitat for birds and mammals. A range of fauna species occur in the TEC, including small mammals (particularly microbats), birds, reptiles, frogs and a large range of invertebrates. Most of these fauna species are not restricted to the TEC and also occur in, and are likely to rely on, other native vegetation in the Cumberland subregion. The TEC is equivalent to the NSW BC Act listed Western Sydney Dry Rainforest and Moist Shale Woodland TECs where key diagnostic and condition thresholds are met. (DoE, 2015h; DSEWPC, 2012b; OEH, 2019j; TSSC, 2013)
EPBC DEFINITION	Only patches of the TEC that meet minimum size and condition thresholds are considered part of the TEC under the EPBC Act. Thresholds relate to factors such as patch size, species richness and weed cover. Details of the thresholds are provided in the listing advice (TSSC, 2013).
DISTRIBUTION	The TEC has a highly restricted distribution, and is confined to the Sydney Basin bioregion, with most occurrences within the Cumberland subregion. Remnants of this TEC occur in the Wollondilly, Camden, Campbelltown, Holroyd, Fairfield, Liverpool, Penrith, Hawkesbury and The Hills LGAs.

	The TEC is restricted to shale soils of the Wianamatta Group, and is found in sheltered slopes, gullies and steep land. It is generally limited to elevations below 300 m. Only approximately 28 per cent of the pre-European extent of the TEC remains. Remnants of the TEC are highly fragmented, with 99 per cent of patches under 10 ha in size, and 60 per cent of fragments under 1 ha in size. It is estimated that the TEC has a total remaining area of 950 ha. (DSEWPC, 2012b; TSSC, 2013)
SOS SITES	The TEC has been categorised under the 'widespread' management stream for both NSW-listed TECs under the SOS program. Management of this category of TECs focuses on planning and regulatory processes, policy and programs, and private land conservation and reservation of land. Currently no management sites have been identified for this TEC.
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for Western Sydney Dry Rainforest and Moist Woodland on Shale (DSEWPC, 2012b) Listing advice for Western Sydney Dry Rainforest and Moist Woodland on Shale (TSSC, 2013) Key Threatening Processes relevant to the TEC are identified in Page 3 of the Conservation Advice There is no Recovery Plan for the TEC Threat Abatement Plans relevant to the TEC are identified in Table 31-22
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicshowcommunity.pl?id=106

APPROACH TO BASELINE DATA

This section provides an overview of the approach to baseline data for the TEC. It:

- *Provides a summary of the approach to vegetation mapping for the strategic assessment which forms the baseline for the TEC mapping*
- *Outlines the vegetation condition states used in the mapping*
- *Identifies the NSW Plant Community Types (PCTs) that are associated with the TEC*
- *Summarises the approach to mapping the EPBC TEC*
- *Summarises the approach to the patch size analysis for the ecological community*
- *Summarises the approach to identifying areas of likely higher long-term viability in the Strategic Assessment Area*

Please refer to Section 11.3 (in Chapter 11) for details about the methods for mapping native vegetation, and Section 11.4.3 for details about the mapping methods for EPBC TECs.

APPROACH TO VEGETATION MAPPING	Native vegetation was mapped at two levels for the strategic assessment. Within the nominated areas, native vegetation was mapped using a method consistent with the BAM. This involved using a combination of API, existing desktop mapping, previous surveys and studies, rapid assessment ground-truthing, and field surveys (including floristic plot surveys). This process resulted in detailed maps of PCTs categorised by condition. Outside the nominated areas, native vegetation was mapped using the best available data integrated into a single dataset. Vegetation condition states were also applied across the broader area. It should be noted that comprehensive on-ground surveys across all native vegetation within the nominated areas was not possible and no surveys were undertaken outside the nominated areas. This means that a set of assumptions around the available data was required to translate the site based condition thresholds for the EPBC TEC so that it could be mapped at the scale of the Strategic Assessment Area. These assumptions are summarised below and explained in detail in Section 11.4.3 of Chapter 11.
VEGETATION CONDITION STATES	Vegetation condition was mapped using the following five condition states. These states generally range from better (intact) to worse (urban native/exotic) condition and are:

	• **Intact:** This condition state was assigned to areas of wooded vegetation community, including regrowth, that displays a range of structural layers and habitat features (e.g. tree hollows and large trees, fallen timber, leaf litter) with a largely unmodified canopy density and a range of age classes and species present
	• **Thinned:** This condition state was assigned to native vegetation in various states of modification, including:
	  o Wooded vegetation with a partly-cleared canopy and a more open structure compared to the intact PCT
	  o Wooded vegetation that has been under scrubbed
	• **Scattered trees:** This condition state includes a single tree or small group of trees surrounded by native or exotic pasture or areas of cultivation. Other structural components of the vegetation have typically been removed
	• **Grasslands:** Grasslands included two separate state zones – exotic grassland and native grasslands
	• **Urban native/exotic:** This condition type was assigned to areas of vegetation within urban areas that consisted of street trees, urban parks and other patches of planted vegetation that could provide habitat for native species

ASSOCIATED PCTs	The following PCTs are associated with the TEC: • 830 Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion • 877 Grey Myrtle dry rainforest of the Sydney Basin Bioregion and South East Corner Bioregion
MAPPING APPROACH	Mapping of the TEC across the Strategic Assessment Area used the following criteria which are based applying the condition thresholds at a landscape scale to the available data: • Patch size ≥ 0.1 ha, AND • At least 20 native species present in sample 0.04 ha plot (based on field verification), AND • Non-native perennial plants no more than 50 per cent of total vegetation cover (based on field verification), AND • Below 300 m elevation, AND • Growing on clay soils derived from Wianamatta Group sediments
PATCH SIZE ANALYSIS	As outlined in Section 31.3, a patch size analysis for the ecological community was undertaken to identify the number and size of patches across the Strategic Assessment Area.
VIABILITY ASSESSMENT	As outlined in Section 31.4, an analysis was undertaken to identify areas of likely higher long-term viability for the TEC in the Strategic Assessment Area The purpose of the analysis was to identify the patches of the TEC within the Strategic Assessment Area that are more likely to be viable in the longer-term to inform the evaluation of the overall outcome of the Plan for the TEC. Viability is defined in a qualitative sense as the "probability of long-term survival of TEC patches". The approach involved reviewing Conservation Advices for each TEC to identify the factors that influence the long-term viability or conservation significance of a patch of the TEC. This review found that Conservation Advices generally identify a similar set of factors that influence long-term viability. Key factors included: • Larger patches are generally more viable than smaller patches • Better condition patches are generally more viable than poorer condition patches • Connected patches are generally more viable than poorer connected patches • Patches with a lower edge/area ratio are generally more viable than patches with a higher edge/area ratio

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the TEC in the Strategic Assessment Area. It includes reference to a map which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where the TEC occurs.

<table>
<tr><td>MAP</td><td>See Map 48.8 for a map of the TEC across the Strategic Assessment Area.</td></tr>
<tr><td>OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA</td><td>The baseline mapping for this assessment has mapped approximately 961 ha of the TEC within the Strategic Assessment Area (see Table 31-23 for further details). Of this, approximately 657 ha has been identified as higher viability through the viability analysis.
The majority of the TEC occurs in the southern part of the Strategic Assessment Area around Picton, in a landscape that has been heavily cleared for farming. In this locality, the TEC often occurs as small to moderate patches along the edges of escarpments surrounded by farmland.
It the nominated areas it occurs within:
• GMAC (15.5 ha) in the central portion near to Rosemeadow
• GPEC (2.4 ha) on the western side near the Mulgoa Nature Reserve
It does not occur in the other nominated areas or transport corridors.
The Conservation Advice does not specifically identify any sites in the Strategic Assessment Area that are important to the TEC. The Conservation Advice states that all patches of a reasonable size and in the highest condition categories as defined in the advice (categories A and B) are considered habitat critical to the survival of the TEC. These are generally:
• Large (≥ 5 ha) or moderate patches (≥ 2 ha and < 5 ha) with a predominately native understory
• Well-connected smaller patches (< 2 ha and ≥ 0.5 ha) with a predominately native understory
The Conservation Advice also identifies several factors affecting the value of a patch, including:
• A larger size and/or a high area to boundary ratio
• Part of a larger remnant of native vegetation or linking other remnants
• Evidence of recruitment of key plant species/range of age cohorts
• High native species richness
• Presence of threatened species
• Low level of weeds and pest animals
The TEC is highly fragmented across the Strategic Assessment Area, comprising 294 patches with an average patch size of 3.2 ha. Only 10 patches are greater than 20 ha. A large number of patches occur in close proximity to existing urban development or farmland and are likely to be exposed to substantial edge effects.</td></tr>
</table>

AVOIDANCE OF IMPACTS

This section provides an overview of the area of the TEC that was avoided through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

31.12.1 NOMINATED AREAS

The baseline mapping for this assessment mapped 15 ha of the TEC within the nominated areas (not including excluded lands). All of this has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 11 ha was avoided for biodiversity purposes
- 4 ha was avoided for other purposes

An additional 3 ha occurs on excluded lands.

A breakdown of avoidance across each nominated area is provided in Table 31-24.

It is important to note that the avoidance calculations in Table 31-24, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 31-24 shows the amounts of habitat within excluded lands for context only.

31.12.2 TRANSPORT

None of the TEC occurs in transport corridors so avoidance of impacts is not necessary.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts. It considers:

- *Predicted impacts within urban capable lands and transport corridors*
- *Potential issues associated with fragmentation*
- *Potential additional impacts from essential infrastructure (within nominated areas but outside the urban capable lands) and tunnels associated with transport projects*

Offsets are provided for any TECs that are subject to direct impacts. The rationale and process for setting offset targets for TECs is set out in Section 8.5.2 of Chapter 8, and explained in detail in the Conservation Priorities Method that supports the Plan.

Implementation of the Plan will not lead to direct impacts or fragmentation of the TEC. As a result the Plan does not provide offsets for the TEC.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the TEC that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the TEC if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

31.12.3 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice identifies a range of threats to the TEC. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential indirect impacts (identified as threats in the Conservation Advice) are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Inappropriate habitat disturbance
- Changes to hydrology
- Diseases, pathogens and dieback
- Invasive fauna

Climate change is also a relevant threat to the ecological community. The extent to which the Plan has considered adaptation to climate change impacts is addressed in Chapter 41.

Impacts from logging and inappropriate grazing were also identified in the Conservation Advice as key threats. However, neither of these are considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate these risks across the Strategic Assessment Area.

INAPPROPRIATE FIRE REGIMES

The TEC contains rainforest and mesic plants which are not well-adapted to fire, and the TEC is negatively impacted by fire events. The existing fragmentation of the landscape means that fire events may lead to localised extinctions of the TEC, as recolonisation of a burnt area by neighbouring populations may not be possible (TSSC, 2013).

Increased fire frequency can be caused by:

- Arson and accidental lighting of fires
- Application of fire by authorities to manage fire risk

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact the TEC. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development. For the TEC this includes the areas in GMAC.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant to the outcome for the TEC being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy for the Strategic Conservation Areas that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
    - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from the TEC. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the TEC from altered fire regimes as a result of development. This is because:

- Avoided lands in GMAC where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting the TEC
- Fire management authorities will be engaged to ensure they understand the requirements of the TEC and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas
- The fire management requirements for the TEC specified in the best practice guidelines will be applied

These controls are consistent with a number of priority conservation actions in the Conservation Advice about the management of fire.

WEED INVASION

The TEC is threatened with invasion and competition by weeds. Notable weeds which threaten this TEC include Lantana (*Lantana camara*) and African Olive (*Olea europa* subsp. *cuspidata*). These weeds are already present in the Cumberland subregion and threaten the TEC (DSEWPC, 2012b).

The TEC is most susceptible to the threat of weeds from development under the Plan where new urban development or transport corridors occur adjacent to the TEC and/or fragments patches of the TEC into smaller patches and introduces edge effects. Key risk areas include the central portion of GMAC where it occurs adjacent to urban capable lands.

The Plan incorporates a range of measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Areas. This includes a number of actions, of which the following are the most relevant to the outcome for the TEC:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

The package of measures in the Plan is expected to adequately manage the risk posed to the TEC from weed invasion. This is because:

- Avoided lands where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- The Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy. This includes the land to be protected under the conservation program for the TEC
- There will be a range of planning controls to minimise the potential spread of weeds during and after construction

These controls are consistent with a number of priority conservation actions in the Conservation Advice about the management of weeds.

INAPPROPRIATE HABITAT DISTURBANCE

Inappropriate habitat disturbance is identified in the Conservation Advice as a threat to the TEC. This relates to a wide range of different mechanisms for disturbance including:

- Dumping of rubbish and garden waste which can directly impact areas of the TEC as well as facilitate increases in weeds (see above) and pollutants
- Inappropriate recreational activities such as ad hoc track building and trail bike use which can directly impact areas of the TEC and facilitate processes such as erosion
- Removal of wood which changes the structure and habitat features of the TEC
- Inadvertent disturbance during construction which has the potential to directly impact the TEC outside approved development areas

Each of these mechanisms have the potential to alter the structure and floristic composition of the TEC.

Inappropriate habitat disturbance within the Strategic Assessment Area may increase due to development within the nominated areas. Occurrences of the TEC considered most at risk are those within GMAC.

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for the TEC. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan is expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development. This is because:

- Avoided lands where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

These controls are consistent with a number of priority conservation actions in the Conservation Advice about the management of disturbance.

CHANGES TO HYDROLOGY

The creation of hard surfaces associated with urban development and transport results in changes to the hydrology of surrounding areas. The main threat to the TEC associated with altered hydrology is increased runoff into patches of the

TEC carrying high nutrient and sediment loads, as well as weed seeds or propagules. This can both encourage weed invasion and cause erosion.

The TEC is most susceptible to the threat of increased runoff from development under the Plan where new urban development occurs adjacent (and upstream or upslope) to the TEC. Key risk areas are those in GMAC. The TEC is not threatened by transport projects because it does not occur within the vicinity of any of the transport corridors.

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for the TEC. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through development controls in the nominated areas in relation to:

- Water cycle management. For example:
  - Water management measures must comply with council's requirements for detention, drainage and water sensitive urban design principles
  - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
- Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
- Soil erosion and sedimentation. For example:
  - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
  - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom 2004) and submitted with each subdivision development application

The package of measures in the Plan is expected to adequately manage the risk to the TEC from changes to hydrology because development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts to the TEC.

DISEASES, PATHOGENS AND DIEBACK

TECs are potentially susceptible to a range of diseases, pathogens and dieback which can substantially affect their long term viability. Recognised threats include myrtle rust.

Development under the Plan may increase the risk of the spread of infection/disease. This is primarily related to:

- Soil transportation on contaminated footwear, vehicles and machinery, and in residential garden establishment
- Increased site visitation rates
- Earthworks and activities conducted during construction
- Increased surface water runoff

The Plan incorporates a range of measures to manage the risks associated with diseases, pathogens and dieback. In summary, these include:

- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
  - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
  - Entering into written agreements with delivery partners to implement priority disease control programs
- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures methods to protect the environment during construction, including best practice site hygiene protocols to minimise spread of *Phytophthora* and Myrtle Rust

The package of measures in the Plan is expected to adequately manage the risk to the TEC from diseases, pathogens and dieback because:

- It supports a landscape scale approach to the issue across the Cumberland subregion
- It will ensure appropriate controls during construction

INVASIVE FAUNA

TECs can be threatened by introduced animals and aggressive native species. These species include:

- Domestic species such as cats and dogs which are related to urban development
- Pest species such as foxes, rats, house mice and rabbits which are primarily related to agricultural development
- Aggressive bird species which compete for resources

Collectively, these animals can lead to declines in biodiversity through:

- Predation
- Damage to vegetation and soils
- Competition for resources

Existing land use within the nominated areas and surrounding region (which includes residential and rural residential areas, and farming) means that these issues are already present in the Strategic Assessment Area and are unlikely to pose a novel threat to the TEC.

However, the extent of proposed new urban development under the Plan means that the threats associated with cats and dogs are likely to be exacerbated. It is likely that there will be an increase in the number of domestic cats and dogs in the local area, which, in turn, may lead to an increase in feral cat and wild dog numbers. The main areas of concern relate to new urban development in GMAC.

In relation to aggressive bird species, the two main drivers for increasing the threat within the TEC are:

- Fragmentation of habitat which creates greater edge effects and facilitates access by aggressive bird species. As outlined above in the analysis of direct impacts, the Plan is considered unlikely to lead to any notable fragmentation to the TEC and as such is not considered an issue
- Habitat disturbance through inappropriate land management which can change the structure of the TEC and facilitate access by aggressive bird species. As outlined above in relation to inappropriate habitat disturbance, the Plan includes a package of measures which are expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development

In relation to the residual risks associated with invasive fauna, the Plan incorporates a range of measures to manage the risks. In summary, these include:

- A commitment (Commitment 17) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the Strategic Conservation Areas. This includes a number of actions with the most relevant to the outcome for the TEC being:
    - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
    - Preparation of a Pest Animal Control Implementation Strategy
    - A process to enter into written agreements with delivery partners to implement the pest animal control program
    - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Development controls that will:
    - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
    - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
    - Require appropriate management and control of pest animals relevant to development sites
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing pests, consistent with the pest animal implementation strategy outlined in Commitment 16

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the TEC from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the TEC to occur due to development of essential infrastructure within the avoided lands of GMAC.

The TEC does not occur within the vicinity of the tunnel footprints for transport and is therefore not at risk of additional impacts from tunnels.

31.12.4 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

Areas of the TEC occur within the avoided lands of GMAC. Of the 15.4 ha, 2.2 ha is in good (intact) condition and 13.2 ha is in moderate (thinned) condition. Impacts to the TEC are possible where it occurs within land avoided for biodiversity purposes (~11.2 ha). The likelihood of impact is reduced where the TEC occurs in riparian corridors or steep slopes (~4.2 ha).

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine if the TEC was present
- Measures to avoid impacts to the listed TEC through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the TEC will occur as a results of essential infrastructure as every effort should be made to avoid and minimise impacts. Any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE TEC

This section considers the likely effects of implementation of the Plan on the long-term viability of the TEC. The analysis has regard for the guidance in the Conservation Advice (there is no Recovery Plan for the TEC), and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also identifies any relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

31.12.5 IMPLICATIONS FOR LONG-TERM VIABILITY

As outlined above, implementation of the Plan will not lead to any direct impacts to the TEC and potential indirect impacts will be managed. This will ensure that the implementation of the Plan does not adversely influence the long-term viability of the TEC.

31.12.6 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the TEC.

31.12.7 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 31-22 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The Plan is not inconsistent with any of the relevant TAPs. Please refer to Section 15.9 of Chapter 15 for a detailed discussion of each TAP and the relationship of the Plan.

Table 31-22: Key Threatening Processes and relevant Threat Abatement Plans for Western Sydney Dry Rainforest and Moist Woodland on Shale

KEY THREATENING PROCESS	RELEVANT THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Predation by feral cats	Threat abatement plan for predation by feral cats (DoE, 2015g)

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

NOMINATED ECOLOGICAL COMMUNITY

31.13 COASTAL FLOODPLAIN EUCALYPT FOREST OF EASTERN AUSTRALIA

This assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan on the ecological community in accordance with the EPBC Terms of Reference. It sets out:

- *Ecological community background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the ecological community*
- *Data tables*

ECOLOGICAL COMMUNITY BACKGROUND

This section sets out the basic information about the ecological community. It provides a description of the ecological community, and an overview of the listing definition and its distribution. These provide context for the impact assessment. At the end of the section are links to key documents that provide additional background information.

NAME	Coastal Floodplain Eucalypt Forest of Eastern Australia
EPBC ACT LISTING	Not currently listed. Nominated for listing as under the EPBC Act an endangered ecological community in the Finalised Priority Assessment List (FPAL)
DESCRIPTION	The nominated TEC (referred to as EC from this point) is a eucalypt forest that occurs on quaternary alluvial soils on coastal floodplains on the east coast of Australia in warm to hot and sub-tropical climate zones. The EC generally ranges from tall open forest to woodland. Occasional localised stands of the EC are closed forest and/or low forest. The EC occurs in a lower and less dense structure on the open floodplains and taller, denser forest on the upper floodplains that include stream flats in the surrounding hills of the floodplain. The EC may have a canopy layer, mid-layer, climbing species and scramblers and understorey. While there is regional variation and intergradation of key species, the structure and function of the ecological community stays largely similar throughout its extent. The canopy layer is generally dominated by *Eucalyptus*, *Angophora*, and *Corymbia* as a single species or a mix of several species. The mid-layer is characterised over its entire range by a number of paperbarks including *Melaleuca linariifolia* (Flax-leaved Paperbark) and *M. styphelioides* (Prickly-leaved Paperbark) and other species including *Acacia floribunda*, *Breynia oblongifolia* (Breynia, Coffee Bush), *Bursaria spinosa* (Sweet Bursaria Blackthorn, Kurwan-D'harawal), *Goodenia ovata* (Hop Goodenia), *Pittosporum revolutum* (Hairy Pittosporum) and *Plectranthus parviflorus* (Cockspur flower). Other paperbarks and species occur in the mid-layer on a local or regional basis. Scrambling species that occur in the ground layer are *Desmodium varians* (Slender Trefoil) and *Veronica plebeia* (Trailing Speedwell) while *Glycine clandestine* (Twining Glycine) and *Stephania japonica* var. *discolor* (Snake Vine) may be found in the sub-canopy and mid-layer. The understory layer is dominated by species that have adapted to a higher level of soil moisture and include perennial forbs, grasses, sedges, rushes and ferns. The following PCT is associated with the EC and has been used to map the EC in the Strategic Assessment Area: 835 Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion.

	A range of fauna species occur in the EC, including mammals (arboreal, ground and burrowing), marsupials, birds, frogs, reptiles and invertebrates. The EC provides important habitat for fauna species in terms of food, nesting, roosting or hunting. The fauna in turn also play an important role in the ecology of the EC through pollination, seed dispersal and soil turnover. In the southern part of its distribution, the EC correlates to parts of one NSW BC Act listed TEC (River-flat Eucalypt Forest on Coastal Floodplains of the NSW North Coast, Sydney Basin and South East Corner bioregions). The southern part of the EC also form parts of Victorian listed ecological communities. The parts of the TEC's range that extend into Queensland and Victoria also form parts of ecological communities listed in other states. (TSSC, 2019c)
EPBC DEFINITION	Only patches of the EC that meet minimum size and condition thresholds will be considered part of the TEC (presuming it becomes listed under the EPBC Act). Thresholds generally relate to factors such as patch size, understorey native vegetation cover, ground cover richness, number of large trees or tree hollows per hectare, evidence of particular mammal species, or whether the patch is contiguous with other native vegetation patches. Details of the proposed thresholds are provided in the Draft Conservation Advice (TSSC, 2019c).
DISTRIBUTION	The EC's extent of occurrence stretches from Sale in Victoria to Gladstone in Queensland. It extends through four IBRA Bioregions: South East Corner, Sydney Basin, NSW North Coast, and South East Queensland. It generally occurs along water courses and drainage lines. The community is important in maintaining river ecosystems and riverbank stability. The EC primarily occurs on elevations below 50 m but may occur on localised floodplain pockets up to and occasionally beyond 250 m. It occurs in riparian corridors, floodplains prone to inundation, older floodplain terraces, and floodplain depressions. The community forms mosaics with other floodplain forest communities and wetlands. (OEH, 2019i; TSSC, 2019c)
SOS SITES	The NSW BC Act listed River-Flat Eucalypt Forest on Coastal Floodplains has been categorised under the 'widespread' management stream for TECs under the SOS program. Management of this category of TECs focuses on planning and regulatory processes, policy and programs, and private land conservation and reservation of land. Three management sites have been identified for this TEC on the Lower and Upper Deua River and Burra Creek Catchment in Eurobodella LGA, south of Ulladulla on the south coast.
RELEVANT PLANS AND POLICIES	Draft Conservation Advice (incorporating listing advice) for Coastal floodplain eucalypt forest of eastern Australia (TSSC, 2019c) Key Threatening Processes relevant to the EC are identified in Table 9 of the draft Conservation Advice There is no Draft Recovery Plan for the EC. However, the NSW BC Act-listed TEC, River-flat Eucalypt Forest, is included within the Cumberland Plain Recovery Plan Threat Abatement Plans relevant to the EC are identified in Table 9 of the Draft Conservation Advice
SPRAT LINK	There is currently no SPRAT profile as the EC is still undergoing assessment.

APPROACH TO BASELINE DATA

This section provides an overview of the approach to baseline data for the ecological community. It:

- *Provides a summary of the approach to vegetation mapping for the strategic assessment which forms the baseline for the ecological community mapping*
- *Outlines the vegetation condition states used in the mapping*
- *Identifies the NSW Plant Community Types (PCTs) that are associated with the ecological community*
- *Summarises the approach to mapping the EPBC ecological community*
- *Summarises the approach to the patch size analysis for the ecological community*
- *Summarises the approach to identifying areas of likely higher long-term viability in the Strategic Assessment Area*

Please refer to Section 11.3 (in Chapter 11) for details about the methods for mapping native vegetation, and Section 11.4.3 for details about the mapping methods for EPBC TECs.

APPROACH TO VEGETATION MAPPING	Native vegetation was mapped at two levels for the strategic assessment. Within the nominated areas, native vegetation was mapped using a method consistent with the BAM. This involved using a combination of API, existing desktop mapping, previous surveys and studies, rapid assessment ground-truthing, and field surveys (including floristic plot surveys). This process resulted in detailed maps of PCTs categorised by condition. Outside the nominated areas, native vegetation was mapped using the best available data integrated into a single dataset. Vegetation condition states were also applied across the broader area. It should be noted that comprehensive on-ground surveys across all native vegetation within the nominated areas was not possible and no surveys were undertaken outside the nominated areas. This means that a set of assumptions around the available data was required to map the nominated EC at the scale of the Strategic Assessment Area. These assumptions are summarised below and explained in detail in Section 11.4.3 of Chapter 11.
VEGETATION CONDITION STATES	Vegetation condition was mapped using the following five condition states. These states generally range from better (intact) to worse (urban native/exotic) condition and are: • **Intact:** This condition state was assigned to areas of wooded vegetation community, including regrowth, that displays a range of structural layers and habitat features (e.g. tree hollows and large trees, fallen timber, leaf litter) with a largely unmodified canopy density and a range of age classes and species present • **Thinned:** This condition state was assigned to native vegetation in various states of modification, including: o Wooded vegetation with a partly-cleared canopy and a more open structure compared to the intact PCT o Wooded vegetation that has been under scrubbed • **Scattered trees:** This condition state includes a single tree or small group of trees surrounded by native or exotic pasture or areas of cultivation. Other structural components of the vegetation have typically been removed • **Grasslands:** Grasslands included two separate state zones – exotic grassland and native grasslands • **Urban native/exotic:** This condition type was assigned to areas of vegetation within urban areas that consisted of street trees, urban parks and other patches of planted vegetation that could provide habitat for native species
ASSOCIATED PCTs	PCT 835 (Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion) is associated with the EC.
MAPPING APPROACH	Given the EC is not yet listed, there were no approved condition thresholds or final definition to use in the mapping. In order to take a precautionary approach to the mapping, PCT 835 was used as a surrogate. It is expected that this mapping will over-estimate the actual occurrence of the future listed TEC, which is expected to have a more restricted definition based on condition thresholds than PCT 835.
PATCH SIZE ANALYSIS	As outlined in Section 31.3, a patch size analysis for the ecological community was undertaken to identify the number and size of patches across the Strategic Assessment Area.
VIABILITY ASSESSMENT	Given the EC has not yet been listed and approved condition thresholds are not available, a viability assessment was not conducted for the EC.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the ecological community in the Strategic Assessment Area. It includes reference to a map which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where the ecological community occurs.

MAP	See Map 48.5 for a map of the TEC across the Strategic Assessment Area.
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	The baseline mapping for this assessment mapped approximately 6,944 ha of the EC within the Strategic Assessment Area (see Table 31-26 for further details). The EC is relatively evenly spread throughout the Strategic Assessment Area. It occurs mainly in GPEC and WSA, with smaller amounts in GMAC. There is no EC mapped in Wilton. The EC mainly occurs as long and narrow patches of vegetation along riparian corridors throughout the Strategic Assessment Area, which may or may not be connected with broader areas of native vegetation. Where the EC is not buffered by the wider presence of native vegetation it is likely to be exposed to significant edge effects, particularly where it occurs in urban areas. The Draft Conservation Advice does not specifically identify any sites in the Strategic Assessment Area that are important to the EC. Rather, it states that all patches of a reasonable size and in the highest condition categories as defined in the advice (categories A and B) are considered habitat critical to the survival of the EC. These are generally: • Patch sizes of ≥ 0.5 ha or well-connected patches with a predominantly native understorey and ≥ 20 large trees (> 45 cm dbh) or tree hollows per hectare • Large patch sizes (≥ 2 ha) or well-connected patches with a predominately native understorey and ≥ 10 large trees (> 45 cm dbh) or tree hollows per hectare The Draft Conservation Advice also identifies several factors affecting the value of a patch, including: • A larger size and/or a high area to boundary ratio • Part of a larger remnant of native vegetation or linking other remnants • Evidence of recruitment of key plant species/range of age cohorts • High native species richness • Presence of threatened species • Low level of weeds and pest animals • Heavily cleared or degraded patches, or patches at the edge of its range The EC is highly fragmented across the Strategic Assessment Area, comprising 1,392 patches (greater than 0.5 ha) with an average patch size of 5.5 ha.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of the ecological community that was avoided through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

31.13.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 335 ha of the EC within the nominated areas (not including excluded lands). Approximately 170 ha (51 per cent) was avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 61 ha was avoided for biodiversity purposes
- 110 ha was avoided for other purposes

An additional 835 ha occurs on excluded lands.

A breakdown of avoidance across each nominated area is provided in Table 31-27.

It is important to note that the avoidance calculations in Table 31-27, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 31-27 shows the amounts of habitat within excluded lands for context only.

31.13.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts. It considers:

- *Predicted impacts within urban capable lands and transport corridors*
- *Potential issues associated with fragmentation*
- *Potential additional impacts from essential infrastructure (within nominated areas but outside the urban capable lands) and tunnels associated with transport projects*

Offsets are provided for any TECs that are subject to direct impacts (this includes the nominated EC). The rationale and process for setting offset targets for TECs is set out in Section 8.5.2 of Chapter 8, and explained in detail in the Conservation Priorities Method that supports the Plan.

Implementation of the Plan will lead to direct impacts to the EC (see Section 31.12.3 for discussion) and increase fragmentation in a number of locations (see Section 31.12.4 for discussion).

31.13.3 DIRECT IMPACTS TO THE EC

Implementation of the Plan will lead to a loss of a total of 210.2 ha of the EC within the nominated areas and transport corridors (see Table 31-28 for detailed stats). This loss represents approximately 3 per cent of the remaining EC in the Strategic Assessment Area and 18 per cent of the EC in the nominated areas.

The majority of the EC impacted:

- Is in thinned or scattered condition (181.7 ha), with 13.6 per cent of direct impacts occurring to patches in intact condition
- Comprises small patches (0.5-5 ha) (45 of the 54 patches impacted, approximately 83 per cent)

The urban footprint within the nominated areas has generally avoided riparian corridors, and therefore avoids the majority of areas mapped as potential TEC.

The most notable direct impacts to the EC occur in the following locations:

- Within the Outer Sydney Orbital Transport Corridor outside the nominated areas, which will impact several small (0.5-5 ha) and medium (5-20 ha) patches and reduce the size of a few larger patches
- Within the Outer Sydney Orbital Transport Corridor within WSA and GPEC, which will impact sections of riparian corridors along Cosgroves Creek, Wianamatta (South Creek) and Ropes Creek. These areas of EC are connected along the corridors, as well as to larger areas of the EC within Wianamatta Regional Park

The potential scale of impacts to the mapped EC is relatively large. However, it should be noted that mapping of the EC is based on PCT 835 and is considered to be conservative. The future listed TEC is expected to have a more restricted distribution based on the application of condition thresholds and actual direct impacts to the listed EC are likely to be smaller.

The risks to the EC from direct impacts are mitigated to a degree because development will impact:

- Patches of the EC that are generally isolated and exposed to edge effects
- Areas that are generally in lower condition (thinned or scattered)

31.13.4 FRAGMENTATION OF THE EC

The Draft Conservation Advice identifies fragmentation as a threat to the EC (TSSC, 2019c).

The most notable fragmentation impacts are associated with the direct impacts from the Outer Sydney Orbital in GPEC. In this area:

- The Outer Sydney Orbital will intersect the middle of several patches of the EC in Wianamatta Regional Park that form part of a larger, well connected patch of native vegetation to the west and Ropes Creek riparian corridor to the south
- The Outer Sydney Orbital will impact the connectivity of a large area of the riparian corridor around Wianamatta (South Creek), north and south of the Western Motorway near St Marys

Fragmentation of the EC will increase its susceptibility to weed invasion and other edge effects and has the potential to reduce its long-term viability in these locations.

31.13.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

To compensate for the predicted direct impacts to the ecological community, the Plan includes a commitment to secure 575 ha of PCT 835 as part of the conservation program. This would:

- Lead to the protection and management of an additional 8.3 per cent of the ecological community within the Strategic Assessment Area
- Increase the level of protection and management of the ecological community by approximately 79 per cent on top of what is currently secured in the Strategic Assessment Area

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the EC that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the EC if:

- *The indirect impact is identified as a threat in a relevant profile or draft conservation advice, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

31.13.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Draft Conservation Advice identifies a range of threats to the EC. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential indirect impacts (identified as threats in the Draft Conservation Advice) are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Inappropriate habitat disturbance
- Changes to hydrology
- Diseases, pathogens and dieback
- Invasive fauna

Climate change is also a relevant threat to the ecological community. The extent to which the Plan has considered adaptation to climate change impacts is addressed in Chapter 41.

Impacts from agricultural activities, including grazing and nutrient enrichment was also identified in the Draft Conservation Advice as a key threat. However, this is not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the risk across the Strategic Assessment Area.

INAPPROPRIATE FIRE REGIMES

High frequency fires are identified as a key threat to the NSW BC Act listed TEC, particularly where the TEC occurs in urban areas (OEH, 2004). Further information with regards to the threats posed by increased fire frequencies, and recommended fire management methodologies, is limited.

Inappropriate fire regimes can be caused by:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact the EC. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development. For the TEC this includes areas throughout GPEC and WSA, with small parts of GMAC.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant to the outcome for the EC being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy for the Strategic Conservation Areas that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
    - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from the EC. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the EC from altered fire regimes as a result of development. This is because:

- Avoided lands where areas of the EC occur will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting the EC
- Fire management authorities will be engaged to ensure they understand the requirements of the EC and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas

WEED INVASION

The majority of remnants of the NSW BC Act listed TEC are impacted by weeds. Weed incursion occurs as a result of physical disturbance to the TEC, rubbish dumping, polluted agricultural and/or urban runoff, road/utility construction activities and grazing of livestock (OEH, 2004).

A large number of weeds are recognised as threats to the NSW BC Act listed TEC, including several grasses, vines and small shrubs and trees, including Lantana (*Lantana camara*), Privets (*Ligustrum sp.*) and African Olive (*Olea europea* subsp. *Cuspidate*), (OEH, 2004).

These weeds are already present within the Strategic Assessment Area and pose a threat to the EC. However, urban and transport development within the Strategic Assessment Area has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or changing conditions to favour weeds.

The EC is most susceptible to the threat of weeds from development under the Plan where new urban development or transport corridors occur adjacent to the EC and/or fragments patches of the EC into smaller patches and introduces edge effects. Key risk areas include:

- Transport corridors within GPEC and WSA, which will result in direct impacts to the potential EC and will increase fragmentation in some locations
- Urban development within GPEC and WSA, which will increase exposure of the EC along riparian corridors to edge effects associated with urban land uses

The Plan incorporates a range of measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Areas. This includes a number of actions, of which the following are the most relevant to the outcome for the EC:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

Importantly for the EC, weeds will be actively managed within the 575 ha to be added to conservation as part of the offset program.

The package of measures in the Plan is expected to adequately manage the risk posed to the EC from weed invasion. This is because:

- Avoided lands where areas of the EC occur will be zoned appropriately to enable an adequate framework for management
- The Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy. This includes the land to be protected under the conservation program for the EC
- There will be a range of planning controls to minimise the potential spread of weeds during and after construction

INAPPROPRIATE HABITAT DISTURBANCE

Inappropriate habitat disturbance is identified in the Draft Conservation Advice as a threat to the EC. This relates to a wide range of different mechanisms for disturbance including:

- Dumping of rubbish and garden waste which can directly impact areas of the EC as well as facilitate increases in weeds (see above) and pollutants
- Inappropriate recreational activities such as ad hoc track building and trail bike use which can directly impact areas of the EC and facilitate processes such as erosion
- Inadvertent disturbance during construction which has the potential to directly impact the EC outside approved development areas

Each of these mechanisms have the potential to alter the structure and floristic composition of the EC.

Inappropriate habitat disturbance within the Strategic Assessment Area may increase due to development within the nominated areas. Occurrences of the EC considered most at risk are those within GPEC and WSA, and to a lesser extent in GMAC.

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for the EC. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan is expected to adequately manage the risk to the EC from inappropriate habitat disturbance as a result of development. This is because:

- Avoided lands where areas of the EC occur will be zoned appropriately to enable an adequate framework for management
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance

- A program of education for the community will be run to help them understand the biodiversity values they live near

CHANGES TO HYDROLOGY

Altered hydrological regimes, including narrowing of riparian corridors, installation of flood mitigation and/or drainage infrastructure, and changes in water quality, have all been identified as threats to the NSW equivalent TEC (OEH, 2019i).

The TEC is most susceptible to the following threats:

- Increase of polluted runoff from development under the Plan where new urban development or transport corridors occur adjacent to the potential TEC. Key risk areas for this threat are located in are located in GPEC and WSA
- Potential installation of flood mitigation and/or drainage infrastructure in localities adjacent to where the EC will be cleared for development of transport corridors. Key risk areas for this threat include areas in proximity to the Outer Sydney Orbital in GPEC and WSA

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for the EC. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5) and transport (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through:

- Development controls in the nominated areas in relation to:
  - Water cycle management. For example:
    - Water management measures must comply with council’s requirements for detention, drainage and water sensitive urban design principles
    - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
  - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
  - Soil erosion and sedimentation. For example:
    - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
    - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom 2004) and submitted with each subdivision development application
- The implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the RMS Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the EC from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts to the EC
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to the EC

DISEASES, PATHOGENS AND DIEBACK

TECs are potentially susceptible to a range of diseases, pathogens and dieback which can substantially affect their long term viability. Recognised threats include dieback caused by the root-rot fungus *Phytophthora cinnamomi*.

Development under the Plan may increase the risk of the spread of infection/disease. This is primarily related to:

- Soil transportation on contaminated footwear, vehicles and machinery, and in residential garden establishment
- Increased site visitation rates
- Earthworks and activities conducted during construction
- Increased surface water runoff

The Plan incorporates a range of measures to manage the risks associated with diseases, pathogens and dieback. In summary, these include:

- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
  - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
  - Entering into written agreements with delivery partners to implement priority disease control programs
- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures methods to protect the environment during construction, including best practice site hygiene protocols to minimise spread of *Phytophthora* and Myrtle Rust

The package of measures in the Plan is expected to adequately manage the risk to the EC from diseases, pathogens and dieback because:

- It supports a landscape scale approach to the issue across the Cumberland subregion
- It will ensure appropriate controls during construction

INVASIVE FAUNA

TECs can be threatened by introduced animals and aggressive native species. These species include:

- Domestic species such as cats and dogs which are related to urban development
- Pest species such as foxes, rats, house mice and rabbits which are primarily related to agricultural development
- Aggressive bird species which compete for resources including the Noisy Miner

Collectively, these animals can lead to declines in biodiversity through:

- Predation
- Damage to vegetation and soils
- Competition for resources

Existing land use within the nominated areas and surrounding region (which includes residential and rural residential areas, and farming) means that these issues are already present in the Strategic Assessment Area and are unlikely to pose a novel threat to the EC.

However, the extent of proposed new urban development under the Plan means that the threats associated with cats and dogs are likely to be exacerbated. It is likely that there will be an increase in the number of domestic cats and dogs in the local area, which, in turn, may lead to an increase in feral cat and wild dog numbers.

In relation to aggressive bird species, the two main drivers for increasing the threat within the EC are:

- Fragmentation of habitat which creates greater edge effects and facilitates access by aggressive bird species. As outlined above, the EC is already highly fragmented and subject to edge effects
- Habitat disturbance through inappropriate land management which can change the structure of the EC and facilitate access by aggressive bird species. As outlined above in relation to inappropriate habitat disturbance, the Plan includes a package of measures which are expected to adequately manage the risk to the EC from inappropriate habitat disturbance as a result of development

In relation to the residual risks associated with invasive fauna, the Plan incorporates a range of measures to manage the risks. In summary, these include:

- A commitment (Commitment 17) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the Strategic Conservation Areas. This includes a number of actions with the most relevant to the outcome for the EC being:
  - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
  - Preparation of a Pest Animal Control Implementation Strategy

  - A process to enter into written agreements with delivery partners to implement the pest animal control program
  - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Development controls that will:
  - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
  - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
  - Require appropriate management and control of pest animals relevant to development sites
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing pests, consistent with the pest animal implementation strategy outlined in Commitment 16

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the ecological community from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the EC to occur due to:

- The development of essential infrastructure within nominated areas but outside the urban capable lands
- Tunnels associated with transport projects

31.13.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

The EC occurs on avoided land within GMAC (14.4 ha), WSA (101 ha) and GPEC (54.9 ha). It is possible that some of these areas will be impacted by essential infrastructure. However, the nature of the EC and its association with riparian corridors reduces its likelihood of being substantially impacted as these areas occur away from the typical locations for essential infrastructure.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area. In the case the EC gets listed under the EPBC Act, these surveys would identify if the listed TEC was present
- Measures to avoid impacts to the listed TEC through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the EC will occur as a results of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

31.13.8 POTENTIAL IMPACTS FROM TUNNELS

The EC occurs within the tunnel footprints for the Metro Rail Future Extension (11.1 ha) and the Outer Sydney Orbital (25.7 ha). The Plan includes commitments to:

- Avoid any direct impacts to the areas where the EC occurs

- Mitigate any potential indirect impacts (e.g. changes to hydrology, ground settling or subsidence) from the transport corridors as part of a future environmental impact assessment process

These commitments are expected to adequately address threats to the EC from the construction and operation of the tunnels. See Section 36.6 in Chapter 36 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE EC

This section considers the likely effects of implementation of the Plan on the long-term viability of the EC. The analysis has regard for the guidance in the Draft Conservation Advice, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also identifies any potentially relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

31.13.9 IMPLICATIONS FOR LONG-TERM VIABILITY

The Draft Conservation Advice (TSSC, 2019c) identifies the following key issues that are likely to have the greatest influence on the long-term viability of the potential TEC:

- Habitat loss and fragmentation
- Indirect impacts including:
  - Inappropriate fire regimes
  - Weed invasion
  - Inappropriate habitat disturbance
  - Changes to hydrology
  - Diseases, pathogens and dieback
  - Invasive fauna

HABITAT LOSS AND FRAGMENTATION

While implementation of the Plan will result in the loss of 210.2 ha of the EC, this is not expected to substantially influence the long-term viability of the potentially listed TEC because:

- The mapping of the EC is based on PCT 835 which provides an over-estimate of both impacts and conservation actions for what might be the listed TEC
- Although the Plan authorises the clearing of 210.2 ha (approximately 3 per cent of the remaining EC), most of this is in thinned and scattered condition. 28.6 ha occurs in intact condition
- The majority of impacts are to small patches, or to the edges of patches
- Transport projects will apply future efforts to avoid impacts to the EC. These processes are set out in Chapter 36
- The Plan commits to protecting and managing 575 ha of PCT 835 as a surrogate for the future listed TEC. These areas will occur in strategic locations as part of the Plan's conservation program

Securing high conservation value EC in the SCAs directly supports a key high priority action in the Draft Conservation Advice to protect and conserve remaining areas of the ecological community.

INDIRECT IMPACTS

The potential indirect impacts associated with inappropriate fire regimes, weed invasion, inappropriate habitat disturbance, changes to hydrology, diseases, pathogens and dieback, and invasive fauna will be managed and mitigated through a number of commitments and actions in the Plan.

Indirect impacts are not expected to influence the long-term viability of the EC.

CONCLUSION

The nature of the impacts to the EC (mostly to smaller patches in lower condition) combined with the commitments to protect 575 ha of PCT 835 and manage indirect impacts will ensure that the implementation of the Plan does not adversely influence the long-term viability of the EC.

31.13.10 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the EC.

31.13.11 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 31-25 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The Plan is not inconsistent with any of the relevant TAPs. Please refer to Section 15.9 of Chapter 15 for a detailed discussion of each TAP and the relationship of the Plan.

Table 31-25: Key Threatening Processes and relevant Threat Abatement Plans for Coastal Floodplain Eucalypt Forest of Eastern Australia

KEY THREATENING PROCESS	RELEVANT THREAT ABATEMENT PLAN
Aggressive exclusion of birds from potential woodland and forest habitat by over-abundant noisy miners (*Manorina melanocephala*)	There is no relevant TAP
Dieback caused by the root-rot fungus (*Phytophthora cinnamomi*)	Threat abatement plan for disease in natural ecosystems caused by *Phytophthora cinnamomi* (DoEE, 2018d)
Infection of amphibians with chytrid fungus resulting in chytridiomycosis	Threat abatement plan for infection of amphibians with chytrid fungus resulting in chytridiomycosis (DoEE, 2016b)
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP
Predation by feral cats	Threat abatement plan for predation by feral cats (DoE, 2015g)
Psittacine Circoviral (beak and feather) Disease affecting endangered psittacine species	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

Table 31-26: Occurrence of Coastal Floodplain Eucalypt Forest of Eastern Australia in the Strategic Assessment Area

Part 6A Attachment Contents

Part 6A Attachment List of Figures

Part 6A Attachment List of Tables

A. Koala terminology

There are many terms used for mapping Koala habitat and understanding Koala ecology. For clarification, Table A-1 lists the terms used in this report.

Table A-1: Koala terminology used in this report

Term	Meaning
Blue Mountains Koala population	This refers to Koalas within the vicinity of the Blue Mountains, which is the closest Koala population to the WSA and GPEC.
Census population size	The total number of Koalas in a population
Connectivity	The degree of continuity and linkage among areas of vegetation. Greater connectivity increases potential gene flow across a landscape
Effective population size	The size of an idealised population (a population which varies in genotype frequencies only due to in the population census size), that would result in the degree of inbreeding and alteration in variance of frequencies observed in the population of interest. This can indicate the number of breeding individuals and degree of genetic diversity of the species
Food tree	Species of tree whose leaves are consumed by Koalas. Koala food trees can generally be considered to be those of the following genus: *Eucalyptus*, *Angophora, Corymbia, Lophostemon* and *Melaleuca*
Genetic diversity	The degree of variation of genes and genetic information of species in a specific area. This includes the genetic differences among individuals in a population
Habitat critical to the survival	Koala habitat that is considered to be important for the species' long-term survival and recovery. The *EPBC Act referral guidelines for the vulnerable Koala* (DoE, 2014) outlines the methodology by which this habitat is identified
Habitat tree	Species of trees which are utilised by Koalas, either as a food source, as a source of refuge or shelter, or to facilitate movement of Koalas through the landscape
Important habitat	Referred to in the Threatened Biodiversity Data Collection and comprises the species polygons for the BAM process. For this project important habitat is comprised of primary and secondary corridors
Inbreeding depression	The decrease in survival and reproduction in naturally outbreeding species caused by inbreeding (mating with genetically similar individuals). Inbreeding may negatively affect fecundity, gamete production and parental capabilities
Koala habitat	Habitat which is suitable for use by Koalas for the purposes of one or more of the following activities: feeding, resting, breeding and/or dispersal between different areas
Koala habitat is comprised of:	
• **High quality habitat**	Defined as the best habitat with the capacity to support higher densities of Koalas
• **Moderate quality habitat**	Defined as lower quality habitat with the capacity to support lower numbers of Koalas
• **Low quality habitat**	Defined as the lowest quality habitat areas, potentially used for movement through the landscape between higher quality areas
Koala metapopulation	A group of Koala populations or sub-populations connected by dispersal
Koala population	A group of Koalas which interbreed and are demographically, genetically, and/or spatially separated from other groups of Koalas

Term	Meaning
Movement corridors	Areas of habitat (often but not always linear) which facilitate the movement and dispersal of Koalas between habitat patches which would otherwise be disconnected
Movement corridors are comprised of:	
• **Primary corridors**	Defined as connected areas of principal habitat (and associated supporting habitat) that provide for ecological function of a population
• **Secondary corridors**	Defined as corridor areas that become narrow to less than 50 metres wide, or that are not connected at both ends
• **Tertiary corridors**	Smaller corridor areas that are not connected at the landscape level
Principal habitat	Comprises contiguous areas of high-quality habitat of sufficient size to support the home ranges of male Koalas
Shelter tree	Species of tree (typically with a dense canopy) which is not used as a Koala feed tree, which Koalas are known to utilise for shelter (particularly during hot periods)
Southern Sydney Koala population	This refers to Koalas within the vicinity of Wilton and GMAC, and includes Koalas from the Campbelltown/Wollondilly/Southern Highlands localities
Supporting habitat	The remaining areas of suitable habitat and vegetation structure that are outside principal habitat. Comprises scattered trees peripheral to and outside of identified Koala movement corridors
Viable population	A self-supporting population with sufficient numbers and genetic variety among healthy individuals and breeding pairs that are well enough distributed to ensure a high probability of survival despite the foreseeable effects of demographic, environmental and genetic events, and of natural catastrophes

B. Detailed background to Koalas in the Strategic Assessment Area

This attachment provides detailed information about Koala populations and ecology in the Strategic Assessment Area. It provides:

- A general background to the species
- An overview of the process of identifying Koala populations in the Cumberland subregion (and vicinity)
- Detailed information about the Koalas and Koala habitat which occurs within and near to Wilton and GMAC
- Relevant information about the Koalas and Koala habitat which occurs near the GPEC and WSA

SPECIES BACKGROUND

Koalas are arboreal marsupials that are distributed within coastal and inland regions of eastern Australia, from South Australia to northern Queensland.

MORPHOLOGY

Although Koalas are recognised as a single species, they have significant differences in morphology and behaviour across the extent of their range (Houlden, Costello et al., 1999). For instance, southern (Victorian) Koalas are on average 80 per cent larger (mean male body weight of 11.8kg) than northern (Queensland) Koalas (mean male body weight of 6.8kg) (Black, Price et al., 2014). There are also obvious variations in body form (including skull shape and fur colour) between northern Koalas and southern Koalas (Black, Price et al., 2014). These differences are the result of adaptions of Koalas to their local environment, which changes significantly between the northernmost and southernmost extent of the species' range.

FEEDING

Koalas are specialist folivores, meaning that they eat leaves and are highly selective in their choice of diet. They are known to eat the leaves of over 100 *Eucalyptus* species and over 30 non-*Eucalyptus* species (including genera such as *Angophora* and *Corymbia*) (OEH, 2018a).

However, local Koala populations typically tend to select their diet from only a small number of trees in their local area, with the preferred tree species varying between populations (McAlpine, Rhodes et al., 2008). McAlpine et al. (2008) proposes that Koalas may select their preferred trees through preferences for certain leaf nutrients (rather than tree species *per se*), and that leaf nutrients may vary between trees of the same species growing in different locations and under different conditions. This may explain why a certain tree species are used by Koalas in some locations but not in others.

Overall, Koalas typically preference trees growing on fertile soils, as fertile soils result in higher leaf nutrient content in trees.

SOCIAL INTERACTIONS

Koalas are territorial animals which exist in complex social networks. Ellis, Melzer & Bercovitch (2009) proposes that Koala habitat use is akin to a checkerboard model, where the ranges of Koalas overlap, yet where individual trees are rarely shared by different Koalas.

Males are more prone to dispersion, whereas female Koalas tend to remain close to natal sites (Houlden, Costello et al., 1999). Male ranges typically tend to be significantly larger than female ranges. The average size of a Koala's home range varies significantly between populations and between different areas and habitats. For example, some home ranges have been recorded to be 10-15 ha, whereas others have been recorded to be as large as 500 ha (NSW Chief Scientist & Engineer, 2016).

Reported densities of Koala populations also significantly vary between different habitats, ranging between 0.006/ha in the South East Forests of NSW to >8/ha in north-eastern Victoria (Close, Ward et al., 2017).

The differences in morphology, habitat preferences and behaviours between populations across the species' range means that research results of individual Koala populations may not be applicable to other populations. This means that local research is often required to determine the specific habitat requirements and conservation needs of any particular local population (McAlpine, Rhodes et al., 2008).

POPULATION NUMBERS AND TRENDS

Koalas had already undergone a series of population bottlenecks prior to European arrival (likely as a result of glacial/interglacial cycles). They therefore already had low genetic diversity prior to the impacts of European activities on the population (Black, Price et al., 2014). The number and density of Koalas in Australia prior to European settlement is unknown, although it is likely that Aboriginal hunting and dingo predation pressures combined to keep Koala populations low (Close, Ward et al., 2017; Tsangaras, Avila-Arcos et al., 2012).

Given uncertainty regarding the number of Koalas originally present in Australia prior to European arrival, determining long-term population trends of the species across its range is difficult. This challenge is further complicated by the cryptic nature of the species (particularly within low-density populations; see for example (Close, Ward et al., 2017)), which makes accurate survey and estimation of current population numbers difficult.

Nonetheless, Adams-Hoskings et al. (2016) estimated the numbers and trends of Koala populations across Australia (as of 2012), shown in Table B-1. The spatial distribution of Koala population trends across Australia is indicated in Figure B-1, sourced from McAlpine et al. (2015). It is noted that both studies acknowledge the presence of varying degrees (and sometimes significant levels) of uncertainty with regards to the accuracy of knowledge of the distribution and trends of Koala populations.

Table B-1: State and national Koala population sizes and trends for 2012, aggregated from bioregional estimates. Adapted from Adams-Hoskings, McBride et al. (2016)

	Queensland	New South Wales	Victoria	South Australia	National Total
Mean Population	79,000	36,000	183,000	33,000	331,000
Population Range	~33,000 - 153,000	~14,000 - 73,000	~77,000 - 327,000	~19,000 - 51,000	~144,000 - 605,000
Mean Population Change (per cent)*	-53	-26	-14	-3	-24

* Mean population change is based on the largest population change in any three-generation period, that is the past three Koala generations (from 15-21 years ago) to the future three Koala generation (15-21 years into the future).

A recent report (Lane, Wallis et al., 2020) set out to quantify the effects of the 2019-20 fires on Koalas in the context of broader population trends in NSW. That report concluded that over the past three Koala generations, numbers in NSW may have declined by a minimum of 28.52 per cent up to a possible 65.95 per cent. The report suggests declines are more likely to have occurred towards the upper estimate, and that the ongoing threats of climate change and high frequency fires will severely threaten the species in NSW over the coming years.

THREATS

Koala populations have been declining as a result of a diverse number of threats, including (McAlpine, Lunney et al., 2015; OEH, 2017):

- Habitat loss
- Habitat modification and fragmentation
- Predation from domestic and feral dogs
- Vehicle strike
- Fire (particularly increased fire intensity which burns the crown of trees)
- Disease (particularly *Chlamydia*)
- Heat stress through drought and heatwaves
- Climate change (which increases drought and heatwaves, but also alters habitat quality)

The presence and prevalence of each threat varies spatially and temporally across the range of the species, and Koala populations are often simultaneously under pressure from multiple threats (Rhodes, Ng et al., 2011). Conservation actions to protect Koala populations should therefore seek to address a suite of threats present for each population, as conservation actions which only target a single threat where multiple threats are present are unlikely to be adequate to safeguard a Koala population (Rhodes, Ng et al., 2011).

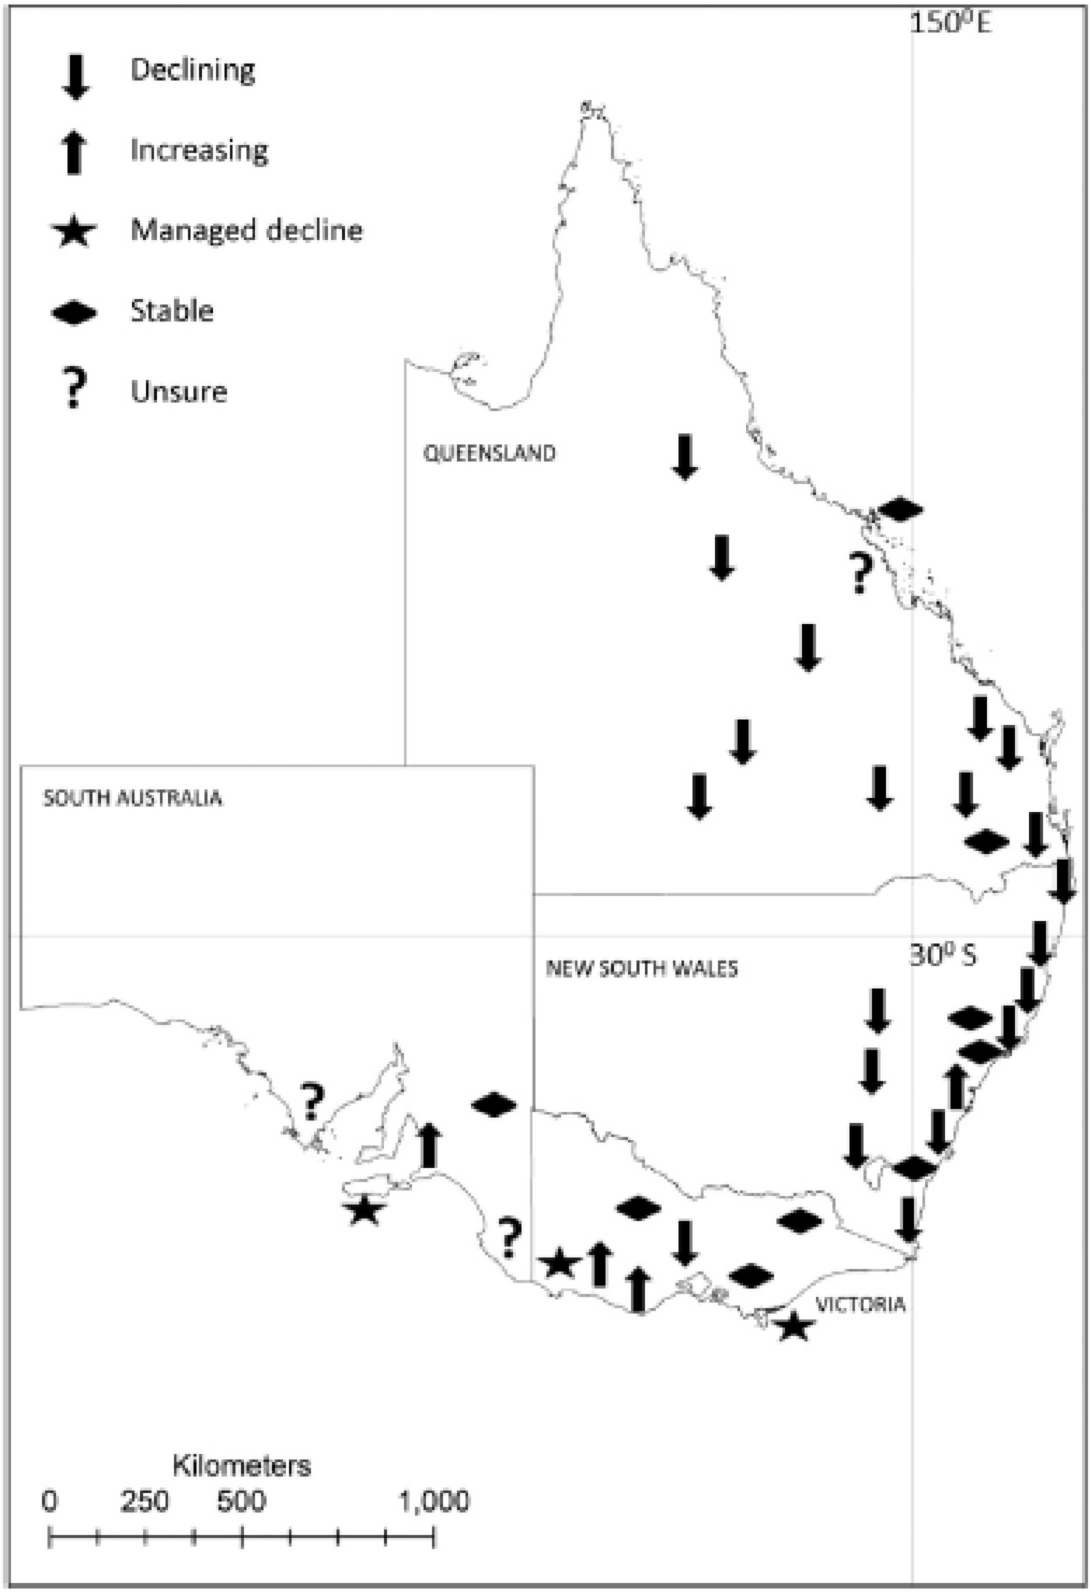

Figure B-1: Koala regional population trend synthesis map, based on the Australian Centre for Ecological and Synthesis expert workshop information (McAlpine, Lunney et al., 2015)(McAlpine et al., 2015)(McAlpine, Lunney et al., 2015) (taken from McAlpine et al., 2015)

IDENTIFYING KOALA POPULATIONS

Literature indicates that different Koala populations may have different habitat requirements and different threats, and therefore appropriate management of Koalas must be targeted to the specific needs of each population (McAlpine, Rhodes et al., 2008). To effectively conserve Koalas within and near the proposed nominated areas, identification and delineation of the characteristics and distributions of local Koala populations is essential.

Koalas are known to exist in the region surrounding Sydney, in wooded areas to the west and south of the main urban areas. Delineation of Koala populations within these regions was undertaken through examination of five different data sources, including:

- Genetic analyses
- Koala record distribution and landscape analysis
- Koala record tracking
- Koala *Chlamydia* distribution
- Koala population trends

The results of each data source were then compiled and analysed to determine the likely distribution and connectivity of Koala populations. The following provides an overview of the assessment process and findings.

GENETIC ANALYSES

Lee et al. (2010) undertook genetic analysis of Koala populations to the west and south of Sydney, and determined that there were three genetically-separate Koala populations:

- South Sydney - which encompassed an area from Heathcote to the Campbelltown region, and had low genetic diversity which indicated a recent population bottleneck event
- Southern Tablelands - which was abruptly genetically distinct from the Heathcote/Campbelltown population, indicating the presence of barrier/s to gene flow between the populations despite physical proximity. The nature of genetic differentiation between the two populations was such that it was likely that any barriers to gene flow between these populations were a recent, not historic, landscape feature. Note that Lee et al. (2010) does not provide detailed information on the sampling point locations used to identify the Southern Tablelands population, and therefore it is unknown whether this population incorporates Koalas from the Southern Highlands or not
- Blue Mountains - which was genetically distinct from both the South Sydney and Southern Tablelands population, and had comparatively higher genetic diversity

Kjeldsen et al. (2019) undertook further genetic analyses on a wide range of Koala populations, including the Blue Mountains, Campbelltown and Southern Highlands Koala populations. Results of this study indicated that:

- Genetic admixture is occurring between the Campbelltown and Southern Highlands Koala populations. Genetic admixture occurs when previously isolated populations begin interbreeding
- The Blue Mountains Koala population is one of the most genetically-diverse Koala populations in Australia

KOALA RECORD DISTRIBUTION AND LANDSCAPE ANALYSIS

The NSW BioNet database was accessed on 17 October 2018, to view the distribution of Koala records across Sydney and the wider region. The data was also cleaned or subject to expert review to ensure all data points were valid. The results are shown in Map 37. Note that a high density of sightings does not necessarily indicate a high density of Koalas yet may instead be indicative of areas where high human presence and activity leads to increased chances of wildlife sightings.

Map 37 indicates a largely continuous presence of Koalas, from north of Campbelltown through to the Southern Highlands. The continuity of Koala records suggests that Koalas are present throughout this region, and therefore there is a high likelihood that Koalas within the Campbelltown locality would be connected to Koalas within the Southern Highlands and beyond. It is further noted that there is an absence of any significant landscape features (e.g. large waterbodies, urban areas, major roads with wildlife fencing) between the Campbelltown locality and the Southern Highlands which would have the capacity to entirely block Koala movements between the two areas.

There are known Koala records in the Blue Mountains, particularly in the locality of Kurrajong. There are very few records of Koalas in the region between the Blue Mountains and the Campbelltown/Southern Highlands region, suggesting that there may not be large populations of Koalas within these areas. Therefore, it is likely that the Blue Mountains Koalas and the Koalas within the Campbelltown/Southern Highlands localities comprise separate populations.

KOALA TRACKING RESEARCH

Recent research has been conducted through the Saving Our Species program administered by OEH. As part of this research, Koalas have been tracked from Appin through to bushland south of Picton Road (Saving Our Species, 2019). These tracking records indicate that Koalas are able to successfully cross Appin Road and Picton Road, and therefore that the Campbelltown Koalas (to the north of Appin Road) and the Southern Highlands Koalas (to the south of Picton Road) currently have some degree of contact with each other through migration (Saving Our Species, 2019).

KOALA CHLAMYDIA DISTRIBUTION

Chlamydia is a genus of bacteria from the family *Chlamydiaceae*. Infection of Koalas with *Chlamydia* can lead to the development of a range of illnesses such as conjunctivitis, genital tract infection and urinary tract infection (Jackson, White et al., 1999). The range of illnesses caused by infection with *Chlamydia* is collectively referred to as Chlamydiosis. It is noted that a Koala which is infected with *Chlamydia* does not always present clinical symptoms of disease.

There are multiple species of *Chlamydia*, of which two are known to infect Koala populations within Australia (Jackson, White et al., 1999). The first of these is *C. pseumoniae*, whilst the second is *C. pecorum* (Jackson, White et al., 1999). Of these two species, *C. pecorum* is more pathogenic, as (Jackson, White et al., 1999):

- Infection with *C. pecorum* is more likely to result in clinical expression of disease
- When clinical expression occurs, *C. pecorum* is more likely to result in severe disease symptoms than *C. pseumoniae*

The Koalas within the Campbelltown locality are recognised as being important for conservation purposes as the Koalas are free of *Chlamydia* (Western Sydney University, 2017). It is likely that (to date) the population has been protected from contracting *Chlamydia* due to isolation from neighbouring populations (Western Sydney University, 2017).

Recent research has been undertaken through the Saving Our Species program to test for the presence of *Chlamydia* and Chlamydiosis within Koalas in the Campbelltown, Wollondilly and Southern Highlands localities using genetic analysis (Saving Our Species, 2019). Results of this research are as follows (Saving Our Species, 2019):

- Koalas within the Southern Highlands are infected with *C. pecorum*, and display clinical symptoms of the disease Chlamydiosis
- Koalas within the Wollondilly locality are infected with *C. pecorum*, yet do not display clinical symptoms of the disease
- Koalas within the Campbelltown locality (within the area bounded by Appin Road to the south and to the west) are not infected with *Chlamydia*

KOALA POPULATION TRENDS

There is a long history of Koala occupation within the Campbelltown locality (Western Sydney University, 2017). The Koala population is known to be recovering from a near extinction event, which may have been caused by hunting pressures associated with the fur trade, a severe outbreak of disease in the 1920s, or some combination of the two (Lee, Zenger et al., 2010). For a number of years, Koalas were extremely rare in the locality, with very few records occurring prior to the 1980's (Biolink, 2016).

Research undertaken by Biolink (2016) and Biolink (2018b) within the Campbelltown City Council Local Government Area has indicated that the Koala population is currently recovering, a trend which is evidenced through increases in the area of habitat utilised by Koalas on an ongoing basis.

There is also evidence that Koalas within the Southern Highlands underwent a near extinction event in the early 1920's, with reliable sightings of Koalas only reoccurring from the 1970's onwards. The population is since thought to have continued its recovery trend, based on historic reports and contemporary reports of increases in sightings, contemporary increases in roadkill occurrences, and from the results of spotlighting surveys conducted in the region (Saving Our Species, 2019; Tilley & Uebel, 1990).

RESULTS AND DELINEATION OF KOALA POPULATIONS WITHIN THE SYDNEY REGION

Genetic analyses have consistently identified the Blue Mountains Koalas as being genetically distinct from the Koala populations within the Southern Tablelands/Southern Highlands/Campbelltown localities (Kjeldsen, Raadsma et al., 2019; Lee, Zenger et al., 2010). Therefore, it is considered that the Blue Mountains Koalas belong to a different ecological population to the Koalas within Southern Tablelands/Southern Highlands/Campbelltown localities. Whilst there may be some degree of dispersal of Koalas between these two areas, the rate of dispersal is likely to be low. The Blue Mountains Koala population is recognised to be an important population for conservation due to its unusually high genetic diversity (Kjeldsen, Raadsma et al., 2019).

Delineation of populations within the Southern Tablelands/Southern Highlands/Campbelltown localities is more complicated. Genetic analysis indicates the following sequence of events has occurred for Koalas within these regions:

- The Koala populations would have originally been well connected (prior to European arrival) (Lee, Zenger et al., 2010)
- There had been a recent (post-European) introduction of some form of barrier which prevented gene flow between the Koalas in the Southern Tablelands and the Koalas in the Campbelltown locality, resulting in genetic differences between these two populations (Lee, Zenger et al., 2010)
- Even more recently, the Koalas within the Southern Highlands and the Campbelltown locality have begun to show signs of genetic mixing again, indicating that these populations are once again connected (Kjeldsen, Raadsma et al., 2019)

The landscape between the Campbelltown and Southern Highlands Koalas consists of largely continuous bushland intersected by several roads with moderate to high traffic densities (Picton Road and Appin Road). It is known that Koalas are able to successfully cross both of these roads. Therefore, there is an apparent absence of any significant landscape barrier which would effectively separate Campbelltown and Southern Highlands Koalas.

It is known that Koalas within the Campbelltown and Southern Highlands localities have previously undergone significant population decline, yet it is understood that both populations are currently in recovery. It is therefore hypothesised that the two Koala populations became separated as a result of contractions in Koala habitat occupancy, and that recent re-connection of the two Koala populations has occurred as a result of the recovery of both populations.

The historical and current distribution of *Chlamydia* supports this hypothesis. The Campbelltown Koala population has long been recognised as being *Chlamydia*-free, a feature which is likely to be the result of the isolation of the Campbelltown Koalas from neighbouring Koala populations (Western Sydney University, 2017). However, recent research has found the presence of *Chlamydia* as far north as Appin, indicating that the infection may be spreading further north into areas which had previously been *Chlamydia*-free (Saving Our Species, 2019).

The results of this analysis have therefore identified two Koala populations for the purposes of assessment within the vicinity of the proposed nominated areas. These populations are identified as:

- Southern Sydney Koala population – this refers to Koalas within the vicinity of Wilton and GMAC, and includes Koalas from the Campbelltown/Wollondilly/Southern Highlands localities
- Blue Mountains Koala population – this refers to Koalas within the vicinity of the Blue Mountains, which is the closest Koala population to the WSA and GPEC

The following sections provide an overview of the characteristics of each population.

SOUTHERN SYDNEY KOALA POPULATION

DELINEATION OF STUDY AREA

As discussed above, the ecological boundaries of Koala populations in the vicinity of Wilton and GMAC are unclear. It is possible that all Koalas within this vicinity are increasingly becoming connected into one large population, which extends north and south beyond the potential areas of impact associated with the proposed development.

Therefore, the study area for this population has been confined to areas of Koala habitat within proximity to the nominated areas, which have potential to be either directly or indirectly impacted by the proposed development.

HABITAT PREFERENCES AND USAGE

The Southern Sydney Koala population exhibits a well-documented preference for vegetation growing on Wianamatta shale soils over Hawkesbury sandstone soils, as a result of the higher nutrient content of shales (OEH, 2018b; Phillips & Callaghan, 2000; Ward, 2002). Ward (2002) found that Koalas were in better condition and bred more successfully on Wianamatta shale soils, while OEH (OEH, 2018b) found a higher density of preferred tree species, and a higher density of observed Koalas, on Wianamatta shale soils. However, Koalas are still known to utilise Hawkesbury sandstone habitats, and can successfully breed in these habitats (Ward, 2002). It is noted that there are few Koala records from Narrabeen shales in the region (Ward, 2002), but this is a very infrequent substrate in the region and mostly found deep in the inaccessible and flooded gorges.

A number of studies have aimed to identify preferred habitat tree species utilised by the Southern Sydney Koala population, the results of which are shown in Table B-2. Koalas have also exhibited preference for trees with greater diameter at breast height (DBH) (Phillips & Callaghan, 2000; Ward, 2002).

Table B-2: Tree species preferred by the Southern Sydney Koala population

Source	Preferred Tree Species
(OEH, 2018b)	*Eucalyptus punctata, E. globoidea, E. pilularis, E. longifolia, E. tereticornis, E. paniculata, Acacia decurrens*
(Ward, 2002)	*Eucalyptus punctata, E. globoidea, E. pilularis, E. agglomerata, E. capitellata, E. eugenioides, E. piperita, Syncarpia glomulifera**
(Sluiter, Close et al., 2002)	*Eucalyptus punctata, E. agglomerata, Corymbia gummifera*
(Phillips & Callaghan, 2000)	*Eucalyptus punctata**, E. agglomerata***

* Shelter tree.

** Preferences only exhibited when tree growing on shale soil.

Of all of the identified preferred habitat trees, grey gum (*Eucalyptus punctata*) is the only species which is consistent across each study. Further, *E. punctata* was identified as a preferred habitat tree for every tracked Koala within the study conducted by (OEH, 2018b), whereas other species were not consistently identified as a preference by all Koalas. Analysis of Koala faecal pellets also indicated that *E. punctata* accounted for a major proportion of Koala diet for three Koalas in the Campbelltown locality, with *E. punctata* accounting for between 66-92 per cent of leaf cuticle fragments in faecal matter (Sluiter, Close et al., 2002).

However, Koala habitat usage patterns are not solely determined by tree species and soil type, but also by a wide range of factors including Koala social interactions and age, in addition to temporal (e.g. seasonal) influences on tree nutritional values (Ellis, Melzer et al., 2009; Ramsay, 1999). For example, Ramsay (1999) found that juvenile Koalas at Nowendoc exhibited different tree preferences to their mothers and that there were seasonal effects upon tree nutrient and anti-nutrient contents, whilst Ellis et al. (2009) found that Koalas rarely re-use the same tree twice or share trees used by other Koalas and that social interactions play a significant role in influencing Koala habitat usage. Therefore, the observed variations in preferred tree species utilised by Koalas may be the result of differences in the wider range of factors which influence tree selection.

HABITAT DISTRIBUTION AND CONNECTIVITY

A range of assessments have been undertaken to assess the key characteristics, quality, distribution and connectivity of Koala habitat within the Plan Area. These assessments include:

- **Species-distribution model:** This provides information on habitat availability and distribution across the Cumberland subregion
- **Corridor habitat happing:** This provides information on habitat availability, distribution, characteristics and connectivity within and near to the four
- **GAPCLoSR:** This is a GIS-based analysis which provides information on habitat connectivity
- **Habitat critical to the survival of the species:** This provides information on the availability and distribution of habitat critical to the survival of the Koala, in accordance with the EPBC referral guidelines

Details of the methods for each assessment is provided in Attachment C.

KOALA HOME RANGE AND DENSITY ESTIMATES

A number of studies have sought to identify the densities and home range sizes of Koalas within the Southern Sydney population (see Table B-3).

Table B-3: Densities and ranges of Koalas within the Southern Sydney Koala population

Source	Koala Density (Koalas/ha)	Female Range (ha)	Male Range (ha)
(OEH, 2018b)	0.078 (within high quality habitat)	Average: 38 n = 3	Average: 114 n=8
	0.017 (within non high-quality habitat)		
	0.052 (overall average across full study area)		
(Ward, 2002)	0.035 ± 0.087 (using a transect method)	MCP* Range^: 28 - 129 MCP Midpoint: 79 90% Harmonic Mean** Range: 12 - 62 90% Harmonic Mean Midpoint: 37 60% Harmonic Mean Range: 5 - 25 60% Harmonic Mean Midpoint: 15 n = 6. It is noted that only 3 female adult Koalas had sufficient fixes to reach the asymptote in home range size.	MCP Range^: 38 - 387 MCP Midpoint: 213 90% Harmonic Mean Range: 12 - 165 90% Harmonic Mean Midpoint: 88.5 60% Harmonic Mean Range: 6 - 72 60% Harmonic Mean Midpoint: 39 n = 5. It is noted that no male adult Koalas had sufficient fixes to reach the asymptote in home range size.
	0.049 (using a home range method)		

^ Range data refers to adult ranges only (females ≥ 3 years old, males ≥ 4 years old) and has been rounded to the nearest hectare.

* Minimum Convex Polygon refers to the maximum area in which the Koala is observed and includes areas which are rarely used by the Koala.

** Harmonic Mean calculates the probability of the Koala being present within a given area. Therefore, the 90 per cent Harmonic Mean provides the range of the Koala within which the animal is present 90 per cent of the time, whilst the 60 per cent Harmonic Mean provides the range of the Koala within which the animal is present 60 per cent of the time.

KOALA POPULATION SIZE ESTIMATES

The assessment area examined within this report is similar in size and distribution to the study area examined in OEH (2018b).

In their assessment, OEH (2018b) calculated the potential population size of Koalas within the assessment area via the following method:

Koala Population Size = Koala Density (Koalas/ha) x Area of Available Habitat (ha)

Given an average recorded density of 0.052 Koalas/ha and a mapped habitat area of 8,293 ha within their assessment area, OEH (2018b) calculated that there was a potential Koala population size of up to 433 Koalas. This is a useful approximation for use in this assessment.

It is noted that calculating the potential size of the Koala population through extrapolation from observed Koala densities and mapped areas of Koala habitat relies upon the following assumptions:

- The reported density of Koalas in each habitat type is accurate (the accuracy of measurements for this parameter have potential to be influenced by field survey techniques, survey timing, survey longevity and sample size)
- All areas of available Koala habitat are occupied by Koalas
- The observed densities of Koalas within each habitat type are in equilibrium (i.e. the population is neither increasing nor decreasing in density)

The size of the Koala population estimated by OEH (2018b) is therefore subject to some degree of uncertainty.

KOALA POPULATION TRENDS

As discussed above, the Koala populations within the Campbelltown and Southern Highlands localities are thought to be expanding (Biolink, 2016, 2018b; Saving Our Species, 2019; Tilley & Uebel, 1990).

Within the Campbelltown locality specifically, is noted that part of the Koala habitat expansion has occurred through Koalas inhabiting areas further to the west, towards and across Appin Road (Biolink, 2018b). Recent survey work conducted by Biolink (2017) confirmed the presence of Koalas along the Nepean River, and found that the Campbelltown Koalas are in contact with the Nepean Koalas. It may be that the increasing westward trend in habitat occupancy of the Campbelltown Koalas may either indicate, or be the result of, strengthened connections with the Nepean Koalas.

POPULATION GENETIC DIVERSITY AND RESILIENCE

Low genetic diversity of a population has the potential to decrease the resilience of the population, through increasing risks associated with factors such as:

- Decreased biological fitness of individual Koalas as a result of inbreeding (known as inbreeding depression)
- Increased vulnerability to environmental change
- Increased vulnerability to threats such as disease

Genetic diversity is measured here as the effective population size (Ne), which is a calculated metric reflecting the population's genetic characteristics. Note that effective population size is distinct from the census population size (Nc), which refers to the total number of Koalas within the population. Available literature in population genetics suggests that an effective population size of between 50 and 100 is typically recommended as an estimate of required genetic diversity to ensure population viability, although it is recognised that such estimates are generalised metrics which may not be applicable for all species (Frankham, Bradshaw et al., 2014).

It is noted that Koalas are thought to have had low genetic diversity prior to European arrival (Tsangaras, Avila-Arcos et al., 2012), indicating that low genetic diversity may be a normal feature of healthy Koala populations. It is further recognised that some of the most successful Koala populations within Australia (which have such large population sizes that they are subject to managed population reduction measures) have very low genetic diversity as a result of strong historic population bottleneck events (McAlpine, Lunney et al., 2015). Therefore, it may be that Koalas have some degree of resilience to low rates of genetic diversity.

Lee et al. (2010) found that the Southern Sydney Koala population had an effective population size of Ne = 16-21, which indicates that the population had a very low genetic diversity and has been subject to a recent population bottleneck event. More recent analysis conducted by Kjeldsen et al. (2019) indicates that genetic mixing has recently begun to occur between Koalas in the Campbelltown and Southern Highlands localities, which would be contributing to increasing the genetic diversity within each of these populations.

Overall, it is noted that Koalas within the Campbelltown and Southern Highlands localities are currently experiencing population expansion (Biolink, 2018b; Saving Our Species, 2019), despite low genetic diversity.

Therefore, whilst it is recognised that the Koalas of Southern Sydney have low genetic diversity, it is considered that this feature of the population is unlikely to pose a significant threat to the population's ongoing recovery, and that other threats (such as habitat loss, disease, vehicle strikes and dog predation) are likely to pose more significant challenges to the population.

EXISTING KEY THREATS TO SOUTHERN SYDNEY KOALA POPULATION

Currently, the key threats to the Southern Sydney Koala population (based on documented threats to the population within the Campbelltown locality) include (Phillips & Biolink, 2016):

- Vehicle strike
- Wildfire
- Dog predation
- Habitat loss

The rates and distribution of Koala roadkill events have been analysed through an examination of available roadkill records within BioNet (as at October 2018). The distribution of roadkill records in the vicinity of Wilton and GMAC are shown in Map 41. It is noted that the true number of roadkill Koalas is likely to be greater than the number of records, as not all roadkill occurrences would necessarily be recorded. Therefore, the true number and rate of Koala roadkill occurrences is unknown. However, the records nonetheless provide insight into trends in the rate and distribution of roadkill events in the locality.

Vehicle strikes of Koalas are becoming more common within the Campbelltown and Wollondilly LGAs. The increasing rates of vehicle strike are correlated with a rapid increase in traffic density within the locality, particularly on Picton Road and Appin Road (OEH, 2018b). The increasing trend in traffic density, and corresponding increase in Koala mortality rates, is likely to continue with further development without the implementation of appropriate mitigation measures (OEH, 2018b).

Further, a number of roadkill hotspots have been identified, where a hotspot is defined as a location with greater than four roadkill Koalas within a 2 km stretch of road (OEH, 2018b). Roadkill hotspots tend to occur where a major road intersects a primary Koala corridor, often near the headwaters of a watercourse. Roadkill hotspots are known to occur at the following locations (OEH, 2018b):

- Picton Road between Cordeaux Dam and Wilton
- Macarthur Drive
- Eastern end of Wilton Road
- Appin Road between Appin and Campbelltown
- Hume Highway at the Bargo exit

The rates of Koala mortalities from the remaining key threats to the population (wildfires, dog predation and habitat loss) are currently unknown. Estimating the severity of these threats is difficult, such threats are typically not highly visible (e.g. dog attack from roaming dogs in bushland) and operate over long timescales (e.g. habitat loss) or in a stochastic manner (e.g. bushfires). It is therefore difficult to identify the prevalence and severity of each threat to the viability of the population as a whole, and subsequently it is difficult to determine how investment in conservation funding to address each threat should be prioritised.

Nonetheless, it is noted that Rhodes et al. (2011) found that, where multiple threats are present in a Koala population, addressing only a single threat is unlikely to achieve the desired result of protecting a Koala population from decline. Therefore, Rhodes et al. (2011) recommend implementation of a range of strategies to target and reduce multiple threats, as focusing on a single, key threat is unlikely to be effective.

BLUE MOUNTAINS KOALA POPULATION

This section provides an overview of the Blue Mountains Koala population, which is the closest Koala population to GPEC and WSA, and the source population for dispersing Koalas which may enter the nominated areas.

HABITAT AVAILABLE WITHIN GPEC AND WSA

An assessment of Koala habitat availability and quality within GPEC and WSA has been conducted through analysis of the following landscape features:

- Habitat mapping
- Consideration of threatening processes
- Consideration of distribution of Koala records

Each of these matters is considered in detail below.

HABITAT MAPPING WITHIN GPEC AND WSA

Three methods of mapping have been conducted to determine the availability and importance of Koala habitat within the GPEC and WSA.

The first method, known as a Species Distribution Model (SDM), did not find any areas of potential Koala habitat within either the GPEC or WSA. The results of the SDM mapping are presented in Map 37.

The second method, known as corridor mapping, found only scattered areas of supporting Koala habitat within the nominated areas. The results of the corridor mapping are presented in Map 38 and Map 39.

The third method, known as habitat critical to the survival mapping, did not map any habitat critical in the nominated areas.

Overall, none of the mapping methods identified the presence of important habitat within either nominated area. Further detail regarding the methodology for preparing the above mapping methods is presented in Attachment C.

CONSIDERATION OF THREATENING PROCESSES

GPEC already contains large areas of existing urban development. Urban environments pose significant threats to Koalas, through factors including high road and traffic densities, high densities of predators such as domestic dogs, landscape hazards such as swimming pools and barriers to movement such as fences.

Whilst Koalas may occasionally occur within areas of vegetation within GPEC, it is considered unlikely that a breeding and persisting population of Koalas would be able to permanently reside in habitat within GPEC, as it is considered likely that the mortality rates of Koalas due to the high threat pressures would be greater than the breeding rate. Therefore, it is probable that habitat currently available within GPEC constitutes 'sink habitat'.

WSA does not currently have such a high density of urban development, and therefore is less likely to have threat densities which are as significant as those in GPEC. However, it is noted that the scarcity of native vegetation within the nominated area would require Koalas to cross large areas of open habitat whilst traversing between vegetation, which would increase the vulnerability of Koalas to threats such as predation by dogs.

Overall, it is considered that significant threat pressures would be present within both nominated areas.

CONSIDERATION OF KOALA RECORD DISTRIBUTION

The BioNet record database has been examined to determine the likelihood that Koalas are present within GPEC and WSA. It is noted that there are high human population densities in both areas, particularly within GPEC, and therefore an absence of records would be likely to accurately reflect an absence of Koalas (as opposed to an absence of surveys).

There are no records of Koalas within WSA Area, and only one Koala record within GPEC which is dated from 1990 in Blackett. A small number of Koala records also occur in semi-rural localities to the north of GPEC, as follows:

- One record is dated from 1984 in the Londonderry locality
- One record is dated from 2006 and located in the Metro offset site near Colebee
- Two records are dated from 2018 and located to the west of Shanes Park

Further Koala records are located to the west of the two , within and in proximity to areas of remnant vegetation associated with the eastern boundary of the Blue Mountains.

Whilst a small number of Koala records occur within and in the vicinity of the GPEC and WSA, the scarcity of these records, and the length of time between sightings, suggests that Koalas are extremely rare within the locality, and that it is very unlikely that there is a persistent population in the locality. Instead, it is more likely that Koala sightings within these localities are of dispersing individuals travelling between areas of more suitable habitat.

*S*ummary

Koala habitat mapping, consideration of threatening processes and Koala BioNet records all suggest that:

- It is very unlikely that suitable Koala habitat is present within either GPEC or WSA
- It is likely that any Koalas which are present within the two are dispersing between areas of more suitable habitat

It is therefore considered that any Koalas within the GPEC or WSA would likely constitute individuals which have dispersed from the Blue Mountains Koala population, as this is the closest habitat area which is known to support a self-sustaining and expanding population from which Koalas are known to disperse.

OVERVIEW OF THE BLUE MOUNTAINS KOALA POPULATION

Compared to the Southern Sydney Koala population, comparatively little is known about the Blue Mountains Koala population. The majority of research in this area has been conducted through the 'Blue Mountains Koala Project', which is run by the non-profit conservation organisation Science for Wildlife (Leigh, pers. comm. 2019).

Research to date has largely focused on Koalas at two sites, around the Kurrajong/Richmond/Wollemi National Park region, and the Kanangra-Boyd/Hartley region, which has contributed to establishing a baseline understanding of the Koala populations in these areas (Leigh, pers. comm.) Preliminary surveys and opportunistic studies have recently been initiated by the 'Blue Mountains Koala Project' in areas between Yarramundi in the north and the Southern Highlands in the south, an area which currently has almost no available data on the presence or characteristics of Koala populations (Leigh, pers. comm. 2019). More intensive research was scheduled to start in late 2018 and data to date includes recent sightings of at least two Koalas in Mulgoa/Silverdale and several in the Lower Blue Mountains as far east as Glenbrook (Leigh, pers. comm. 2019).

Research to date has established the following characteristics of Koalas in the Blue Mountains:

- The Blue Mountains Koala population is important for conservation purposes as it has the highest recorded levels of genetic diversity of any Koala population in Australia (Kjeldsen, Raadsma et al., 2019)
- The Blue Mountains are likely to be an important refuge for Koalas under climate change, and research is still underway to assess how many Koalas occupy the protected area versus the urban fringe or use only developed land. There is potential for anthropogenic threats in developed areas to impact the viability of the Koala population/s in the protected area network.
- Increased sightings of Koalas in semi-rural and urban areas near the Blue Mountains indicate that the Koala population of the Blue Mountains (from the north of Kurrajong through to the Southern Highlands) is currently expanding, with greater number of dispersing Koalas being observed over time (Leigh, pers. comm. 2019). This is also linked with the fact that the Cumberland subregion supports richer soils and vegetation types that are likely to attract Koalas moving from the protected area.
- Koalas are able to disperse long distances. For example, one young male Koala was tracked from Mulgoa (near Penrith), down to the locality near Picton (a distance of over 30 km) (Leigh, pers. comm. 2019)
- The Koalas within the Kurrajong/Richmond/Wollemi locality may have a *Chlamydia* infection rate of up to 30 per cent. Despite this, the population is currently expanding (Leigh, pers. comm.)

As discussed previously, the 2019-20 bushfires affected significant areas of the Blue Mountains. The long-term implications for the Koala population are not currently known, but it can be presumed that the fires had a significant negative impact.

C. Koala habitat mapping and connectivity analysis

INTRODUCTION

Three forms of Koala habitat mapping were undertaken for this project. They include:

- A species distribution model (SDM) for the species across the Cumberland subregion
- Corridor habitat mapping
- Mapping of habitat critical to the survival of the species

In addition, a connectivity analysis was undertaken for part of the Southern Sydney population.

This attachment provides an overview of the methodology of each form of mapping and analysis.

SPECIES DISTRIBUTION MODEL FOR THE CUMBERLAND SUBREGION

RMIT University was engaged to prepare SDMs for a total of nineteen EPBC listed species found within the Cumberland subregion (see Supporting Document G). As part of this assessment, an SDM was prepared for Koalas.

The overall purpose of preparing the SDMs was to (Gordon & Koshkina, 2018):

- Provide context for detailed environmental impact analysis being undertaken within the nominated areas, such as through providing information about the relative importance of different areas of habitat within each nominated area compared to the rest of the subregion
- Assist in evaluating commitments by providing indicative information about the amount of habitat available for biodiversity offsetting
- Enable indicative impact assessment of transport corridors

The SDM for Koalas was prepared through the following process (Gordon & Koshkina, 2018):

1. Species records for Koalas within the Cumberland subregion were sourced from BioNet and examined. The following records were removed:
    - Erroneous/inaccurate records
    - Records which were *not* associated with native vegetation were also removed, as records outside of native vegetation were taken to represent dispersing male Koalas outside of regular habitat areas following the breeding season, or of records of areas that previously supported vegetation that is no longer there
2. A range of environmental parameters associated with Koala records were tested for their capacity to predict Koala occurrence across the subregion. The parameters which were selected for use in the SDM were those which:
    - Performed well in predicting Koala occurrence
    - Did not increase the risk of introducing bias into the model
3. The selected environmental parameters, in addition to Koala records, were used as inputs to generate three different SDMs. Each SDM adopted a different modelling methodology which accounted for different types of bias which were likely to be present within the input data
4. The outputs of each SDM were correlated, and a final SDM map was produced with the following categories:
    - 'Unlikely to occur' – Locations where none of the SDM models showed the species occurring
    - 'Potential to occur' – Locations where at least one of the SDM models showed the species occurring. These areas are the most appropriate for assessing potential impacts on the target species
    - 'Likely to occur' – Locations where all three of the SDM models showed the species occurring. These areas are the most appropriate for targeting conservation actions such as offsetting

The results of the SDM mapping are indicated in Map 37. Results show the presence of higher quality ('likely to occur') Koala habitat in the south of the Cumberland Plain, with small areas of lower quality habitat ('potential to occur') occurring elsewhere in the subregion (predominantly to the north-west and west). Overall, results indicate that there is likely to be very little Koala habitat available within the Cumberland subregion.

Despite there being few Koala records within the Cumberland subregion, it is recognised that there is an abundance of Koala records in close proximity to the boundaries of the Cumberland subregion. For instance, Gordon & Koshkina (2018) recognise that there are over 2,700 records of Koalas within a 10 km buffer distance of the subregion boundary.

It is important to recognise that the SDM mapping only shows areas where Koalas are likely to be present based on environmental predictors. This mapping does not take into account other key considerations, such as connectivity, habitat quality, minimum habitat patch sizes for population viability or presence of threats. Therefore, the SDM is best interpreted as an indicative map which shows the extent and distribution of potential habitat available within the subregion; it does not necessarily indicate which areas of habitat are the most important locations to conserve a species (Gordon & Koshkina, 2018).

CORRIDOR HABITAT MAPPING

The corridor habitat mapping built on the work of OEH in mapping habitat around Wilton and GMAC (OEH, 2018b). Mapping was undertaken for:

- Wilton Growth Area (Wilton) and Greater Macarthur Growth Area (GMAC)
- Greater Penrith to Eastern Creek Investigation Area (GPEC) and Western Sydney Aerotropolis (WSA)

MAPPING METHOD FOR WILTON AND GMAC

The mapping method for Wilton and GMAC is driven by the "long-established relationship between the presence of Koalas and vegetation that grow on higher fertility soils such as shale or shale-transition soils" (OEH, 2018b).

There are five steps in the mapping method:

1. Map Koala habitat
2. Identify principal and supporting habitat
3. Identify movement corridors
4. Categorise corridors into primary, secondary and tertiary
5. Define important habitat

Spatial scope of the mapping

The spatial scope of the mapping for Wilton and GMAC was:

- The two nominated areas
- Connected habitat between them
- Habitat to the east to the edge of the Strategic Assessment Area
- West to Bargo

Step 1: Map Koala habitat

Using Plant Community Types (PCTs) (see Table C-1), Koala habitat was mapped into three categories (Table 1):

- High quality habitat (HQH) = all shale and shale-enriched vegetation types with a dominant eucalypt canopy
- Moderate quality habitat (MQH) = Eucalypt-dominated riparian sandstone communities, rainforest communities on shale with some eucalypts present, and regenerating *Acacia* scrubs on shale. **NB:** based on the vegetation within Wilton and GMAC and the surrounding land in the Plan Area there are no PCTs that meet this definition of moderate quality
- Low quality habitat (LQH) = Low-fertility sandstone vegetation communities including heaths, heathy woodlands, swamps, and rocky woodlands

Table C-1: PCTs and Koala habitat in Wilton and GMAC

PCT	HQH	MQH	LQH
724 - Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion	Y		

PCT	HQH	MQH	LQH
725 - Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion	Y		
830 - Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Y		
835 - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	Y		
849 - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	Y		
850 - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Y		
1081 - Grey Gum woodland on the edges of the Cumberland Plain, Sydney Basin Bioregion.	Y		
1181 - Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion	Y		
1395 - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion.	Y		
1292 - Water Gum - Coachwood riparian scrub along sandstone streams, Sydney Basin Bioregion			Y
883 - Hard- leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion			Y
1800 - Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley			Y

STEP 2: IDENTIFY PRINCIPAL AND SUPPORTING KOALA HABITAT

Principal habitat is defined as HQH patches greater than 100 ha that contain Koala records.

The remainder of habitat is defined as "supporting".

STEP 3: IDENTIFY MOVEMENT CORRIDORS

Movement corridors include:

- All principal habitat except for those patches of principal habitat that are separated by more than 1 km
- Smaller patches of HQH within 100 m of patches of principal habitat in corridors
- Patches of MQH or LQH that connect patches of principal habitat within corridors or are entirely within principal habitat in corridors
- Scattered trees where they are completely or largely contained within corridors

Movement corridors exclude:

- Patches of principal habitat that are separated by more than 1 km
- Patches of MQH or LQH peripheral to corridors
- Scattered trees peripheral to corridors

Step 4: Categorise corridors into primary, secondary and tertiary

Primary corridors are identified as:

- Movement corridors that include patches of principal habitat which are contiguous (gaps between trees <100 m) and together contain greater than 380 ha

Secondary corridors are identified as:

- Movement corridors that include patches of principal habitat separated by more than 100 m from scattered trees or other principal habitat
- Are narrow or have pinch points of less than 50 m wide
- Together contain between 100 ha and 380 ha of principal habitat
- Otherwise, if containing greater than 380 ha of habitat or are not narrow, secondary corridors are those that do not connect to primary corridors on both ends

Tertiary corridors are identified as:

- Patches of principal habitat not linked to primary corridors
- Together contain between 30 ha and 100 ha of principal habitat
- Do not connect to other corridors on both ends
- Otherwise, if containing greater than 100 ha of habitat, tertiary corridors are those that lead away from other corridors

Step 5: Define important habitat

Important habitat comprises the species polygons for Koala. It is made up of primary and secondary corridors.

MAPPING METHOD FOR GPEC AND WSA

The Koala habitat mapping method for GPEC and WSA is based on the same concepts used for Wilton and GMAC. However, the same quantitative thresholds used for Wilton and GMAC are not transferrable to other areas. For this reason, habitat quality, and area thresholds for Koala habitat and corridors are not defined, nor any buffer areas.

This method of mapping is only indicative in identifying areas that could potentially be utilised by Koalas.

There are four steps:

1. Map Koala habitat
2. Identify principal and supporting habitat
3. Identify potential movement corridors
4. Categorise potential corridors into primary, secondary and tertiary
5. Define important habitat

Spatial scope of the mapping

The spatial scope of the mapping for this method included the GPEC and WSA boundaries.

Step 1: Map Koala habitat

Koala habitat is identified as PCTs (excluding derived grasslands and urban native condition classes) that contain preferred Koala feed trees (see Table C-2) (DECC 2008; Environment Protection Authority 2016).

Table C-2: PCTs - Potential Koala habitat GPEC, WSA and buffer area

PCT No.	PCT Name	Type of feed tree (DECC 2008)
724	Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion	Primary

PCT No.	PCT Name	Type of feed tree (DECC 2008)
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion	Primary
830	Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Primary
835	Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	Primary
849	Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	Primary
850	Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Primary
883	Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion	Primary
941	Mountain Blue Gum - Thin-leaved Stringybark open forest on river flat alluvium in the Sydney Basin Bioregion	Supplementary
1067	Parramatta Red Gum woodland on moist alluvium of the Cumberland Plain, Sydney Basin Bioregion	Primary
1081	Red Bloodwood - Grey Gum woodland on the edges of the Cumberland Plain, Sydney Basin Bioregion	Secondary
1083	Red Bloodwood - scribbly gum heathy woodland on sandstone plateaux of the Sydney Basin Bioregion	Supplementary
1181	Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion	Secondary
1281	Turpentine - Grey Ironbark open forest on shale in the lower Blue Mountains, Sydney Basin Bioregion	Secondary
1319	White Stringybark - Grey Gum grassy forest on shale caps of the Woronora Plateau, Sydney Basin Bioregion	Secondary
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion	Secondary
1787	Red Bloodwood - Scribbly Gum - Stringybark open forest on sandstone ridges along the western side of the Woronora and Hornsby plateaus	Secondary
1789	Smooth-barked Apple - Blackbutt - Red Bloodwood open forest in enriched sandstone gullies of the western Woronora plateau	Secondary
1790	Red Bloodwood - Grey Gum - Stringybark open forest on enriched sandstone ridges of the western Woronora plateau and lower Blue Mountains	Secondary
1800	Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley	Primary
1841	Smooth-barked Apple - Turpentine - Blackbutt tall open forest on enriched sandstone slopes and gullies of the Sydney region	Primary

STEP 2: IDENTIFY PRINCIPAL AND SUPPORTING KOALA HABITAT

Principal habitat is defined as potential habitat (above) that contains Koala records.

The remainder of habitat is defined as “supporting”. PCTs representative of supporting habitat are not listed in this document.

STEP 3: IDENTIFY POTENTIAL MOVEMENT CORRIDORS

Potential movement corridors include all identified Koala habitat, except for those patches that are separated by more than 1 km.

STEP 4: CATEGORISE CORRIDORS INTO PRIMARY, SECONDARY AND TERTIARY

Primary corridors are identified as:

- Patches of principal habitat which are contiguous (gaps between trees <100 m).

Secondary corridors are identified as:

- Patches of principal habitat separated by more than 100 m from other habitat.
- Are narrow or have pinch points of less than 50 m wide.
- Patches of principal habitat that do not connect to primary corridors on both ends.

Tertiary corridors are identified as:

- Patches of principal habitat not linked to primary corridors.
- Do not connect to other corridors on both ends.

STEP 5: DEFINE IMPORTANT HABITAT

Important habitat comprises the species polygons for Koala. It is made up of primary and secondary corridors.

HABITAT CONNECTIVITY MAPPING – GAPCLOSR

Mapping of habitat connectivity was undertaken using a GIS-based spatial analytical framework known as the Generalised Approach to Planning Connectivity at Local and Regional Scales (GAPCLoSR) (Biolink, 2018a). The text below provides a high level summary of that work, and the full report should be read to understand the project.

GAPCLoSR enables examination of issues associated with landscape connectivity and fragmentation. However, it is noted that the model only considers the length and arrangement of dispersal pathways; it does not consider other important factors which impact corridor usage (such as corridor width). The model is therefore useful as a support tool which enables more detailed analysis.

GAPCLoSR takes into account two key factors:

- The ecological needs and movement characteristics of the target species (e.g. the key characteristics of preferred habitat, the distribution and extent of preferred habitat, the greatest distance of open ground which can be crossed by the target species and the total distance which can be moved across the landscape by the species)
- The extent to which the existing landscape enables, influences and/or impedes movement of the target species

The program was used to investigate three different scenarios:

- **Baseline (*status quo*):** This constituted an analysis of the distribution of current habitat patches and connectivity through the Plan Area
- **Scenario 1:** This constituted analysis in which clearing occurred within the urban capable footprint, and where Appin Road was upgraded to a multi-lane dual carriageway with wildlife fencing on the eastern side of the road
- **Scenario 2:** This constituted analysis in which clearing occurred within the urban capable footprint, and where Appin Road was upgraded to a multi-lane dual carriageway with wildlife fencing on the eastern side of the road, with a wildlife crossing in place at the Ousedale-Mallaty corridor

METHODOLOGY

The basic model process involves inputting of key landscape features, determining the capacity for Koala movement across each landscape feature, and then analysing the spatial distribution of the overall landscape to determine the degree of connectivity and fragmentation across the Plan Area.

MAPPING LANDSCAPE FEATURES

Key landscape features within the model included:

- Transport infrastructure (e.g. roads and railway lines)
- Hydrology (drainage lines, canals, etc)
- Vegetation cover (including Preferred Koala Habitat)
- Mining and quarrying
- Agricultural areas (grazing and horticulture)
- Urban, commercial and industrial areas

Preferred Koala Habitat (PKH) was determined through the following process:

1. Vegetation mapping data was sourced from OEH and from publicly available NSW Government databases
2. Vegetation maps were analysed, and the following areas were removed from analysis as being non-suitable for Koala habitat:
    - Cleared areas
    - Highly-disturbed areas
    - Areas of scattered trees
    - Areas where satellite imagery did not match the vegetation type
3. Remaining vegetation layers are all considered to be Preferred Koala Habitat (PKH)
4. Areas of PKH were then classified into different sub-categories based on the availability of Preferred Koala Food Trees[1] (PKFTs). The following classes were made:
    - Primary Koala Habitat – where primary PKFTs comprise the dominant or co-dominant overstory species
    - Secondary Koala Habitat (Class A) – where primary PKFTs are a sub-dominant component of the overstory species
    - Secondary Koala Habitat (Class B) – primary PKFTs are absent, but the vegetation type is dominated by one or more 'secondary' PKFT
    - Secondary Koala Habitat (Class C) – primary PKFTs are absent, but one or more 'secondary' PKFTs are present as a sub-dominant component of the overstory species
    - Other – does not contain PKFT
5. Each vegetation class was then assigned a different movement cost as follows:
    - Where PKH (of any class) is within a 'habitat patch' (i.e. area of habitat >10ha, an area defined by the authors), there are no movement costs
    - When PKH is present as a corridor, Primary Koala Habitat has no movement cost, and Secondary Class Habitat has an increasing scale of movement cost (with the least movement cost for Class A, and the highest movement cost for Class C)

ALLOCATING RESISTANCE VALUES TO LANDSCAPE FEATURES

Each landscape feature was then assigned a Percentage Resistance Value (PRV). This value refers to the effort or cost it takes for a Koala to cross a particular land-use type or class.

The resistance of the Plan Area to Koala movement was then calculated as follows:

1. A rasterised surface was produced from land use layers of the Plan Area
2. Each pixel was then assigned a dispersal cost for Koalas to cross at each point. Dispersal costs were calculated through considering each of the land use layers present for each pixel

---

[1] These include the following: *E. moluccana, E. longifolia, E. punctata, E. viminalis, E. tereticornis*

3. In instances where multiple land use layers intersected at a particular point, it was important to define which data layer took precedence over the other. The following outlines the precedence in terms of their cost value:
   a) Connectivity structures spanning roads, train lines and aqueducts
   b) Train lines and aqueducts
   c) Roads
   d) Hydrology
   e) Vegetation cover (including PKH and non-PKH)
   f) Urban / commercial / industrial / agricultural land uses
4. A Gap Crossing Layer of 220 m was applied as a buffer around all vegetation, which was taken to be the maximum distance that a Koala would travel across an open area (based on Euclidian distance of all Koala records within the region from the nearest patch of mapped vegetation).

MAPPING HABITAT CONNECTIVITY

The locations and importance of connectivity corridors through the Plan Area were then modelled as follows:

a) The PRV of each pixel was examined
b) The cumulative PRV cost of any potential pathway between habitat patches was calculated
c) If the cumulative PRV cost of any potential pathway between habitat patches exceeded a threshold value, then a pathway would not be formed

It is noted that this method for identifying connectivity corridors does not rely on the Euclidian distance between habitat patches, but instead considers how hostile the landscape is to movement.

HABITAT CRITICAL TO THE SURVIVAL OF THE SPECIES MAPPING

In order to address the requirements of the EPBC Act referral guidelines for the vulnerable Koala (CoA 2014) a map was prepared to identify habitat critical to the survival of the Koala. This mapping was prepared by adapting the method proposed in Koala Habitat Assessment Tool (KHAT) (Table 4, CoA 2014) for use with the data available within the nominated areas and broader Strategic Assessment Area.

The KHAT scores five attributes related to the quality and extent of Koala habitat, with each attribute scored out of 2. A total score of 10 is possible, and habitat a score of five or greater is habitat critical to the survival of the Koala. The five attributes considered in the KHAT are:

- Koala occurrence
- Vegetation composition
- Habitat connectivity
- Key existing threats
- Recovery value

A number of data sets were compiled for use in the mapping of habitat critical to the survival of the Koala within the Strategic Assessment Area. A method was then prepared based on the KHAT for use in the Strategic Assessment Area.

As a first step the habitat units to be assessed were defined by combining a compilation vegetation data set (Biosis 2019) with the mapping of Koala corridors for this project. These units were then interrogated against a number of different data sets (Step 2 – Step 6) to identify habitat critical to the survival of the Koala. Data sets used to define habitat critical to the survival of the Koala include Koala sighting records (OEH, 2018), Koala corridor mapping, an assessment of connectivity and key existing threats (road kill records (OEH, 2018) and adjacency to urban areas).

The method applied is described in Table C-3.

Table C-3: Method used to map habitat critical to the survival of the Koala within the Strategic Assessment Area

Step	KHAT attribute	Approach	Score allocated	Data used
Step 1	N/A	Habitat units were defined by combining a compilation vegetation data set (Biosis 2019) with the mapping of Koala corridors. Koala corridors were assigned to individual habitat units by Plant Community Type (PCT) and broad vegetation condition (intact, scattered etc). All internal linework between habitat units was dissolved where PCT, condition and corridor rank were identical. In the case of a Koala corridor not being allocated a PCT or condition state due to the land not being identified as native vegetation: Polygons smaller than 0.5 ha were removed from the habitat units layer Polygons >0.5 ha were allocated a PCT of 9999 and a condition of Unknown The habitat units were used as the based layer for the assessment.	N/A	Biosis 2019 - Compilation vegetation data set (100 km buffer from Cumberland subregion). Layer includes Biosis nominated area vegetation mapping, and where this isn't available a compilation of the best available data sets, including: Remnant Vegetation of the western Cumberland subregion, 2013 Update. VIS_ID 4207 The Native Vegetation of the Sydney Metropolitan Area - Version 3.1 (OEH, 2016) VIS_ID 4489 South East Local Land Services Biometric vegetation map, 2014. VIS_ID 4211 Southeast NSW Native Vegetation Classification and Mapping - SCIVI. VIS_ID 2230 Koala corridor mapping
Step 2	Koala occurrence	Koala occurrence was scored based on Koala records recorded within, and adjacent to, the Strategic Assessment Area over a five year period (2014 – 2018). Distance buffers were applied to allocate appropriate scores.	2 - Within 1 km of a record 1 - Within 1-2 km from a record 0 - Beyond 2 km from a record	Koala BioNet species records (OEH, 2018)
Step 3	Vegetation composition	Each habitat unit was allocated a vegetation composition score. The Koala corridors mapped for the Strategic Assessment Area were used as a surrogate for this score.	2 - Primary and secondary corridors 1 - Tertiary corridors 0 - Supporting habitat	Koala corridor mapping

Step	KHAT attribute	Approach	Score allocated	Data used
Step 4	Habitat connectivity	A score for habitat connectivity was calculated for each habitat unit. This was done by, first, calculating the patch size of each habitat unit. Habitat units were considered to be part of the same patch where adjacent or within 100 m of another patch. Patches were then separated where intersected by a major road or rail line as these features are likely to create barriers to the movement of corridors. The roads identified for this analysis include those classified as Arterial, Motorway or Primary Road.	2 - >500 ha of contiguous habitat 1 - 300-500 ha of contiguous habitat 0 - <300ha of contiguous habitat	NSW Spatial Data Services (Six Clip and Ship) (2019) – Railway and Road Segment (where road = Arterial, Motorway or Primary Road)
Step 5	Key existing threats	Key existing threats were assessed, with the lower score taken for each habitat unit. Threat from road kill was determined by calculating the distance from each road kill record to each habitat unit. The threat from existing urban development was determined by calculating the distance from existing urban areas to each habitat unit.	The lowest of: Threat from road kill (road kill records from 2014 - 2018). 2 - >2 km from road kill record 1 - 1-2 km from road kill record 0 - 0-1 km from road kill record Threat from urban land use (adjacency to urban land): 2 - >2 km from existing urban area 1 - 1-2 km from existing urban area 0 - 0-1 km from existing urban area	Koala BioNet species records (observation type = roadkill) (OEH, 2018) NSW Spatial Data Services (SiX Clip and Ship) (2019) – General cultural area (where area = Builtup)
Step 6	Recovery value	Each habitat unit was allocated a score based on whether the habitat is likely to be important for achieving the interim recovery objectives for the species. The Koala corridors mapped for the Strategic Assessment Area were used as a surrogate for this score.	2 - Primary and secondary corridors 1 - Tertiary corridors 0 - Supporting habitat	Koala corridor mapping

32 Migratory species impact assessment

This Chapter assesses the potential impacts to migratory species from the Plan.

The Strategic Assessment Area supports a number of migratory bird species that are protected under the EPBC Act. There are two key policy statements that apply to these species:

- The *Draft Referral guideline for 14 migratory birds listed under the EPBC Act* (DoE, 2015). Potential impacts to species relating to this guideline are assessed in Section 32.1. Assessment of migratory birds in this section is also supported by guidance material from the *Significant Impact Guidelines 1.1* (DoE, 2013b)
- The *Industry guidelines for avoiding, assessing and mitigating impacts on EPBC Act listed migratory shorebird species* (DoEE, 2017). Potential impacts to species relating to this guideline are assessed in Section 32.2

There are no other listed migratory species that are relevant to the assessment.

32.1 MIGRATORY BIRDS

Nine species listed in the migratory bird referral guidelines (DoE, 2015) have been observed within the Strategic Assessment Area. These species have large areas of important habitat in Australia, of which less than 1 per cent will be impacted by the Plan.

Potential direct and indirect impacts to the nine species as a result of the Plan are considered to be negligible.

Only one of the species (White-throated Needletail) has been observed in ecologically significant numbers in the Cumberland subregion. This species is almost exclusively aerial and found over a wide range of habitats including extensively modified and urban areas. Development under the Plan is considered unlikely to disrupt this species' use of the Strategic Assessment Area.

This section sets out:

- The regulatory context for assessing impacts to migratory birds
- The approach to the impact assessment
- Baseline information about migratory birds in the Strategic Assessment Area
- Analysis of the potential impacts
- An overview of relevant conservation measures
- Evaluation of the outcome for migratory birds

32.1.1 REGULATORY CONTEXT

This section assesses impacts to the species discussed in the *Referral guideline for 14 birds listed as migratory species under the EPBC Act* (DoE, 2015). The section also outlines approval considerations under the EPBC Act.

REFERRAL GUIDELINES

The guidelines relate to site-by-site assessments under the EPBC Act (Parts 7-9) and set out three pathways for significant impacts to migratory birds:

- Impacts to habitat: Substantial modification of important habitat, or
- Impacts to individuals: Serious disruption of an ecologically significant proportion of a population
- Establishment of invasive species that is harmful to the migratory species in an area of important habitat for the migratory species

Only one pathway needs to be met to be considered a significant impact.

The migratory bird referral guidelines provide definitions of "important habitat" for each species, in addition to thresholds to define a "substantial modification" and an "ecologically significant proportion" of each species' habitat or population.

Substantial modification of important habitat is defined using a threshold of 1 per cent of the species' total habitat in Australia. A threshold of 0.1 per cent of the species' total population in Australia is used to require proponents to collect further information on the species' presence, including surveys.

Similarly, an ecologically significant proportion of a population is defined as 1 per cent of the species' total population, with a 0.1 per cent threshold triggering a requirement for additional information and surveys. This threshold is based on the number of individuals from a given species that use the relevant area over a year.

With regards to the introduction of invasive species in important habitat for migratory birds, the migratory bird referral guidelines are unclear about the scale of impact associated with introduced species which is required to trigger a significant impact. To resolve this, assessment of impacts from invasive species draws on guidance provided in the Significant Impact Guidelines 1.1.

EPBC ACT APPROVAL CONSIDERATIONS

Section 146L of the EPBC Act sets out the approval considerations in relation to migratory species. In summary, the outcomes of the Plan must not be inconsistent with any of the international agreements relating to migratory species. Of relevance to migratory birds are:

- The Bonn Convention (or the Convention on the Conservation of Migratory Species)
- The bilateral agreements for the conservation of migratory birds between the Government of Australia and the Government of Japan (JAMBA), the Government of China (CAMBA), and the Government of the Republic of Korea (ROKAMBA)

The *Wildlife Conservation Plan For Migratory Shorebirds* (DoEE, 2015) provides a useful summary of Australia's commitments under these agreements. The key obligations (of relevance to this assessment) which cut across the various agreements in different forms are for Australia to:

- Conserve and where possible restore habitats
- Mitigate and manage threats to migratory birds

It is also noted in the Wildlife Conservation Plan that the EPBC Act is the key piece of legislation which gives effect to Australia's international obligations. Following the process and meeting the requirements of the EPBC Act implicitly means that those obligations will be met.

32.1.2 APPROACH TO IMPACT ASSESSMENT

The following sections outline the assessment methodology used to assess impacts to habitat and individuals, and impacts associated with the establishment of harmful invasive species in migratory species habitat.

IMPACTS TO HABITAT AND INDIVIDUALS

The assessment drew on the concepts of substantial modification of habitat and ecologically significant proportions of a population set out in the migratory bird referral guidelines. It was based on available desktop information and used the 1 per cent threshold for impacts to habitat and impacts to individuals rather than the 0.1 per cent threshold. This is an appropriate threshold given the geographic scale and strategic nature of the assessment; noting the 0.1 per cent thresholds for additional surveys are based on site-by-site assessments.

The assessment considered two questions for each impact pathway (see Table 32-1).

Table 32-1: Steps for identifying significant impacts

Steps	Impacts to habitat	Impacts to individuals
Step one	Do the urban capable land and transport corridors contain over 1 per cent of important habitat for the species, as identified in the migratory bird referral guidelines?	Do the urban capable land and transport corridors support over 1 per cent of the population of the species in Australia, as identified in the migratory bird referral guidelines?

Steps	Impacts to habitat	Impacts to individuals
Step two	If so, will the classes of action modify, destroy, or isolate the relevant habitat?	If so, will the classes of action disrupt the lifecycle of the relevant population?

The steps for each impact pathway are discussed further below.

Impacts to habitat

Table 2 of the migratory bird referral guidelines provides definitions of important habitat, which occur as written descriptions of habitat features utilised by each migratory bird. The consulting team has identified all PCTs that correspond with the descriptions of important habitat set out in the migratory bird referral guidelines, which has been used to assess the distribution of important habitat within the Strategic Assessment Area. Given the general nature of habitat descriptions provided in the migratory bird referral guidelines and the large number of PCTs which contain potentially suitable habitat features, this mapping approach is considered to be precautionary.

Step 1 compared the impacts to the PCTs associated with important habitat within the urban capable land and transport corridors against the thresholds set out in the migratory bird referral guidelines (DoE, 2015).

The impact analysis showed that potential impacts would not exceed the 1 per cent thresholds set out in guidelines for any of the species, so it was not necessary to apply Step 2.

Impacts to individuals

Step 1 drew on observation records from Birdlife Australia, the Atlas of Living Australia, and BioNet Atlas. These records reflect observations as well as organised surveys. The analysis used a conservative estimate of individuals based on the total recorded sightings of each species per year across the Cumberland subregion.

Some of the species are more prevalent in Australia during the summer. To ensure that all the birds that are recorded in a summer season are counted together, the analysis combined records between the 1st of July and the 30th of June the following year. For example, the Atlas of Living Australia contains 210 Fork-tailed Swift records in the Cumberland subregion between July 1st, 1982 and June 30th, 1983. Most of these are over the 1982-83 summer and are recorded in this analysis as occurring in 1982-83.

The impact analysis showed that only one species (White-throated Needletail) is present in the Strategic Assessment Area in ecologically significant numbers. For this species, Step 2 was applied to consider the extent and type of impacts to foraging and roosting habitat to determine whether the Plan is likely to disturb an ecologically significant proportion of the population.

IMPACTS FROM INTRODUCTION OR ESTABLISHMENT OF INVASIVE SPECIES IN IMPORTANT HABITAT

The migratory bird guidelines state that "*An action is likely to have a significant impact on a migratory species if there is a real chance or possibility that it will... result in an invasive species that is harmful to the migratory species becoming established in an area of important habitat for the migratory species*."

The migratory bird referral guidelines do not provide sufficient guidance with regards to what scale of impact is required to trigger assessment as a significant impact with regards to invasive species. Therefore, the assessment of impacts from invasive species draws on guidance from the Significant Impact Guidelines 1.1.

The *Significant impact guidelines 1.1* (DoE, 2013b) define important habitat as habitat which meets one of the following criteria:

- Habitat utilised by a migratory species occasionally or periodically within a region that supports an ecologically significant proportion of the population of the species
- Habitat that is of critical importance to the species at particular life-cycle stages
- Habitat utilised by a migratory species which is at the limit of the species range
- Habitat within an area where the species is declining

The impacts from introduction or establishment of invasive species in important habitat has therefore been assessed with regards to the habitat definition provided in the Significant Impact Guidelines 1.1.

APPROACH TO EPBC ACT APPROVAL CONSIDERATIONS

Regulatory requirements were considered at the end of the assessment by drawing together the results of the impact analysis, examination of the benefits of the conservation measures in the Plan and reviewing any specific requirements for migratory species.

32.1.3 MIGRATORY BIRDS IN THE STRATEGIC ASSESSMENT AREA

Nine species covered by the migratory bird referral guidelines have been observed within the Strategic Assessment Area. The species and their habitat and population thresholds are listed in Table 32-2.

Table 32-2: Migratory birds and impact thresholds in the Strategic Assessment Area

Common name	Scientific name	1% threshold for impacts to habitat	1% threshold for impacts to individuals (individuals)
Oriental Cuckoo, Himalayan Cuckoo	*Cuculus saturatus*	250,000 ha	10,000
Fork-tailed Swift	*Apus pacificus*	*	1,000
Rufous Fantail Southern	*Rhipidura rufifrons rufifrons*	2,600 ha	1,100
Satin Flycatcher	*Myiagra cyanoleuca*	4,400 ha	1,700
Black-faced Monarch	*Monarcha melanopsis*	865 ha	465
White-throated Needletail+	*Hirundapus caudacutus*	*	100
Spectacled Monarch Southern	*Symposiachrus trivirgatus*	1,300 ha	410
Osprey	*Pandion haliaetus*	840 km of coastline	240
Yellow Wagtail	*Motacilla flava*	*	10,000

* No thresholds are available for these species due to a lack of knowledge or rarity

+ The White-throated Needletail is also listed as a vulnerable species and is assessed both in this chapter as a migratory species, and in Chapter 30 as a threatened species

32.1.4 IMPACT ANALYSIS

This section considers the impacts to each species in Table 32-2 using the approach described above.

IMPACTS TO HABITAT

The total area of impacts to native vegetation within the urban capable land and transport corridors is 1,777.8 ha. This is well below the threshold for Oriental Cuckoo (250,000 ha) and Satin Flycatcher (4,400 ha). There is no coastline in the Strategic Assessment Area, but 135 km of potential Osprey habitat exists along the Nepean and Hawkesbury Rivers within the Strategic Assessment Area. This is also well below the threshold for substantial modification of important habitat for Osprey (840 km of coastline).

The Fork-tailed Swift, White-throated Needletail and Yellow Wagtail do not have thresholds for substantial modification of important habitat. The guidelines note that roosting habitat for White-throated Needletail is poorly understood and may be a constraint on the species. This will be considered below.

This leaves three species to consider:

- Rufous Fantail Southern
- Black Faced Monarch
- Spectacled Monarch Southern

The guidelines describe important habitat for each of these species. Table 32-3 gives these descriptions, along with the corresponding PCTs that could be impacted by the Plan, and the extent of potential impacts to those PCTs.

Table 32-3 shows that the potential impacts to the three species are well below the thresholds for substantial modification of important habitat.

The Plan will not substantially modify, destroy or isolate an area of important habitat for any of the migratory birds listed in the guidelines.

Table 32-3: Important habitat and potential impacts for three migratory bird species

Species (threshold in ha)	Important habitat	Corresponding PCTs within the urban capable land and transport corridors	Extent of potential impacts (ha)*
Rufous Fantail Southern (2,600)	Moist, dense habitats, including mangroves, rainforest, riparian forests and thickets, and wet eucalypt forests with a dense understorey. When on passage a wider range of habitats are used including dry eucalypt forests and woodlands and Brigalow shrublands.	724, 725, 781, 830, 835, 849, 850, 889, 1181, 1395, 1800	1,777.8
Black Faced Monarch (865)	Wet forest specialist, found mainly in rainforest and wet sclerophyll forest, especially in sheltered gullies and slopes with a dense understorey of ferns and/or shrubs.	830, 835, 1800	184.4
Spectacled Monarch Southern (1,300)	Dense vegetation, mainly in rainforest but also in moist forest or wet sclerophyll and occasionally in other dense vegetation such as mangroves, drier forest and woodlands.	724, 725, 781, 830, 835, 883, 1800	275.5

* Impact calculations exclude impacts to derived native grasslands, as all three species require forests, woodlands, or dense vegetation

IMPACTS TO INDIVIDUALS

Ecologically significant proportions of populations

Atlas of Living Australia, Birdlife Australia and BioNet Atlas records for each species were aggregated over 12-month periods starting from July 1st each year since 1979-80. Prior to 1979-80, sightings were recorded sporadically and in small numbers that are not helpful for this analysis.

For each 12-month period, the total number of sightings was defined as the largest number of records for that period from either the Atlas of Living Australia, Birdlife Australia, or BioNet Atlas data sets.

Table 32-4 sets out the total number of records for each species for the ten 12-month periods with the highest numbers of records since 1980. It also provides the year in which those sightings were made.

Table 32-4: Years with the largest number of records of migratory birds in the Cumberland subregion since 1980

	Ranked year of highest number of records (number of individuals (year))									
Species	**First**	**Second**	**Third**	**Fourth**	**Fifth**	**Sixth**	**Seventh**	**Eighth**	**Ninth**	**Tenth**
Fork-tailed Swift	250 (1985-86)	210 (1982-83)	158 (2016-17)	52 (2017-18)	15 (2006-07)	12 (2003-04)	8 (2012-13)	8 (2012-13)	7 (2013-14)	7 (1981-82)
Oriental Cuckoo	1 (2015-16)	1 (2013-14)	1 (2009-10)	Species only recorded in three years						
White-throated Needletail	2576 (2016-17)	2208 (2012-13)	1472 (2017-18)	884 (2015-16)	739 (2014-15)	676 (2011-12)	644 (2013-14)	593 (2010-11)	356 (2009-10)	233 (1986-87)

	Ranked year of highest number of records (number of individuals (year))									
Species	**First**	**Second**	**Third**	**Fourth**	**Fifth**	**Sixth**	**Seventh**	**Eighth**	**Ninth**	**Tenth**
Black-faced Monarch	53 (2016-17)	20 (2013-14)	17 (2014-15)	14 (2017-18)	12 (2011-12)	11 (2015-16)	11 (2012-13)	5 (2005-06)	4 (2010-11)	4 (2003-04)
Yellow Wagtail	2 (2016-17)	2 (2012-13)	Species only recorded in two years							
Satin Flycatcher	26 (2014-15)	10 (2012-13)	9 (2013-14)	8 (2011-12)	6 (2016-17)	5 (2017-18)	4 (2003-04)	3 (2004-05)	3 (1997-98)	2 (1983-84)
Osprey	16 (2013-14)	12 (2012-13)	9 (2010-11)	5 (2017-18)	5 (2014-15)	3 (2016-17)	3 (2015-16)	2 (2003-04)	1 (2004-05)	1 (1989-90)
Rufous Fantail Southern	137 (2016-17)	84 (2017-18)	48 (2016-15)	48 (2013-14)	44 (2014-15)	39 (2012-13)	39 (2011-12)	14 (2010-11)	13 (2009-10)	8 (2000-01)
Spectacled Monarch Southern	1 (1986-87)	Species only recorded in one year								

All of the species in Table 32-4 are well below the thresholds for ecologically significant populations except for the White-throated Needletail. The threshold for this species is 100 birds, and it has been recorded in flocks of up to 300 individuals, with over 2,000 records per year in two years. Based on this data, it has been assumed that an ecologically significant proportion of its population uses the Strategic Assessment Area.

For the other species, the records are sufficiently low across the entire Cumberland subregion that it is unlikely that the urban capable land or transport corridors support an ecologically significant proportion of their populations.

<u>Potential Impacts to the White-throated Needletail</u>

The White-throated Needletail is a large swift. It has two subspecies, of which only one (*Hirundapus caudacutus caudacutus)* occurs in Australia. This subspecies breeds in central and eastern Siberia, northern Mongolia, Northern China and the Korean Peninsula, Sakhalin and Japan, and migrates to Australia for the non-breeding season (DoEE, 2018d).

There is limited information of the ecology of this species. In Australia, it is often found in large flocks of hundreds or thousands of birds. It is widespread in eastern and south-eastern Australia. The species is an insect feeder and is almost exclusively aerial in Australia. It occurs over a wide range of habitats, ranging from heavily treed forests to open habitats such as farmland, heathland or mud flats (DoEE, 2018d).

It is not threatened in NSW and is listed as vulnerable under the EPBC Act. There is limited data on total population and population trends in Australia, but there is some evidence that the population and area of occupancy is in decline (DoEE, 2018d).

Impacts to foraging habitat

The species has been observed foraging over a wide range of habitats. The Atlas of Living Australia, Birdlife Australia and BioNet Atlas contain numerous records in or above heavily modified and urban environments. The species is aerial while foraging and is often observed in areas of updraughts (e.g. above cliffs, ridges, and dunes, in the smoke of bushfires, in whirlwinds, or along the edges of low pressure systems) (TSSC, 2019).

The species appears to prefer certain geographic and meteorological conditions, rather than relying on particular kinds of vegetation. It is unlikely that modification of habitat from the Plan will substantially alter the species' use of the Strategic Assessment Area or the urban capable land and transport corridors. There are no anticipated impacts to foraging habitat from the Plan.

Impacts to roosting habitat

There are limited records of the White-throated Needletail roosting and it was previously thought that the species was exclusively aerial in Australia. Records now suggest that the species roosts in tall trees and may prefer roosting sites on ridgelines. There is some evidence that the species uses traditional roosting sites although there are no records of these sites in the Cumberland subregion.

The species is wide-ranging and not known to roost within the Strategic Assessment Area. The Plan will conserve large areas of high-quality woodland, which will ensure the species has continued access to potential roosting sites within the Cumberland subregion. There is a low risk of impacts to roosting habitat from the Plan.

Summary of impacts to the White-throated Needletail

The Plan is unlikely to disrupt foraging within the Cumberland subregion. It is possible that roosting sites may be present within the urban capable land and transport corridors, but there are no records of this and the risk of loss of roosting habitat is low. The Plan will ensure the conservation of high-quality woodland which will provide continued access to potential roosting habitat within the Strategic Assessment Area. The Plan will not seriously disrupt the lifecycle of the proportion of the White-throated Needletail population that frequents the Cumberland subregion.

IMPACTS FROM INTRODUCTION OR ESTABLISHMENT OF INVASIVE SPECIES IN IMPORTANT HABITAT

The migratory bird referral guidelines identify introduced species that present key threats to some of the migratory bird species. A migratory species can be significantly impacted under the guidelines if one of the relevant introduced species becomes established in an area of important habitat as a result of an action. Four of the species known to occur within the Cumberland subregion have key threats listed in the guidelines (see Table 32-5).

Table 32-5: Invasive species harmful to migratory species in the Strategic Assessment Area

Species	Invasive species harmful to the migratory species
Osprey	Any introduced species that causes a large reduction in fish stocks
Black-faced Monarch	Black Rat (*Rattus rattus*) Vines that invade riparian habitats
Spectacled Monarch	Black Rat (*Rattus rattus*) Vines that invade riparian habitats
Rufous Fantail	Black Rat (*Rattus rattus*) Vines that invade riparian habitats

Impacts associated with introduced species are only significant if they occur within important habitat for the relevant migratory species. As noted above, with regards to the assessment of impacts relating to invasive species, the important habitat has been defined in this section based on the definition provided in the Significant Impact Guidelines 1.1.

There is no important habitat for any of the four migratory species in Table 32-5 within the Cumberland subregion, because:

- None of the habitat in the Strategic Assessment Area is of critical importance to Osprey, Black-faced Monarch, Spectacled Monarch, or Rufous Fantail at particular life stages
- The Cumberland subregion is not at the limit of any of these species' range
- None of these species are present in ecologically significant proportions (as shown in Table 32-4)
- There is no evidence that the populations of Osprey, Black-faced Monarch, Spectacled Monarch, or Rufous Fantail are in decline within the Strategic Assessment Area. Table 32-4 shows:
  - An increase in observations of Osprey and Black-faced Monarch within the Strategic Assessment Area since 2010
  - Only one record of Spectacled Monarch in the Cumberland subregion (from 1986-87) which is inadequate to establish a population trend
  - Numerous observations (over 200 birds in two 12-month periods) of Rufous Fantail in 1982-83 and 1985-86, but these seem anomalous and the species has been observed in increasing numbers in the last 10 years

The Plan includes a range of commitments and actions to minimise and avoid indirect impacts, including from introduced species (see Chapter 15 for details). The populations of Osprey, Black-faced Monarch, Spectacled Monarch and Rufous Fantail using the Strategic Assessment Area are small, and the region is of limited importance for these species. The management measures for indirect impacts are considered sufficient to minimise the risk of these impacts to migratory birds within the Strategic Assessment Area.

32.1.5 CONSERVATION MEASURES THAT WILL BENEFIT MIGRATORY BIRDS

The Plan includes a range of conservation measures that will benefit the migratory birds discussed in this section. The Plan will set aside for conservation a minimum of 5,475 ha of native vegetation with a focus on large, well connected, high quality patches. This will protect foraging and passage habitat for these species within the Cumberland subregion.

32.1.6 EVALUATION OF THE OUTCOME FOR MIGRATORY BIRDS

As outlined in Section 32.1.1, the outcomes of the Plan must not be inconsistent with any of the international agreements relating to migratory species. The key obligations (of relevance to this assessment) which cut across the various agreements in different forms are for Australia to:

- Conserve and where possible restore habitats
- Mitigate and manage threats to migratory birds

The Plan is not inconsistent with these obligations:

- The potential impacts to the nine species listed in the guidelines are below the thresholds for substantial modification of important habitat for all species
- Only the White-throated Needletail is present in the Strategic Assessment Area in ecologically significant numbers. The species is known to forage above a wide range of habitats and is unlikely to be disrupted or displaced by development. There are no known roosting sites within the Cumberland subregion, and the commitments and actions in the Plan will protect potential roosting sites and other vegetation to benefit the species

32.2 MIGRATORY SHOREBIRDS

Thirty-seven species of migratory shorebirds regularly visit Australia during their non-breeding season (from the Austral spring to autumn). The majority of those breed in the northern hemisphere and use the East Asian-Australasian Flyway which stretches from Siberia and Alaska, through east and south-east Asia, to Australia and New Zealand. They depend upon a range of sites along the flyway for breeding, staging, feeding and roosting. In Australia, coastal and freshwater wetlands provide important habitat (DoEE, 2015).

Twenty-one of these species have been recorded within the Cumberland subregion. Two of those have been recorded at a site level in important numbers. They are the Sharp-tailed Sandpiper and Latham's Snipe.

Potential impacts to migratory shorebirds as a result of the Plan are considered to be negligible. No important habitat will be lost, and the risk of indirect impacts such as degradation of habitat and disturbance of birds is considered to be low.

This section sets out:

- The regulatory context for assessing impacts to migratory shorebirds
- The approach to the impact assessment
- Baseline information about migratory shorebirds in the Strategic Assessment Area
- Analysis of the potential impacts
- An overall conclusion

32.2.1 REGULATORY CONTEXT

GUIDELINES

The *Industry guidelines for avoiding, assessing and mitigating impacts on EPBC Act listed migratory shorebird species* (DoEE, 2017) provide guidance about how the EPBC Act applies to that group of species. They are designed to be read in conjunction with the *Significant Impact Guidelines 1.1 – Matters of National Environmental Significance* (DoE, 2013b).

Impact pathways

The guidelines set out four pathways by which impacts can be significant to migratory shorebirds:

- Loss of important habitat
- Degradation of important habitat leading to a substantial reduction in migratory shorebird numbers
- Increased disturbance within important habitat leading to a substantial reduction in migratory shorebird numbers
- Direct mortality of birds leading to a substantial reduction in migratory shorebird numbers

Definition of important habitat

Important habitat for migratory shorebirds is a key concept outlined in the guidelines. It relates to three of the impact pathways.

Important habitats are sites that meet one or more of the following criteria:

- Habitat that is already identified as internationally important
- Habitat that regularly supports 0.1 per cent of the flyway population of a single species of migratory shorebird. Estimates of the flyway populations for each of the species is provided in the *Revision of the East Asian-Australasian Flyway Population Estimates for 37 listed Migratory Shorebird Species* (Hansen, Fuller et al., 2016)
- Habitat that regularly supports 2,000 migratory shorebirds, or
- Habitat that regularly supports 15 migratory shorebird species (DoEE, 2017)

There are different criteria for identifying important habitat for Latham's snipe (*Gallinago harwickii*). This is because this species does not typically aggregate in large flocks and uses different habitat to the other species discussed in the migratory shorebird guidelines. Important habitat for Latham's snipe is:

- Any area that has been previously identified as internationally important for the species, or

- Any area that supports at least 18 individuals of the species (DoEE, 2017)

Avoiding and/or mitigating impacts

The guidelines also outline a set of general measures to avoid and/or mitigate impacts to shorebirds. Measures include:

- Making every effort to avoid habitat loss
- Ensuring habitat is not degraded through the introduction of exotic species; changes to hydrology or water quality (including toxic inflows); fragmentation of habitat or exposure to litter or pollutants; and exposure of acid sulphate soils
- Mitigating against the impacts of disturbance
- Considerations around direct mortality to shorebirds
- Consideration of climate change

WILDLIFE CONSERVATION PLAN FOR MIGRATORY SHOREBIRDS

The Wildlife Conservation Plan for Migratory Shorebirds (DoEE, 2015) provides a framework to guide the conservation of migratory shorebirds in Australia. It:

- Summarises Australia's commitments to migratory shorebirds under international conventions and agreements
- Outlines national actions to support shorebird conservation

The Wildlife Conservation Plan is consistent with the EPBC Act referral guidelines. Particularly in relation to the definition of important habitat and the discussion of threats.

EPBC ACT APPROVAL CONSIDERATIONS

Migratory species

Section 146L of the EPBC Act sets out the approval considerations in relation to migratory species. In summary, the outcomes of the Plan must not be inconsistent with any of the international agreements relating to migratory species. Of relevance to migratory shorebirds are:

- The Bonn Convention (or the Convention on the Conservation of Migratory Species)
- The bilateral agreements for the conservation of migratory birds between the Government of Australia and the Government of Japan (JAMBA), the Government of China (CAMBA), and the Government of the Republic of Korea (ROKAMBA)

The Wildlife Conservation Plan (DoEE, 2015) provides a useful summary of Australia's commitments under these agreements. The key obligations (of relevance to this assessment) which cut across the various agreements in different forms are for Australia to:

- Conserve and where possible restore habitats
- Mitigate and manage threats to shorebirds

It is also noted in the Wildlife Conservation Plan that the EPBC Act is the key piece of legislation which gives effect to Australia's international obligations. Following the process and meeting the requirements of the EPBC Act implicitly means that those obligations will be met.

Threatened species

A number of the migratory shorebirds are also listed as threatened. These species are addressed both in this chapter as a migratory species, and in Chapter 30 as threatened species.

32.2.2 APPROACH TO IMPACT ASSESSMENT

This assessment primarily draws on the concepts presented in the migratory shorebird guidelines and is based on:

- Development of baseline information, which includes:
    - Compilation of available records for shorebird species

  - Habitat mapping (including the identification of important habitat) across the Cumberland subregion
- Analysis of potential direct and indirect impacts with a focus on:
  - The four potential impact pathways set out in the Guidelines
  - The general measures to avoid and/or mitigate impacts to shorebirds set out in the Guidelines
- Consideration of regulatory requirements for migratory and (where relevant) threatened species

BASELINE INFORMATION

Compilation of records

Records were compiled from the Birdlife Australia Database and the OEH BioNet Database. This is considered to be the most complete data for shorebirds in the Cumberland subregion.

Approach to habitat mapping within the Cumberland subregion

Habitat mapping was undertaken broadly in accordance with the approach outlined in the EPBC guidelines. However, the method applied was more precautionary than required under the EPBC guidelines to ensure that no important habitat sites were missed (see 'limitations in the baseline data' below).

The process involved the following steps:

Step 1: Analysis of records across the Cumberland subregion

Records were compiled and examined across the whole of the Cumberland subregion. The initial step considered the subregion as a single habitat unit to determine which species exceeded the thresholds for important habitat across the whole area (i.e. which species occur in numbers greater than the threshold when records are summed across the whole subregion).

Step 2: Identification of important migratory shorebird habitat sites

The spatial distribution of records was then assessed to identify the individual wetland and waterbody (or wetland mosaic) where the thresholds were exceeded at a site level. Each wetland that was identified as important for migratory shorebirds had its boundary marked and a 250-metre buffer applied. This buffer distance is consistent with the guidelines which suggest buffer distances ranging from 165 to 255 m to mitigate against disturbance (DoEE, 2017).

For ephemeral wetlands the threshold was considered across every year where records were held.

For permanent wetlands, the guidelines suggest considering the last five years. The approach taken for this assessment was to look at records for the last 20 years for sites that were thought to be permanent. This acknowledges the uncertainty in determining if habitat sites are permanent or ephemeral across the Strategic Assessment Area.

Step 3: Identification of potential migratory shorebird habitat

The remaining potential migratory shorebird habitat in the subregion was determined based on the presence of suitable wetlands throughout the landscape that exceed 1.5 ha in area. This 1.5 ha threshold was used as a proxy for the minimum disturbance distance for shorebirds of 150 m.

Wetland mapping layers were interrogated from the Directory of Important Wetlands (DoEE, 2018c) and the LPI topographical data Hydro Area layer (LPI, 2016) to identify areas of potential habitat.

Limitations in the baseline data

The data used in the habitat mapping is the best available across the Cumberland subregion. It incorporates:

- Historical records from both BioNet and Birdlife Australia
- Wetland and waterbody mapping from DAWE and LPI

However, there has not been a systematic survey for migratory shorebirds across the subregion and it is likely that shorebirds visit a number of sites where there are no records.

To address uncertainty in the data a precautionary approach was taken. This involved:

- Considering the whole of the Cumberland subregion to determine what species occurred in numbers greater than the important habitat thresholds when their records were summed for all sites
- Mapping potential habitat using wetland and waterway mapping

APPROACH TO ANALYSING IMPACTS

Direct and indirect impacts were assessed by considering the four impact pathways identified in the guidelines.

The potential loss of important habitat was calculated by:

- Intersecting the urban capable land and transport corridors with the habitat mapping
- Considering potential changes to hydrology, water quality or vegetation structural changes near important habitat sites

Potential degradation and disturbance within important habitat, and potential direct mortality of migratory shorebirds were assessed through:

1. Identifying the activities under the Plan that may lead to these impacts
2. Considering how those activities are proposed to be managed under the Plan (noting that Chapter 15 provides a detailed description and analysis of how indirect impacts will be managed)
3. Analysing the residual risk to important habitat and shorebirds

APPROACH TO EPBC ACT APPROVAL CONSIDERATIONS

Regulatory requirements were considered at the end of the assessment by drawing together the results of the impact analysis, examination of the benefits of the conservation measures in the Plan and reviewing any specific requirements for migratory and (where relevant) threatened species.

32.2.3 MIGRATORY SHOREBIRDS IN THE STRATEGIC ASSESSMENT AREA

Migratory shorebirds are found at a number of sites within and adjacent to the Strategic Assessment Area during their seasonal occurrence in the southern hemisphere. Site usage varies based on the extent and quality of habitat.

This section provides:

- An overview on the migratory shorebirds recorded in the Cumberland subregion
- An overview of habitat in the subregion
- Site profiles for important habitat

MIGRATORY SHOREBIRDS RECORDED IN THE CUMBERLAND SUBREGION

A total of 21 species have been recorded across the Cumberland subregion (see Table 32-7). Of these:

- Four have been recorded in numbers that exceed the thresholds for important habitat when the subregion is considered as a single habitat unit. They are Sharp-tailed Sandpiper, Latham's Snipe, Black-tailed Godwit and Bar-tailed Godwit
- Two have exceeded thresholds for important habitat at the individual site level. They are Sharp-tailed Sandpiper and Latham's Snipe
- Five are also listed as threatened species under the EPBC Act. They are Bar-tailed Godwit (vulnerable), Curlew Sandpiper (critically endangered), Eastern Curlew (critically endangered), and Red Knot (endangered)

OVERVIEW OF SHOREBIRD HABITAT

A total of 11 important sites occur for migratory shorebirds across the subregion (see Map 49). None of these sites will be directly impacted by development under the Plan.

Table 32-6: Summary of migratory shorebird habitat sites

Habitat type	Number of sites	Total area of habitat (ha)
Important habitat within the Strategic Assessment Area	5	182.3
Important habitat within the broader Cumberland subregion	6	54.5

The important habitat sites can be broadly placed into five groups based on their location:

- Sites in the Strategic Assessment Area:
    - Sites 7, 9, 17 and 21 all occur near to the Hawkesbury River in the north of the Strategic Assessment Area
    - Site 19 occurs in the Mt Annan Botanic Gardens to the west of GMAC
- Sites outside the Strategic Assessment Area in the broader Cumberland subregion:
    - Sites 1 and 11 occur in the Marsden Park North Precinct of the existing North West Growth Area
    - Sites 3, 13 and 15 all occur within the vicinity of Sydney Olympic Park
    - Site 5 occurs outside in the suburb of Panania

It is important to note that important migratory shorebird habitat has been mapped for use in BAM assessments. No important migratory shorebird habitat has been identified within the Strategic Assessment Area.

A number of sites are subject to existing management (e.g. as a nature reserve). The section below provides a profile for each site.

Table 32-7: List of migratory shorebird species occurring within the Cumberland subregion (species in excess of important habitat thresholds = blue, threatened species = bold)

Common name	Scientific name	EPBC Act listing status	0.1% flyway population threshold (Hansen, Fuller et al., 2016)	Species exceeds 0.1% across the whole Strategic Assessment Area?	Number of individual sites exceeding the 0.1% flyway population threshold	Sites where key^ species have been recorded
Bar-tailed Godwit	***Limosa lapponica***	**Migratory Vulnerable#**	**325**	**Yes**	**0**	**9, 13, 15**
Black-tailed Godwit	*Limosa limosa*	Migratory	160	Yes	0	7, 9, 13, 21
Common Greenshank	*Tringa nebularia*	Migratory	110	No	0	1, 3, 7, 9, 13, 21

Wood Sandpiper	*Tringa glareola*	Migratory	130	No	0	1, 3, 9, 21

^ For species occurring in excess of important habitat thresholds and/or threatened species

Two subspecies of *L. lapponica* regularly occur in Australia. In the non-breeding season, *L. l. bauera* (listed as migratory and vulnerable) occurs along the north and east coasts of Australia (TSSC, 2016b). *L. l. menzbieri* (listed as migratory and critically endangered) on the other hand occurs predominately in Western Australia (TSSC, 2016c) and is not considered likely to occur in the Cumberland subregion.

* For Latham's Snipe important habitat is defined based on the presence of 18 birds rather than the 0.1 per cent threshold which is 30 individuals

SITE PROFILES FOR IMPORTANT HABITAT

Profiles for each of the eleven important habitat sites within the Cumberland subregion are provided below.

Site 1

SITE DETAILS	
Site ID number:	1
Site name:	Old Riverstone Meatworks ponds
Location:	Outside the Strategic Assessment Area within the broader Cumberland subregion
Approximate distance to nearest development area:	5.6 km
Important habitat for:	Sharp-tailed Sandpiper (187 birds recorded in 2005)
Total species recorded:	9
Area of important habitat:	8.1 ha
Area with buffer:	57.1 ha
DESCRIPTION & LANDSCAPE CONTEXT	
Site 1 is comprised of a group of former wastewater ponds associated with the old Riverstone Meatworks in the Marsden Park North Precinct of the existing North West Growth Area. The site is currently surrounded by farm land to the West, North and East; and low density development to the South. The Precinct is in the process of being rezoned and options are being explored for re-creating shorebird habitat in the vicinity before removing the old ponds (NSW NPWS, 2000).	

Site 3

SITE DETAILS	
Site ID number:	3
Site name:	Mason Park Wetlands
Location:	Outside the Strategic Assessment Area on the eastern edge of the Cumberland subregion
Approximate distance to nearest development area:	21 km
Important habitat for:	Sharp-tailed Sandpiper (120 birds recorded in 2004; 150 in 2005; 112 in 2007; and 100 in 2009)
Total species recorded:	8
Area of important habitat:	7.8 ha
Area with buffer:	60.2 ha
DESCRIPTION & LANDSCAPE CONTEXT	
The Mason Park Wetlands occur near to Sydney Olympic Park. The wetlands are bounded by Saleyards and Powells Creeks, and used to form part of the once extensive estuarine environment of the Parramatta River. They contain remnant salt marsh communities and are recognised for their habitat value for migratory shorebirds (NSW NPWS, 2003).	

Site 5

SITE DETAILS	
Site ID number:	5
Site name:	N/A
Location:	Outside the Strategic Assessment Area within the broader Cumberland subregion
Approximate distance to nearest development area:	8.5 km
Important habitat for:	Latham's Snipe (50 birds recorded in 1983)
Total species recorded:	1
Area of important habitat:	3.7 ha
Area with buffer:	45.1 ha
DESCRIPTION & LANDSCAPE CONTEXT	
Site 5 is an unnamed ephemeral water body. It occurs approximately 500 m from the Georges River and is not connected to any other waterways.	

Site 7

SITE DETAILS	
Site ID number:	7
Site name:	Bushell's Lagoon
Location:	In the north of the Strategic Assessment Area, to the north of the Hawkesbury River
Approximate distance to nearest development area:	14 km
Important habitat for:	Sharp-tailed Sandpiper (100 birds recorded in 2002)
Total species recorded:	12
Area of important habitat:	118.1
Area with buffer:	317.2
DESCRIPTION & LANDSCAPE CONTEXT	
Bushell's Lagoon is a natural, ephemeral water body that occurs on the floodplain of the Hawkesbury River. It is connected to a number of first order streams. The wetland is surrounded by farm land.	

Site 9

SITE DETAILS	
Site ID number:	9
Site name:	Pitt Town Lagoon
Location:	In the north of the Strategic Assessment Area, to the east of the Hawkesbury River
Approximate distance to nearest development area:	15 km
Important habitat for:	Sharp-tailed Sandpiper (183 birds recorded in 2005; 1,000 in 2006; 261 in 2009; 100 in 2013)
Total species recorded:	15

Area of important habitat:	39.6 ha
Area with buffer:	130.5 ha
DESCRIPTION & LANDSCAPE CONTEXT	
Pitt Town lagoon is part of the Pitt Town Nature Reserve and is managed by NSW National Parks. The site is mostly surrounded by farmland and flows into the Hawkesbury River to the north. The site is recognised for its habitat value for migratory shorebirds (NSW NPWS, 2000).	

Site 11

SITE DETAILS	
Site ID number:	11
Site name:	N/A
Location:	Outside the Strategic Assessment Area within the broader Cumberland subregion
Approximate distance to nearest development area:	5.5 km
Important habitat for:	Sharp-tailed Sandpiper (187 birds in 2012)
Total species recorded:	4
Area of important habitat:	0.9 ha
Area with buffer:	30.0 ha
DESCRIPTION & LANDSCAPE CONTEXT	
Site 11 is a grassy area in a developed area of the Riverstone Precinct of the existing North West Growth Area. The site appears unlikely to provide suitable long term habitat for migratory shorebirds, but was identified as important based on the number and accuracy of available records.	

Site 13

SITE DETAILS	
Site ID number:	13
Site name:	Wanngal Wetland
Location:	Outside the Strategic Assessment Area on the eastern edge of the Cumberland subregion
Approximate distance to nearest development area:	22 km
Important habitat for:	Sharp-tailed Sandpiper
Total species recorded:	12
Area of important habitat:	32.1 ha
Area with buffer:	117.7 ha
DESCRIPTION & LANDSCAPE CONTEXT	
Wanngal Wetland is part of the Newington Nature Reserve within Sydney Olympic Park. It is part of a highly modified estuarine wetland system. The site contains a range of important ecological values and contains significant areas of remnant saltmarsh and mangroves in excellent condition. It is recognised for its habitat value for migratory shorebirds (NSW NPWS, 2003).	

Site 15

SITE DETAILS	
Site ID number:	15
Site name:	N/A
Location:	Outside the Strategic Assessment Area on the eastern edge of the Cumberland subregion
Approximate distance to nearest development area:	21.5 km
Important habitat for:	Sharp-tailed Sandpiper (202 birds recorded in 2012)
Total species recorded:	4
Area of important habitat:	2.0 ha
Area with buffer:	38.0 ha
DESCRIPTION & LANDSCAPE CONTEXT	
Site 15 is located within the Sydney Olympic Park precinct. It occurs adjacent to Brickpit Park and is an ephemeral waterbody that is not connected to other waterways.	

Site 17

SITE DETAILS	
Site ID number:	17
Site name:	Yarramundi Lagoon
Location:	In the north of the Strategic Assessment Area, to the east of the confluence of the Grose and Nepean Rivers
Approximate distance to nearest development area:	4 km
Important habitat for:	Latham's Snipe (counts for the species not available, however, multiple records occur for 2002, 2003 and 2004 – taking a precautionary approach the site has been identified as important)
Total species recorded:	1
Area of important habitat:	10.3 ha
Area with buffer:	102.4 ha
DESCRIPTION & LANDSCAPE CONTEXT	
Yarramundi Lagoon is a linear shaped wetland that occurs in the active floodplain of the Hawkesbury – Nepean River (LandArc, 2007). The site is surrounded by farmland and is connected to the Hawkesbury River to the north through a chain of first order streams and small wetlands.	

Site 19

SITE DETAILS	
Site ID number:	19
Site name:	N/A
Location:	In the south of the Strategic Assessment Area, to the west of GMAC

Approximate distance to nearest development area:	1.4 km
Important habitat for:	Latham's Snipe (species has multiple records across a number of years – taking a precautionary approach the site has been identified as important)
Total species recorded:	2
Area of important habitat:	0.2 ha
Area with buffer:	26.1 ha
DESCRIPTION & LANDSCAPE CONTEXT	
Site 19 is a small wetland that occurs in the Mt Annan Botanic Gardens. It is part of a chain of managed ponds that drains north towards Annan Creek.	

Site 21

SITE DETAILS	
Site ID number:	21
Site name:	McGraths Hill Wetland
Location:	In the north of the Strategic Assessment Area, to the south of the Hawkesbury River
Approximate distance to nearest development area:	11 km
Important habitat for:	Sharp-tailed Sandpiper (276 birds recorded in 1982)
Total species recorded:	13
Area of important habitat:	14.1 ha
Area with buffer:	77.4 ha
DESCRIPTION & LANDSCAPE CONTEXT	
McGraths Hill Wetland is part of an effluent reuse and wetland project (associated with a sewerage treatment plant). The site occurs on a floodplain and drains into Wianamatta (South Creek) and ultimately into the Hawkesbury River.	

32.2.4 IMPACT ANALYSIS

This section considers the potential impacts to migratory shorebirds against the four impact pathways identified in the EPBC referral guidelines (DoEE, 2017). It also provides a brief consideration of climate change and an evaluation of the outcomes for shorebirds as listed migratory species.

LOSS OF IMPORTANT HABITAT

As outlined in the guidelines (DoEE, 2017), loss of important habitat can occur through either:

- Direct loss: e.g. through clearing, inundation, infilling or draining
- Indirect loss: e.g. through changes to hydrology, water quality or vegetation structural changes near roosting areas

Direct loss

There will be no direct loss of important habitat (or habitat buffers) due to development under the Plan. No important habitat areas occur closer than 1.4 km from the urban capable land and transport corridors and the majority of important sites are significantly further away.

Indirect loss

Changes to hydrology and water quality

Urban development and transport have the potential to lead to changes to hydrology and water quality. This is related to a range of factors but includes:

- Potential disruption to natural water flows
- The increase of hard surfaces leading to increased runoff
- Potential introduction of a range of contaminants that may affect water quality (e.g. nutrients, chemicals)

Migratory shorebird habitat that would be at risk of these effects are sites that are:

- In close proximity to development areas
- Hydrologically well connected (e.g. downstream) to development areas

None of the important habitat sites meet these criteria. Table 32-8 provides an analysis of the risk to each site due to potential changes in hydrology and water quality. Sites are grouped according to their general location in the Cumberland subregion. The risk of impacts is low in all cases.

Table 32-8: Risk of hydrology or water quality changes to important migratory shorebird habitat sites

Sites	Risk of impacts due to changes in hydrology and water quality
Sites within the Strategic Assessment Area:	
Sites 7, 9, 17 and 21	These sites occur in the north of the Strategic Assessment Area on (or close to) the floodplain of the Hawkesbury River. The broad area is downstream of much of the western third of the Cumberland subregion which includes all or part of the four nominated areas and transport corridors. The sites are relatively distant from the nearest development (4 km to 14 km). They would not be immediately influenced by any potential changes to hydrology or water quality. They are also subject to a range of existing influences such as: • Water extraction • Nutrient and chemical inputs from adjacent farmland • Sewerage treatment While broadly downstream of development, they are not considered to be well connected because: • They occur upstream of the Hawkesbury River on the floodplain • They are relatively distant from the development Risks to these sites is considered to be low.
Site 19	This site occurs in the Mt Annan Botanic Gardens to the west of GMAC. It is part of a managed series of ponds. The area is not hydrologically connected to the development in GMAC where the water flows to the east. Risks to this site are considered to be low.
Sites outside the Strategic Assessment Area in the broader Cumberland subregion:	
Sites 1 and 11	These sites occur within or near to existing development in the Marsden Park North Precinct of the existing North West Growth Area (outside the Strategic Assessment Area). Site 1 is comprised of wastewater ponds at the old Riverstone Meatworks. The Precinct is in the process of being rezoned and options are being explored for re-creating shorebird habitat in the vicinity before removing the old ponds (DPE, 2018). Site 11 appears unlikely to provide suitable long term habitat for migratory shorebirds (it is a grassy area surrounded by development), but was identified as important based on the number and accuracy of available records. Risks to these sites are considered to be low.

Sites	Risk of impacts due to changes in hydrology and water quality
Sites 3, 13 and 15	These sites all occur within or close to Sydney Olympic Park on the eastern edge of the Cumberland subregion. The area is approximately 20 km from the nearest development and not connected hydrologically. Risks to these sites are considered to be low.
Site 5	Site 5 occurs outside the Strategic Assessment Area in the suburb of Panania. It is an unnamed ephemeral water body that occurs approximately 500 m from the Georges River. The site is not connected to any other waterways and risks are considered to be low.

Whilst the risk of impacts due to changes in hydrology and water quality are low, the Plan includes commitments and actions to ensure that development will be planned and managed to control and manage environmental risks from indirect impacts. This includes actions relating to:

- Water Sensitive Urban Design
- Sediment and erosion controls for construction and operational phases of development
- Protection of waterways, groundwater, and riparian corridors

These commitments and actions further reduce the risk of potential impacts to important migratory shorebird habitat sites.

Changes to vegetation structure

Changes to vegetation structure can arise from factors such as increased vegetation cover or encroachment of buildings (DoEE, 2017). This may be possible at sites that are in close proximity to development.

Given the distance of important habitat to development, the risks of changes to vegetation structure is considered to be low.

DEGRADATION OF IMPORTANT HABITAT LEADING TO A SUBSTANTIAL REDUCTION IN MIGRATORY SHOREBIRD NUMBERS

The guidelines (DoEE, 2017) set out examples of the types of activities that can lead to degradation of important habitat. They include:

- Activities occurring in coastal or estuarine environments. For example:
  - Substantial loss of marine or estuarine vegetation
  - Invasion of intertidal mudflats by weeds
  - Exposure of acid sulphate soils
- Water pollution and changes to the water regime

Activities in coastal or estuarine environments

No development under the Plan will occur in coastal or estuarine environments.

Of the eleven important habitat sites, none are coastal and three occur within or close to estuarine areas. The three that occur within or close to estuarine areas are the three sites in proximity to Sydney Olympic Park. All of the sites are subject to existing management and will not be influenced by development under the Plan.

Risks from activities in coastal or estuarine environments are nil.

Water pollution and changes to the water regime

Potential water pollution and changes to the water regime are similar issues to those discussed above in relation to hydrology and water quality.

The risks to all sites are considered to be low because:

- They are generally distant to development

- No sites are hydrologically well connected
- There are commitments and actions in the Plan to manage and control environmental risks from indirect impacts

INCREASED DISTURBANCE WITHIN IMPORTANT HABITAT LEADING TO A SUBSTANTIAL REDUCTION IN MIGRATORY SHOREBIRD NUMBERS

As outlined in the guidelines (DoEE, 2017), increased disturbance to migratory shorebirds is a key threat within Australia. It may occur through:

- Construction activities (e.g. demolition)
- Residential and recreational activities such as four-wheel-driving, jet- and water-skiing, power boating, fishing, walking, wind-surfing, kite-surfing, walking dogs, noise and night-lighting

Migratory shorebird habitat that would be at risk of these effects are sites that are:

- In close proximity to development areas
- Publicly accessible for recreation (particularly where this is not managed to protect shorebirds)
- Adjacent to recreation areas (e.g. waterways used for boating etc)

Table 32-9 provides an analysis of the risk to each site due to potential increases in disturbance. Sites are grouped according to their general location in the Cumberland subregion. The risk of impacts is low in all cases.

Table 32-9: Risk of increased disturbance within important habitat leading to impacts to migratory shorebirds

Sites	Risk of impacts due to increased disturbance
Sites within the Strategic Assessment Area:	
Sites 7, 9, 17 and 21	These sites occur in the north of the Strategic Assessment Area on (or close to) the floodplain of the Hawkesbury River. ***Proximity to development*** The sites are relatively distant from the nearest development (4 km to 14 km). They would not be immediately influenced by disturbance from activities under the Plan. ***Accessibility*** It is considered unlikely that development under the Plan will lead to a significant increase in access and use of the sites: • Sites 7 and 17 are surrounded by farmland and while likely subject to a current level of disturbance, their distance from the nominated areas and landscape context make it unlikely that development under the Plan will lead to increased disturbance • Site 9 is part of the Pitt Town Nature Reserve and is managed by NSW National Parks. Access is managed and increased disturbance is considered unlikely • Site 21 is part of an effluent reuse facility. Increased disturbance is considered unlikely ***Proximity to recreation areas*** None of the sites occur within proximity to high intensity recreational areas. They are either: • Surrounded by farm land (Sites 7 and 17) • Part of a nature reserve where access and use is managed (Site 9) • Part of an effluent reuse facility (Site 21) ***Overall risks*** The overall risks to these sites from increased disturbance are considered to be low.
Site 19	This site occurs in the Mt Annan Botanic Gardens to the west of GMAC. It is part of a managed series of ponds. ***Proximity to development*** This site is the closest to a development area under the Plan (approximately 1.4 km from GMAC). However, it is sufficiently distant to ensure that it would not be immediately influenced by disturbance from activities under the Plan.

Sites	Risk of impacts due to increased disturbance
	Accessibility The area is currently accessible as part of the Botanic Gardens. It is possible that visitation will increase as the population of Western Sydney increases. However, dog walking, which is one of the key causes of disturbance, is prohibited in the gardens. It is considered unlikely that disturbance to shorebirds will significantly increase. ***Proximity to recreation areas*** The site does not occur within proximity to high intensity recreational areas. ***Overall risks*** The overall risks to these sites from increased disturbance are considered to be low.
Sites outside the Strategic Assessment Area in the broader Cumberland subregion:	
Sites 1 and 11	These sites occur within or near to existing development in the Marsden Park North Precinct of the existing North West Growth Area (outside the Strategic Assessment Area). Site 1 is comprised of wastewater ponds at the old Riverstone Meatworks. The Precinct is in the process of being rezoned and options are being explored for re-creating shorebird habitat in the vicinity before removing the old ponds (DPE, 2018). Site 11 appears unlikely to provide suitable long term habitat for migratory shorebirds (it is a grassy area surrounded by development), but was identified as important based on the number and accuracy of available records. Risks to these sites are considered to be low.
Sites 3, 13 and 15	These sites all occur within or close to Sydney Olympic Park on the eastern edge of the Cumberland subregion. ***Proximity to development*** The sites are approximately 20 km from the nearest development and would not be immediately influenced by disturbance from activities under the Plan. ***Accessibility*** The sites are currently accessible as part of the Sydney Olympic Park. However, access is managed and the area is already subject to significant visitation. It is considered unlikely that disturbance to shorebirds will significantly increase. ***Proximity to recreation areas*** The sites do not occur within proximity to high intensity recreational areas. ***Overall risks*** The overall risks to these sites from increased disturbance are considered to be low.
Site 5	Site 5 is an unnamed ephemeral water body that occurs outside the Strategic Assessment Area in the suburb of Panania. ***Proximity to development*** The site is approximately 8.5 km from the nearest development and would not be immediately influenced by disturbance from activities under the Plan. ***Accessibility*** The site is currently accessible. However, it is bordered by a range of disturbed areas and recreational opportunities appear to be limited. Given that it occurs in an existing suburb, it is considered unlikely that disturbance to shorebirds will significantly increase due to development under the Plan. ***Proximity to recreation areas*** The site does not occur within proximity to high intensity recreational areas. ***Overall risks*** The overall risks to this site from increased disturbance are considered to be low.

DIRECT MORTALITY OF BIRDS LEADING TO A SUBSTANTIAL REDUCTION IN MIGRATORY SHOREBIRD NUMBERS

As outlined in the guidelines (DoEE, 2017), direct mortality of birds may results from activities relating to:

- Bird strike due to:
    - Development of wind farms in migration or movement pathways
    - Aeroplanes or fixed structures such as towers with support cables
- Inappropriate waste management and chemical or oils spills

Bird strike

Development under the Plan does not relate to windfarms, aeroplanes or large fixed structures with support cables. Risks of significant bird strike due to the development are considered to be low.

Inappropriate waste management and chemical or oils spills

Potential impacts due to inappropriate waste management and chemical or oils spills are similar issues to those discussed above in relation to hydrology and water quality.

The risks to all sites are considered to be low because:

- They are generally distant to development
- No sites are hydrologically well connected
- There are commitments and actions in the Plan to manage and control environmental risks from indirect impacts. This includes an action relating to pollution avoidance and reduction, including spill management and response plans

Risks associated with these causes of direct mortality are considered to be low.

CONSIDERATION OF CLIMATE CHANGE

The guidelines (DoEE, 2017) suggest that "areas landward of important shorebird habitat areas should be maintained in an undeveloped state to allow the natural coastal processes of erosion and accretion to respond to possible rising sea levels".

None of the important habitat sites in the Cumberland subregion occur in coastal areas and consideration of climate change in this context is not considered relevant.

Chapter 41 of the report describes how the Plan more broadly has considered the extent to which it facilitates adaptation to climate change for MNES, including consideration of any particularly vulnerable matters.

EVALUATION OF THE OUTCOME FOR MIGRATORY SHOREBIRDS

As outlined in Section 32.2.1, the outcomes of the Plan must not be inconsistent with any of the international agreements relating to migratory species. The key obligations (of relevance to this assessment) which cut across the various agreements in different forms are for Australia to:

- Conserve and where possible restore habitats
- Mitigate and manage threats to shorebirds

The Plan is not inconsistent with these obligations. There will be:

- No direct impacts to important habitat
- Low to negligible risks of indirect impacts to important habitat
- Commitments and actions in the Plan to manage and control threats to shorebirds from development

32.2.5 CONCLUSION

Potential impacts to migratory shorebirds as a result of the Plan are considered to be negligible. No important habitat will be lost, and the risk of indirect impacts such as degradation of habitat and disturbance of birds is considered to be low.

The outcomes of the Plan for these species meets the regulatory requirements for listed migratory and (where relevant) threatened species under the EPBC Act.

33 Ramsar impact assessment

33.1 INTRODUCTION

While there are no Ramsar sites in the Strategic Assessment Area, the Towra Point Nature Reserve occurs downstream in the Botany Bay Catchment.

This Chapter sets out:

- Australia's international conservation obligations with regards to Towra Point Nature Reserve
- A general description of the Towra Point Nature Reserve
- The Ramsar listing criteria
- A summary of the ecological character of the site
- Analysis of the potential direct, indirect and facilitated impacts
- An overall conclusion

The analysis shows that an impact to the ecological character of the Towra Point Nature Reserve is not expected as a result of implementation of the Plan. There will be no direct impacts and potential indirect impacts will be adequately mitigated.

Attachment A sets out more detail about the ecological character of the site.

Potential cumulative impacts to Towra Point Nature Reserve are considered in Chapter 38.

33.2 INTERNATIONAL AGREEMENTS AND OBLIGATIONS TO PROTECT TOWRA POINT

Australia is party to a number of international agreements and treaties which require protection of significant wetlands and habitat for migratory birds. These include (DECCW & SMCMA, 2010):

- The Ramsar Convention on Wetlands
- The Convention on the Conservation of Migratory Species of Wild Animals (Bonn)
- The Japan - Australia Migratory Bird Agreement (JAMBA)
- The China - Australia Migratory Bird Agreement (CAMBA)
- The Republic of Korea–Australia Migratory Bird Agreement (ROKAMBA)
- The East Asian - Australasian Flyway Partnership (EAAFP)

The Ramsar Convention aims to prevent the degradation and loss of important wetlands across the globe through requiring implementation of appropriate site management and conservation principles.

The Bonn Convention is an environmental treaty of the United Nations, and aims to conserve migratory species within their migratory ranges. The Bonn convention is the only global convention which specialises in the conservation of migratory species, their habitats and migration routes. As of 1 November 2019, there were 130 Parties to the Convention.

JAMBA, Bonn, CAMBA and ROKAMBA are bilateral agreements which provide for protection of migratory birds and their important habitats.

The EAAFP is an informal and voluntary initiative which aims to protect migratory waterbirds and their habitats. Members of EAAFP include countries, intergovernmental agencies, NGOs and the international business sector.

33.3 GENERAL DESCRIPTION OF TOWRA POINT NATURE RESERVE

The Towra Point Nature Reserve has an area of 603.7 ha, located on the southern shore of Botany Bay opposite Sydney Kingsford Smith International Airport. The site is approximately 16 km from the centre of Sydney, within the Sutherland Shire local government area (see Figure 33-1).

The Towra Point Nature Reserve is an estuarine wetland complex. It is the largest of its type in the Sydney region and supports vegetation types that are regionally significant, including around 40 per cent of the remaining mangrove communities and 60 per cent of the remaining saltmarsh communities in Sydney. It is also an important link for migratory shorebirds on the East Asian-Australasian Flyway, supporting 30 out of 80 species of birds listed under international bilateral agreements (JAMBA, CAMBA, ROKAMBA). The site is comprised of the following eight wetland types:

- 'Marine subtidal aquatic beds', including significant areas of seagrass meadows within and adjacent to the Towra Point Nature Reserve
- 'Sand, shingle or pebble shores', including the itinerant sand spits and islands around Towra Point that are continually changing as a result of sand movement. These areas provide important habitat for shorebirds. They include Towra Spit Island, formed in 1991 from the tip of Towra Point when it became separated by a channel. Since its formation, it has been recognised as the second most important nesting site in NSW for the little tern
- 'Estuarine waters'. Those that surround Towra Point include Botany Bay, Georges River, Cooks River, Woolooware Bay, Quibray Bay and Weeney Bay. Approximately 1,400 ha of these surrounding waters have been designated as the Towra Point Aquatic Reserve
- 'Intertidal mud, sand or salt flats', including 156 (low tide) ha of muddy sand flats that extend along the shoreline from mean low water spring to mean high water spring tides. These areas are high in organic matter and provide rich feeding grounds for many shorebirds
- 'Intertidal marshes', including around 134 ha of saltmarsh within and adjacent to Towra Point Nature Reserve, which occurs on the landward side of adjacent areas of mangrove. The saltmarsh at Towra Point is one of the largest stands in NSW
- 'Intertidal forested wetlands', supporting a significant 385 ha of mangrove within and adjacent to Towra Point Nature Reserve
- 'Coastal brackish lagoons' and 'Coastal freshwater lagoons'. There are three named lagoons at Towra Point including Towra Lagoon, Mirrormere and Weedy Pond, and at least three unnamed lagoons that have no ecological information. All lagoons meet the definition of Sydney Freshwater Wetlands – an endangered ecological community in NSW

The Towra Point Nature Reserve is in the Botany Bay catchment which covers 1,165 km^2 and supports a population of approximately 2 million people (OEH, 2012; SMCMA, 2011). The Georges and Cooks Rivers and their tributaries flow into Botany Bay.

The entire Ramsar site lies within the boundary of the Towra Point Nature Reserve which is managed by the NSW National Parks and Wildlife Service (OEH, 2012). The site is also adjacent to the Towra Point Aquatic Reserve (see Figure 33-2) which is an important nursery area for fish and invertebrates, provides important habitat for migratory seabirds and is rich in marine biodiversity.

Figure 33-1 shows the Ramsar site within the context of its upstream catchment. The data for the catchment was downloaded from the Australian Government Department of Agriculture, Water and Environment spatial data viewer (http://www.environment.gov.au/fed/catalog/main/home.page). The data layer was derived using:

- "Each of the Ramsar Wetland site's boundaries
- A 10 km buffer area to each site, clipped to 3km where the buffer area extends seawards from the coast
- A catchment for each site from an upstream trace process using the Australian Hydrological Geospatial Fabric (Geofabric) features and relationships
- A multi-ring buffer, intersect and erase process to divide the catchment into distance bands from the Ramsar site"

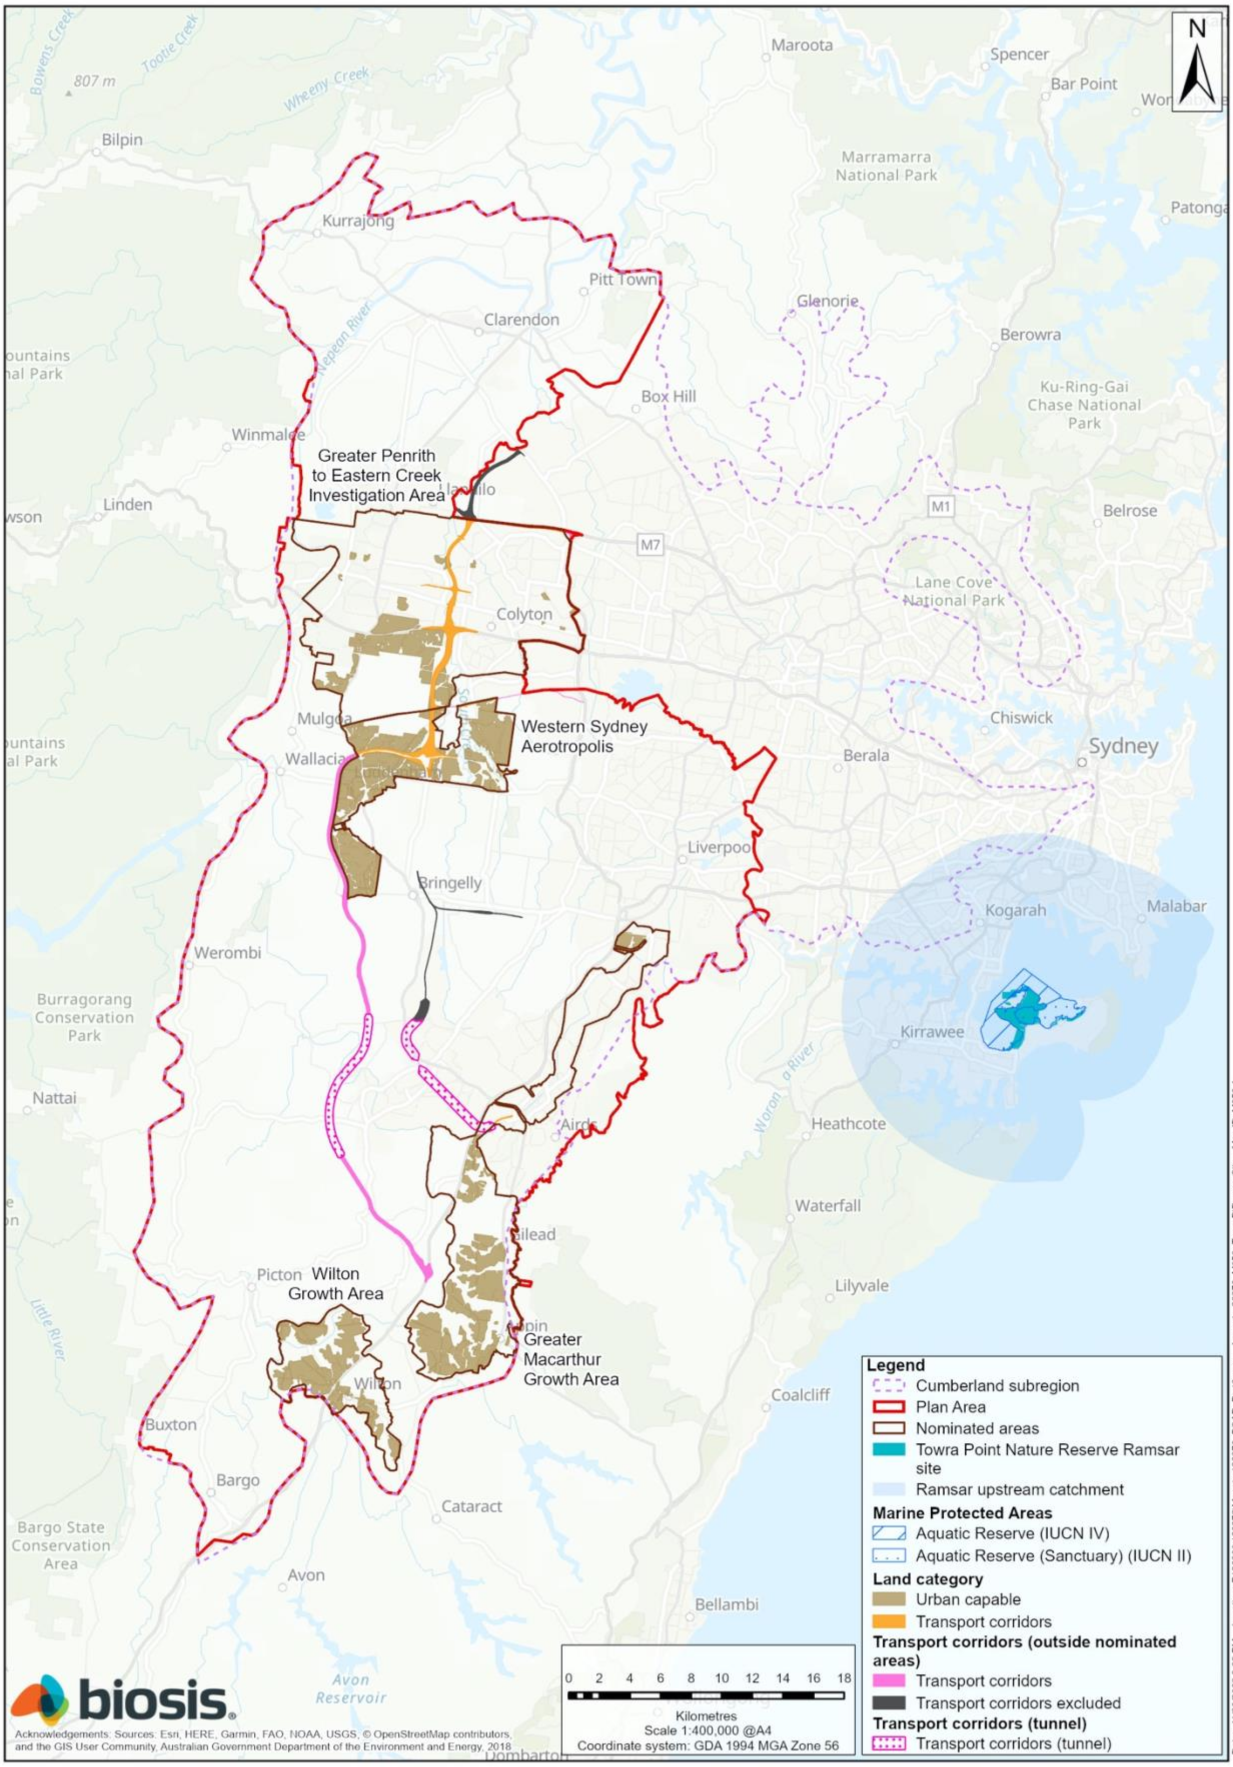

Figure 33-1: Map of Towra Point Nature Reserve Ramsar site in the Sydney Basin Bioregion

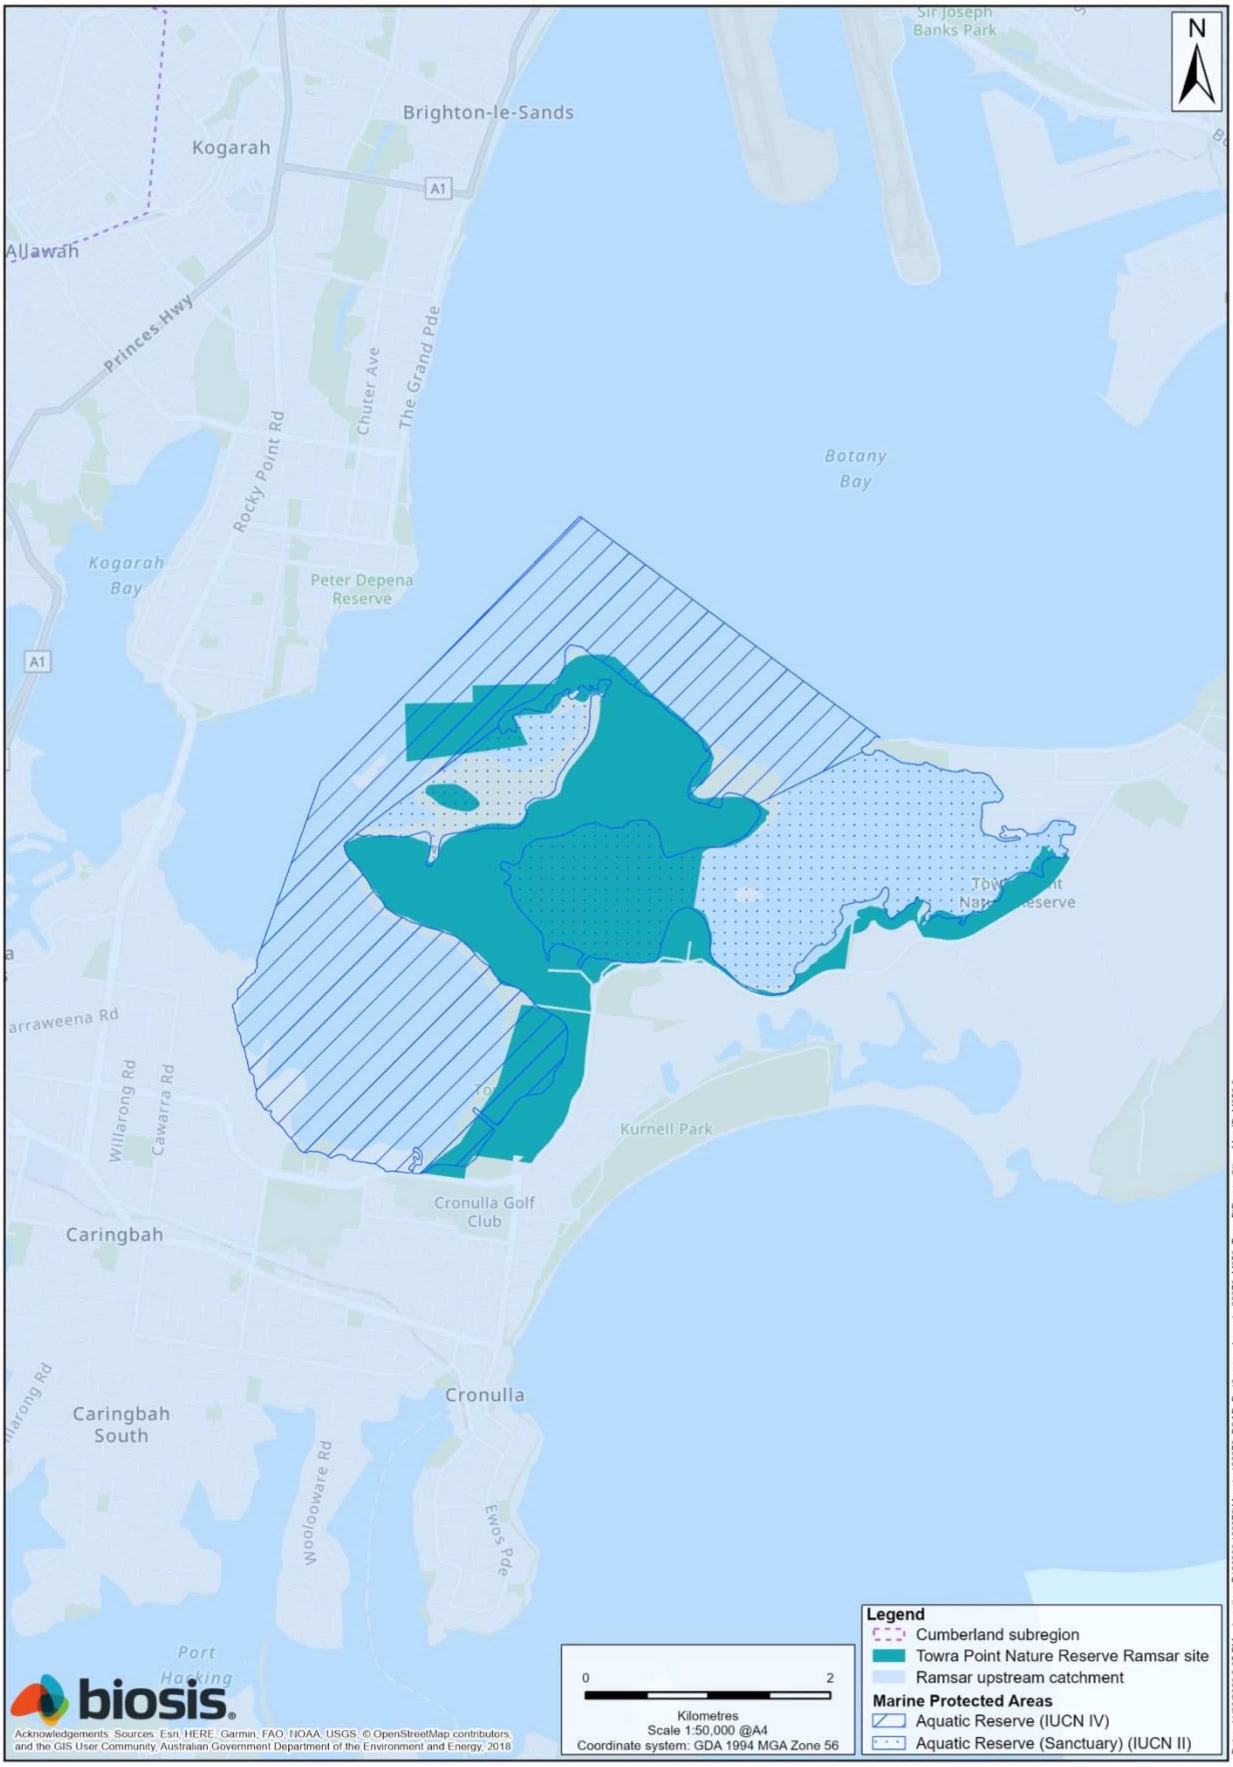

Figure 33-2: Site map of Towra Point Nature Reserve Ramsar site

33.4 RAMSAR LISTING CRITERIA

The Towra Point Nature Reserve was listed as a Wetland of International Importance under the Ramsar Convention in February 1984. For a wetland to be designated as a Ramsar site it must satisfy one or more of the Ramsar listing criterion. Towra Point Nature Reserve is considered to meet criteria 2, 3, 4 and 8 (see Table 33-1). Note that these criteria have changed since the original listing in 1984 due to administrative changes.

Table 33-1: Criteria for Ramsar listing

Criterion	Justification
2: A wetland should be considered internationally important if it supports vulnerable, endangered, or critically endangered species or threatened ecological communities	It supports three EPBC Act listed threatened species • Grey-headed flying fox (*Pteropus poliocephalus*) • Magenta lilly pilly (*Syzygium paniculatum*) • Green and golden bell frog (*Litoria aurea)*
3: A wetland should be considered internationally important if it supports populations of plant and/or animal species important for maintaining the biological diversity of a particular biogeographic region	In 1993 Botany Bay was recognised as one of the four most important migratory wading bird sites in NSW. Towra Spit Island was recognised as the second most important breeding area in NSW for the little tern *(Sterna albifrons)* (NSW NPWS, 2001) Towra Point is home to seagrass beds, mangrove and saltmarsh communities that provide critical habitat for juvenile fish and crustaceans (DECCW & SMCMA, 2010) The site also provides critical links for ecological connectivity and supports species that are uncommon elsewhere in the Sydney region (DECCW & SMCMA, 2010)
4: A wetland should be considered internationally important if it supports plant and/or animal species at a critical stage in their life cycles, or provides refuge during adverse conditions	Towra Point provides habitat for species of juvenile fish and crustaceans at a vulnerable stage in their life cycle. Such as the common silver biddy *(Gerres ovatus)*, yellow fin bream *(Acanthopagrus australis)*, flat-tailed mullet *(Liza argentea)*, and luderick *(Girella tricuspidata)* Migratory shorebirds use Towra Point as a critical stopover on migratory routes from Korea, Japan, China, Russia, Siberia and Alaska during September to April (DECCW & SMCMA, 2010)
8: A wetland should be considered internationally important if it is an important source of food for fishes, spawning ground, nursery and/or migration path on which fish stocks, either within the wetland or elsewhere, depend	The site provides habitat and food sources for at least 25 species of fish of economic importance. The seagrass, mangroves, and saltmarshes provide important habitat for protection for juvenile and migratory fish as well as food sources (DECCW & SMCMA, 2010)

By designating Towra Point Nature Reserve as a Ramsar site, Australia is obligated to establish and implement a management framework that aims to conserve the wetland and ensure its wise use. ‘Wise use’ under the Convention is broadly defined as maintaining the ‘ecological character’ of the wetland.

Ecological character is defined under the Ramsar Convention as the combination of the ecosystem components, processes, benefits and services that characterise the wetland at a given point in time (Ramsar Convention, 2005). It provides a baseline description of the wetland at the time of listing and often incorporates limits of acceptable change (LAC). LACs are the “range of variation in the components, processes and benefits or services that can occur without causing a change in the ecological character of the site” (DEWHA, 2008).

Ecological character is also the main element for the consideration of significant impacts under the EPBC Act. The significant impact guidelines (DoE, 2013b) state that:

> *An action is likely to have a significant impact on the ecological character of a declared Ramsar wetland if there is a real chance or possibility that it will result in:*
>
> - *areas of the wetland being destroyed or substantially modified*
> - *a substantial and measurable change in the hydrological regime of the wetland, for example, a substantial change to the volume, timing, duration and frequency of ground and surface water flows to and within the wetland*
> - *the habitat or lifecycle of native species, including invertebrate fauna and fish species, dependent upon the wetland being seriously affected*
> - *a substantial and measurable change in the water quality of the wetland – for example, a substantial change in the level of salinity, pollutants, or nutrients in the wetland, or water temperature which may adversely impact on biodiversity, ecological integrity, social amenity or human health, or*
> - *an invasive species that is harmful to the ecological character of the wetland being established (or an existing invasive species being spread) in the wetland.*

This assessment uses these guidelines to discuss the potential impacts to the Towra Point Nature Reserve.

33.5 SUMMARY OF THE ECOLOGICAL CHARACTER OF THE SITE

The Ecological Character Description (ECD) for Towra Point was developed retrospectively in 2010 (DECCW & SMCMA, 2010). It identifies in detail the critical components, processes, services and benefits of the site, along with the limits of acceptable change.

Table 33-2 provides a high level summary of the ecological character of the site and Attachment A provides more detail.

Table 33-2: High level summary of the ecological character of Towra Point

Component of ecological character	Key points	Limits of acceptable change (LAC)
Components and processes		
Geomorphology	• Towra Point was formed as a result of dynamic wind, wave, and tidal processes over time. In particular from the dynamic movement of marine sand from Botany Bay and fluvial mud from the Georges River • Since its listing, a range of factors (anthropogenic and natural) have altered its geomorphology. Notably, sediment connecting Towra Spit Island to the mainland was dredged in 2004 and needs to continuously be managed to maintain the ecological value of the Island • The wetland is low lying and the flora and fauna reflect their tolerance to salt water • The sedimentation processes of erosion and accretion facilitate the movement and colonisation of vegetation. They also create mudflats that provide favourable habitat for migratory birds and mangroves	• The LAC for geomorphology is the same as those set for the little tern because the spit is an important breeding and roosting habitat for migratory birds (including the little tern) • The LAC is the 'successful annual breeding in one out of every two years' of the little tern
Hydrology	• The site is part of a dynamic system and relies on the hydrological processes of tides, wave action, and groundwater • Anthropogenic changes (before and after listing) have affected tidal movements and wave action • The site is situated on the Botany Bay Sand Aquifer that extends from Centennial Park in the north, to Botany Bay and Kurnell Peninsula in the south, and west to Rockdale • The area around the wetland provides an important point of recharge for the aquifer	• Limits of acceptable change for groundwater are determined by the relevant water quality guidelines (ANZECC & ARMCANZ, 2000; ANZG, 2018)
Physiochemical environment	• At Towra Point the physiochemical environment determines water quality, which is vital for sustaining the diverse range of flora and fauna • The key components of the physiochemical environment at Towra Point are: o Salinity o Nutrients o Heavy metals o Turbidity	• Water quality guidelines for marine water have been used to determine limits of acceptable change for the physiochemical environment (ANZECC & ARMCANZ, 2000; ANZG, 2018)

Component of ecological character	Key points	Limits of acceptable change (LAC)
Biota	• Towra Point supports a number of regionally significant flora that occur as distinct vegetation zones across the wetland. Critical components include: o Seagrass o Mangroves o Saltmarsh o Substantial areas of terrestrial vegetation • Towra Point is one of the last remaining wetlands of its type in the Sydney region and provides important habitat for a number of threatened and migratory species. Fauna species present at the site include: o Macro-invertebrates o Fish o Reptiles and amphibians (including the Green and Golden Bell Frog) o Mammals (including the Grey-headed Flying Fox) o Birds (189 species, important habitat for migratory shorebirds, important site for the Little Tern (*Sternula albifrons*))	• LACs have been developed (where possible) for vegetation and a range of specific species
Climate	• Climate exists as an ecosystem regulator and plays an important role in maintaining equilibrium • The flora and fauna at Towra Point have adapted to the temperate climate of the region. Climate change and anthropogenic changes around Botany Bay are altering the intensity of climatic parameters	• Parameters for climate cannot be managed at a local scale. It has therefore been identified that LACs cannot be set for climate for Towra Point Nature Reserve Ramsar site
Services and benefits		
Provisioning services	• Provisioning services include: o Fisheries production o Trophic relay (transfer of energy and nutrients to different parts of the estuary)	• N/A
Regulating services	• Regulating services of Towra Point Ramsar site include: o Maintenance of hydrological regimes o Shoreline stabilisation and storm protection o Biological control of pests and disease o Pollution control	• N/A

Component of ecological character	Key points	Limits of acceptable change (LAC)
Cultural services	• Cultural services of Towra Point Ramsar site include: o Recreation and tourism o Science and education o Aesthetic amenity o Aboriginal heritage o Non-Aboriginal heritage	• N/A
Supporting services	• Supporting services of Towra Point Ramsar site include: o Hydrological processes o Food webs o Physical habitat o Nutrient cycling o Primary production o Sediment trapping and stabilisation o Biodiversity o Special ecological, physical or geomorphic features o Threatened wetland species, habitats and ecosystems o Priority wetland species o Ecological connectivity	• N/A

33.6 ANALYSIS OF POTENTIAL IMPACTS

33.6.1 DIRECT IMPACTS

Towra Point Nature Reserve is located outside the Strategic Assessment Area. The Ramsar site is approximately 23 km from the nearest nominated area (see Figure 33-1) and the Plan will not result in any direct impacts on the site.

33.6.2 INDIRECT OR FACILITATED IMPACTS

The Plan has the potential to cause the following indirect and facilitated impacts on Towra Point Nature Reserve:

- Reduction in surface water quality and changes to surface water flows due to run-off from urban and industrial, infrastructure, and transport development in the upstream catchment
- Potential changes to the ecological character of the reserve from increased recreational use from increased populations in Western Sydney facilitated by the urban development

CHANGES TO SURFACE WATER FLOWS AND REDUCTION IN WATER QUALITY

Nature, extent and duration of indirect impacts

Towra Point Nature Reserve is located in the Botany Bay catchment, which comprises four major sub-catchments:

- Direct to Botany Bay (this incorporates the minor sub-catchment of South Botany Bay, which would most directly influence Towra Point Nature Reserve)
- Cooks River
- Georges River
- Woronora River

A small part of the Strategic Assessment Area is located within the Georges River sub-catchment. Water quality within Towra Point Nature Reserve may be affected by the development through:

- Urban development within a part of GMAC that overlaps with the Georges River sub-catchment (170 ha)
- Transport corridors that occur within the Georges River sub-catchment (9 ha)

Towra Point Nature Reserve is also connected to the Botany Sand Aquifer, which extends from Centennial Park to Botany Bay and Kurnell Peninsula. The development occurs outside this area and is unlikely to impact on this aquifer.

Potential impacts to surface water quality may occur due to construction activities and an increased extent of urban land. Construction activities have the potential to impact water quality entering the Georges River and its tributaries for the duration of construction through the following pathways:

- Soil disturbance as part of construction activities may lead to an increase in erosion and runoff which would mean more sediments and nutrients entering the system
- Introduction of contaminants as a result of spillage or improper use and disposal of hazardous substances

Urban development may affect water quality entering the Georges River as a result of:

- Disruption to natural flows and processes
- Increase of hard surfaces leading to an increased volume of water entering downstream waterways
- Introduction of contaminants into surface water, such as nutrients, sediment and other pollutants

The components, processes, services and benefits of the ecological character of the Towra Point Nature Reserve that may be affected by these indirect impacts are identified in Table 33-4 and Table 33-5.

The exact location and timing of construction activities within GMAC are not known at this time, which means the nature and extent and duration of possible changes to water quality entering the Georges River cannot be quantified. However, there are a number of factors which substantially reduce the level of risk to the ecological character of Towra Point Nature Reserve from construction and a change in land use. These include:

- Distance of the development to Towra Point: GMAC is approximately 23 km from Towra Point. This distance provides a buffer to potential impacts relating to an increase in water flows and will reduce any sediment load and level of nutrients and contaminants reaching Towra Point
- Well flushed nature of the wetland: Towra Point is part of a tide-dominated estuarine system. Tidal movement means that suspended solids can only reside in the bay for a short time, leading to a well flushed water body and relatively high water quality
- Vegetated buffers on all riparian corridors: the development has avoided riparian corridors (see Chapter 14). This riparian vegetation will minimise direct runoff into waterways and act as a sink for nutrients and sediments

Commitments to address indirect impacts

Mitigation of urban and industrial development

As part of implementing the commitment to mitigate indirect and prescribed impacts from development to best practice standards (Commitment 5), a Development Control Plan (DCP) will be prepared for each nominated area by either the Department (in the case of Department led precincts) or by the relevant councils in collaboration with the Department.

A DCP provides detailed guidelines and environmental standards for new development, which need to be considered when preparing a development application seeking development approval.

DCPs for each nominated area will be prepared in accordance with:

- Standard format for DCPs and a set of model provisions prepared by the Department to apply across NSW
- Any processes and guidelines for preparing DCPs specific to each council
- Current best practice standards, guidelines or targets (e.g. water quality standards for urban runoff)

Two broad types of development controls will be implemented under each DCP:

- General environmental controls that will benefit the environment generally, including biodiversity values
- Specific controls that apply to specific species and TECs in specific locations or broader nominated areas. These controls have been identified through this Assessment Report and are needed to address residual risks to species or TECs that remain after implementation of the general environmental controls

Several general environmental controls are relevant to managing indirect impacts from the urban and industrial development on Towra Point Nature Reserve. These development controls are examples of controls typically included by councils in DCPs and likely to be implemented in the nominated areas (see Chapter 15, Section 15.6.1).

A detailed description of the process to implement these development controls in the nominated areas, including Department oversight and assurance mechanisms, is provided in Chapter 15, Section 15.6.1.

It is considered that these general environmental controls and the process to implement them described in Chapter 15 are adequate to mitigate impacts to Towra Point Nature Reserve from urban and industrial development and no additional measures are considered necessary for the protection of the site.

Table 33-3: General environmental controls relevant to managing indirect impacts on Towra Point

Control type	Summary of example control in draft Wilton DCP
Water cycle management	• Water management measures must comply with council's requirements for detention, drainage and water sensitive urban design principles • Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways

Control type	Summary of example control in draft Wilton DCP
Water quality	• Stormwater systems must be constructed and maintained to achieve EES water quality targets
Soil erosion and sedimentation	• Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development • Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom, 2004) and submitted with each subdivision development application
Disturbance to saline soils	• Salinity Management Plans must be prepared in accordance with the Western Sydney Salinity Code of Practice 2004 (WSROC, 2004) and submitted with each subdivision development application
Contaminated soils	• All subdivision development applications must be accompanied by a Stage 1 Preliminary Site Investigation. Where this identifies potential site contamination, a Stage 2 detailed site investigation must be prepared • A Remediation Action Plan (RAP) must be prepared for areas identified as contaminated land in the Stage 2 Site Investigation

Mitigation of infrastructure and transport corridors

A different process will be implemented under the Plan to mitigate the indirect impacts of infrastructure and the transport corridors. For both types of development, the Plan includes commitments to mitigate indirect and prescribed impacts (Commitment 5.3 for infrastructure, and Commitment 6 for transport). These commitments will be delivered for both types of development through a process of environmental assessment and approval that will be applied to detailed design of each infrastructure and transport project at the time the project is brought forward for development.

For infrastructure development, the assessment process will be undertaken under Part 4 or Part 5 of the EP&A Act (or equivalent at the time). State Environmental Planning Policy (SEPP) (Infrastructure) 2007 provides a framework for determining how most types of infrastructure are assessed under the EPA Act.

For transport development, the assessment process will be undertaken under the State Significant Infrastructure approval process (or equivalent at the time) under the EP&A Act.

These future environmental assessment and approval processes will assess and identify mitigation measures to manage the non-biodiversity related potential environmental impacts of the projects. This process will, for example, assess the potential for a project to result in changes to surface water flows and water quality impacts, based on the detailed design of the project, and identify mitigation measures to address these risks.

These processes therefore provide the mechanism to identify and implement mitigation measures to manage the potential indirect impacts on Towra Point Nature Reserve from the infrastructure and transport development and no additional measures are considered necessary for the protection of the site.

A detailed description of the assessment and approval process for transport corridors and infrastructure, including Department oversight and assurance mechanisms, is provided in Chapter 15, Section 15.6.2 and 15.6.3.

Conclusion

It is considered unlikely that there will be a reduction in surface water quality to a point that there are notable or consequential impacts to the ecological character of the Towra Point Nature Reserve. There are several factors that substantially reduce the potential for water quality impacts from the development on Towra Point and the commitments and processes under the Plan to manage indirect impacts is considered to adequately mitigate any residual risks.

POTENTIAL CHANGES TO ECOLOGICAL CHARACTER FROM INCREASED RECREATIONAL USE

Nature, extent and duration of indirect impacts

The development under the Plan will lead to increased numbers of people in Western Sydney that may result in increased visitation to Towra Point Nature Reserve, which could lead to a degradation of site values.

The components, processes, services and benefits of the ecological character of the Towra Point Nature Reserve that may be affected by increased recreational use are summarised in Table 33-6.

Existing management of visitor access

Access to Towra Point is restricted by permits. In addition to being listed as a Ramsar site, Towra Point is also a nature reserve. Nature Reserves differ from National Parks as they only allow restricted access. Permits are granted for scientific and educational purposes and are fully supervised.

There are two areas that do not require permits to access. These are Quibray Bay viewing platform and Towra Point day use area. The day use area is restricted to the shoreline of Towra Point beach and is only accessible by boat (OEH, 2012).

Activities associated with visitation to Towra Point beach day use area include:

- Recreational fishing
- Use of Towra Point beach recreational area

These activities have the potential to impact fish stocks as a result of recreational fishing, in addition to beach nesting birds. While Towra Spit Island and other habitats for threatened beach nesting birds do not permit public access, beach nesting birds such as the Little Tern are susceptible to disturbance as a result of human activity in the wider area, including swimmers, boats, fishers and divers (DECC, 2008).

There is a Plan of Management for Towra Point Nature Reserve that sets out a range of management strategies to be implemented by the NSW National Parks and Wildlife Service (NSW NPWS, 2001). The Plan includes a range of measures to manage visitor use and enforce of prohibitions and restrictions on access, including (DECC, 2008):

- Restricting access to areas of threatened species habitat, including Towra Spit Island, which is a significant nesting site for the Little Tern
- Use of signage, brochures, media releases and regular on-site patrols to educate the public regarding the importance of Towra Spit Island
- Implementing temporary beach closures and fencing off large areas around nesting colonies where required
- Provision of day-use access to nearby Towra Beach and shorebird viewing platforms to enable safe public engagement with the wetland while protecting wetland values
- Multiple management measures to raise public awareness of the importance of shorebird conservation

These existing measures to manage potential impacts associated with human visitation to Towra Point Nature Reserve are expected to be adequate to manage potential increases in visitor numbers resulting from the urban development.

Conclusion

The potential risk to the ecological character of Towra Point Nature Reserve as a result of an increased number of visitors is considered minimal. Due to existing high population densities in proximity to Towra Point Nature Reserve, the reserve implements a wide range of ongoing and comprehensive management measures to manage the potential impacts associated with human visitation, and these are expected to adequately address this risk.

33.7 ADDRESSING OBLIGATIONS UNDER THE RAMSAR CONVENTION

Section 4.7 of the ToRs requires the Assessment Report to consider the extent to which the impacts of the Plan are consistent with Australia's international obligations, including the Ramsar Convention. The Ramsar Convention's broad aims are to halt the worldwide loss of wetlands and to conserve, through wise use and management, those that remain. This requires international cooperation, policy making, capacity building and technology transfer.

The Plan includes a combination of avoidance and mitigation measures relevant to managing indirect impacts on Towra Point Nature Reserve. As described in section 33.6.2 and considered further in Chapter 15, the Plan includes a commitment to mitigate indirect and prescribed impacts from development to best practice standards (Commitment 5) as well as from the transport development (Commitment 6).

The Plan also includes a monitoring, evaluation and reporting program (MER) (see Sub-Plan A) that provides for public reporting on progress in achieving the commitment and actions, and regular and consistent monitoring and evaluation to inform adaptive management responses. Commitment 27 includes an action to publish yearly updates over the life of the Plan.

The Ramsar Convention has been considered in the development of the Plan, which requires avoidance, mitigation and management measures for Ramsar wetlands. The Plan requires information related to the development to be publicly available to ensure equitable sharing of information and improved knowledge relating to the site.

Impacts to Towra Point Nature Reserve are unlikely and loss of wetlands is not foreseeable. The Plan is not considered to be inconsistent with the Ramsar Convention.

34 World and National Heritage impact assessment

Fires within Greater Blue Mountains World Heritage Area

NSW experienced extensive bushfires throughout the spring and summer of 2019-20. As of 3rd February 2020, the fires had burnt 5.37 million hectares of land (approximately 7 per cent of NSW). This includes 37 per cent of the national park estate, including 81 per cent of the Greater Blue Mountains World Heritage Area (DPIE, 2020).

An assessment of the potential impacts of the Plan on the Greater Blue Mountains World Heritage Area in relation to fire is provided in section 34.2.5.

World Heritage and National Heritage sites are Matters of National Environmental Significance (MNES) and are protected under the Commonwealth EPBC Act.

This Chapter assesses the potential impacts to World Heritage and National Heritage sites from urban, transport and agricultural development under the Plan. It sets out:

- The regulatory context for World and/or National Heritage properties
- A discussion of each of the properties listed in Table 34-1, including:
    - An assessment of potential direct, indirect and facilitated impacts
    - An assessment of the consistency of the Plan with the regulatory requirements for each property

There are three World and/or National Heritage listed sites in or near the Strategic Assessment Area that could potentially be impacted by development under the Plan. Table 34-1 lists these sites and their World Heritage and National Heritage listing status.

The Greater Blue Mountains World Heritage Area is located close to the nominated areas and has been considered in detail. The other heritage sites are further from the urban capable land and transport corridors and are unlikely to impacted, and have been considered in less detail.

In summary, the direct and indirect impacts to these sites from the Plan are negligible. There is the possibility of facilitated impacts from increased visitor numbers, but visitor impacts are already managed at each site and the existing management arrangements for these sites are considered sufficient to manage this risk.

Table 34-1: World and National Heritage sites in or near the Strategic Assessment Area

Site	World Heritage status	National Heritage status
Greater Blue Mountains World Heritage Area	Listed	Listed
Parramatta Female Factory and Institutions Precinct	-	Listed
Old Government House and Government Domain	Part of Australian Convict Sites listing (one of 11 sites across Australia)	Listed

34.1 REGULATORY CONTEXT

The EPBC Act sets out a range of protections for World Heritage and National Heritage properties. This assessment draws on four components of this regulatory framework:

- The concept of Outstanding Universal Value
- The EPBC Act Significant Impact Guidelines 1.1 (DoE, 2013b)
- EPBC Act Section 146G: Approvals relating to declared World Heritage properties
- EPBC Act Section 146H: Approvals relating to National Heritage places

Each of these components is discussed in detail below.

34.1.1 OUTSTANDING UNIVERSAL VALUE

The concept of Outstanding Universal Value (OUV) is defined in the *Operational Guidelines for the Implementation of the World Heritage Convention* (the Guidelines, UNESCO, 2017) as "cultural and/or natural significance which is so exceptional as to transcend national boundaries and to be of common importance for present and future generations of all humanity".

For a World Heritage Property to be considered to have OUV, it must:

- Meet one or more of the ten World Heritage criteria listed in the Guidelines (UNESCO, 2017)
- Meet the conditions of integrity and/or authenticity (noting that authenticity is not relevant to the Greater Blue Mountains Area as a natural area)
- Have an adequate protection and management system

The OUV of a World Heritage Property is articulated in a Statement of Outstanding Universal Value which is typically prepared at the time of inscription. Besides describing the attributes of the property that contribute to its OUV, the Statement of OUV provides the basis for the future protection and management of the property.

34.1.2 SIGNIFICANT IMPACT GUIDELINES 1.1

This assessment draws on key concepts outlined in the EPBC Act Significant Impact Guidelines 1.1 (DoE, 2013b) in relation to World and National Heritage. These guidelines describe three pathways for significant impacts to World Heritage properties or National Heritage places.

Actions are likely to have significant impacts if there is a real chance or possibility that they will lead to:

- A loss of one or more World or National Heritage values
- Degradation or damage to one or more World or National Heritage values
- Notable alteration, obscuring, or diminishment of one or more World or National Heritage values

These concepts have been used to discuss the potential likelihood and severity of impacts to OUV. The World or National Heritage values for each site will be identified in the relevant section.

34.1.3 APPROVALS RELATING TO DECLARED WORLD HERITAGE PROPERTIES

Section 146G of the EPBC Act sets out the approval considerations in relation to World Heritage properties. It requires the outcomes of the Plan to not be inconsistent with any of:

- Australia's obligations under the World Heritage Convention
- The Australian World Heritage management principles
- A management plan for a World Heritage property that falls under the Sections 316 or 321 of the EPBC Act

The strategic assessment process is consistent with the requirements for public consultation and environmental impact assessment in the Australian World Heritage management principles.

The Australian World Heritage management principles set out requirements for public consultation in the management of and assessment of the possibility of significant impacts to World Heritage properties. These requirements are consistent with the strategic assessment process.

The World Heritage Convention sets out a broad range of obligations to recognise and protect World Heritage properties and cooperate internationally for the ongoing preservation. As outlined below, the potential impacts to World Heritage properties from the Plan are acceptable, and the Plan is not inconsistent with these obligations.

A key test for approval for World Heritage properties is that the outcomes of the Plan are not inconsistent with the property's management plan. The relevant management plans under Sections 316 or 321 of the EPBC Act are discussed in the EPBC Act Approval Considerations section for each property.

34.1.4 APPROVALS RELATING TO NATIONAL HERITAGE PLACES

Section 146H of the EPBC Act sets out the approval considerations in relation to National Heritage places. It requires the outcomes of the Plan to not be inconsistent with any of:

- The National Heritage management principles
- An agreement to which the Commonwealth is a party in relation to a National Heritage place
- A management plan for a National Heritage place that falls under Sections 324S or 324X of the EPBC Act

The National Heritage management principles relate to the identification, protection, management and use of National Heritage places. The principles are broadly consistent with the strategic assessment process.

A key requirement for approval under the EPBC Act is whether the outcomes of the Plan are inconsistent with any relevant management plans or agreements for each National Heritage place. The relevant plans are discussed in the EPBC Act Approval Considerations section for each property.

34.2 GREATER BLUE MOUNTAINS WORLD HERITAGE AREA

The Greater Blue Mountains World Heritage Area (GBMWHA) is listed as both a World Heritage site and a National Heritage place. It occurs adjacent to the Cumberland subregion (see Figure 34-1).

This section assesses the likely impacts of the proposed development under the Plan on the GBMWHA. It sets out:

- A brief description of the area
- The relevant EPBC Act approval considerations
- The values of the World Heritage area
- The relationship between the Plan and the GBMWHA
- The potential direct, indirect and facilitated impacts to the values of the GBMWHA associated with the Plan
- Consistency with the Strategic Plan for the World Heritage area
- An evaluation of the adequacy of the outcome

This assessment shows that the only relevant potential impacts to the OUV of the GBMWHA from the Plan are from facilitated impacts. Specifically, the Plan will support population growth near the World Heritage area which may increase the extent and intensity of impacts from visitor use.

The GBMWHA is made up of eight conservation reserves, each of which is protected and managed for conservation. The management plans for these reserves sufficiently address impacts associated with visitor use. Provided these conservation reserves continue to monitor and adaptively manage impacts from visitors over time, the risk of impacts to the OUV of the GBMWHA from the development under the Plan is considered minimal.

34.2.1 DESCRIPTION OF THE GREATER BLUE MOUNTAINS WORLD HERITAGE AREA

The GBMWHA covers 1.03 million ha to the west of the Strategic Assessment Area. It extends between 60 and 180 km inland from central Sydney, between Bowral in the south, and Newcastle and Mudgee to the north (DECC, 2009b).

It contains a deeply incised sandstone plateau with a wide range of forest ecosystems, mallee scrubs, swamps, deep valleys, cliffs, canyons and rivers. It protects large areas of wilderness and provides habitats for an internationally significant diversity of flora, fauna and ecological communities. It provides connectivity between coastal ecosystems to the east and the western slopes and is an important north-south corridor (DECC, 2009b).

The park is adjacent to Sydney and urban areas in the Hunter and Central Coast regions. It provides important opportunities for education, recreation, research and access to wilderness (DECC, 2009b).

34.2.2 EPBC ACT APPROVAL CONSIDERATIONS

The Greater Blue Mountains World Heritage Area Strategic Plan (the Strategic Plan) was published in 2009 for the management of the World Heritage property as described by Section 321 of the EPBC Act. The Strategic Plan also acts as a management plan for a National Heritage place under Section 324X of the EPBC Act.

A key consideration for approval of the Plan is that it is not inconsistent with the Strategic Plan. This section sets out the broad objectives of the Strategic Plan and the conditions the Plan must meet to be approvable under the EPBC Act.

OBJECTIVES OF THE STRATEGIC PLAN

The Strategic Plan sets out a range of values that are expressed in the GBMWHA. Some of these are recognised as being Outstanding Universal Values, while others support OUV within the GBMWHA or could potentially be listed in the future. The Outstanding Universal Values and these supporting values are discussed below. To manage these values, the Strategic Plan lists ten key management issues, each of which has one or more objectives and a range of desired outcomes and management responses. The key management issues and their objectives are provided in Table 34-2.

Table 34-2: Key management issues and objectives for the GBMWHA

Key management issue	Objective
Integrity	• To maintain, and wherever possible, improve the current and future integrity of the GBMWHA
Major impacts	• To reduce the potential for major impacts to adversely affect the integrity of the GBMWHA. Major impacts include mining adjacent to or underlying the GBMWHA, highway construction through the GBMWHA, or other development within or adjacent to the GBMWHA
Biodiversity	• To conserve the GBMWHA's biodiversity and ensure the ecological viability and capacity for ongoing evolution of its World Heritage and other natural values is maintained
Geodiversity	• To protect the GBMWHA's geodiversity
Water catchment protection	• To maintain and improve the water quality and water catchment values of the GBMWHA
Cultural heritage	• To identify, formally recognise and protect the cultural heritage values of the GBMWHA • To manage the GBMWHA jointly with local Indigenous people
Landscape, natural beauty and aesthetic values	• To protect the landscape, natural beauty and aesthetic values of the GBMWHA
Recreation and visitor use	• To provide for an appropriate range of recreation and visitor use, consistent with the protection of World Heritage and related values
Social and economic issues	• Consistent with the protection of World Heritage and other values, optimise the potential and existing social and economic benefits derived from visitation to the GBMWHA
Education, community participation and consultation	• To encourage community stewardship of the GBMWHA through education, consultation and the provision of opportunities for community participation in its protection

There are a large number of desired outcomes, many of which are not relevant to implementation of the Plan. Desired outcomes that may be affected by the Plan are discussed individually as appropriate.

TEST FOR APPROVAL

For approval under the EPBC Act, the Plan must not be inconsistent with the Strategic Plan. To achieve this, it must not:

- Prevent the achievement of any of the objectives
- Prevent any of the desired outcomes

These conditions are considered after a discussion of the potential impacts of the Plan.

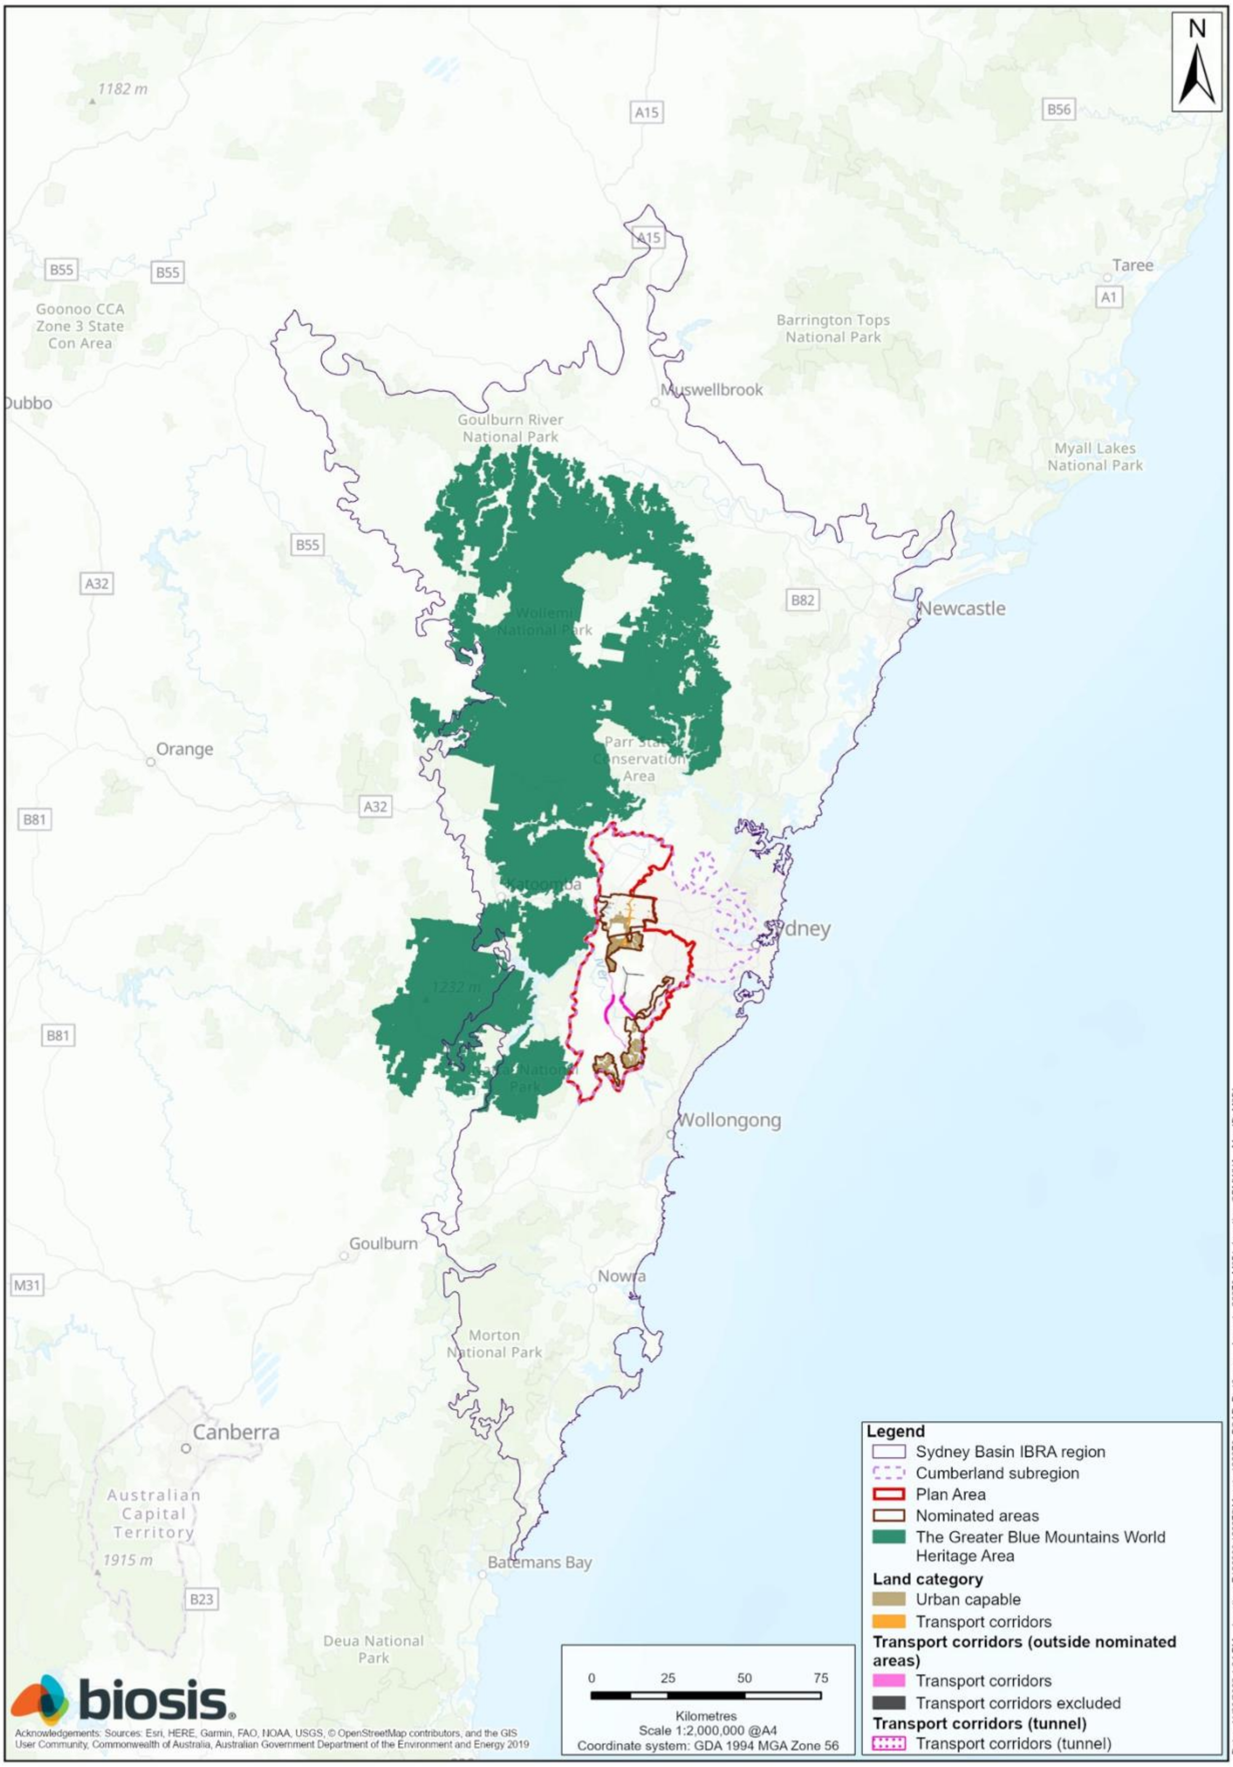

Figure 34-1: The Greater Blue Mountains World Heritage Area

34.2.3 THE VALUES OF THE GREATER BLUE MOUNTAINS WORLD HERITAGE AREA

The GBMWHA is World and National Heritage listed because it contains globally significant examples of eucalyptus evolution and diversification and an outstanding diversity of ecosystems, habitats and ecological communities.

World Heritage Listing

As a World Heritage Area, the GBMWHA is recognised under the *World Heritage Convention* as having OUV. A Statement of OUV was not prepared for the GBMWHA at the time of inscription. However a retrospective Statement of OUV was adopted by the World Heritage Commission in 2013 (UNESCO, 2018c) and is summarised below.

Criteria and attributes

The GBMWHA meets two criteria for OUV:

- **Criterion (ix):** it is an outstanding example representing significant ongoing ecological and biological processes in the evolution and development of terrestrial, fresh water, coastal and marine ecosystems and communities of plants and animals
- **Criterion (x):** it contains the most important and significant natural habitats for in-situ conservation of biological diversity, including those containing threatened species of outstanding universal value from the point of view of science or conservation (UNESCO, 2017)

While the precise wording of the listing criteria are periodically updated by UNESCO, the natural heritage criteria that have been met in the GBMWHA reflect ecological and biological processes; and biological diversity including threatened species. The criteria listed in this report are those in the 2017 Operational Guidelines.

The attributes that meet these criteria are discussed in Table 34-3.

Table 34-3: Outstanding Universal Values of the Greater Blue Mountains World Heritage Area

World Heritage listing criteria	Examples of World and National Heritage attributes
Criterion (ix): it is an outstanding example representing significant ongoing ecological and biological processes in the evolution and development of terrestrial, fresh water, coastal and marine ecosystems and communities of plants and animals	The GBMWHA has: • Outstanding and representative examples in a relatively small area of the evolution and adaptation of the genus Eucalyptus and eucalypt-dominated vegetation on the Australian continent • Wide and balanced representation of eucalypt habitats including wet and dry sclerophyll forests and mallee heathlands with localised swamps, wetlands and grassland • Significant examples of eucalypt evolution and diversification • Examples of dynamic processes that cover the full range of interactions between eucalypts, understorey, fauna, environment and fire • Primitive species of outstanding significance to the evolution of the earth's plant life (e.g. the Wollemi pine *Wollemia nobilis* and the Blue Mountains pine *Pherosphaera fitzgeraldii*) (UNESCO, 2018a)
Criterion (x): it contains the most important and significant natural habitats for in-situ conservation of biological diversity, including those containing threatened species of outstanding universal value from the point of view of science or conservation	The GBMWHA contains: • An outstanding diversity of habitats, plant communities, species and ecosystems (152 plant families, 484 genera and approximately 1,500 species) • A significant proportion of the Australian continent's biodiversity, especially its scleromorphic flora • Exceptionally high levels of species diversity in the Myrtaceae, Fabaceae, and Proteaceae plant families, including 13 per cent of the world's eucalyptus species • Primitive and relictual species with Gondwanan affinities • Many plants of conservation significance (114 endemic species and 177 threatened species)

World Heritage listing criteria	Examples of World and National Heritage attributes
	• More than 400 vertebrate taxa (of which 40 are threatened) including around one third of Australia's bird species (265 species) • An estimated 120 butterfly and 4,000 moth species and rich cave invertebrate fauna (UNESCO, 2018b)

Integrity

All World Heritage properties are required to meet the conditions of integrity. This is defined by the Guidelines (UNESCO, 2017) as "a measure of the wholeness and intactness of the natural and/or cultural heritage and its attributes". An assessment of the integrity of a property is required to determine the extent to which the property:

- Includes all elements necessary to express its OUV
- Is of adequate size to ensure the complete representation of the features and processes which convey the property's significance
- Suffers from adverse effects of development and/or neglect

The Statement of OUV for the GBMWHA (UNESCO, 2018b) sets out the features of the property that meet these conditions.

- The GBMWHA is of a sufficient size (over 1 million ha) and connectivity to protect its biota and ecosystem processes despite anomalies in its boundary that reduce the protective effect of its size
- Much of the property neighbours State Forests and State Conservation Areas which provide protection to the World Heritage area
- Designated wilderness areas (covering 65 per cent of the property) and closed and protected catchments provide additional protections
- Most of the natural bushland within the property is of high wilderness quality and remains close to pristine
- Plant communities and habitats within the property form a largely undisturbed matrix with little disruption from structures, earthworks, or other human intervention
- The complexity of the property's geological structure, geomorphology and water systems are critical to the evolution of its outstanding biodiversity and require the same level of protection
- The property has a strong and ongoing connection with Aboriginal people from six language groups. Continuation of this custodial relationship is fundamental to the protection of the property's integrity

Protection

All World Heritage properties are required to be adequately protected and managed to ensure that their OUV (including the conditions of integrity at the time of inscription) are sustained or enhanced over time (UNESCO, 2017).

The Guidelines outline the broad level requirements for effective protection and management. This includes:

- Appropriate legislative, regulatory and contractual measures for protection
- Boundaries for effective protection
- Buffer zones
- Appropriate management systems

Finally, the Guidelines provide for the sustainable use of World Heritage Areas where that use does not adversely impact on the OUV of the property.

The GBMWHA is completely contained within the following conservation reserves:

- Blue Mountains National Park
- Gardens of Stone National Park
- Jenolan Caves Karst Conservation Reserve
- Kanangra-Boyd National Park
- Nattai National Park

- Thirlmere Lakes National Park
- Wollemi National Park
- Yengo National Park

Large areas in the southern part the GBMWHA are within the catchment for Sydney's water. These areas are protected under *Sydney Water Catchment Management Act 1998* that restricts access and acceptable use. This affords an additional level of protection.

All of these reserves are managed by the NSW National Parks and Wildlife Service (UNESCO, 2018b) and are subject to a range of State Government legislation.

In addition to the Strategic Plan, plans of management have been gazetted for the seven national parks listed above and a draft plan of management has been published for the Jenolan Caves Karst Conservation Reserve (UNESCO, 2018b). The plan of management for each conservation reserve is listed in Table 34-4.

Table 34-4: Plans of management for the GBMWHA

Conservation reserve	Plan of management title	Publisher	Year of publication
Blue Mountains National Park	Blue Mountains National Park Plan of Management	DECC	2001
Gardens of Stone National Park	Gardens of Stone National Park Plan of Management	DECC	2009
Kanangra-Boyd National Park	Kanangra-Boyd National Park Plan of Management	NSW NPWS	2001
Nattai National Park	Nattai Reserves Plan of Management	NSW NPWS	2001
Thirlmere Lakes National Park	Thirlmere Lakes National Park Plan of Management	NSW NPWS	1997
Wollemi National Park	Wollemi National Park Plan of Management	NSW NPWS	2001
Yengo National Park	Yengo National Park Finchley Aboriginal Area Plan of Management	DECC	2009
Jenolan Caves Karst Conservation Reserve	Jenolan Karst Conservation Reserve Draft Plan of Management	OEH	2013

NATIONAL HERITAGE LISTING

The GBMWHA meets four criteria for National Heritage listing. It was judged to meet these criteria on the basis of its World Heritage listing. The criteria are:

- **Criterion A Events, Processes** by virtue of meeting World Heritage criteria (ix) and (x)
- **Criterion B Rarity** by virtue of meeting World Heritage criterion (x)
- **Criterion C Research** by virtue of meeting World Heritage criteria (ix) and (x)
- **Criterion D Principal characteristics of a class of places** by virtue of meeting World Heritage criterion (ix) (DoEE, 2018a)

The GBMWHA's National Heritage listing is based on its World Heritage status. An assessment of the significance of impacts to the GBMWHA's OUV is considered sufficient to determine the acceptability of impacts to its National Heritage values.

SUPPORTING ATTRIBUTES

The Strategic Plan sets out a number of values that are not recognised as having OUV, but support, complement, or interact with the GBMWHA's World Heritage values. Some of these may be nominated for World Heritage listing in the future. The supporting values described in the Strategic Plan are set out in Table 34-5. Some of these attributes have already been discussed in the Statement of OUV. Only the attributes that have not already been identified in the World Heritage listing will be considered further below.

Table 34-5: Supporting values of the GBMWHA

Value	Description
Geodiversity and biodiversity	These attributes are discussed in the Statement of OUV
Water catchment	The GBMWHA protects a large number of pristine catchment areas, which make a substantial contribution to water storage for human use as well as water quality and natural flows for the Hawkesbury-Nepean and Goulburn-Hunter river systems
Indigenous values	This attribute is discussed in the Statement of OUV
Historic values	The GBMWHA includes numerous places of historic significance to European settlement of Australia
Recreation and tourism	The GBMWHA provides settings for recreation and tourism that are outstanding and increasingly rare by world standards, adjacent to a major city
Wilderness	This attribute is discussed in the Statement of OUV
Social and economic	The GBMWHA has considerable social and economic value as a tourism destination
Research and education	The variety of ecological communities and landscapes and associated cultural sites makes the GBMWHA ideal for research and educational visits
Scenic and aesthetic	The GBMWHA contains some of the most dramatic scenery in Australia with views of uninterrupted forest wilderness, contrasting forested slopes and cleared valleys, sandstone canyons and pagoda rock formations. The Jenolan Karst Conservation Reserve contains extensive aesthetic caves
Bequest, inspiration, spirituality and existence	The GBMWHA has value as a unique and important landscape that can be experienced by future generations and contributes to Aboriginal cultural continuity

34.2.4 HOW DEVELOPMENT UNDER THE PLAN RELATES TO THE GBMWHA

The proposed urban capable land and transport corridors do not occur within or overlap with the GBMWHA.

The western boundary of the Strategic Assessment Area is adjacent to the World Heritage area immediately west of GPEC. The Strategic Assessment Area and the World Heritage area overlap slightly close to the southern end of the Strategic Assessment Area.

GPEC is the nearest nominated area, occurring approximately 1 km from the edge of the World Heritage area, as shown in Figure 34-2. The distance from the GBMWHA to key locations within the urban capable land and transport corridors is given in Table 34-6.

Table 34-6: Distance between GBMWHA and key locations in the urban capable land and transport corridors

Location	Distance
Urban capable land in Greater Penrith to Eastern Creek Investigation Area (GPEC)	1 km
Urban capable land in Western Sydney Aerotropolis (WSA)	5.3 km
Urban capable land in Wilton Growth Area (Wilton)	6.5 km
Urban capable land in Greater Macarthur Growth Area (GMAC)	15.8 km

The proposed development will support an increasing population in Western Sydney. The Metropolis of Three Cities plan projects that the population of the Western Parkland City will increase from 740,000 in 2016 to over 1.5 million in 2056 (GSC, 2018). Population growth of this size in close proximity to the GBMWHA is anticipated to increase visitor numbers and in turn increase the pressure on the World Heritage Area from visitors.

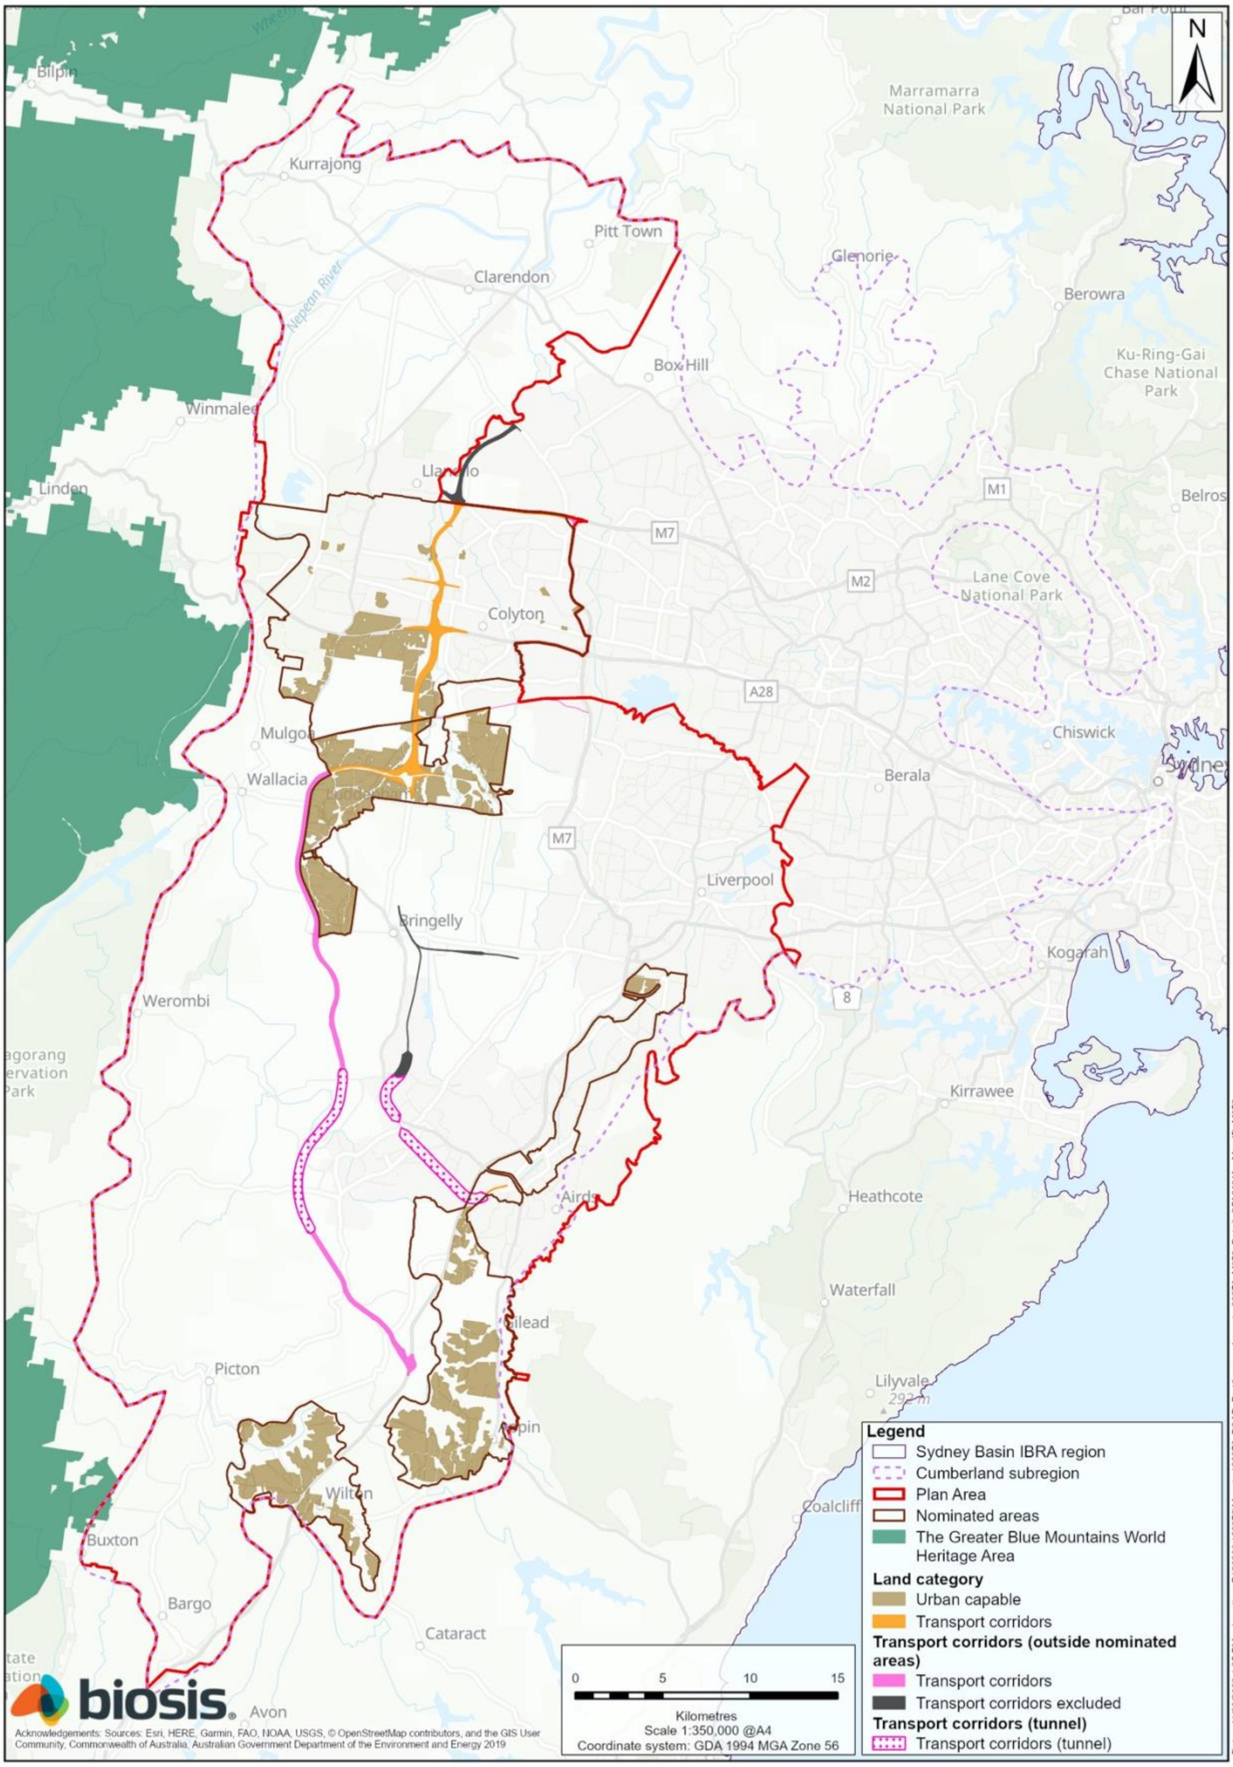

Figure 34-2: GBMWHA and the Plan Area

34.2.5 POTENTIAL IMPACTS TO OUTSTANDING UNIVERSAL VALUE

It is not reasonably foreseeable that any of the impacts described in this section will affect the level of conservation protection for the GBMWHA. As a result, this section will focus on the possibility of impacts to the OUV and integrity of the GBMWHA, as well as its supporting values.

Potential direct impacts

The Plan does not include any actions or development within the GBMWHA. As a result, there will be no direct impacts to OUV or the GBMWHA's supporting values from the Plan.

Potential indirect impacts

Potential indirect impacts to the GBMWHA are discussed below in relation to:

- Habitat connectivity
- Edge effects
- Visual impacts
- Other impacts

Habitat connectivity

Of the attributes that support criterion (x), several wide-ranging fauna species (e.g. bats, such as the Grey-headed Flying-fox, and birds) are likely to move between the World Heritage Area and the Cumberland subregion. This is particularly the case in the context of the recent bushfires, which affected over 81 per cent of the Greater Blue Mountains World Heritage Area (DPIE, 2020) and may have increased the importance of habitat outside the area for these species.

Habitat within the nominated areas may provide connectivity for these wide ranging species to foraging resources or smaller areas of habitat within or surrounding the subregion, including protected areas to the north-east and south-east of the subregion, or the Holsworthy Military Reserve to the south-east.

The direct impacts of urban and other development may reduce habitat connectivity within the nominated areas for wide-ranging fauna species associated with GBMWHA, which may affect ecosystem processes that may cause impacts to the OUV and integrity of the GBMWHA, as well as its supporting values.

Habitat connectivity refers to the degree of connectedness of areas of habitat. Habitat connectivity can include:

- Corridors of vegetation linking other areas of habitat
- Isolated patches of habitat that provide 'stepping stones' between other areas of habitat
- Habitat features (such as large trees with hollows) scattered within areas of non-habitat (e.g. urban land) that provide habtiat connectivity between intact areas of habitat

Habitat connectivity was mapped within the nominated areas as part of this Assessment Report by:

- Identifying BIO Map regional corridors and core areas (DECCW, 2010), which have been identified by EES and represent the areas where the protection and management of native vegetation is likely to maximise benefits to biodiversity within the subregion. These areas are likely to represent the most important areas of habitat connectivity in the nominated areas for the majority of species[1]
- Identifying local corridors using the native vegetation mapping to identify connected patches of native vegetation. This was done visually in GIS, with only contiguous patches identified as being connected

---

- [1] Note that EES has only identified BIO Map corridors within the boundaries of the Cumberland subregion. To undertake the mapping for the small parts of the nominated areas outside the subregion the Priority Conservation Lands layer (DECCW, 2010) (EES used this layer as basis for BIO Map) or the native vegetation map prepared for this Assessment Report (see Chapter 11) was used to extend the BIO Map corridor mapping

- Identify any remaining native vegetation not within a regional corridor or local corridor as:
  - Connected patches – within 100 m of another patch of woody vegetation
  - Isolated patches – greater than 100 m from another patch of woody vegetation

Key areas of habitat connectivity in the nominated areas are shown in Map 19.The impacts of urban and other development on this habitat connectivity are described in Table 34-7.

Urban and other development is not considered likely to impact habitat connectivity within the nominated areas to the extent that this would cause impacts to the OUV and integrity of the GBMWHA, as well as its supporting values through impacts to wide-ranging fauna species. The vast majority of BIO Map regional corridors/core areas and smaller habitat corridors have been avoided and will not be impacted. Where impacts occur to these areas, this is generally to the edges of habitat and connectivity is generally maintained. Many smaller connected and isolated patches of habitat will be directly impacted, which is likely to reduce habitat connectivity within the nominated areas for more mobile species, such as microbats and birds. These impacts are not considered substantial in the context of maintaining habitat connectivity within the broader landscape and between the nominated areas and GBMWHA.

Furthermore, the conservation program under the Plan (see Part 2) will result in:

- Protecting a minimum of 5,473 hectares of native vegetation and habitat in the subregion (Commitment 8)
- Securing priority habitat corridors in the subregion (Commitment 12)
- Undertaking ecological restoration in priority sites (Commitment 13)
- Managing landscape threats in strategic locations to improve habitat values, including weeds (Commitment 16) and pests (Commitment 17) and fire (Commitment 17)

Importantly, the strategic conservation areas (SCAs) where these commitments will be delivered represent the areas in the Cumberland subregion that are considered most likely to be viable in the long-term and to maximise ecological function and connectivity across the landscape. In determining the location of the SCAs, priority was given to including the largest, best condition and best-connected areas of native vegetation remaining in the subregion (see Part 2).

The Plan also includes several mitigation measures that will minimise impacts to habitat connectivity within the nominated areas for wide-ranging fauna species. These are described in Chapter 15, and include:

- Retain large trees (including dead trees) (≥50cm DBH) during precinct planning where possible
- Retain areas of high density proteaceae shrubs where possible, particularly along riparian corridors
- Establish minimum setbacks for urban development around flying fox camps
- Design road crossings of waterways to minimise impacts to vegetated riparian corridors and species movements

These commitments and mitigation measures are considered to adequately address any residual risks of impacts to habitat connectivity that may cause impacts to the OUV and integrity of the GBMWHA, as well as its supporting values.

Table 34-7: Potential impacts on habitat connectivity from urban and other development in the nominated areas

Nominated area	Nature	Extent	Duration
Wilton	**Direct impacts:** The vast majority of BIO Map regional corridors/core areas have been avoided and will not be directly impacted. The main direct impact occurs in the southern part of the nominated area where the development will remove part of a corridor/core area that connects native vegetation either side of the nominated area in this location. The impact reduces the width of the corridor/core area by about half. Connectivity is maintained to the south and east of the impacted area. In all other areas, direct impacts occur only to the edges of corridors/core areas in a few locations and connectivity along these areas is maintained There are very minor direct impacts to the local corridor on the eastern side of the nominated area between the Hume Motorway and Wilton Road The majority of impacts to connected vegetation occur to smaller scattered patches in the middle of the nominated area and to the edge of larger areas of connected vegetation where it occurs adjacent to BIO Map regional corridors/core areas around the nominated area	**Direct impacts:** The following approximate amounts of each category of habitat connectivity will be directly impacted by the development: • BIO Map corridors – 78.9 ha (7.6 per cent) • Local corridor – 6 ha (2.9 per cent) • Connected vegetation – 140 ha (25.7 per cent) • Isolated vegetation – 1 ha (47 per cent)	Long-term
	Indirect impacts: The development may cause a range of indirect impacts to areas of habitat connectivity. Key risks are weed invasion, pest animals, changes to hydrology, increased risk of fire, and human disturbance	**Indirect impacts:** Areas of habitat connectivity adjacent to urban capable lands	Temporary or long-term
GMAC	**Direct impact:** The vast majority of BIO Map regional corridors/core areas have been avoided and will not be directly impacted. Direct impacts occur only to the edges of corridors/core areas in a few locations. There are no locations were direct impacts completely sever or significantly narrow a core area/corridor and connectivity is maintained for these areas of habitat connectivity across all parts of the nominated area The vast majority of the local corridor in the middle of the southern part of the nominated area has been avoided and is not directly impacted. Impacts occur only to the edges of the corridor and connectivity is maintained in this location across the nominated area The majority of impacts to connected vegetation occur to smaller scattered patches, where patches will be completely cleared. Impacts also occur to the edges of several larger areas of connected vegetation in the southern part of the nominated area. In these cases, the size of the patches will be reduced, but the impacts will not generally sever connectivity between this connected vegetation and other areas of native vegetation, such as BIO Map corridors/core areas	**Direct impacts:** The following approximate amounts of each category of habitat connectivity will be directly impacted by the development: • BIO Map corridors – 45 ha (2 per cent) • Local corridor – 19 ha (12 per cent) • Connected vegetation – 217 ha (21 per cent) • Isolated vegetation – 2 ha (16 per cent)	Long-term

Nominated area	Nature	Extent	Duration
	Indirect impacts: The development may cause a range of indirect impacts to areas of habitat connectivity. Key risks are weed invasion, pest animals, changes to hydrology, increased risk of fire, and human disturbance	**Indirect impacts:** Areas of habitat connectivity adjacent to urban capable lands	Temporary or long-term
WSA	**Direct impact:** The vast majority of BIO Map regional corridors/core areas have been avoided and will not be directly impacted. The main direct impact occurs in the south-eastern part of the nominated area where the development will remove the majority of a corridor/core area that connects Wianamatta (South Creek) and Kemps Creek in the Kemps Creek area. While this area is identified as a regional corridor, connectively has already been completely severed in this location by existing industrial land use. In all other areas, direct impacts occur only to the edges of corridors/core areas in a few locations and connectivity along these areas is maintained The majority of local corridors have been avoided and will not be directly impacted. Direct impacts occur: • At Cosgrove Creek in the middle part of the nominated area where the OSO severs the riparian corridor in two locations • At Badgerys Creek in the middle part of the nominated area where the OSO severs the riparian corridor in one location The majority of impacts to connected vegetation occur to smaller scattered patches, where patches will be completely cleared. Impacts also occur to the edges of several larger areas of connected vegetation in the north-eastern, middle and southern parts of the nominated area. In some cases, the impacts will sever or reduce connectivity between this connected vegetation and other areas of connected vegetation within and outside the nominated area	**Direct impacts:** The following approximate amounts of each category of habitat connectivity will be directly impacted by the development: • BIO Map corridors – 22.3 ha (7.0 per cent) • Local corridor – 34.2 ha (27.5 per cent) • Connected vegetation – 279.1 ha (52.5 per cent) • Isolated vegetation – 10.8 ha (67.1 per cent)	Long-term
	Indirect impacts: The development may cause a range of indirect impacts to areas of habitat connectivity. Key risks are weed invasion, pest animals, changes to hydrology, increased risk of fire, and human disturbance	**Indirect impacts:** Areas of habitat connectivity adjacent to urban capable lands	Temporary or long-term

<table>
<tr><th>Nominated area</th><th>Nature</th><th>Extent</th><th>Duration</th></tr>
<tr><td rowspan="2">GPEC</td><td>Direct impact:
The majority of BIO Map regional corridors/core areas have been avoided and will not be directly impacted. The main direct impacts occur:
• Within Wianamatta Regional Park where the OSO severs the eastern part of the regional park that is connected to Ropes Creek with the western part of the park
• Along Wianamatta (South Creek) where the OSO directly impacts the Wianamatta (South Creek) riparian corridor and severs the narrow connection along the corridor that links Wianamatta Regional Park and Orchid Hills
In all other areas direct impacts have been avoided, except in the western part of the nominated area near Glenmore Park where there is a small direct impact to the edge of a corridor/core area
No local corridors occur within the nominated area
The majority of impacts to connected vegetation occur to smaller scattered patches, where patches will be completely cleared. Impacts also occur to the edges of several larger areas of connected vegetation in some parts of the nominated area. In these cases, the size of the patches will be reduced, but the impacts will not generally sever connectivity between this connected vegetation and other areas of native vegetation, such as BIO Map corridors/core areas</td><td>Direct impacts:
The following categorises of habitat connectivity will be directly impacted by the development:
• BIO Map corridors – 178.9 ha (7.0 per cent)
• Local corridor – 0 ha (0 per cent)
• Connected vegetation – 190 ha (17 per cent)
• Isolated vegetation – 0.5 ha (6.3 per cent)</td><td>Long-term</td></tr>
<tr><td>Indirect impacts:
The development may cause a range of indirect impacts to areas of habitat connectivity. Key risks are weed invasion, pest animals, changes to hydrology, increased risk of fire, and human disturbance</td><td>Indirect impacts:
Areas of habitat connectivity adjacent to urban capable lands</td><td>Temporary or long-term</td></tr>
</table>

Edge effects

Potential indirect impacts from the Plan relating to edge effects, such as the introduction of weeds and feral animals, changes to water quality, inappropriate fire regimes or disturbance from light or noise are also considered unlikely to affect the OUV or the supporting values of the GBMWHA for the following reasons:

- The urban capable land and transport corridors are at least 1 km from the GBMWHA. Where development occurs close to the World Heritage area (e.g. on the western edge of the footprints in GPEC), it takes place in existing urban or highly modified environments. These areas have already been disturbed, and further disturbance is unlikely to lead to substantial edge effects
- Most of the development proposed by the Plan is over 5 km from the edge of the GBMWHA. This distance is sufficient to protect the World Heritage area from edge effects
- The urban capable land and transport corridors are downstream of or outside the catchment for the GBMWHA. The Plan is therefore unlikely to influence aquifer drawdown, ground water quality or surface water quality relating to the GBMWHA
- A range of mitigation and management measures will be undertaken as part of implementation of the Plan to address potential construction impacts and edge effects. These measures are identified in Part 2 of this report and further minimise the risks associated with potential indirect impacts

Visual impacts

Scenic and aesthetic attributes are identified in the Strategic Plan as a supporting value for the World Heritage Area. Of particular relevance are views of uninterrupted forest wilderness, contrasting forested slopes and cleared valleys, sandstone canyons and pagoda rock formations. However, these views are not typically related to the Cumberland subregion.

Development within parts of the nominated areas will be visible from some areas in the GBMWHA. However, impacts to scenic and aesthetic values are likely to be limited in scope and scale because:

- The Cumberland subregion does not represent the key scenic values identified in the Strategic Plan
- Development that does occur near to the GBMWHA will generally occur within existing urban or highly modified environments, or where it occurs in greenfield areas, will be distant from the World Heritage area and is likely to have limited visual impact
- The urban capable land and transport corridors are only visible from the eastern fringes of the World Heritage area and are not visible from the most popular and sensitive tourism and recreation sites (e.g. the Jamison Valley south of Echo Point or Wentworth Falls lookouts, the Grose Valley east of Evans or Govetts Leap lookouts, Kanangra Walls, or other wilderness areas)

Visual impacts will be negligible and do not present a risk to the scenic and aesthetic values of the GBMWHA.

Other impacts

It is not anticipated that the Plan will indirectly impact on the social, economic, cultural, historical, Indigenous, or other values of the GBMWHA.

POTENTIAL FACILITATED IMPACTS

Facilitated impacts are the main source of risk to the GBMWHA from the Plan and the focus of the remaining Chapter.

The population of Sydney is already growing, and the overarching Strategic Plan and the plans of management for each individual reserve within the GBMWHA recognise the pressure from increasing visitors as a major management challenge. The Plan will facilitate further population growth, potentially intensifying these impacts.

The potential impacts from increased visitors to the GBMWHA are:

- Disturbance from people, vehicles and horses
- Increased frequency of fires
- Removal of bushrock and fallen timber
- Introduced plants

- Development or increased maintenance of visitor or management facilities or infrastructure

The plans of management set out a range of policies and actions, and monitoring processes for managing the impacts listed above. The impacts and the relevant management and monitoring policies are discussed below.

Increased disturbance from people, vehicles and horses

Additional visitors to the GBMWHA may increase disturbance to flora, fauna, ecological communities, geological features, and cultural or historical sites. This is listed as a key management challenge in the GBMWHA Strategic Plan (DECC, 2009b). The impacts of disturbance vary according to the type, intensity and frequency of visitor use and the sensitivity of the ecosystems and landscape features found throughout the World Heritage area. Unmarked tracks in wilderness areas may see around a thousand visits, remote wilderness areas may not be visited at all, and popular lookouts or tracks may see over a million visits each year. Visitors may be on foot, in vehicles, with horses (in limited parts of the GBMWHA), using watercraft, or using ropes to rock climb or access canyons.

Potential impacts are varied and include soil loss and compaction, loss of vegetative cover, erosion, lack of regeneration, creation of fireplaces, damage to trees, removal of firewood, installation of rock climbing and canyoning anchors, individual mortality of flora and fauna, incorrect disposal of waste, and damage to cultural or historic sites (DECC, 2001).

Potential impacts to Outstanding Universal Value and supporting values

The OUV of the GBMWHA reflects its outstanding examples of eucalyptus diversification and evolution and its diversity of habitats, ecological communities, and species. Without appropriate management, increased disturbance from people, vehicles and horses could notably diminish or alter these values through:

- Impacts across large areas, or to many high-quality sites that support examples of eucalyptus diversification and evolution
- Intense impacts in important, sensitive areas especially habitats for species and ecological communities with a limited extent in the World Heritage area
- Any impacts to highly sensitive areas, including habitat for the Wollemi pine

Impacts that notably diminish the integrity of the GBMWHA are unlikely, but could result from:

- Widespread impacts in otherwise pristine environments
- Impacts to culturally sensitive areas

Impacts to supporting values including geodiversity and biodiversity, water catchments, Indigenous and historical values, recreation and tourism, wilderness, and scenic and aesthetic values could be notably degraded by:

- Intense impacts in sensitive areas, especially geological formations, historic and cultural sites, or key visitor locations
- Widespread impacts across high-quality areas such as water catchments, visitor sites, or areas of scenic and aesthetic value
- Impacts in highly sensitive areas, especially wilderness areas

Impacts to the protection arrangements for the GBMWHA are not reasonably foreseeable.

Impacts that notably diminish OUV or its supporting values from disturbance by people, vehicles and horses are only likely if they occur across many sites or in highly sensitive areas.

Existing management and monitoring policies

Disturbance by people, vehicles and horses is already managed in the conservation reserves that make up the GBMWHA. The sections in the plans of management for each conservation reserve that discuss management or monitoring of these impacts are listed in Table 34-8.

Table 34-8: Management and monitoring of impacts from people, vehicles and horses

Conservation Reserve	Management of Impacts	Monitoring
Blue Mountains National Park	• s3.2 lists management of recreation and tourism to ensure minimal impacts as a specific objective of the plan. • s1.1 established a policy to manage erosion from visitor use and management activities. • s4.3 lists policies and actions to manage impacts from visitor use (including people, vehicles and horses).	• s3.3 emphasises monitoring and improved management of public and commercial recreation opportunities with potential adverse impacts. • s4.3 lists a range of monitoring actions for different types of use within the park.
Gardens of Stone National Park	• s4.3 lists policies and actions to manage impacts from visitor use (including people, vehicles and horses). • s4.1.1 commits NPWS to develop maintenance priorities to minimise erosion from roads, trails and tracks.	• s4.3.1 commits to monitor visitor impacts at popular sites around the park.
Kanangra-Boyd National Park	• s3.2 describes management of recreation and tourism within the park to minimise impacts is a specific objective for the plan of management. • s1.1 commits to manage erosion from visitor use and management activities. • s4.3 lists policies and actions to manage impacts from visitor use (including people, vehicles and horses).	• s3.3 commits to monitoring of recreation and commercial tourism with potential adverse impacts. • s4.3 lists a range of monitoring actions for different types of use within the park.
Nattai National Park	• s3 lists appropriate recreational use as an objective of the plan of management. • s4.3 sets out a limited set of appropriate uses for the park and policies and actions to manage impacts from these uses.	• s4.3 lists monitoring priorities including water quality and four-wheel drive access and impacts.
Thirlmere Lakes National Park	• s3.2 lists appropriate recreational use as an objective of the plan of management. • s4.3 sets out a limited set of appropriate uses for the park and policies and actions to manage impacts from these uses.	• The plan of management does not list actions or policies for monitoring of impacts from visitor use.
Wollemi National Park	• s4.1.1 commits to minimise erosion from management activities. • s4.3 list policies and actions to manage impacts from visitor use (including people, vehicles and horses).	• s4.3 commits to monitor a range of impacts from visitor use within the park.
Yengo National Park	• s3.0 lists maintenance of dispersed, low-impact recreation activities as a management objective. • s4.3 gives management policies and actions for use of the park	• s4.3 lists monitoring actions for the park.
Jenolan Caves Karst Conservation Reserve	• s3.5 sets out policies and actions for managing impacts from visitor use within the reserve.	• Table 5 in s3.5 sets out a range of monitoring processes for impacts associated with visitor use.

The plans of management set out an extensive set of policies and actions to manage impacts from visitors across the GBMWHA. They include actions to limit the areas that are subject to impacts from visitors, manage impacts in areas of frequent visitation, limit visitor numbers in wilderness and key recreation areas, and protect sensitive environments. The plans address impacts to OUV and supporting values.

These policies and actions are considered sufficient to mitigate the existing risk from visitor use and have been developed to manage increasing visitor pressure. Monitoring programs are generally sufficient to inform adaptive management and enable policies and actions to be changed to manage increasing impacts as required. The one exception is Thirlmere Lakes National Park, which does not have a monitoring program for impacts associated with visitor use.

Increased frequency of fires

NSW experienced extensive bushfires throughout the spring and summer of 2019-20. As of 3rd February 2020, the fires had burnt 5.37 million hectares of land (approximately 7 per cent of NSW). This includes 81 per cent of the Greater Blue Mountains World Heritage Area (DPIE, 2020). Of the fire affected national parks in NSW, 23 per cent were subject to full canopy damage, 36 per cent had partial canopy damage, and for 27 per cent the canopy was unburnt. Note that areas where the canopy was unburnt may have been affected by fire through the understorey (DPIE, 2020).

The full impact of the fires will not be understood for some time. However, the extent and intensity of the fires will have notably altered or diminished many of the attributes that contribute to OUV within the GBMWHA.

High frequency fire is identified as a key threatening process for all of the national parks in the GBMWHA.

Currently arson is the most common ignition source for bushfires in the Blue Mountains National Park and escaped campfires and burnoffs are also a significant source of fires (35 per cent and 9 per cent respectively) (Hammill & Tasker, 2010). The population increase in Western Sydney associated with the Plan could facilitate an increase in the number of deliberate or accidental fires in the GBMWHA and could increase overall fire frequency in the World Heritage area.

Fire regimes in the GBMWHA are also predicted to be affected by climate change. The recent NSW bushfires may have been exacerbated by climate change. Climate change modelling suggests that dangerous fire conditions will occur more often and over a longer season by 2050 (Hammill & Tasker, 2010). This has the potential to amplify the impacts of deliberate or accidental fires in the GBMWHA.

Potential impacts to Outstanding Universal Value and supporting values

Inappropriate fire regimes could notably diminish or alter all of the attributes that contribute to OUV within the GBMWHA. The risk to OUV from fires facilitated by the Plan depends on the location of the fires and their contribution to the broader fire regime. OUV is at risk from:

- Widespread fires in wet sclerophyll forest, especially where those fires burn the canopy
- Frequent (less than five to seven years apart), intense fires, especially where these fires are widespread or in ecosystems with a limited extent within the GBMWHA
- Any intense fires in highly sensitive areas (e.g. Wollemi pine habitat) or rainforest areas
- Intense or widespread fires in refugia areas (including rainforests, wetlands, swamps, and wet sclerophyll forests)

Impacts that notably diminish the integrity of the GBMWHA could result from:

- Frequent fires that degrade the condition of natural bushland in previously undisturbed areas or disrupt the structure and composition of plant communities
- Frequent, intense fires in drought conditions that degrade wetland and swamp environments that regulate water flow
- Fires that damage or degrade culturally sensitive areas

All of the supporting values of the GBMWHA are at risk from potential fires facilitated by the Plan, especially from:

- Fires that threaten visitor infrastructure, businesses or homes in or near the GBMWHA
- Fires that damage cultural or historical sites
- Widespread fires in water catchments, areas of scenic or aesthetic value

- Changes to OUV that follow from increased fire frequency and affect the research, bequest, and existence values of the GBMWHA

Impacts to the protection arrangements for the GBMWHA are not reasonably foreseeable.

Impacts that notably diminish OUV from potential fires facilitated by the Plan are only likely if they burn in sensitive areas or are intense fires that occur too frequently.

Existing management strategies

Fire frequency and intensity and the risk of accidental or deliberate fires are managed within the conservation reserves that make up the GBMWHA. Fuel loads are managed within the GBMWHA and, where appropriate and possible, fires are contained or extinguished to protect human life and property and biodiversity.

Under the Enhanced Bushfire Management Program, NSW NPWS plans to treat over 135,000 hectares per year in 800 or more hazard reduction activities across NSW, including within GBMWHA. Over 1,000 burns were carried out by NPWS in the last 5 years. Achieving this target is dependent on suitable weather conditions for burning safely and effectively.

Climate change is predicted to increase fire seasons and reduce these opportunities and NSW NPWS is continuing to adapt its fire management strategies to a changing climate (Hammill & Tasker, 2010).

The sections in the plans of management for each conservation reserve that discuss management of impacts from fire or monitoring of fire management practices are listed in Table 34-9.

Table 34-9: Management and monitoring of impacts from increased frequency of accidental fires

Conservation Reserve	Management of Impacts	Monitoring
Blue Mountains National Park	• s4.1.5 sets out the fire management policies and actions • The plan of management stands alongside the Blue Mountains National Park Reserve Fire Management Plan	• s4.1.5 and §4.3.10 prioritise research into fire behaviour and effects within the World Heritage area
Gardens of Stone National Park	• s4.1.5 sets out a range of fire management policies and actions to protect threatened species and fire sensitive areas • A fire management plan will be developed for the park	• s4.1.5 encourages research into fire ecology
Kanangra-Boyd National Park	• s4.1.4 sets out a range of fire management policies and actions to protect threatened species and fire sensitive areas • The plan of management stands alongside the Kanangra-Boyd National Park Fire Management Plan	• s4.1.4 encourages research into fire behaviour and ecology
Nattai National Park	• s4.1.4 sets out fire management policies and actions for the park	• s4.1.4 encourages research into fire behaviour and ecology
Thirlmere Lakes National Park	• s4.1.4 sets out fire management policies and actions for the park	• s4.1.4 commits to develop criteria for measure fire regime thresholds and review fire regimes annually
Wollemi National Park	• s4.1.5 sets out fire management policies and actions for the park	• s4.1.5 encourages research into fire behaviour and ecology

Conservation Reserve	Management of Impacts	Monitoring
Yengo National Park	• s4.1.5: NPWS will develop a fire management strategy for the Park including annual hazard reduction burns, assessment of neighbouring farm dams for fire management purposes, and maintenance of management trails	• s4.1.3: NPWS will undertake biodiversity surveys to improve fire management
Jenolan Caves Karst Conservation Reserve	• s3.5 includes policies and actions to manage the risk from accidental fires • s4.2 sets out a range of policies and actions to manage fire in the conservation reserve	• s4.2 includes commitments to monitor fire regimes and their impact on threatened flora

The discussion above shows that fires that could notably diminish OUV fall into two main categories:

- Individual fire events in sensitive areas
- Changes to fire regimes across the GBMWHA

It is possible that population growth associated with the Plan could facilitate an individual fire event that impacts OUV or its supporting values. However, the risk of deliberate or accidental fires in the GBMWHA in sensitive areas is already managed under the existing protection arrangements for the GBMWHA.

Impacts from potential changes to fire regimes across the GBMWHA are more difficult to assess.

Considered in isolation, it is possible that the risk of additional fires facilitated by the Plan could contribute to a broader change in fire regimes across the GBMWHA. This is unlikely and management of fire loads, management of visitor use, total fire bans, and policing of arson are already used to mitigate this risk. Existing monitoring and adaptive management programs are sufficient to manage any increase in this risk facilitated by the Plan.

Climate change is projected to increases the frequency of dangerous fire conditions and has the potential to amplify the impacts of deliberate or accidental fires in the GBMWHA. However, there are many ignition events from existing sources to start fires, and the Plan is unlikely to substantially increase these. It is considered that the existing protection arrangements for the GBMWHA are sufficient to manage the risk of increased fire frequency from the Plan.

Increased spread of introduced plants

A number of introduced plant species are already present in the GBMWHA. Introduced plants are listed as a key management challenge or important threatening process in some of the plans of management for the conservation reserves that make up the GBMWHA. Increased visitor use of the World Heritage area has the potential to introduce weed species or spread existing infestations to new areas.

Potential Impacts to Outstanding Universal Value and supporting values

The OUV attributes that support the GBMWHA's outstanding examples of eucalyptus diversification and evolution and diversity of habitats, ecological communities, and species could be notably diminished or altered by:

- Introduction and establishment of weeds in habitats for species and ecological communities that have a limited extent within the GBMWHA
- Infestation of sensitive habitats by introduced plants
- Introduction and establishment of weeds in large areas across the GBMWHA
- Introduction of weeds to highly sensitive areas (e.g. Wollemi pine habitat)

Impacts that notably diminish the integrity of the GBMWHA could result from:

- Spread of or establishment of new weed infestations in undisturbed areas
- Introduction of weeds to culturally sensitive areas

The impacts of introduced plants to the supporting values of the GBMWHA are likely to be limited. Notable impacts could result from:

- Infestation of wilderness areas or popular recreation areas by introduced plants
- Infestation of sensitive historic or cultural sites by weeds

Impacts to the protection arrangements for the GBMWHA are not reasonably foreseeable.

Introduced plants are only likely to notably alter or diminish the OUV or supporting values of the GBMWHA following the widespread introduction and establishment of weeds or new weed infestations in sensitive areas. Natural processes can also transfer weeds, which can amplify the impacts of human activity. In particular, weeds are often spread along watercourses. Introduction of weeds in new catchments or riparian corridors presents a greater risk to OUV.

Existing management strategies

All of the conservations reserves except for Thirlmere Lakes National Park note the presence of substantial weed infestations from a range of introduced plant species. These are typically in disturbed areas, areas of grazing land that have been incorporated into the conservation reserves, or along watercourses.

All the conservation reserves have plans to manage existing infestations or new outbreaks. The sections in each plan that deal with management and monitoring of introduced plants are given in Table 34-10.

Table 34-10: Management and monitoring of impacts from increased movement of disease and introduced plants

Conservation Reserve	Management of Impacts	Monitoring
Blue Mountains National Park	• s4.1.4 lists management policies and actions for introduced plants.	• s4.1.4 commits to develop an introduced species management database. • s4.3.10 gives priority to research into introduced species.
Gardens of Stone National Park	• s4.1.3 commits to manage introduced plants, with priority given to species that have a high capacity for dispersal.	• s4.1.3 commits to systematically survey introduced plants and monitor weed control programs.
Kanangra-Boyd National Park	• s4.1.3 lists management policies and actions for introduced plants.	• s4.1.3 commits to monitoring of introduced plant management activities.
Nattai National Park	• s4.1.2 commits to manage impacts from introduced plants. • s4.1.5 commits to implement control programs for introduced plants in wilderness areas.	• s4.3.3 prioritises research into management of introduced plants.
Thirlmere Lakes National Park	• s4.1.2 states that current levels of infestation in the park are low and sets out a range of priorities for control of introduced plants in the event of future outbreaks.	• s4.1.2 commits to develop a Pest Species Management Plan for the park.
Wollemi National Park	• s4.1.4 commits to manage impacts from introduced plants.	• s4.1.4 commits to monitor control programs for introduced plants.
Yengo National Park	• s4.1.4 commits NPWS to develop a program for control of weeds, consider strategic burning for Blackberry and other weeds, and survey and control infestations in the Macdonald River and Webbs Creek catchment.	• s4.1.3 commits NPWS to undertake biodiversity surveys to improve management of introduced plants. • s4.1.4 commits NPWS to undertake weed surveys and monitor weed control activities every 2 years.
Jenolan Caves Karst Conservation Reserve	• s4.1 sets out a range of actions and policies to manage introduced plants within the conservation reserve.	• s4.1 commits to monitor introduced plant control activity.

All of the plans of management for the conservation reserves within the GBMWHA include policies and actions to manage introduced plants. They all contain commitments to monitor weeds or encourage research into weeds. As visitor pressure on the conservation reserves increases, these monitoring commitments will be sufficient to ensure that management actions and policies can be altered as required.

Removal of bushrock and fallen timber

Bushrock is an important habitat feature for a range of flora and fauna in the GBMWHA. Its removal is identified as one of three key threatening processes in the Blue Mountains National Park Plan of Management (DECC, 2001). Bushrock removal impacts on habitat for a range of species within the World Heritage area and can increase erosion.

The plan of management for the Gardens of Stone National Park also lists illegal collection of fallen timber for firewood as a major threat to vegetation communities (DECC, 2009a). This potential impact is similar in its management and impacts to removal of bushrock and will be included in the discussion below.

Potential impacts to Outstanding Universal Value and supporting values

Collection of bushrock is unlikely to impact any attributes of OUV that relate to eucalyptus diversification and evolution in the GBMWHA. However, without appropriate management, bushrock removal could notably diminish or alter the attributes associated with outstanding diversity of species and ecological communities, especially through:

- Widespread bushrock removal or removal of bushrock or fallen timber from sensitive areas that impacts flora or fauna with a limited extent in the GBMWHA
- Bushrock removal in habitat for threatened species that are dependent on this habitat feature (e.g. the Broad-headed snake (DoE, 2014b))

Impacts that notably diminish the integrity of the GBMWHA are unlikely, but could result from:

- Extensive bushrock removal in undisturbed areas
- Intensive bushrock removal in sensitive areas that impacts the property's geological structure, geomorphology and water systems
- Bushrock removal in culturally sensitive areas

Impacts to supporting values from removal of bushrock are likely to be limited. Impacts could follow from:

- Disturbance of geological features in areas that contribute to the geodiversity of the GBMWHA
- Widespread removal of bushrock that leads to erosion in water catchments

Impacts to the protection arrangements for the GBMWHA are not reasonably foreseeable.

Impacts that notably diminish OUV from bushrock removal and firewood collection are only likely if they occur across many sites or in highly sensitive areas.

Existing management strategies

Bushrock removal is prohibited from all of the conservation reserves that make up the GBMWHA. Education and law enforcement has reduced the incidence of illegal bushrock removal, but the practise is still a problem in some easily accessible areas that are remote from management supervision (DECC, 2001). Illegal bushrock removal is managed under all of the plans of management for the conservation reserves that make up the World Heritage area. The relevant sections for management and monitoring of impacts are set out in Table 34-11.

Table 34-11: Management and monitoring of impacts from removal of bushrock

Conservation Reserve	Management of Impacts	Monitoring
Blue Mountains National Park	• s4.1.4: Commits to manage bushrock removal	• No specific commitment is made to monitor bushrock removal, but s4.3 commits to monitor a range of impacts at visitor facilities which could include bushrock removal.
Gardens of Stone National Park	• s4.1.2: Education programs in the local community will discourage collection of firewood and bushrock. Signage will be altered to note penalties associated with collection of firewood and bushrock.	• No commitment is made to monitor bushrock removal.
Kanangra-Boyd National Park	• Bushrock removal is not listed as management concern in the plan of management.	• The plan of management does not include monitoring of bushrock removal.
Nattai National Park	• Bushrock removal is associated with unauthorised vehicle access. §4.3.2 sets out a range of policies and actions to limit and manage unauthorised access.	• s4.3.2 commits to supervise and monitor four-wheel drive access.
Thirlmere Lakes National Park	• Bushrock removal is not listed as management concern in the plan of management.	• The plan of management does not include monitoring of bushrock removal.
Wollemi National Park	• s4.1.3 notes that bushrock is “managed reasonably well” within the park. No policies or actions are given for bushrock removal.	• The plan of management does not include monitoring of bushrock removal.
Yengo National Park	• s4.1.3: Notes bushrock removal as a significant threat to reptiles and amphibians in the park. Policies commit to maintain plant and animal diversity and distribution. • s4.1.1: Commits to manage unauthorised use of management trails – a key means of illegal bushrock removal.	• No specific commitments are made to monitor bushrock removal. However, commitments are made to monitor trail use (§4.3.3) and species distributions (§4.1.3) which will capture the main means of bushrock removal and its impacts.
Jenolan Caves Karst Conservation Reserve	• Bushrock removal is not listed as management concern in the plan of management.	• The plan of management does not include monitoring of bushrock removal.

Bushrock removal is recognised as a threatening process for a number of fauna species within the GBMWHA. It is managed in four of the eight conservation reserves within the GBMWHA. There is no commitment to monitor bushrock removal or the key activities that are associated with it (e.g. unauthorised vehicle access) at:

- Gardens of Stone National Park (although the plan of management includes bushrock removal management actions)
- Kanangra-Boyd National Park
- Thirlmere Lakes National Park
- Wollemi National Park
- Jenolan Caves Karst Conservation Reserve

Without appropriate monitoring for this threatening process across the World Heritage area, potential increases in bushrock removal associated with population growth in Western Sydney could impact on the OUV or the supporting values of the GBMWHA. Bushrock removal may not be a serious risk to these reserves, either because of the ecology and landscape of the reserve or the current patterns in visitor use. If visitor use of these reserves changes, it may be necessary to monitor bushrock removal to support best practice management of this threatening process.

Development and maintenance of new visitor facilities or increased maintenance of existing facilities

An increase in visitors to the World Heritage area will increase the demand for and maintenance requirements of a range of facilities and infrastructure, including:

- Information and interpretation centres or signage
- Camping and day use facilities
- Walking tracks
- Roads and parking areas
- Service trails
- Toilets and waste disposal facilities

Facilities and infrastructure are essential for appropriate and sustainable use of the GBMWHA and are often used to manage or mitigate other impacts from visitor use. However, the construction and maintenance of these structures or earthworks can lead to a range of impacts, including:

- Clearing
- Individual mortality
- Altered surface water hydrology and erosion
- Reduced water quality
- Fragmentation and edge effects

Development and maintenance activity in conservation reserves is often required to mitigate or manage impacts from visitor use. NSW NPWS do not have complete control over where development and maintenance activities are required, and these works may be necessary in sensitive areas within the GBMWHA.

Potential impacts to Outstanding Universal Value

Without appropriate management, the cumulative impacts from development and maintenance of visitor facilities could notably alter or diminish the OUV of the GBMWHA. Attributes of OUV that relate to the outstanding examples of eucalyptus diversification and evolution and the diversity of habitats, species and ecological communities could be notably impacted by:

- Impacts across many high-quality or important sites that support examples of eucalyptus diversification and evolution
- Intense impacts over large areas, or in important, sensitive areas especially habitats for species and ecological communities with a limited extent in the World Heritage area
- Any impacts to highly sensitive areas, including habitat for the Wollemi pine

Impacts that notably diminish the integrity of the GBMWHA are unlikely, but could result from:

- Widespread impacts in otherwise pristine environments
- Impacts to culturally sensitive areas

Development of additional visitor infrastructure is likely to have beneficial effects on many supporting values of the GBMWHA. Impacts could result from:

- Impacts in wilderness areas or water catchments
- Widespread impacts in areas of scenic or aesthetic value

Impacts to the protection arrangements for the GBMWHA are not reasonably foreseeable.

Impacts that notably diminish OUV from development and maintenance of visitor facilities are only likely if they occur across many important sites or in highly sensitive areas.

Existing management strategies

The plans of management for the conservation reserves that make up the GBMWHA include a range of measures to limit the impacts from the provision of visitor facilities. These range from limiting the development of new infrastructure to locating infrastructure in appropriate areas and managing impacts from maintenance work. Importantly, the plans of management include possible closures of areas that are subject to intense impacts from visitor use, which allows recovery of these areas without the need for substantial infrastructure. The plans of management also set out mitigation measures and controls to ensure that where new infrastructure is required it minimises impacts on the supporting values of the GBMWHA.

Table 34-12 gives the relevant sections within each plan of management for management and monitoring of impacts from visitor infrastructure.

Table 34-12: Management and monitoring of impacts from development or maintenance of visitor facilities

Conservation Reserve	Management of Impacts	Monitoring
Blue Mountains National Park	• s4.3 sets out a range of management actions and policies for new and existing visitor infrastructure.	• s4.3.10 sets out monitoring programs for impacts from management facilities and activities.
Gardens of Stone National Park	• s4.3.10 sets out a range of management actions and policies for new and existing visitor infrastructure.	• s4.3 commits to monitor a range of impacts associated with visitor infrastructure around the park.
Kanangra-Boyd National Park	• s4.3.12 sets out a range of management actions and policies for new and existing visitor infrastructure.	• s4.3 commits to monitor a range of impacts associated with visitor infrastructure around the park.
Nattai National Park	• s4.3.4 sets out management action and policies for new and existing visitor infrastructure.	• s4.3 commits to monitor a range of impacts associated with visitor infrastructure around the park.
Thirlmere Lakes National Park	• s4.3 sets out management action and policies for new and existing visitor infrastructure.	• The plan of management does not list actions or policies for monitoring of impacts from new or existing infrastructure.
Wollemi National Park	• s4.3.10 sets out a range of management actions and policies for new and existing visitor infrastructure.	• s4.3 commits to monitor a range of impacts associated with visitor infrastructure around the park.
Yengo National Park	• s4.3.8 sets out policies and actions to minimise impacts from management operations.	• s4.3.8 describes a range of long-term adaptive actions that including monitoring of impacts from management operations.
Jenolan Caves Karst Conservation Reserve	• s5.1 sets out policies and actions to minimise impacts from management operations.	• Table 5 in s3.5 sets out a range of monitoring processes for impacts associated with management activities.

All of the conservation reserves within the GBMWHA have actions and policies to manage impacts from new visitor facilities and maintenance of existing facilities. These actions and policies typically include commitments to review infrastructure needs and decommission or upgrade facilities as required. Appropriate monitoring or adaptive management commitments are made at all the conservation reserves except for Thirlmere Lakes National Park. While it is likely that the management arrangements at Thirlmere Lakes National Park are adequate, impacts from visitor use and increased maintenance or new development of visitor facilities and infrastructure should be monitored as appropriate to ensure that management measures can be adjusted to minimise impacts as visitor pressures increase.

34.2.6 CONSISTENCY WITH THE STRATEGIC PLAN

Neither the Plan nor its likely impacts will prevent the achievement of any of the objectives for management of the GBMWHA set out in the Strategic Plan. The likely effects of the Plan on each of the key management issues are discussed in Table 34-13.

Table 34-13: Impacts of the Plan on the management objectives for the GBMWHA

Key management issue and objectives	Likely impacts of the Plan
Integrity • To maintain, and wherever possible, improve the current and future integrity of the GBMWHA.	Current management and monitoring measures are considered sufficient to ensure that the Plan does not undermine or prevent future improvement of the integrity of the GBMWHA.
Major impacts • To reduce the potential for major impacts to adversely affect the integrity of the GBMWHA. Major impacts include mining adjacent to or underlying the GBMWHA, highway construction through the GBMWHA, or other development within or adjacent to the GBMWHA.	The Plan will not have major impacts on the GBMWHA and will not reduce the opportunities to manage or minimise major impacts from other projects.
Biodiversity • To conserve the GBMWHA's biodiversity and ensure the ecological viability and capacity for ongoing evolution of its World Heritage and other natural values is maintained.	Current management and monitoring measures are sufficient to ensure that the Plan does not appreciably impact the biodiversity or ecological viability of the GBMWHA.
Geodiversity • To protect the GBMWHA's geodiversity.	Current management and monitoring measures are sufficient to ensure that the Plan does not appreciably impact the geodiversity of the GBMWHA.
Water catchment protection • To maintain and improve the water quality and water catchment values of the GBMWHA.	Current management and monitoring measures are sufficient to ensure that the Plan does not appreciably impact water quality of the catchment values of the GBMWHA.
Cultural heritage • To identify, formally recognise and protect the cultural heritage values of the GBMWHA. • To manage the GBMWHA jointly with local Indigenous people.	Current management and monitoring measures are sufficient to ensure that the Plan does not appreciably impact cultural heritage values within the GBMWHA. The Plan will not affect joint management of the GBMWHA with local Indigenous people.
Landscape, natural beauty and aesthetic values • To protect the landscape, natural beauty and aesthetic values of the GBMWHA.	The Plan is anticipated to have minor visual impacts along part of the eastern fringe of the GBMWHA. These impacts will not appreciably affect the landscape, natural beauty or aesthetic values of the GBMWHA, which are located elsewhere in the World Heritage area.
Recreation and visitor use • To provide for an appropriate range of recreation and visitor use, consistent with the protection of World Heritage and related values.	The Plan is likely to increase visitor pressures on the GBMWHA. Current management and monitoring measures are sufficient to manage these impacts and ensure an appropriate range of recreation and visitor use opportunities.
Social and economic issues • Consistent with the protection of World Heritage and other values, optimise the potential and existing social and economic benefits derived from visitation to the GBMWHA.	The Plan is likely to enhance the social and economic benefits. Where impacts are possible (e.g. from increasing fire frequency), the current management and monitoring measures are sufficient to manage the risk to social and economic benefits.

Key management issue and objectives	Likely impacts of the Plan
Education, community participation and consultation • To encourage community stewardship of the GBMWHA through education, consultation and the provision of opportunities for community participation in its protection.	The Plan is not anticipated to affect this objective.

The desired outcomes have also been reviewed and found to be not inconsistent with the Plan. There are too many desired outcomes to warrant a detailed discussion here, but they are generally consistent with the objectives for each management issue and thus not affected by the Plan.

34.2.7 CONCLUSION

The potential facilitated impacts of the Plan on the GBMWHA are intensifications of existing threats that are already managed across the conservation reserves that make up the World Heritage area. The management plans for each of the reserves set out a range of management actions and monitoring programs that will support adaptive management of these threats over the life of the Plan. The protection arrangements for each of the conservation reserves and the GBMWHA as a whole are considered adequate to manage the potential facilitated impacts associated with the Plan.

The Plan will not prevent the achievement of any of the objectives or desired outcomes for the management of the GBMWHA set out in the Strategic Plan. It is not inconsistent with the Strategic Plan.

34.3 PARRAMATTA FEMALE FACTORY AND INSTITUTIONS PRECINCT

The Parramatta Female Factory and Institutions Precinct (the Precinct) is a National Heritage site whose values relate to the history of convict women and institutional care of women and children in Australia. It is located in North Parramatta, 13 km from the nearest urban capable land or transport corridor, and is unlikely to be impacted by the Plan.

34.3.1 DESCRIPTION OF THE PRECINCT

The Precinct is located between Fleet Street and the Parramatta river in North Parramatta (PFFPA, 2018). Its location is shown in Figure 34-3. The site covers 7.3 ha and contains a range of buildings from the early 19th to late 20th centuries. Some buildings are still occupied, while others are vacant and dilapidated. The site has served a range of purposes typically related to institutionalisation of women and children, including:

- The Parramatta Female Factory (1821-1847)
- The Parramatta Lunatic Asylum (under various names, 1847-1983)
- The Roman Catholic Orphanage (1844-1886)
- The Parramatta Girls Industrial School (1886-1974)
- The Norma Parker Centre (1974-2008) (DoEE, 2018b)

After several name changes, the site of the Parramatta Lunatic Asylum was renamed the Cumberland Hospital in 1983. The Cumberland Hospital and the NSW Institute of Psychiatry continue to operate at the site.

34.3.2 EPBC ACT APPROVAL CONSIDERATIONS

The Parramatta North Historic Sites Consolidated Conservation Management Plan (TKD Architects, 2017) meets the conditions of Section 146H of the EPBC Act for a plan of management for this National Heritage place. It sets out a range of principles for management of heritage values at the site. These principles prioritise:

- The need to understand, retain, protect and communicate heritage values at the site
- Application of best-practise heritage management guidelines including ensuring that works at the site are carried out by appropriately skilled and experienced people
- Community engagement in the management and care of the site

To meet the requirements of the EPBC Act, the Plan must not make it impossible to follow these principles or meet their aims.

34.3.3 HERITAGE VALUES

The Precinct meets three criteria for National Heritage listing:

- Criterion A Events, Processes
- Criterion B Rarity
- Criterion C Research

The Precinct provides insight into the experiences of women and children, particularly convict women, in institutions over 150 years of Australian history. It reflects government attitudes to vulnerable women and children and the role of institutions in the welfare system over 150 years. It is a physical locus of the stories of women and children who were institutionalised and whose experiences have often been dismissed or disbelieved (DoEE, 2018b).

There are limited examples of sites associated with convict women in Australia. Nine of 12 female factories have been completely demolished. The presence of original buildings and walls in the Precinct and its connection to the history of convict women and institutionalised women and children make the site outstandingly valuable to the nation (DoEE, 2018b).

Further archaeological study within and around the Precinct has the potential to reveal more about the lives of convict women and the history of institutional care (DoEE, 2018b).

The heritage values for the Precinct are expressed in the remaining physical fabric of the precinct including the buildings, grounds and walls of the Female Factory, Roman Catholic Orphanage, Parramatta Girls Industrial School, The Norma Parker Centre and the Cumberland Hospital (DoEE, 2018b).

34.3.4 POTENTIAL IMPACTS FROM THE PLAN

The Precinct is over 13 km from the urban capable land or transport corridors in an existing urban area. Its heritage values are expressed in structures and areas that are unlikely to be susceptible to indirect or facilitated impacts. It is unlikely that there will be any impacts to the National Heritage values of the Precinct as a result of implementation of the Plan. The Plan will not prevent the application of any of the principles from the management plan for this National Heritage place, nor will it prevent the management plan from achieving its aims.

34.3.5 CONCLUSION

There are unlikely to be any notable impacts to the National Heritage values of the Parramatta Female Factory and Institutions Precinct as a result of the Plan. The Plan is not inconsistent with the plan of management for National Heritage values at this site.

34.4 OLD GOVERNMENT HOUSE AND THE GOVERNMENT DOMAIN

Old Government House and the Government Domain is World and National Heritage place in North Parramatta. Its buildings and open spaces played a role in the early government and agriculture of colonial Australia and have been recognised as having heritage value (DoEE, 2018b). The site is over 12 km from the nearest urban capable land or transport corridor and unlikely to be impacted by the Plan.

34.4.1 DESCRIPTION OF THE HERITAGE PLACE

The Government Domain covers an area of 85 ha and contains buildings, memorials, relics, historic plantings, and archaeological sites. It is mostly made up of open, grassy areas and includes patches of native vegetation. These open spaces were the site of early colonial agriculture including some of the first successful crops in Australia (DoEE, 2018b). Its location is shown in Figure 34-3.

Situated at the southern end of the Government Domain, Old Government House is the site of the first governor's residence in Parramatta. The first governor's cottage was constructed in 1790 and the house and its surrounding buildings were variously extended, renovated and replaced over the next 65 years. The house ceased to be used as an official residence, fell into disrepair, and was leased out in 1856. It was extensively restored and renovated in 1909 when the building was repurposed as a school. It was acquired by the National Trust in 1967, which has undertaken a range of restoration works to return the house to the configuration that was used by Governor Macquarie. The house and surrounding grounds is now used as a museum (DoEE, 2018b).

34.4.2 EPBC ACT APPROVAL CONSIDERATIONS

The key management document for this World Heritage property is the Old Government House and Domain, Parramatta Park Management Plan (PPT, 2009). This document serves as a management plan under Section 146G of the EPBC Act.

The management plan sets out a range of policies for management of World Heritage and National Heritage values at the site. Summarised, these policies have the following objectives:

- Manage the landscape, buildings, and other structures at the site to conserve their historical values, ensuring maintenance, new works and repairs maintain or restore the historical character of the site
- Ensure the Government Domain grounds are primarily used for recreation, sport and entertainment, and that use of Old Government House enhances and facilitates understanding of its history and significance
- Restore, protect and maintain natural systems within the site
- Maintain historical views and the infrastructure at and around the site to preserve the character of the site
- Promote and enable research at the site

To meet the requirements of the EPBC Act, the Plan must not prevent the achievement of any of these objectives.

34.4.3 HERITAGE VALUES

Old Government House and the Government Domain meets four criteria for National Heritage listing:

- Criterion A Events, Processes
- Criterion C Research
- Criterion D Principal characteristics of a class of places
- Criterion H Significant people (DoEE, 2018b)

It is also one of 11 convict sites across Australia that are jointly listed as a World Heritage place, under two criteria:

- Criterion (iv): recognising the importance of these buildings to the system of deportation and forced labour that contributed to the British Empire's colonial project
- Criterion (vi): recognising that these sites are an outstanding example of the transportation of convicts to colonial lands and reflect the history of attitudes to penal, political and colonial systems in contemporary and modern Europe. (UNESCO, 2018a)

The site is a tangible link with the earliest days of colonial history in Australia which has been recognised as having outstanding heritage value for all Australians. Old Government House is the oldest surviving public building in mainland Australia and contains:

- Brick floors from the 1790 cottage of Governor Phillip
- Rooms dated to 1799, constructed by order of Governor Hunter
- Rooms dated to 1818, constructed by order of Governor Macquarie (DoEE, 2018b)

The house, surrounding buildings, relics and open areas are examples of convict workplaces and important sites in the foundation of British settlement in Australia. These areas have the potential to yield further insight through archaeological research (DoEE, 2018b).

The Government Domain contains historic agricultural areas (an area called "the Crescent"), a dairy, a bathhouse, a Boer War Memorial, carriageways and gatehouses, and the remains of Governor Brisbane's astronomical observatory. These elements reflect Australia's development from a penal colony dependant on Great Britain to a self-governing nation. Old Government House provides evidence of the development of early administration in the colony (DoEE, 2018b).

Old Government House and the Government Domain provide a connection to the life and work of Australia's early colonial governors. The house and surrounding buildings provide insight into Governors Phillip, Hunter, King, Macquarie, and Brisbane, who all lived and worked at the site (DoEE, 2018b).

34.4.4 POTENTIAL IMPACTS FROM THE PLAN

Old Government House and the Government Domain is over 12 km from the urban capable land or transport corridors in an existing urban area. Its heritage values are expressed in structures and areas that are unlikely to be susceptible to indirect or facilitated impacts.

The *Conservation Agreement for the protection and conservation of the World Heritage Values and National Heritage Values of the Australian Convict Sites, Old Government House and Domain, Parramatta New South Wales* notes possibility of impacts to the landscape values of the sites from development in nearby urban areas (DoE, 2013a), but the urban capable land and transport corridors are well outside the range of possible visual impacts.

It is unlikely that there will be any impacts to the National Heritage values of Old Government House and the Government Domain as a result of the Plan. The Plan will not prevent the achievement of any of the objectives from the management plan for this property.

34.4.5 CONCLUSION

There are unlikely to be notable impacts to the World or National Heritage values of Old Government House and the Government Domain as a result of the Plan. The outcomes of the Plan are not inconsistent with the management plan for the property.

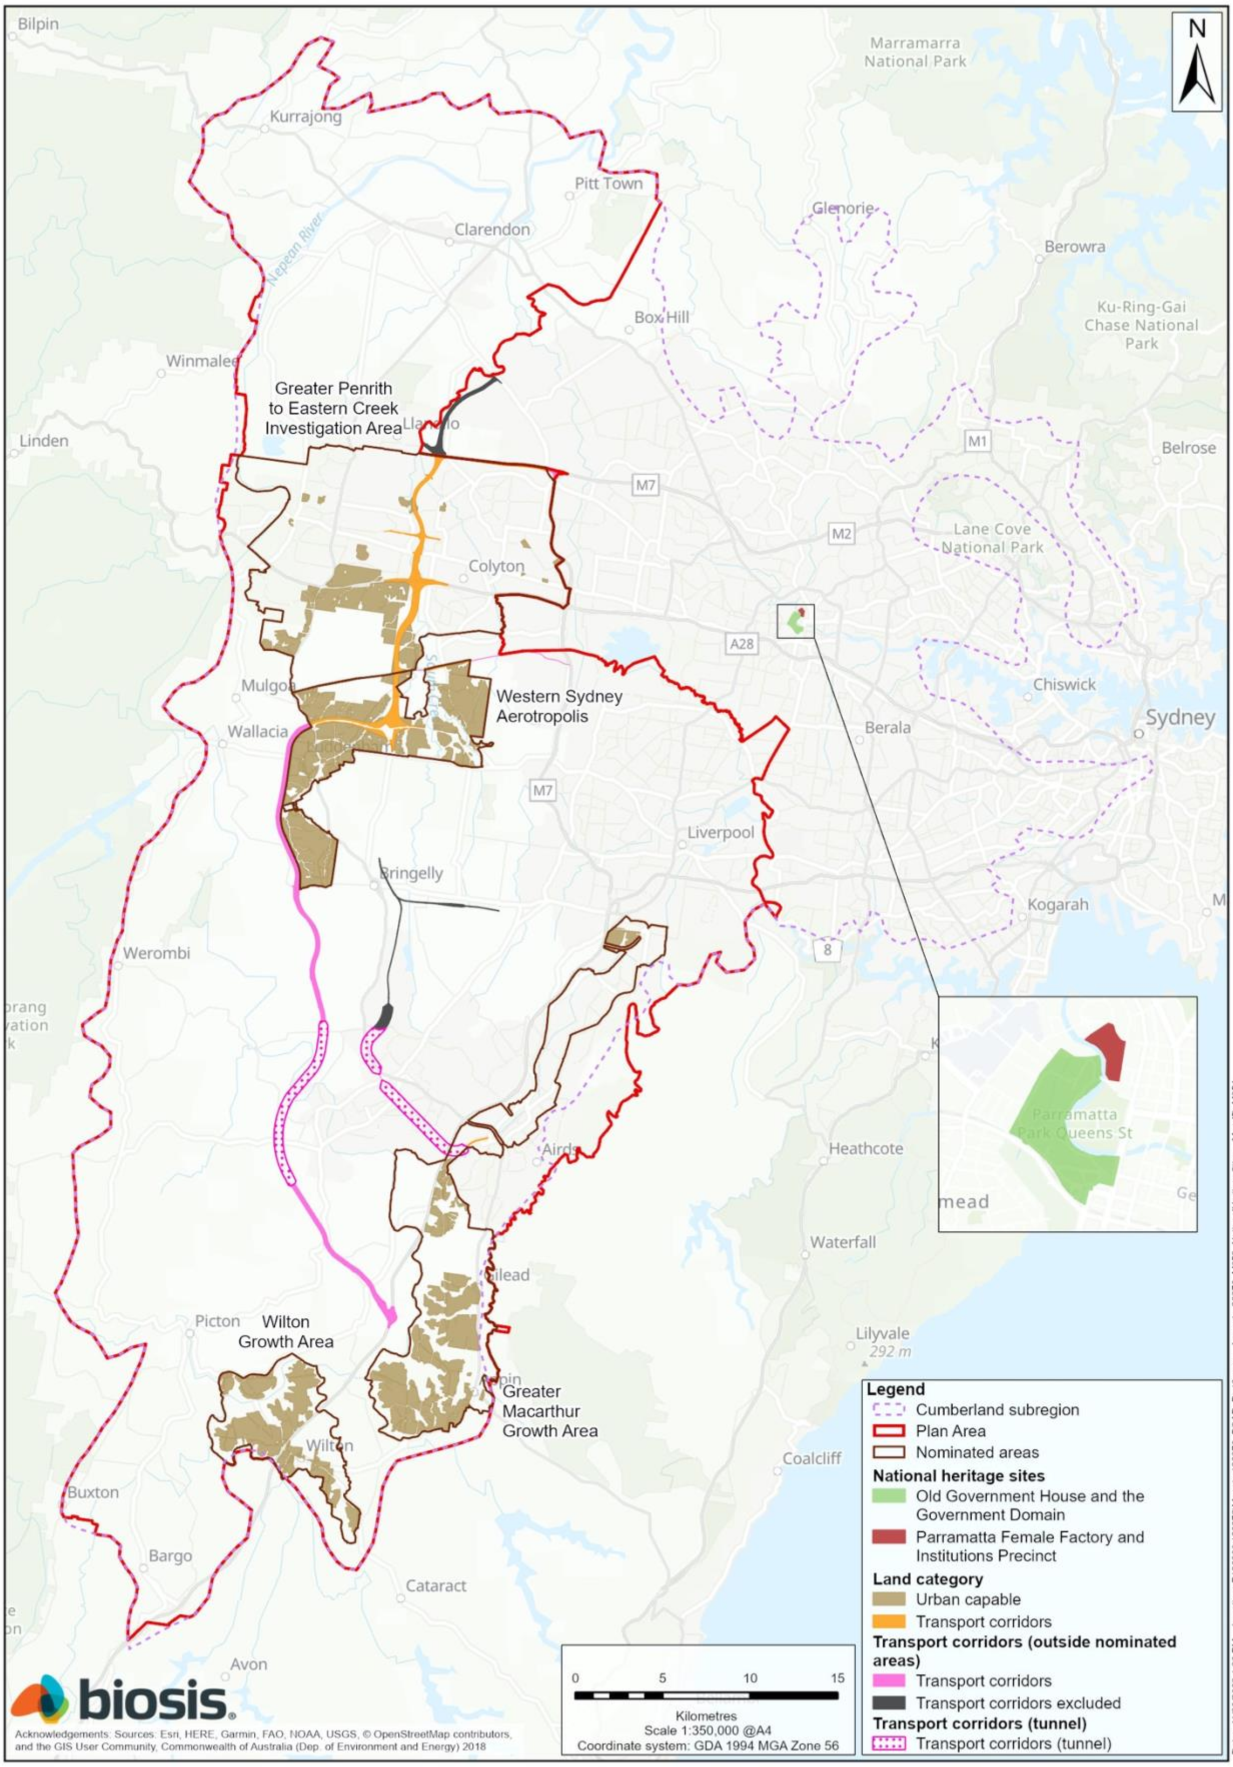

Figure 34-3: The location of Parramatta Female Factory and Institutions Precinct, Old Government House and the Government Domain

35 Commonwealth land impact assessment

35.1 INTRODUCTION

Commonwealth land is a matter protected under Section 26 of the EPBC Act. There are 12 known Commonwealth land sites within the Strategic Assessment Area (see Map 54.1), excluding Shanes Park.

This Chapter provides an assessment of potential impacts to the environment on this land from the urban and industrial, infrastructure, agribusiness and transport development under the Plan.

The impact assessment has been based on desktop information and framed around the Commonwealth's *Significant Impact Guidelines 1.2 – Actions on, or impacting upon, Commonwealth land and Actions by Commonwealth Agencies* (DSEWPC, 2013). The assessment provides an understanding of the range of environmental values on each site.

Three of the 12 Commonwealth land sites occur within the nominated areas:

- Site 3 in GPEC
- Site 4 in GMAC
- Site 5 in GPEC

None of these sites will be directly impacted by urban, industrial, infrastructure or agribusiness development.[2]

Potentially only one site (Site 10) will be directly impacted by development – by the transport corridors outside the nominated areas. However, three other sites – Site 4 (Western Sydney University), Site 6 (Camden Airport) and Site 7 (a small site at Grassmere) – may also be directly impacted by the tunnels associated with the transport corridors. The tunnels extend under these sites and some disturbance to the land surface within these sites may be necessary for construction activities and permanent infrastructure.

While all Commonwealth sites are potentially at risk from indirect and facilitated impacts, the likelihood of many of these impacts varies significantly between sites, and this largely depends on each sites proximity to the urban capable land and transport corridors in the context of that impact. For example, construction of the development is very unlikely to cause any indirect impacts to Commonwealth sites that are distant (many km) from construction areas.

35.1.1 SHANES PARK

Shanes Park is currently Commonwealth land that occurs along the northern boundary of GPEC (north of Willmot). The M7/Ropes Crossing Link Road will directly impact approximately 4.7 hectares of native vegetation in Shanes Park, comprising Commonwealth-listed Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest.

The NSW Government is currently in the process of finalising a Deed of Transfer with the Australian Government which will transfer the land to the NSW Minister for Environment. It is anticipated that this transfer will occur in the coming months. The impacts on TECs and species within Shanes Park are addressed in Chapters 29, 30 and 31.

---

[2] For three of these sites, GIS analysis suggests there are very small direct impacts, as follows:

- Site 4 – 0.3 ha along the southern boundary of the site
- Site 5 – 0.001 ha along the northern and eastern boundary of the site
- Site 8 – 0.1 ha along the northern and western boundaries of the site

Inspection of aerial photos and cadastre boundaries shows that there are slight errors with the GIS spatial data of the boundaries of the urban capable land and transport corridors in these areas and direct impacts will not occur to these sites.

35.2 ASSESSMENT APPROACH

35.2.1 COMMONWEALTH ASSESSMENT CRITERIA

There are 12 Commonwealth land sites in the Strategic Assessment Area, excluding Shanes Park.

Under the EPBC Act, an assessment of impacts to Commonwealth land needs to consider the whole of the environment, which is much broader than MNES. Environment in this context is defined under Section 528 to include:

- Ecosystems and their constituent parts, including people and communities; and
- Natural and physical resources; and
- The qualities and characteristics of locations, places and areas; and
- Heritage values of places; and
- The social, economic and cultural aspects of a thing mentioned in paragraph (a), (b), (c) or (d).

Direct, indirect and facilitated impacts have been assessed for the 12 Commonwealth land sites in the Strategic Assessment Area using the Commonwealth's *Significant Impact Guidelines 1.2* (DSEWPC, 2013). The sites have been described and assessed against the list of matters required to be considered in the guidelines, including:

- Landscapes and soils
- Water resources
- Biodiversity values – vegetation and plant and animal species
- Conservation and special use areas
- Heritage values
- Services and infrastructure/people and communities

35.2.2 DATA SOURCES

The assessment in this Chapter is based on the desktop information outlined in Table 35-1. Profiles for each of the 12 Commonwealth land sites have been generated from this information (see sections 35.3 to 35.3.12).

The limitations in the data for Commonwealth land are similar to the limitations for the Assessment Report generally (see Chapter 13). Key limitations include:

- Ground truthing was not generally undertaken as part of the impact assessment for Commonwealth land
- Impacts on species are based on potential habitat mapping (the Knowledge-Based Method (KBM) and Species Distribution Model (SDM) methods), which are likely to over-predict the extent of actual habitat

Table 35-1: Data sources for the Commonwealth land assessment

Data type	Data source
General	• Unclipped spatial data of Commonwealth land in Strategic Assessment Area provided by the Commonwealth of Australia • Existing reports and statutory documents such as the Biodiversity Offset Delivery Plan for Western Sydney, Liverpool Biodiversity Management Plan, Holsworthy MUR Project, Western Sydney Airport EIS, Local Environmental Plans • Information generated as part of the broader strategic assessment for MNES, including species habitat mapping across the Cumberland subregion, Strategic Assessment Area boundary, and the urban capable land and transport corridors
Soils	• Area of soil landscapes from eSPADE v2.0 (OEH, 2018a).
Waterways and topography	• Mapped watercourses and waterbodies in NSW from the *Water Management (General) Regulation 2018* hydroline spatial data 1.0

Data type	Data source
Vegetation	• Vegetation mapping for this project: o Vegetation mapping for this project within the nominated areas (Biosis 2018) o EPBC TEC mapping for this project across the Cumberland subregion (Biosis 2019) • Existing vegetation mapping: o Remnant Vegetation of the Western Cumberland Subregion 2013 Update VIS_ID 4207 (OEH 2013) o The Native Vegetation of the Sydney Metropolitan Area VIS_ID 4489 (OEH 2016)
Fauna and flora	• Threatened flora and fauna records from Atlas of NSW Wildlife (BioNet) • Important populations spatial data provided by Biosis and created from BioNet records • Commonwealth SPRAT database • NSW Threatened Species Profiles • OEH Threatened Biodiversity Data Collection • Recovery plans and conservation advices
Heritage	• World, Commonwealth and National heritage list and Register for the National Estate information from the Australian Heritage Database • NSW Heritage information from the Office of Environment and Heritage website • World, Commonwealth, and National heritage list spatial data from the Department of Environment and Energy database • Register for the National Estate (non-statutory) spatial data from the Department of Environment and Energy database • State Heritage Register (curtilages & centroids) from the NSW SEED database
Landscape context	• Area of priority conservation lands (PCLs) from the NSW SEED database • Area of core and corridors from the Biodiversity Investment Opportunities Map (BIO Map)

35.3 ASSESSMENT OF IMPACTS TO EACH SITE

35.3.1 SITE 1 (RAAF TRANSMITTING STATION)

PROFILE

SITE DETAILS	
Owner	The Commonwealth of Australia
Site name	RAAF Transmitting Station
Site ID number	1
Area	63.3 ha
Address	419-499 Londonderry Road, Londonderry NSW
Folio	1/598180, 1/91240
General description	Site 1 is located at 419-499 Londonderry Road, Londonderry. Based on available information, the site has limited ecological value. A main building with four smaller outhouses is located in the south-west corner of the site. It is located within the Strategic Assessment Area approximately 50 km north-west of the Sydney CBD
Site map	The location of Site 1 is shown in Map 54.2

DISTANCE FROM URBAN CAPABLE LANDS/ TRANSPORT CORRIDORS

Site 1 is located approximately 9 km from the nearest development under the Plan

LANDSCAPES AND LANDFORMS

The site occurs in a gently undulating low rise landscape on Tertiary terraces of Hawkesbury-Nepean River system

SOIL AND SUBSTRATES

The soil landscape is made up of Berkshire Park soil. Berkshire Park soil consists of heavy clays and clayey sands that are made up of less than a third of soil aggregates (OEH, 2018a)

WATER

The site has a first order watercourse that flows from north-south through the north-east corner of the site. It is a tributary of Rickabys Creek (DoI, 2019; DTA, DCA et al., 2019)

The site occurs within the Hawkesbury-Nepean catchment. Water quality is variable throughout the area. The majority of the upper reaches of streams and rivers are healthy, while downstream reaches are affected by historical land uses (e.g. clearing, urbanisation) (GES, 2018)

VEGETATION

The site is largely unvegetated other than a narrow strip of vegetation that forms part of a riparian corridor, connecting with larger areas of vegetation to the north and east of the site

Approximately 1 ha (or 1.7 per cent of the site) has been mapped as native vegetation

Plant Community Types (PCTs)/NSW listed threatened ecological communities (TECs)

PCT number	PCT name	NSW TEC name	BC Act status	Area (ha)
724	Broad-leaved Ironbark – Grey Box – Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion	Shale Gravel Transition Forest in the Sydney Basin Bioregion	Endangered	0.3
725	Broad-leaved Ironbark – Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion	Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion	Endangered	0.0
883	Hard-leaved Scribbly Gum – Parramatta Red Gum healthy woodland of the Cumberland Plain, Sydney Basin Bioregion	Castlereagh Scribbly Gum Woodland in the Sydney Basin Bioregion Castlereagh Swamp Woodland Community	Vulnerable Endangered	0.4
1067	Parramatta Red Gum on moist alluvium of the Cumberland Plain, Sydney Basin Bioregion	Castlereagh Swamp Woodland Community	Endangered	0.4

Commonwealth listed threatened ecological communities (TECs)

Commonwealth TEC name	EPBC Act status	Area (ha)
Castlereagh Scribbly Gum and Agnes Banks Woodlands of the Sydney Basin Bioregion	Endangered	0.1
Cooks River/Castlereagh Ironbark Forest of the Sydney Basin Bioregion	Critically Endangered	<0.1
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest	Critically Endangered	0.2

Threatened flora species			
Name	**EPBC Act or BC Act status**	**Area of potential habitat (ha)**	**Number of BioNet records**
Dillwynia tenuifolia	Vulnerable (BC Act)	0.0	1
Persoonia nutans (Nodding Geebung)	Endangered (BC Act & EPBC Act)	63.3	1
Acacia bynoeana (Bynoe's Wattle)	Vulnerable (BC Act) Endangered (EPBC Act)	56.1	0
Micromyrtus minutiflora	Endangered (BC Act) Vulnerable (EPBC Act	63.3	0
Persoonia hirsuta (Hairy Geebung)	Endangered (BC Act & EPBC Act)	0.6	0
Pimelea spicata (Spiked Rice-flower)	Endangered (BC Act & EPBC Act)	1.4	0
Pomaderris brunnea (Brown Pomaderris)	Endangered (BC Act) Vulnerable (EPBC Act)	0.4	0
Pultenaea parviflora	Endangered (BC Act) Vulnerable (EPBC Act)	21.8	0
BIO Map Priority Investment Areas			
No BIO Map core or corridor areas have been identified on this site			
ANIMAL SPECIES			
There is one threatened species record known from the site – Cumberland Plain Land Snail			
Threatened fauna species			
Name	**EPBC Act or BC Act status**	**Area of potential habitat (ha)**	**Number of BioNet records**
Litoria aurea (Green and Golden Bell Frog)	Endangered (BC Act) Vulnerable (EPBC Act)	7.9	0
Pommerhelix duralensis (Dural Land Snail)	Endangered (BC Act & EPBC Act)	49.3	0
Pteropus poliocephalus (Grey-headed Flying-fox)	Vulnerable (BC Act & EPBC Act)	0.1	0
Petauroides volans (Greater Glider)	Vulnerable (EPBC Act)	0.8	0
Anthochaera phrygia (Regent Honeyeater)	Critically Endangered (BC Act & EPBC Act)	1.1	0
Dasyurus maculatus maculatus (Spot-tailed Quoll)	Vulnerable (BC Act) Endangered (EPBC Act)	0.8	0
Lathamus discolor (Swift Parrot)	Endangered (BC Act) Critically Endangered (EPBC Act)	1.1	0
Meridolum corneovirens (Cumberland Plain Land Snail)	Endangered (BC Act)	0.0	1
CONSERVATION AND SPECIAL USE AREAS			
There are no conservation or special use areas present on this site The closest conservation or special use areas are: • Western Sydney University EucFACE experiment site (approximately 1.4km north) • Agnes Banks Nature Reserve (approximately 3km west) • Castlereagh Nature Reserve (approximately 3km south)			

HERITAGE PLACES AND ITEMS
It is not known whether the site has any historic or indigenous heritage values. The site is not listed in the Australian Heritage Database as having heritage values
SERVICES AND INFRASTRUCTURE/PEOPLE AND COMMUNITIES
The site is a former RAAF transmitting station and appears to be no longer in use Medium density urban housing borders the southern edge of the site, while low density rural lots border the north, east and part of the western edge of the site No mining or petroleum tenements exist on this site (NNTT, 2020) No Native Title Claims exist over this site (NNTT, 2020)

IMPACT ASSESSMENT

Direct impacts

There will be no direct impacts to Site 1 due to the Plan.

Indirect and facilitated impacts

Site 1 occurs approximately 9 km from the nearest development under the Plan – urban and industrial development and transport development within GPEC. The site is also located upstream of the nearest development and within a separate sub-catchment. The location of the site relative to the development means:

- The site is very unlikely to be impacted by impacts typically associated with construction of the development in GPEC, such as air quality, noise, construction traffic, or the spread of weeds or disease
- The site will not be impacted by soil erosion of sedimentation, changes to surface and groundwater quantity and flows, or water quality impacts associated with the construction and operation of the development

Furthermore, the site no longer appears to be in use. If this is the case, the development would not disrupt any services or infrastructure or affect the health or safety of any person associated with the site.

The potential indirect or facilitated impacts associated with the development in GPEC and the key values of the environment of Site 1 that are potentially impacted are shown in Table 35-2.

Table 35-2: Potential indirect impacts on Site 1 associated with the development

Potential indirect impact	Extent within site 1	Duration	Values of site potentially impacted
Construction			
Clearing of habitat during construction of the development that links the site to other areas of habitat, leading to impacts on biodiversity values	Whole of site	Long term	Biodiversity values

Biodiversity values

There is a small amount of potential habitat for native species at Site 1, primarily associated with the riparian corridor on the site. This riparian corridor is connected to vegetation within the surrounding area and also to the Hawkesbury River.

The connectivity of this riparian corridor to the surrounding area will not be directly impacted by development under the Plan, and therefore the habitat values of the site are unlikely to be impacted indirectly by the Plan.

Commitments and mitigation measures

No commitments or mitigation measures are considered necessary to address the potential indirect impacts on the environment of Site 1 from the development under the Plan.

35.3.2 SITE 2 (RICHMOND AIR BASE)

PROFILE

SITE DETAILS	
Owner	The Commonwealth of Australia
Site name	RAAF Richmond Air Base and surrounding area
Site ID number	2
Area	379.1 ha
Address	115 Dight St, Richmond NSW 5 Wood St, Richmond NSW 24-162 Percival St, Clarendon NSW
Folio	197/824047, 2/90072, 196/824045, 1/616709, 5-67244683, 11-13/563483, 1-3/572977
General description	Site 2 is made up of several lots of land located adjacent to each other at the addresses given above. Approximately 1.2 per cent of the site is covered by vegetation. The southern part of the site is comprised of a landing strip with aeroplane hangars and other smaller buildings located towards the north east of the site. The part of the site located on Percival street appears to mostly comprise exotic grassland with a few buildings located in the north west corner The site is used as a Royal Australian Airforce (RAAF) base. It is located approximately 47 km north-west of the Sydney CBD, within the Strategic Assessment Area
Site map	The location of Site 2 is shown in Map 54.3
DISTANCE FROM URBAN CAPABLE LANDS/ TRANSPORT CORRIDORS	
Site 2 is located over 12 km from the nearest development under the Plan	
LANDSCAPES AND LANDFORMS	
The site is mostly flat and occurs on the terraces and floodplain of the Nepean River	
SOIL AND SUBSTRATES	
The soil landscape of Site 2 is made up of: • 86 ha of Freemans Reach soil – Freemans Reach soil consists of deep brown sands and loams on the active floodplain of the Nepean River • 293 ha of Richmond soil – Richmond soils consist of orange to red clay loams, clays, and sands that are poorly structured (OEH, 2018a) • < 1 ha of Upper Castlereagh soil – Upper Castlereagh soil consists of apedal sandy clay loam or fine sandy clay loam overlying light medium clay	
WATER	
The site is bordered by bordered on the eastern side by Rickabys Creek, a minor perennial creek. Two canal lanes occur in the east of the site and drain into Rickabys Creek The site occurs within the Hawkesbury-Nepean catchment. Water quality is variable throughout the area. The majority of the upper reaches of streams and rivers are healthy, while downstream reaches are affected by historical land uses (e.g. clearing, urbanisation) (GES, 2018)	
VEGETATION	
There is 5 ha of native vegetation on the site and the vegetation is relatively isolated from other areas of vegetation

Glossopsitta pusilla (Little Lorikeet)	Vulnerable (BC Act)	0.0	1

CONSERVATION AND SPECIAL USE AREAS

There are no conservation or special use areas present on this site

The closest conservation or special use areas are:

- Windsor Downs Nature Reserve (approximately 3.5 km south)
- Pitt Town Nature Reserve (approximately 4.5 km north east)

HERITAGE PLACES AND ITEMS

A large part of the site is listed as a historic place on the Commonwealth Heritage List (place ID 105653) and is also registered as a historic place on the Register of the National Estate (non-statutory) (place ID 102845) as *RAAF Base Richmond*. The site meets six of the nine Commonwealth Heritage List listing criteria:

- Criterion A (Process): the site is associated with a number of events and cultural phases that have been significant in the development of the Royal Australian Air force (DoEE, 2018a)
- Criterion B (Rarity): the site demonstrates the design and construction of Australia's first purpose built military air force base under British influences in the 1930s (DoEE, 2018a)
- Criterion D (Characteristic value): the site includes features that demonstrates the principal characteristics (design, layout, architectural style) of the first purpose built military air force base under British influences in the 1930s (DoEE, 2018a)
- Criterion E (Aesthetic characteristics): parts of the site are valued in the wider community for its cultural, aesthetic and social associations (DoEE, 2018a)
- Criterion F (Technical achievement): the site illustrates the achievements of the Commonwealth architectural staff in the 1930s (DoEE, 2018a)
- Criterion G (Social value): parts of the site are valued in the wider community for its cultural, aesthetic and social associations (DoEE, 2018a)

It is not known whether the site has any other historic or indigenous heritage values. The site is not listed in the Australian Heritage Database as having other heritage values

SERVICES AND INFRASTRUCTURE/PEOPLE AND COMMUNITIES
The site is an RAAF air base. It operates the majority of the RAAFs fixed wing aircraft. It includes a single 2,134 m runway. The base includes the headquarters building of the 36th and 37th Squadron. The base also serves as the headquarters for the Air Lift Group, and houses the following wing units: No. 84 Wing (air-to-air refuelling), No. 86, No. 37 (transport), No.44 (air traffic control), No. 1 (combat communication), No. 22 (air force reserve), No. 87 (photography), No. 285 (flight simulator) and No. 3 (combat support hospital). No mining or petroleum tenements exist on this site (NNTT, 2020) No Native Title Claims exist over this site (NNTT, 2020)

Impact assessment

Direct impacts

There will be no direct impacts to Site 2 due to the Plan.

Indirect and facilitated impacts

Site 2 occurs over 12 km from the nearest development under the Plan – urban and industrial development and transport development within GPEC. The site is also located upstream of the nearest development and within a separate sub-catchment. The location of the site relative to the development means:

- The site is very unlikely to be impacted by impacts typically associated with construction of the development in GPEC, such as air quality, noise, construction traffic, or the spread of weeds or disease
- The site will not be impacted by soil erosion of sedimentation, changes to surface and groundwater quantity and flows, or water quality impacts associated with the construction and operation of the development

The potential indirect or facilitated impacts associated with the development under the Plan and the key values of the environment of Site 2 that are potentially impacted are shown in Table 35-3.

Table 35-3: Potential indirect impacts on Site 2 associated with the development

Potential indirect impact	Extent within site 1	Duration	Values of site potentially impacted
Construction			
Clearing of habitat during construction of the development that links the site to other areas of habitat, leading to impacts on biodiversity values	Whole of site	Long term	Biodiversity values
Operation			
Disruption to land uses, services or infrastructure	Whole of site	Long term	People and communities

Biodiversity values

Although Site 2 is mostly cleared, there are small areas of vegetation present which provide some habitat values for several species, including two species of threatened birds. It is likely that some common, urban-adapted native fauna species inhabit or move through the site, based on the presence of PCTs and condition/quality of the vegetation.

Approximately 2 ha of vegetation on the site is part of a BioMap corridor (OEH, 2015) and is therefore considered to be important for landscape connectivity in the region. The main connectivity from the site to other areas of habitat comprises the riparian corridor associated with the Hawkesbury River. The site is also marginally connected to Castlereagh Nature Reserve to the south along Rickabys Creek.

The development under the Plan will not disrupt these two main habitat connectivity links from the site to the surrounding area, and therefore the habitat values of the site are unlikely to be impacted indirectly by the Plan.

People and communities

Increased populations associated with urban development under the Plan has the potential to disrupt the services provided by the site as a RAAF base due to:

- The potential need to reduce noise impacts from aircraft in new residual areas
- Increased pressure on roads, transport and other infrastructure that service site 1

These potential indirect impacts are considered unlikely.

Many existing urban areas surround Site 2, including the University of Western Sydney Hawkesbury campus, and the site already has in place policies and procedures to minimise noise to surrounding urban areas (Department of Defence, 2020b). The majority of the flying training occurs in designated training areas to the north west of the base. These areas are situated predominantly over semi-rural, rural and farming areas of the Blue Mountains region minimising the time that aircraft spend over residential areas (Department of Defence, 2020b). Noise modelling shows the areas most affected by aircraft noise (Australian Noise Exposure Forecast levels > 20) are limited to areas in the vicinity of the site and distant from the nearest urban development in GPEC (Department of Defence, 2020a).

The Plan addresses the issue of increased pressure on roads, transport and other infrastructure that service Site 2 to some extent by supporting the delivery of major transport projects for Western Sydney. It is also expected that future transport and other infrastructure needs will be further provided for through future planning processes.

Commitments and mitigation measures

No commitments or mitigation measures are considered necessary to address the potential indirect impacts on the environment of Site 2 from the development under the Plan.

35.3.3 SITE 3 (PENRITH TRAINING DEPOT)

Profile

SITE DETAILS	
Owner	The Commonwealth of Australia
Site name	Penrith Training Depot
Site ID number	3
Area	3.7 ha
Address	10 The Crescent, Penrith NSW
Folio	10/1159973
General description	This site is the Penrith Training Depot that houses a sub-unit of the 5th Combat Engineer Squadron. The site is located at 10 The Crescent, Penrith NSW. The site is mostly unvegetated and comprises five groups of buildings. A rail corridor borders the southern side of the site. The site is located in the Strategic Assessment Area in Penrith, approximately 50 km north-west of the Sydney CBD
Site map	The location of Site 3 is shown in Map 54.4
DISTANCE FROM URBAN CAPABLE LANDS/ TRANSPORT CORRIDORS	
Site 3 is located approximately 0.8 km from nearest development under the Plan. Site 3 is surrounded by large areas of existing urban and/or commercial development and is not directly connected to any substantial vegetation corridors or habitat patches	
LANDSCAPES AND LANDFORMS	
The site occurs mainly in a flat landscape the Quaternary terraces of the Nepean and Georges River with a small area of the site transitioning to undulating rolling low hills	
SOIL AND SUBSTRATES	
The soil landscape of Site 3 is made up of: • < 1 ha Luddenham soil – Luddenham soils exist in varying forms depending on their location on a slope. Podzolic soils or earthy clays, yellow podzolic soils, and prairie soils are found on crests, upper slopes, and drainage lines respectively (OEH, 2018a) • 3 ha Richmond soil – Richmond soils consist of orange to red clay loams, clays, and sands that are poorly structured (OEH, 2018a)	
WATER	
The site is flat and contains no watercourses or waterbodies (DoI, 2019; DTA, DCA et al., 2019) The site occurs within the Hawkesbury-Nepean catchment. Water quality is variable throughout the area. The majority of the upper reaches of streams and rivers are healthy, while downstream reaches are affected by historical land uses (e.g. clearing, urbanisation) (GES, 2018)	
VEGETATION	
The site is largely unvegetated and isolated from other areas of vegetation. Inspection of aerial photos shows scattered trees along the northern and eastern edges of the site. No Commonwealth-listed TECs are mapped as occurring on site.	

Plant Community Types (PCTs)/ NSW listed threatened ecological communities (TECs)

PCT number	PCT name	NSW TEC name	BC Act status	Area (ha)
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	Cumberland Plain Woodland in the Sydney Basin Bioregion	Critically Endangered	0.3

Threatened flora species

Name	EPBC Act or BC Act status	Area of habitat (ha)	Number of BioNet records
Acacia pubescens (Downy Wattle)	Vulnerable (BC Act & EPBC Act)	0.3	0
Dillwynia tenuifolia	Vulnerable (BC Act)	0.1	0

BIO Map Priority Investment Areas

No BIO Map core or corridor areas have been identified on this site

ANIMAL SPECIES

There are several records of Grey-headed Flying Fox known from the site

Threatened fauna species

Name	EPBC Act or BC Act status	Area of habitat (ha)	Number of BioNet records
Anthochaera phrygia (Regent Honeyeater)	Critically Endangered (BC Act & EPBC Act)	0.3	0
Lathamus discolor (Swift Parrot)	Endangered (BC Act) Critically Endangered (EPBC Act)	0.3	0
Pteropus poliocephalus (Grey-headed Flying-fox)	Vulnerable (BC Act & EPBC Act)	0.0	14 (wires records)

CONSERVATION AND SPECIAL USE AREAS

There are no conservation or special use areas present on this site

The closest conservation or special use areas are:

- Wianamatta Regional Park/Metro offset site (approximately 2.5km north east)
- Mulgoa Nature Reserve (approximately 4.5km south west)
- Blue Mountains National Park (approximately 4.5km south west)

HERITAGE PLACES AND ITEMS

While not registered as a heritage site under the *Penrith Local Environment Plan 2010*, Site 3 has some heritage values in association with its use as a military depot facility from World War 2 up to the Vietnam War and was the main engineering depot of the Eastern Command from 1943. During much of this time, Thornton Hall, a residence located near the site which was constructed in the 1870's, was used as the Commanding Officer's quarters (OEH, 2020)

It is not known whether the site has any other historic or indigenous heritage values. The site is not listed in the Australian Heritage Database as having heritage values

SERVICES AND INFRASTRUCTURE/PEOPLE AND COMMUNITIES

The site is a multi-user depot that is surplus to Defence capability requirements and is being prepared for sale in the 2020-21 financial year (DoD, n.d.). The site contains 1 large building, 3 medium sized buildings and 10-11 small structures scattered across the site.

No mining or petroleum tenements exist on this site (NNTT, 2020).

No Native Title Claims exist over this site (NNTT, 2020).

IMPACT ASSESSMENT

Direct impacts

There will be no direct impacts to Site 3 due to the Plan.

Indirect and facilitated impacts

Site 3 is located within a high density existing urban/commercial district within Penrith, approximately 0.8 km from the nearest urban capable land. This urban capable land comprises small areas to the north and west of the site separated from the majority of the urban development in GPEC, which occurs approximately 3 km to the south. The site is also located upstream of the nearest urban development and within a separate sub-catchment.

The location of the site relative to the development and within a high density existing urban area means:

- The site is very unlikely to be impacted by impacts associated with construction of the development in GPEC, such as air quality, noise, construction traffic, or the spread of weeds or disease
- The site will not be impacted by soil erosion of sedimentation, changes to surface and groundwater quantity and flows, or water quality impacts associated with the construction and operation of the development
- The heritage values of the site will not be impacted by alterations to the setting of the place inconsistent with its values, such as through changes to the surrounding landscape causing visual or amenity impacts

The site is largely unvegetated (contained scattered trees only) and isolated from other areas of vegetation and has no or little biodiversity value. While records of Grey-headed Flying Fox occur on the site, these are wires records indicating injured individuals have been found in the area, and are unlikely to indicate regular use of the site.

The site does not appear to be currently in use and is being prepared for sale in the 2020-21 financial year (DoD, n.d.). The development is unlikely to disrupt existing land uses, services or infrastructure.

Furthermore, the site is not open to the public, and therefore increased populations associated with the urban development will not lead to disturbance to the heritage values of the site through increased visitor use.

Commitments and mitigation measures

No commitments or mitigation measures are considered necessary to address the potential indirect impacts on the environment of Site 3 from the development under the Plan.

35.3.4 SITE 4 (WESTERN SYDNEY UNIVERSITY – CAMPBELLTOWN CAMPUS)

Profile

SITE DETAILS	
Owner	The Commonwealth of Australia
Site name	Western Sydney University - Campbelltown Campus
Site ID number	4
Area	92.5 ha
Address	Narellan Road and Gilchrist Drive, Campbelltown NSW
Folio	3098/12300
General description	The Campbelltown Campus of the University of Western Sydney is located at Narellan Road and Gilchrist Drive, Campbelltown NSW. It is used for tertiary education purposes. The campus contains 24.3 per cent native vegetation cover that is predominantly associated with drainage lines. Much of the remainder of the site has been developed or is cleared of vegetation. It is located approximately 45 km south-west of the Sydney CBD
Site map	The location of Site 4 is shown in Map 54.5
DISTANCE FROM URBAN CAPABLE LANDS/ TRANSPORT CORRIDORS	
Site 4 occurs within the footprint of the eastern end of the Metro Rail Future Extension tunnel The closest urban development occurs approximately 250 m from the south-western boundary of the site. The landscape between this urban development area and the boundary of Site 4 consists of a railway line and cleared fields, with some thin vegetation corridors predominantly located to the east. Bow Bowing Creek, and its associated riparian corridor, links the proposed urban capable land with the Site 4 boundary to the east	
LANDSCAPES AND LANDFORMS	
The site occurs in a landscape with gently undulating rises to rolling low hills, which have been predominately cleared or modified for development. The surrounding areas comprise residential land uses, with newer residential developments in the immediate vicinity and established areas of Campbelltown to the north (over Narellan Road), and east and south (over Menangle Road). The Hume Motorway lies to the west, and rural land to the south west	
SOIL AND SUBSTRATES	
The soil landscape at Site 4 is made up of: • 80 ha of Blacktown soil – Blacktown soils are a hard setting soils that have a shallow to moderately deep depth of > 100 cm (OEH, 2018a) • 13 ha of Luddenham soil – Luddenham soils exist in varying forms depending on their location on a slope. Podzolic soils or earthy clays, yellow podzolic soils, and prairie soils are found on crests, upper slopes, and drainage lines respectively (OEH, 2018a)	
WATER	
The site occurs within the Georges River catchment. The University campus topography is undulating. There are two main drainage lines in the middle of the site that are largely vegetated. These flow into a series of constructed/modified waterbodies that subsequently flow into Bow Bowing Creek (DoI, 2019; DTA, DCA et al., 2019)	
VEGETATION	
Approximately 24.3 per cent (22.5 ha) of the site is covered by native vegetation, which is predominantly associated with the drainage lines. The remainder of the site is developed or comprises of open fields/grassland No Commonwealth-listed TECs are mapped as occurring on site. Coastal Floodplain Eucalypt Forest of Eastern Australia (currently being assessed for listing) occurs in several patches across the site (note that the mapping of this TEC was based on PCT 835 and is likely to overestimate the extent of the TEC) The site contains potential habitat for several Commonwealth-listed species, but no species records for the site occur The vegetated areas are isolated from any substantial areas of vegetation by development, the nearest being approximately 6 km to the east beyond Campbelltown's suburbs connected to Dharawal and Heathcote National Parks.	

Vegetation on site is partially connected to the vegetated corridor along the motorway and other vegetated drainage lines in the areas, which together may provide a level of stepping-stone connectivity for fauna

Community Types (PCTs)/ NSW listed threatened ecological communities (TECs)

PCT number	PCT name	NSW TEC name	BC Act status	Area (ha)
835	Forest Red Gum – Rough-barked Apple grassy woodland on alluvium flats of the Cumberland Plain, Sydney Basin Bioregion	River-Flat Eucalypt Forest on Coastal Floodplains of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions	Endangered	17.5
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	Cumberland Plain Woodland in the Sydney Basin Bioregion	Critically Endangered	5.0

Threatened ecological communities (TECs)

TEC name	EPBC Act status	Area (ha)
Coastal floodplain eucalypt forest of eastern Australia	Currently being assessed for listing under EPBC Act	17.5

Threatened flora species

Name	EPBC Act or BC Act status	Area of habitat (ha)	Number of BioNet records
Pomaderris brunnea (Brown Pomaderris)	Endangered (BC Act) Vulnerable (EPBC Act)	15.0	0
Acacia pubescens (Downy Wattle)	Vulnerable (BC Act & EPBC Act)	16.4	0
Marsdenia viridiflora subsp. *viridiflora*	Endangered Population (BC Act)	16.1	0
Pilularia novae-hollandiae (Austral Pillwort)	Endangered (BC Act)	1.1	0

BIO Map Priority Investment Areas

No BIO Map core or corridor areas have been identified on this site

ANIMAL SPECIES

There is one record of a NSW-listed species – the Cumberland Plain Land Snail – known from the site, and several records of this species and other threatened fauna, including Large-eared Pied Bat, immediately adjacent to the site

It is likely that some common, urban-adapted native fauna species inhabit or move through the site, based on the presence of PCTs and condition/quality of the vegetation described above

Threatened fauna species

Name	EPBC Act or BC Act status	Area of habitat (ha)	Number of BioNet records
Pteropus poliocephalus (Grey-headed Flying-fox)	Vulnerable (BC Act & EPBC Act)	13.3	0
Botaurus poiciloptilus (Australasian Bittern)	Endangered (BC Act & EPBC Act)	13.2	0
Meridolum corneovirens (Cumberland Plain Land Snail)	Endangered (BC Act)	16.3	1

Cercartetus nanus (Eastern Pygmy-possum)	Vulnerable (BC Act)	8.7	0
Chalinolobus dwyeri (Large-eared Pied Bat)	Vulnerable (BC Act & EPBC Act)	16.3	0
Anthochaera phrygia (Regent Honeyeater)	Critically Endangered (BC Act & EPBC Act)	17.5	0
Rostratula australis (Australian Painted Snipe)	Endangered (BC Act & EPBC Act)	0.3	0
Petaurus norfolcensis (Squirrel Glider)	Vulnerable (BC Act)	0.2	0
Lathamus discolor (Swift Parrot)	Endangered (BC Act) Critically Endangered (EPBC Act)	17.5	0
Haliaeetus leucogaster (White-bellied Sea-eagle)	Vulnerable (BC Act)	2.2	0

CONSERVATION AND SPECIAL USE AREAS
There are no conservation or special use areas present on this site The closest conservation or special use areas are: • Australian Botanic Gardens at Mt Annan (approximately 100m west) • Metro offset site in Claymore (approximately 2km north) • William Howe Regional Park (approximately 2.5km west)
HERITAGE PLACES AND ITEMS
It is not known whether the site has any historic or indigenous heritage values. The site is not listed in the Australian Heritage Database as having heritage values
SERVICES AND INFRASTRUCTURE/PEOPLE AND COMMUNITIES
The site is a university campus with approximately 6,500 students. Facilities at the site include education facilities, student accommodation, food outlets, library, recreational facilities, religious centres and a range of other services The site is accessed by via Hume Motorway and Narellan Road, and Macarthur Train Station The following tenement exists on this site (NNTT, 2020): • Petroleum tenement (PPL4) No Native Title Claims exist over this site (NNTT, 2020)

IMPACT ASSESSMENT

Direct impacts

Site 4 occurs within the footprint of the eastern end of the Metro Rail Future Extension tunnel and may be directly impacted by construction of the tunnel. There will be no direct impacts to Site 4 due to other development under the Plan (although note the GIS boundary error discussed in section 35.1, which wrongly suggests there are very small direct impacts).

Metro Rail Future Extension tunnel

An assessment of the tunnel impacts on biodiversity values is provided in Chapter 36. This section provides a summary of the potential impacts of the tunnel in relation to the environment of Site 4.

It is not possible to determine at this stage the specific nature, extent and duration of the direct impacts of the Metro Rail Future Extension tunnel on Site 4. Development for the tunnels will generally occur within the tunnel footprints and direct impacts to the land surface will only occur within small areas of the footprint (see Part 2).

Disturbance to the land surface of Site 4 from the tunnel may occur due to:

- Construction activities

- Ancillary infrastructure, including ventilation systems
- Other infrastructure, such as entry and exit ramps and connection and tie in with existing roads and infrastructure
- Pedestrian and cyclist facilities
- Drainage work, pavement and finishing work

This may result in:

- Clearing of native vegetation and habitat
- Disturbance or destruction of buildings, roads and other infrastructure, and associated disruption of services
- Visual impacts from any permanent infrastructure, including ventilation shafts and the entrance to the tunnel, which is located within Site 4 (as indicated by the current extent of the tunnel footprint)

The most important biodiversity values within the tunnel footprint of Site 4 that may be directly impacted are:

- Small amounts of Coastal Floodplain Eucalypt Forest of Eastern Australia – the potential for notable impacts to this TEC is low. While several small patches of the TEC have the potential to be directly impacted, the amount of impact in the context of the amount remaining in the Strategic Assessment Area is not substantial
- Records and habitat of Cumberland Plain Land Snail – direct impacts to this species may be notable, as the species is listed as endangered in NSW, is restricted to the Cumberland subregion, and several records occur immediately adjacent to Site 4 at the south-eastern end of the site, suggesting a notable population may occur in the area (the notes attached to several of the records suggest the individuals recorded were not alive, however, there is potential for the population to occur at the site)

The Plan includes commitments that are expected to adequately address these potential direct impacts (see below).

Indirect and facilitated impacts

Site 4 has the potential to be indirectly impacted by construction and operation of:

- Metro Rail Future Extension tunnel, which occurs within the site
- Urban and industrial, and infrastructure development, which occurs approximately 250 m to the south of the site

The potential indirect and facilitated impacts associated with these developments and the key values of the environment of Site 4 that are potentially impacted are shown in Table 35-4.

Table 35-4: Potential indirect impacts on Site 4 associated with the development

<table>
<tr><th>Potential indirect impact</th><th>Extent within site 4</th><th>Duration</th><th>Values potentially impacted</th></tr>
<tr><td colspan="4">Construction</td></tr>
<tr><td>Soil erosion and disturbance from vegetation clearing and earthworks</td><td rowspan="5">Vicinity of the tunnel footprint
Southern end of the site closest to urban capable land</td><td rowspan="5">Generally short term</td><td rowspan="5">People and communities
Biodiversity values</td></tr>
<tr><td>Changes to water quality from soil erosion or disturbance of contaminated soils</td></tr>
<tr><td>Air quality, noise impacts, and visual or other impacts to amenity</td></tr>
<tr><td>Construction traffic causing disruption or reduced accessibility to the site</td></tr>
<tr><td>Spread of weeds, disease, fauna disturbance and inadvertent impacts on adjacent habitat</td></tr>
<tr><td>Disruption to land uses, services or infrastructure</td><td>Whole of site</td><td>Generally short term</td><td>People and communities</td></tr>
</table>

Operation			
Ground settlement and subsidence from tunnels due to the tunnel void or groundwater removal, leading to disturbance to the land surface	Vicinity of the tunnel footprint	Short to long term	People and communities Biodiversity values
Changes to surface water and groundwater quantities and flows due to groundwater drawdown caused by the tunnel void and additional runoff from urban areas	Vicinity of tunnel footprint Bow Bowing Creek	Long term	Water resources Biodiversity values
Disruption to land uses, services or infrastructure	Whole of site	Long term	People and communities

Biodiversity values

Construction of the tunnel may cause notable indirect impacts to biodiversity values in Site 4 from the spread of weeds, disease, fauna disturbance and inadvertent impacts on adjacent habitat or vegetation. The tunnel also has the potential to cause ground settlement and subsidence due to the tunnel void or groundwater removal leading to disturbance to the land surface, as well as groundwater drawdown, both of which may impact biodiversity values.

The most important biodiversity values within the tunnel footprint of Site 4 that may be indirectly impacted are:

- Small amounts of Coastal Floodplain Eucalypt Forest of Eastern Australia – the indirect impacts to this TEC are unlikely to be notable (see explanation above for direct impacts)
- Records and habitat of Cumberland Plain Land Snail – the indirect impacts to this species may be notable (see explanation above for direct impacts)

The Plan includes commitments that are expected to adequately address these potential impacts on biodiversity values in Site 4 resulting from construction and operation of the tunnel (see below).

Water resources – Bow Bowing Creek

Construction of the tunnel may impact the water quality of Bow Bowing Creek from soil erosion, disturbance of contaminated soils, or spillage of chemicals and fuels used during construction. Furthermore, groundwater drawdown from the tunnel may affect flows to Bow Bowing Creek, as well as the water quality of the waterway due to any need for ongoing disposal of groundwater from the tunnel. Additional runoff from increased hard surfaces associated with the urban and industrial development has the potential to increase surface water flows in Bow Bowing Creek and impact the water quality of the waterway.

These potential impacts on Bow Bowing Creek are considered to be minor. The waterway is already located in an urban environment, and has been subject to previous development including impoundment, clearing of riparian vegetation and the creation of artificial channels along some sections. Furthermore, the Plan includes commitments that are expected to adequately address these potential impacts on water resources in Site 4 (see below).

People and communities

Construction of the tunnel has the potential to significantly disrupt the university facilities at Site 4 as a result of potential temporary closures to parts of the site to allow construction, or include construction sites, disruption to pedestrian or traffic access to or within the site, and air quality and noise impacts. The Plan includes commitments that are expected to adequately address these potential construction impacts (see below).

If construction of infrastructure within urban capable land in the vicinity of Site 4, there may be minor disruption to road or pedestrian traffic, or noise disturbance. However, the impact to students and others using the site is likely to be minor, as the site is already within an existing urban environment.

The increase in populations in the area facilitated by the urban development is likely to increase the demand for educational services and other infrastructure at the site. This is likely to be overall a positive benefit to the university and is expected to be adequately managed through existing management and operational processes.

Population increases may also lead to increased pressure on roads, transport and other infrastructure that service the university. However, the Plan intends to provide for future transport needs by supporting the delivery of major transport projects for Western Sydney. It is also expected that future transport and infrastructure needs of the university will be provided for through existing local and regional planning processes.

The urban development may also positively impact Site 4 through increased provision of housing, which will increase demand for education services and the availability of housing options close to the university for students and staff.

Commitments and mitigation measures

The Plan includes commitments to mitigate direct and indirect impacts from construction and operation associated with transport corridors, urban and industrial development, and infrastructure development. These commitments and processes to deliver these comments are different for each type of development.

Metro Rail Future Extension tunnel - direct impacts

The Plan includes a commitment to avoid and minimise impacts from the transport corridors outside the nominated areas (Commitment 4). This includes the following at Western Sydney University (Commitment 4.1):

- Avoiding and minimising impacts where possible to:
  - Existing infrastructure
  - Populations and habitat of Cumberland Plain Land Snail
- Minimising disruption to existing services

This avoidance process will be undertaken during strategic planning and detailed design of the Metro Rail Future Extension tunnel project. The process will seek to avoid and minimise direct impacts of the tunnel to Site 4, including impacts to existing infrastructure and disruption to university services, as well as biodiversity values.

This commitment is considered to adequately address the risks associated with the potential direct impacts of the Metro Rail Future Extension tunnel on Site 4. Note that each transport project will be subject to an environmental assessment process under the EP&A Act. While this assessment will not apply to tunnel activities on Site 4 (as Commonwealth land is outside the jurisdiction of NSW planning laws), the minimisation of impacts to infrastructure and disruption to existing services will occur in accordance with standard construction management processes.

Metro Rail Future Extension tunnel - indirect impacts

The Plan includes a commitment to mitigate indirect and prescribed impacts from transport development (Commitment 6). This includes the following measure relevant at Western Sydney University (Commitment 6.2):

- Implement mitigation measures to address impacts on Cumberland Plain Land Snail, including to manage the spread of weeds and disturbance to ground shelter habitat

This commitment will be delivered through an environmental assessment process that will apply to each transport project under the EP&A Act (currently the State Significant Infrastructure approval process) to assess and manage the direct and indirect impacts of the project. A description of the process is provided in Chapter 15, section 15.6.3.

This process will assess the environmental impacts of the construction and operation of the tunnel project based on detailed design, in accordance with the standard requirements and policies applying to major infrastructure assessments in NSW (see Chapter 15, section 15.6.3). The current process requires an assessment of risks to the environment and the identification of avoidance and mitigation measures to manage these risks. This will include the assessment and management of indirect impacts of the tunnel project that may affect Site 4, including construction activities, changes to surface and groundwater flows and water quality, including groundwater drawdown, noise and air quality impacts, impacts to traffic and accessibility, and disruption to services and infrastructure.

This assessment process therefore provides the mechanism to identify and implement mitigation measures to manage the potential indirect impacts on Site 4 from the transport development.

A detailed description of the assessment and approval process for transport, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.3.

Urban and industrial development

The Plan includes a commitment to mitigate indirect and prescribed impacts from development to best practice standards (Commitment 5). This commitment will be delivered through development controls specified in Development Control Plans (DCPs) and implemented through the standard development application process that occurs under the NSW planning system. A description of the process is provided in Chapter 15, section 15.6.1.

Relevant councils will prepare a DCP for each nominated area in collaboration with the Department and in accordance with standard processes for developing DCPs in NSW. The DCP will include development controls relevant to addressing the indirect and facilitated impacts of the urban and industrial development that may affect Site 4.

The general environmental controls likely to be included in DCPs are set out in Chapter 15, section 15.6.1, and include:

- Preparation of Construction Environmental Management Plans to manage on-site construction impacts
- Controls for managing impacts to:
    - Hydrology and water quality
    - Noise and air quality
    - Construction traffic

These development controls and the process for implementing them are expected to adequately address the potential indirect and facilitated impacts of the urban and industrial development that will occur adjacent to Site 4.

A detailed description of the development controls and implementation process, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.1.

Infrastructure development

The Plan includes a commitment to mitigate indirect and prescribed impacts from infrastructure development (Commitment 5.3). This commitment will be delivered through an environmental assessment and approval process that will be applied to detailed design of each infrastructure project at the time the project is brought forward for development. This will be undertaken under Part 4 or Part 5 of the EP&A Act (or equivalent at the time). State Environmental Planning Policy (SEPP) (Infrastructure) 2007 provides a framework for determining how most types of infrastructure are assessed under the EPA Act.

This assessment process will assess and identify mitigation measures to manage the non-biodiversity related potential environmental impacts of the project. This will include the assessment and management of indirect impacts of any infrastructure projects that may affect Site 4, including construction activities, noise and air quality impacts, impacts to traffic and accessibility, and disruption to services and infrastructure.

This process therefore provides the mechanism to identify and implement mitigation measures to manage the potential indirect impacts on Site 4 from the infrastructure development.

A detailed description of the assessment and approval process for infrastructure, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.2.

35.3.5 SITE 5 (DEFENCE ESTABLISHMENT ORCHARD HILLS)

PROFILE

SITE DETAILS	
Owner	The Commonwealth of Australia
Site name	Defence Establishment Orchard Hills
Site ID number	5
Area	1,970.7 ha
Address	2042B The Northern Rd, Mulgoa NSW 2042-2550 The Northern Road, Orchard Hills NSW 2304A The Northern Road, Orchard Hills NSW 18C The Haven, Orchard Hills NSW 66A Wentworth Road, Orchard Hills NSW 1-17 Stockdale Road, Orchard Hills NSW 114-122 Patons Lane, Orchard Hills NSW
Folio	4/238092, 1-3/238092, 6/578629, 9/238092, 2/589479, 1-2/586093, 1/629326, 11/598345, 1-17/242968
General description	Defence Establishment Orchard Hills is an explosive ordnance depot. It is used for the storage of munitions, weapon ranges, firing ranges, firefighting training, and above and below ground fuel storage (DoD, 2017). It occurs within the Strategic Assessment Area, approximately 50 km west of the Sydney CBD. Approximately 42.0 per cent of the site is covered by native vegetation communities. The site contains areas of high biodiversity value, with parts of the site proposed as an offset site for the new Western Sydney Airport (DIRDC, 2018)
Site map	The location of Site 5 is shown in Map 54.6
DISTANCE FROM URBAN CAPABLE LANDS/ TRANSPORT CORRIDORS	
Urban capable land and transport corridors are located immediately adjacent to Site 5, including: • Along most of the northern and eastern boundaries of the site • Small areas of either end of the southern border of the site (i.e. the south-western and south-eastern edges) • Approximately half of the western boundary of the site	
LANDSCAPES AND LANDFORMS	
This site occurs in a landscape with gently undulating rises to floodplains, valley flats and drainage depressions	
SOIL AND SUBSTRATES	
The soil landscape at Site 5 is made up of: • 1,706 ha of Blacktown soil – Blacktown soils are hardsetting soils that have a shallow to moderately deep depth of > 100 cm (OEH, 2018a) • 265 ha of Wianamatta (South Creek) soil – Wianamatta (South Creek) soils are deep layered sediments that occur over bedrock or relict soils (minerals/structures that have not undergone metamorphic change while the surrounding rock has) (OEH, 2018a)	
WATER	
The site occurs within the Hawkesbury-Nepean catchment. Water quality is variable throughout the area. The majority of the upper reaches of streams and rivers are healthy, while downstream reaches are affected by the negative effects of historical land uses (e.g. clearing, urbanisation) (GES, 2018) Watercourses that flow through the site include first to fourth order streams. Blaxland Creek is a fourth order stream into which the majority of the site drains. It diagonally dissects the site, flowing in a south-west to north-east direction (DIRDC, 2018). Blaxland Creek and its tributaries are some of the least disturbed catchment areas remaining in the	

Cumberland subregion, and are regarded as one of the most pristine creek systems on Wianamatta Shale in Western Sydney. The creek system has a high diversity of species which are sensitive to disturbance, and provides habitat for species that have largely disappeared from more impacted watercourses in the region. Blaxland Creek at Orchard Hills provides a benchmark to measure disturbance of riparian corridors elsewhere on the Cumberland subregion, and is listed as part of the Commonwealth heritage value of the site (DoEE, 2018a)

A tributary of Cosgroves Creek also occurs in the south-east corner of the site (DoEE, 2018a; DoI, 2019)

VEGETATION

Native vegetation covers approximately 42 per cent (828.2 ha) of the site and mostly occurs in a large patch within the north-east and part of the south-east of the site that is broadly associated with Blaxland Creek and its tributaries

The site contains the largest and least disturbed remnant of Cumberland Plain Woodland and large and intact areas of Coastal Floodplain Eucalypt Forest of Eastern Australia (currently being assessed for listing under EPBC Act), and is regarded as an important area for the conservation of these two TECs in the subregion. The natural values of these vegetation communities are listed as part of the Commonwealth heritage value of the site (DoEE, 2018a)

The vegetation at Orchard Hills is located within a largely cleared, agricultural/rural residential landscape, which contains scattered, smaller patches of vegetation, paddock and garden trees, through which vegetated riparian corridors provide important connectivity pathways for native flora and fauna. The main vegetated areas which Orchard Hills is connected to includes vegetated areas to the west (linking the site to the Blue Mountains), and riparian corridors to the north-east linking the site to Wianamatta (South Creek). Dense urban development is located to the north and north-west of the site, which limits habitat connectivity in these directions

Community Types (PCTs)/ NSW listed threatened ecological communities (TECs)

PCT number	PCT name	NSW TEC name	BC Act status	Area (ha)
835	Forest Red Gum – Rough-barked Apple grassy woodland on alluvium flats of the Cumberland Plain, Sydney Basin Bioregion	River-Flat Eucalypt Forest on Coastal Floodplains of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions	Endangered	129.3
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	Cumberland Plain Woodland in the Sydney Basin Bioregion	Critically Endangered	651.5
850	Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Cumberland Plain Woodland in the Sydney Basin Bioregion	Critically Endangered	17.9
1800	Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter Valley	River-Flat Eucalypt Forest on Coastal Floodplains of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions	Endangered	29.4

Commonwealth listed threatened ecological communities (TECs)

TEC name	EPBC Act status	Area (ha)
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest	Critically Endangered	426.5

Coastal floodplain eucalypt forest of eastern Australia	Currently being assessed for listing under EPBC Act	129.3

Threatened flora species

Name	EPBC Act or BC Act status	Area of habitat (ha)	Number of BioNet records
Dillwynia tenuifolia	Vulnerable (BC Act)	137.7	4
Grevillea juniperina subsp. *juniperina* (Juniper-leaved Grevillea)	Vulnerable (BC Act)	665.7	9
Marsdenia viridiflora subsp. *viridiflora*	Endangered Population (BC Act)	815.2	14
Pultenaea parviflora	Endangered (BC Act) Vulnerable (EPBC Act)	0.8	4
Acacia pubescens (Downy Wattle)	Vulnerable (BC Act & EPBC Act)	726.5	0
Pimelea spicata (Spiked Rice-flower)	Endangered (BC Act & EPBC Act)	1,135.9	0
Maundia triglochinoides	Vulnerable (BC Act)	28.7	0
Pilularia novae-hollandiae (Austral Pillwort)	Endangered (BC Act)	11.5	0
Pimelea curviflora var. *curviflora*	Vulnerable (BC Act & EPBC Act)	299.6	0
Pultenaea pedunculata (Matted Bush-pea)	Endangered (BC Act)	481.8	0

BIO Map Priority Investment Areas

The site has been identified on BIO Map as containing over 1,100 ha of core areas and 279 ha of corridors

Type	Area (ha)
Core areas	1,113.5
State and Regional Biodiversity Corridors	279.3

ANIMAL SPECIES

The site contains substantial areas of habitat for native fauna species. There are 68 bird species and 10 reptile species that have been recorded at the site as well as several native marsupial mammals, including Easter Grey Kangaroo (*Macropus giganteus*), Swamp Wallabies (*Wallabia bicolor*) and Common Wallaroos (*Macropus robustus*) (DIRDC, 2018)

Threatened fauna species

Name	EPBC Act or BC Act status	Area of habitat (ha)	Number of BioNet records
Pteropus poliocephalus (Grey-headed Flying-fox)	Vulnerable (BC Act & EPBC Act)	699.9	4
Botaurus poiciloptilus (Australasian Bittern)	Endangered (BC Act & EPBC Act)	85.5	0
Meridolum corneovirens (Cumberland Plain Land Snail)	Endangered (BC Act)	786.5	34
Cercartetus nanus (Eastern Pygmy-possum)	Vulnerable (BC Act)	363.4	0

Callocephalon fimbriatum (Gang-gang Cockatoo)	Vulnerable (BC Act)	93.7	0
Petauroides volans (Greater Glider)	Vulnerable (EPBC Act)	356.0	0
Hieraaetus morphnoides (Little Eagle)	Vulnerable (BC Act)	150.9	0
Anthochaera phrygia (Regent Honeyeater)	Critically Endangered (BC Act & EPBC Act)	828.2	0
Myotis macropus (Southern Myotis)	Vulnerable (BC Act)	55.9	0
Dasyurus maculatus maculatus (Spot-tailed Quoll)	Vulnerable (BC Act) Endangered (EPBC Act)	760.0	0
Lophoictinia isura (Square-tailed Kite)	Vulnerable (BC Act)	179.1	0
Petaurus norfolcensis (Squirrel Glider)	Vulnerable (BC Act)	780.9	0
Lathamus discolor (Swift Parrot)	Endangered (BC Act) Critically Endangered (EPBC Act)	828.2	0
Haliaeetus leucogaster (White-bellied Sea-eagle)	Vulnerable (BC Act)	179.1	0
Artamus cyanopterus cyanopterus (Dusky Woodswallow)	Vulnerable (BC Act)	0.0	1
Burhinus grallarius (Bush Stone-curlew)	Endangered (BC Act)	0.0	2
Chthonicola sagittata (Speckled Warbler)	Vulnerable (BC Act)	0.0	10
Daphoenositta chrysoptera (Varied Sittella)	Vulnerable (BC Act)	0.0	4
Ephippiorhynchus asiaticus (Black-necked Stork)	Endangered (BC Act)	0.0	1
Micronomus norfolkensis (Eastern Coastal Free-tailed Bat)	Vulnerable (BC Act)	0.0	1
Miniopterus orianae oceanensis (Large Bent-winged Bat)	Vulnerable (BC Act)	0.0	2
Petroica boodang (Scarlet Robin)	Vulnerable (BC Act)	0.0	1
Stagonopleura guttata (Diamond Firetail)	Vulnerable (BC Act)	0.0	1

CONSERVATION AND SPECIAL USE AREAS

Large parts of the site are proposed to be secured as an offset for the impacts of Stage 1 of Western Sydney Airport (DIRDC, 2018). The offset will comprise restoration and management of at least 900 ha of native vegetation, including Cumberland Plain Woodland, at the site. Other conservation or special use areas near the site include Mulgoa Nature Reserve (approximately 1.5km west) and an offset site in Glenmore Park (approximately 1.5km west)

HERITAGE PLACES AND ITEMS

Approximately 1,370 ha (70 per cent) of the site is listed on the Commonwealth Heritage List and the Register of the National Estate (non-statutory) as *Orchard Hills Cumberland Plain* Woodland, including for its natural values.

The site meets four of the nine Commonwealth Heritage listing criteria:

- Criterion A: Orchard Hills has evidence of historic canal works from the 1890s. It contains the largest and least disturbed remaining remnant of Cumberland Plain Woodland as well as some of the least disturbed catchment areas. Blaxland Creek supports a higher level of macro-invertebrate diversity than elsewhere in Western Sydney (DoEE, 2018a)
- Criterion B: Orchard Hills contains threatened species and TECs, and tributaries of Blaxland Creek are considered to have regional conservation significance for invertebrate species (DEWHA, 2007; DoEE, 2018a).
- Criterion C: Tributaries of Blaxland Creek provide a benchmark to measure disturbance of riparian areas

elsewhere on the Cumberland Plain. The lack of fire at Orchard Hills for 50 years also provides valuable research into the regeneration of Cumberland Plain Woodland (DoEE, 2018a) • Criterion D: Orchard Hills demonstrates the principle characteristics of Cumberland Plain Woodland, Sydney River Flat Forest in the Penrith area, and examples of some of the most outstanding remaining Forest Red gum trees. It also contains numerous indigenous sites along the main steam (DoEE, 2018a) It is not known whether the site has any other historic or indigenous heritage values. The site is not listed in the Australian Heritage Database as having any other heritage values
SERVICES AND INFRASTRUCTURE/PEOPLE AND COMMUNITIES
The site is an explosive ordnance depot managed for defence capability purposes, defence training activities and the use and safe storage of explosives. Site facilities include munitions storage, weapon ranges, firing ranges, fire-fighting training areas, and fuel storage and distribution from above ground and underground storage tanks. The site also contains a sewage treatment plant. Two historical landfills also exist, containing non-putrescible refuse, including building rubble and asbestos containing materials. The majority of the site provides a buffer zone for the safe use and storage of explosives to nearby residential and rural residential land uses (Department of Defence, 2017) No mining or petroleum tenements exist on this site (NNTT, 2020) No Native Title Claims exist over this site (NNTT, 2020)

IMPACT ASSESSMENT

Direct impacts

There will be no direct impacts to Site 5 due to development under the (although note the GIS boundary error discussed in section 35.1, which wrongly suggests there are very small direct impacts).

Indirect and facilitated impacts

Site 5 has the potential to be indirectly impacted by construction and operation of:

- OSO, which occurs adjacent to the eastern boundary of the site
- Urban and industrial, and infrastructure development, which occurs along the boundaries of all sides of the site, particularly the northern, eastern and western boundaries

The potential indirect and facilitated impacts associated with these developments and the key values of the environment of Site 5 that are potentially impacted are shown in Table 35-5.

Table 35-5: Potential indirect impacts on Site 5 associated with the development

Potential indirect impact	Extent within Site 5	Duration	Values potentially impacted
Construction			
Soil erosion and disturbance from vegetation clearing and earthworks	Boundaries of the site	Generally short term	People and communities Biodiversity values/heritage values (natural)
Changes to water quality from soil erosion or disturbance of contaminated soils			
Air quality, noise impacts, and visual or other impacts to amenity			
Construction traffic causing disruption or reduced accessibility to the site			
Spread of weeds, disease, fauna disturbance and inadvertent impacts on adjacent habitat			
Clearing of habitat during construction of the development that links the site to other areas of habitat, leading to impacts on biodiversity values	Whole of site	Long term	Biodiversity values/heritage values (natural)

Disruption to land uses, services or infrastructure	Whole of site	Generally short term	People and communities
Operation			
Changes to surface water flows due to additional runoff from urban areas	Vicinity of tunnel footprint Bow Bowing Creek	Long term	Water resources Biodiversity values/heritage values (natural)
Disruption to land uses, services or infrastructure	Whole of site	Long term	People and communities

Biodiversity values/heritage values (natural)

Construction of urban, industrial, and infrastructure development and the OSO adjacent to the boundaries of the site may cause indirect impacts to biodiversity values from the spread of weeds, disease, fauna disturbance and inadvertent impacts on adjacent habitat or vegetation.

The site is of very high conservation value. The site is listed on the Commonwealth Heritage List, including for its natural values. It contains very large areas of good condition native vegetation, including TECs and known populations of several threatened flora and fauna species. The site has also been identified on BIO Map as containing large areas of core areas and corridors, and is located within the Cumberland Conservation Corridor, which is a community led, government-recognised proposal to help address the conservation of biodiversity values and especially connectivity of habitat in the Cumberland subregion (DIRDC, 2018).

The most important biodiversity values within Site 5 that may be indirectly impacted are:

- Cumberland Plain Woodland and Coastal Floodplain Eucalypt Forest of Eastern Australia – indirect impacts to these TECs may be notable, as the site contains very large and intact areas of these TECs
- Records and habitat of *Marsdenia viridiflora* subsp. *viridiflora*, *Pultenaea parviflora* and Cumberland Plain Land Snail, as well as several other threatened flora and fauna species

Two large areas in the northern and southern parts of the site are proposed to be secured as an offset for Stage 1 of Western Sydney Airport (DIRDC, 2018). The offset will comprise restoration and management of at least 900 ha of native vegetation and include large areas of Cumberland Plain Woodland, Coastal Floodplain Eucalypt Forest of Eastern Australia, and records and habitat for *Marsdenia viridiflora* subsp. *viridiflora* and several other threatened flora and fauna species. The offset site also includes large parts of the riparian corridor of Blaxland Creek (DIRDC, 2018).

It is expected that the establishment and management of the offset site would adequately mitigate any key risks to the most important biodiversity values on the site from indirect impacts of the development under the Plan. Under the offset proposal, the Department of Infrastructure, Transport, Regional Development and Communications (DITRDC) would provide funds for the intensive management of the offset site for biodiversity conservation and restoration for a period of up to 20 years. This would include the management of weeds and other landscape scale threats to the biodiversity values of the site. Management actions would be undertaken in accordance with an Offset Plan prepared under an agreement with the Department of Defence, who would be responsible for managing the site. Furthermore, the Plan includes commitments that are expected to adequately minimise the risk of potential impacts on biodiversity values in Site 5 resulting from construction and operation of the development (see below).

Clearing of habitat that links the site to other areas of habitat has the potential to lead to impacts on the biodiversity values of the site due to a reduction in habitat connectivity to and from the site.

The key areas of habitat connectivity associated with the site are:

- Riparian corridors and small patches of native vegetation and scattered paddock trees to the north and east of the site that link to a larger riparian corridor associated with Wianamatta (South Creek)
- Larger patches of native vegetation and scattered paddock trees to the south-west of the site that provide some connectivity to riparian corridors and large areas of habitat associated with the Blue Mountains

The development has the potential to result in a reduction in habitat connectivity from the loss of small patches of native vegetation and scattered paddock trees to the north and east of the site. Habitat connectivity in this area, particularly associated with the riparian corridor along Wianamatta (South Creek), will also be potentially impacted by the OSO, which may lead to a reduction in connectivity to the site. The Plan includes a commitment to avoid and minimise impacts of the transport corridors in riparian corridors (Commitment 3) (see below), and this is expected to adequately address this risk.

The larger patches of native vegetation and scattered paddock trees to the south-west of the site will not be impacted by the development. Furthermore, riparian corridors that connect to the site have been avoided as part of the design of the urban capable land (see Chapter 14) and will not be impacted by the development.

Water resources

Construction and operation of the urban, industrial, and infrastructure development adjacent to the southern and western boundaries of the site has the potential to cause changes to surface water flows and impact the water quality of Blaxland Creek and its tributaries that occur within the site due to:

- Soil erosion, disturbance of contaminated soils, or spillage of chemicals and fuels used during construction
- Increased urban run-off during operation as a result of increased hard surfaces from urban areas

Potential impacts to Blaxland Creek and its tributaries are notable as this system within the site contains some of the least disturbed catchment areas remaining in the Cumberland subregion, has a high diversity of species which are sensitive to disturbance, and provides habitat for species that have largely disappeared from other watercourses in the region. The creek system at the site provides a benchmark to measure disturbance of riparian corridors elsewhere in Cumberland subregion, and is listed as part of the Commonwealth heritage value of the site (DoEE, 2018a)

Urban, industrial, and infrastructure development to the east and north of the site and construction of the OSO to the east of the site are unlikely to impact Blaxland Creek and its tributaries within the site as these areas are generally inn separate sub-catchments and surface run-off generally occurs south west to north east across the site.

Processes to manage changes to surface water flows and water quality impacts will implemented under the Plan (see below). The Plan also includes a specific commitment to manage these impacts at Blaxland Creek. These measures are expected to adequately address the potential impacts on water resources in Site 5 (see below).

People and communities

Construction of the urban, industrial, infrastructure and transport development is considered unlikely to disrupt services at the site. The majority of the site includes buffer zones to mitigate risks associated with the use and storage of explosives on adjacent residual areas (Department of Defence, 2017). These buffers are likely to mitigate any potential disruption to services from many construction activities, such as through air or noise impacts.

The Plan includes commitments that are expected to adequately address other potential impacts associated with construction, such as disruption to site access associated with construction traffic (see below).

Increased populations associated with urban development under the Plan has the potential to disrupt the services provided by the site as a defence base due to:

- Risks associated with the use and storage of explosives
- Increased pressure on roads, transport and other infrastructure that service the site

These potential indirect impacts are considered unlikely.

Existing urban areas already occur in the vicinity of the site, including low density rural residual areas immediately adjacent to and surrounding the majority of the site, as well as higher density urban areas to the west and north east of the site. The site already has in place measures to mitigate the risks associated with the use and storage of explosive on adjacent residual areas, including buffer zones that comprise the majority of the site (Department of Defence, 2017), and it is therefore not expected that the development will disrupt the use of the site for this purpose.

The Plan addresses the issue of increased pressure on roads, transport and other infrastructure that service Site 5 to some extent by supporting the delivery of major transport projects for Western Sydney. It is also expected that future transport and other infrastructure needs will be adequately provided for through future planning processes.

Commitments and mitigation measures

The Plan includes commitments to mitigate indirect impacts from construction and operation associated with transport corridors, urban and industrial development, and infrastructure development. These commitments and processes to deliver these comments are different for each type of development.

Transport development

The Plan includes a commitment to mitigate indirect impacts from transport corridors (Commitment 6). This commitment will be delivered through an environmental assessment process that will apply to each transport project under the EP&A Act (currently the State Significant Infrastructure approval process) to assess and manage the direct and indirect impacts of the project. A description of the process is provided in Chapter 15, section 15.6.3.

This process will assess the environmental impacts of the construction and operation of the OSO based on detailed design, in accordance with the standard requirements and policies applying to major infrastructure assessments in NSW (see Chapter 15, section 15.6.3). The current process requires an assessment of risks to the environment and the identification of avoidance and mitigation measures to manage these risks. This will include the assessment and management of indirect impacts that may affect Site 5, including construction activities.

This assessment process therefore provides the mechanism to identify and implement mitigation measures to manage the potential indirect impacts on Site 5 from the OSO.

A detailed description of the assessment and approval process for transport, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.3.

Urban and industrial development

The Plan includes a commitment to mitigate indirect and prescribed impacts from development to best practice standards (Commitment 5). This commitment will be delivered through development controls specified in Development Control Plans (DCPs) and implemented through the standard development application process that occurs under the NSW planning system. A description of the process is provided in Chapter 15, section 15.6.1.

Relevant councils will prepare a DCP for each nominated area in collaboration with the Department and in accordance with standard processes for developing DCPs in NSW. The DCP will include development controls relevant to addressing the indirect and facilitated impacts of the urban and industrial development that may affect Site 5, particularly changes to surface water flows and water quality impacts on Blaxland Creek and its tributaries.

The general environmental controls likely to be included in DCPs are set out in Chapter 15, section 15.6.1, and include:

- Preparation of Construction Environmental Management Plans to manage on-site construction impacts
- Controls for managing impacts to:
  - Hydrology and water quality
  - Noise and air quality
  - Construction traffic

The Plan also include a specific measure as part of Commitment 5.1 to put in place development controls though the relevant DCP to ensure urban, industrial, and infrastructure development adjacent to the southern and western boundaries of the site mitigates impacts to surface water flows and the water quality of Blaxland Creek.

These development controls and the process for implementing them are expected to adequately address the majority of the potential indirect and facilitated impacts of the urban and industrial development that will occur adjacent to Site 5.

A detailed description of the development controls and implementation process, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.1.

Infrastructure development

The Plan includes a commitment to mitigate indirect and prescribed impacts from infrastructure development (Commitment 5.3). This commitment will be delivered through an environmental assessment and approval process that will be applied to detailed design of each infrastructure project at the time the project is brought forward for development. This will be undertaken under Part 4 or Part 5 of the EP&A Act (or equivalent at the time). State Environmental Planning Policy (SEPP) (Infrastructure) 2007 provides a framework for determining how most types of infrastructure are assessed under the EPA Act.

This assessment process will assess and identify mitigation measures to manage the non-biodiversity related potential environmental impacts of the project. This will include the assessment and management of indirect impacts of any infrastructure projects that may affect Site 4, including construction activities, noise and air quality impacts, impacts to traffic and accessibility, and disruption to services and infrastructure.

This process therefore provides the mechanism to identify and implement mitigation measures to manage the potential indirect impacts on Site 4 from the infrastructure development.

A detailed description of the assessment and approval process for infrastructure, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.2.

35.3.6 SITE 6 (CAMDEN AIRPORT)

PROFILE

SITE DETAILS	
Owner	The Commonwealth of Australia
Site name	Camden Airport
Site ID number	6
Area	186.7 ha
Address	766 Aerodrome Road, Cobbitty NSW
Folio	102/112144
General description	Camden airport is located at 766 Aerodrome Road Hanger, Camden, NSW. The site is a general aviation airport that facilitates the operation of small aircrafts in the commercial, private, sports and recreational aviation areas (CAL, 2015). Approximately 26.3 per cent of the site is covered by native vegetation. It occurs within the Strategic Assessment Area, approximately 50 km south-west of the Sydney CBD
Site map	The location of Site 6 is shown in Map 54.7
DISTANCE FROM URBAN CAPABLE LANDS/ TRANSPORT CORRIDORS	
The site occurs within the footprint of the tunnel section of the OSO from Cobbitty to Cawdor. The nearest urban capable land occurs approximately 9 km to the west within GMAC	
LANDSCAPES AND LANDFORMS	
This site occurs in a flat landscape on Tertiary and Quaternary floodplains and terraces of the Nepean River	
SOIL AND SUBSTRATES	
The soil landscape at site 6 is made up of: • 8 ha of Blacktown soil – Blacktown soils are a hardsetting soils that have a shallow to moderately deep depth of > 100 cm (OEH, 2018a) • 178 ha of Theresa Park soil – Theresa Park soils occur on Tertiary and Quaternary floodplains and terraces • < 1 ha of unknown soil	
WATER	
The site occurs within the Hawkesbury-Nepean catchment. Water quality is variable throughout the area. The majority of the upper reaches of streams and rivers are healthy, while downstream reaches are affected by historical land uses (e.g. clearing, urbanisation) (GES, 2018) The site is flat and contains one minor, non-perennial drainage line in the north-eastern part of the site and is bordered on the east, south and western sides by the Nepean River	
VEGETATION	
Vegetation covers approximately 26.3 per cent (49.2 ha) of the Camden Airport site. These vegetated areas occur on the banks of the Nepean River that runs along the edge of the site	

Community Types (PCTs)/ NSW listed threatened ecological communities (TECs)				
PCT number	**PCT name**	**NSW TEC name**	**BC Act status**	**Area (ha)**
0	Cleared	N/A	N/A	137.5

Petauroides volans (Greater Glider)		Vulnerable (EPBC Act)	33.4	0

Anthochaera phrygia (Regent Honeyeater)	Critically Endangered (BC Act & EPBC Act)	49.2	0
Rostratula australis (Australian Painted Snipe)	Endangered (BC Act & EPBC Act)	1.6	0
Lathamus discolor (Swift Parrot)	Endangered (BC Act) Critically Endangered (EPBC Act)	49.2	1
Meridolum corneovirens (Cumberland Plain Land Snail)	Endangered (BC Act)	0.0	1
*Micronomus norfolkensis (*Eastern Coastal Free-tailed Bat)	Vulnerable (BC Act)	0.0	2
Miniopterus orianae oceanensis (Large Bent-winged Bat)	Vulnerable (BC Act)	0.0	1
Petroica boodang (Scarlet Robin)	Vulnerable (BC Act)	0.0	1
*Scoteanax rueppellii (*Greater Broad-nosed Bat)	Vulnerable (BC Act)	0.0	2
CONSERVATION AND SPECIAL USE AREAS			
The 49 ha of native vegetation on the site is protected as a registered property agreement administered by the BCT			
HERITAGE PLACES AND ITEMS			
The Camden Airport Environment Strategy (Camden Airport Limited, 2015) identifies the heritage values present on the property With regards to indigenous heritage, an Aboriginal Archaeological Survey of the site in 2009 identified an artefact scatter which contained flaked stone artefacts along an access track leading to the Nepean River. This site was registered on the NSW Aboriginal Heritage Information Management System (AHIMS). The stone artefacts have since been relocated off the access track to another on-Airport location under an Aboriginal Heritage Impact Permit (AHIP). While the access track provides tangible evidence of previous Aboriginal occupation, it is noted that Aboriginal representatives have indicated the site does not have specific cultural significance which would require ongoing protection (Camden Airport Limited, 2015) With regards to non-indigenous heritage, the site was first developed in the 1930's, with the original airport hangar still in use today. The site was used during World War II by the Royal Australian Air Force (RAAF), with structures from that period still present on site today. No structures on site pre-date the 1930's (Camden Airport Limited, 2015) The site is listed for heritage purposes within the *Camden Local Environment Plan 2010*, and on the Register of the National Estate (RNE), which is a non-statutory list which closed in 2007 (Camden Airport Limited, 2015)			
SERVICES AND INFRASTRUCTURE/PEOPLE AND COMMUNITIES			
The site is a general aviation airport, hosting small commercial, private and recreational aircraft operations Aviation facilities at the site include • Taxiways and aprons • Lighting • Air traffic control • Navaids • Refuelling Passenger facilities at the site include: • Parking • Ground transportation No mining or petroleum tenements exist on this site (NNTT, 2020) No Native Title Claims exist over this site (NNTT, 2020)			

IMPACT ASSESSMENT

Direct impacts

Site 6 occurs within the footprint of the OSO tunnel and may be directly impacted by construction of the tunnel. There will be no direct impacts to Site 6 due to other development under the Plan.

OSO tunnel

An assessment of the tunnel impacts on biodiversity values is provided in Chapter 36. This section provides a summary of the potential impacts of the tunnel in relation to the environment of Site 6.

It is not possible to determine at this stage the specific nature, extent and duration of the direct impacts of the OSO tunnel on Site 6. Development for the tunnels will generally occur within the tunnel footprints and direct impacts to the land surface will only occur within small areas of the footprint (see Part 2).

Disturbance to the land surface of Site 6 from the tunnel may occur due to:

- Construction activities
- Ancillary infrastructure, including ventilation systems
- Other infrastructure, such as entry and exit ramps and connection and tie in with existing roads and infrastructure
- Pedestrian and cyclist facilities
- Drainage work, pavement and finishing work

This may result in:

- Clearing of native vegetation and habitat
- Disturbance or destruction of buildings, roads and other infrastructure, and disruption of services
- Visual impacts from any permanent infrastructure, including ventilation shafts

It is unlikely that the development of the OSO tunnel would impact sites of heritage significance, as indigenous heritage items have previously been removed from their original position on the site for protection, and non-indigenous heritage items on site include site infrastructure such as airport hangars which are unlikely to be directly impacted.

The most important biodiversity values within the tunnel footprint of Site 6 that may be directly impacted are:

- Small amounts of Coastal Floodplain Eucalypt Forest of Eastern Australia – the potential for notable impacts to this TEC is low. While several small patches of the TEC have the potential to be directly impacted, the amount of impact in the context of the amount remaining in the Strategic Assessment Area is not substantial
- Records and habitat of *Eucalyptus benthamii* and *Pomaderris brunnea* – direct impacts to these species may be notable, as large important populations of each species occur in the tunnel footprint
- Riparian corridor of Nepean River – Site 6 occurs within parts of the riparian corridor of the Nepean River. The corridor contains native vegetation that provides habitat and records of *Eucalyptus benthamii* and *Pomaderris brunnea* as well as likely providing habitat for several common species. It also provides a narrow habitat corridor link across the landscape from Site 6, including to several other larger patches of habitat nearby

Almost all native vegetation and other biodiversity values within Site 6 occur around the western, southern and eastern edges of the site end within the area covered by the Registered Property Agreement.

The Plan includes commitments that are expected to adequately address these potential direct impacts (see below).

Potential Indirect impacts

Site 6 has the potential to be indirectly impacted by construction and operation of the OSO tunnel.

The nearest urban and industrial and infrastructure development is too distant (over 9 km) to be impacted by construction of the development. However, there may be indirect impacts on the site from increased populations in the area associated with urban development.

The potential indirect and facilitated impacts associated with this development and the key values of the environment of Site 6 that are potentially impacted are shown in Table 35-6.

Note that it is considered unlikely that heritage values of the site will be indirectly impacted. Indigenous heritage items have previously been removed from the site for protection purposes, whilst non-indigenous heritage items are of an industrial nature (and includes infrastructure such as airport hangars). It is therefore considered that addition of potential infrastructure associated with a tunnel (such as air vents) would not be inconsistent with the visual amenity and general characteristics of the site.

Table 35-6: Potential indirect impacts on Site 6 associated with the development

<table>
<tr><th>Potential indirect impact</th><th>Extent within Site 6</th><th>Duration</th><th>Values potentially impacted</th></tr>
<tr><td colspan="4">Construction</td></tr>
<tr><td>Soil erosion and disturbance from vegetation clearing and earthworks</td><td rowspan="5">Vicinity of the tunnel footprint</td><td rowspan="5">Generally short term</td><td rowspan="5">People and communities
Biodiversity values</td></tr>
<tr><td>Changes to water quality from soil erosion or disturbance of contaminated soils</td></tr>
<tr><td>Air quality, noise impacts, and visual or other impacts to amenity</td></tr>
<tr><td>Construction traffic causing disruption or reduced accessibility to the site</td></tr>
<tr><td>Spread of weeds, disease, fauna disturbance and inadvertent impacts on adjacent habitat</td></tr>

Riparian corridor within Nepean River</td><td>Long term</td><td>Water resources
Biodiversity values</td></tr>
<tr><td>Disruption to land uses, services or infrastructure</td><td>Whole of site</td><td>Long term</td><td>People and communities</td></tr>
</table>

Biodiversity values

Construction of the tunnel may cause notable indirect impacts to biodiversity values from the spread of weeds, disease, fauna disturbance and inadvertent impacts on adjacent habitat or vegetation. The tunnel also has the potential to cause ground settlement and subsidence due to the tunnel void or groundwater removal leading to disturbance to the land surface, as well as groundwater drawdown, both of which may impact biodiversity values.

The most important biodiversity values within the tunnel footprint of site 6 that may be indirectly impacted are:

- Small amounts of Coastal Floodplain Eucalypt Forest of Eastern Australia – the potential for notable impacts to this TEC is low (as above for direct impacts)
- Records and habitat of *Eucalyptus benthamii* and *Pomaderris brunnea* – indirect impacts to these species may be notable (as above for direct impacts)

- Riparian corridor of Nepean River – The riparian corridor contains native vegetation that provides habitat and records of *Eucalyptus benthamii* and *Pomaderris brunnea* as well as likely providing habitat for several common species. It also provides a narrow habitat corridor link across the landscape from Site 6

The Plan includes commitments that are expected to adequately address these potential impacts on biodiversity values in site 4 resulting from construction and operation of the tunnel (see below).

People and communities

Construction of the tunnel has the potential to significantly disrupt the aviation and passenger facilities at Site 6 as a result of potential temporary closures to parts of the site to allow construction or provide for construction sites, disruption to pedestrian or traffic access to or within the site, and air quality and noise impacts. The Plan includes commitments that are expected to adequately address these potential construction impacts (see below).

The increase in populations in the area facilitated by the urban development is likely to increase the demand for aviation services and passenger facilities at the site. This is likely to be overall a positive benefit to the airport and is expected to be adequately managed through existing management and operational processes.

Population increases may also lead to increased pressure on roads, transport and other infrastructure that service the university. However, the Plan intends to provide for future transport needs by supporting the delivery of major transport projects for Western Sydney. It is also expected that future transport and infrastructure needs of the airport will be provided for through existing local and regional planning processes.

Commitments and mitigation measures

The Plan includes commitments to mitigate direct and indirect impacts from construction and operation of the tunnel.

Direct impacts

The Plan includes a commitment to avoid and minimise impacts from the transport corridors outside the nominated areas (Commitment 4). This includes the following at Camden Airport (Commitment 4.1):

- Avoiding and minimising impacts where possible to:
  - Existing infrastructure
  - Registered Property Agreement site
  - Populations and habitat of *Eucalyptus benthamii* and *Pomaderris brunnea*
- Minimising disruption to existing services

This avoidance process will be undertaken during strategic planning and detailed design of the OSO tunnel project. The process will seek to avoid and minimise direct impacts of the tunnel to Site 6, including impacts to existing infrastructure and disruption to aviation services, as well as biodiversity values.

This commitment is considered to adequately address the risks associated with the potential direct impacts of the OSO tunnel on Site 6. Note that each transport project will be subject to an environmental assessment process under the EP&A Act. While this assessment will not apply to tunnel activities on Site 6 (as Commonwealth land is outside the jurisdiction of NSW planning laws), the minimisation of impacts to infrastructure and disruption to existing services will occur in accordance with standard construction management processes.

Indirect impacts

The Plan includes a commitment to mitigate indirect and prescribed impacts from transport development (Commitment 6). This includes the following measures relevant to Camden Airport (Commitment 6.2):

- Implement mitigation measures to address impacts on *Eucalyptus benthamii* and *Pomaderris brunnea*, including to manage hydrological disturbance, spread of weeds and disease, and soil erosion and sedimentation

This commitment will be delivered through an environmental assessment process that will apply to each transport project under the EP&A Act (currently the State Significant Infrastructure approval process) to assess and manage the direct and indirect impacts of the project. A description of the process is provided in Chapter 15, section 15.6.3.

This process will assess the environmental impacts of the construction and operation of the tunnel project based on detailed design, in accordance with the standard requirements and policies applying to major infrastructure assessments in NSW (see Chapter 15, section 15.6.3). The current process requires an assessment of risks to the environment and the identification of avoidance and mitigation measures to manage these risks. This will include the assessment and management of indirect impacts of the tunnel project that may affect Site 6, including construction activities, changes to surface and groundwater flows and water quality, including groundwater drawdown, noise and air quality impacts, impacts to traffic and accessibility, and disruption to services and infrastructure.

This assessment process therefore provides the mechanism to identify and implement mitigation measures to manage the potential indirect impacts on Site 6 from the transport development.

A detailed description of the assessment and approval process for transport, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.3.

35.3.7 SITE 7

PROFILE

SITE DETAILS	
Owner	The Commonwealth of Australia
Site name	N/A
Site ID number	7
Area	4.7 ha
Address	12 Werombi Road, Grasmere NSW
Folio	5/221387
General description	The site located at 12 Werombi Road, Grasmere NSW. It is understood the site is a space weather monitoring site run by the Bureau of Meteorology. It occurs within the Strategic Assessment Area, approximately 53 km south-west of the Sydney CBD
Site map	The location of Site 7 is shown in Map 54.8
DISTANCE FROM URBAN CAPABLE LANDS/ TRANSPORT CORRIDORS	
The site occurs within the footprint of the tunnel section of the OSO from Cobbitty to Cawdor. The nearest urban capable land occurs approximately 9 km to the west within GMAC	
LANDSCAPES AND LANDFORMS	
This site occurs in a landscape of gently undulating rises on Wianamatta Group shales	
SOIL AND SUBSTRATES	
The soil landscape at Site 7 is Blacktown soil. Blacktown soils are a hardsetting soils that have a shallow to moderately deep depth of > 100 cm (OEH, 2018a)	
WATER	
The site occurs within the Hawkesbury-Nepean catchment. Water quality is variable throughout the area. The majority of the upper reaches of streams and rivers are healthy, while downstream reaches are affected by historical land uses (e.g. clearing, urbanisation) (GES, 2018) A minor non-perennial watercourse intersects the north-west corner of the site. The Nepean River occurs approximately 600 m north east of the site	
VEGETATION	
Native vegetation covers the whole site. The vegetation that occurs on the site is Cumberland Plain Woodland, a Commonwealth and NSW-listed TEC. The TEC is in thinned condition. The vegetation is relatively isolated, and is bounded by Werombi Road to the south, and existing urban development to the west and east. There is some connectivity to the north of the site with the riparian corridor of the Nepean River	

Plant Community Types (PCTs)/ NSW listed threatened ecological communities (TECs)				
PCT number	**PCT name**	**NSW TEC name**	**BC Act status**	**Area (ha)**
0	Cleared	N/A	N/A	0.1
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	Cumberland Plain Woodland in the Sydney Basin Bioregion	Critically Endangered	1.0

850	Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Cumberland Plain Woodland in the Sydney Basin Bioregion	Critically Endangered	3.5
Commonwealth listed threatened ecological communities (TECs)				
TEC name			**EPBC Act status**	**Area (ha)**
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest			Critically Endangered	4.5
Threatened flora species				
Name		**EPBC Act or BC Act status**	**Area of habitat (ha)**	**Number of BioNet records**
Pimelea spicata (Spiked Rice-flower)		Endangered (BC Act & EPBC Act)	4.4	0
Pomaderris brunnea (Brown Pomaderris)		Endangered (BC Act) Vulnerable (EPBC Act)	1.9	0
BIO Map Priority Investment Areas				
No BIO Map core or corridor areas have been identified on this site				
ANIMAL SPECIES				
There are no threatened fauna records known from the site				
Threatened fauna species				
Name		**EPBC Act or BC Act status**	**Area of habitat (ha)**	**Number of BioNet records**
Pommerhelix duralensis (Dural Land Snail)		Endangered (BC Act & EPBC Act)	4.3	0
Pteropus poliocephalus (Grey-headed Flying-fox)		Vulnerable (BC Act & EPBC Act)	4.4	0
Anthochaera phrygia (Regent Honeyeater)		Critically Endangered (BC Act & EPBC Act)	4.5	0
Lathamus discolor (Swift Parrot)		Endangered (BC Act) Critically Endangered (EPBC Act)	4.5	0
CONSERVATION AND SPECIAL USE AREAS				
There are no conservation or special use areas on the site. A Registered Property Agreement protecting biodiversity values occurs at Camden Airport (approximately 700 m north of the site on the other side of the Nepean River)				
HERITAGE PLACES AND ITEMS				
It is not known whether the site has any historic or indigenous heritage values. The site is not listed in the Australian Heritage Database as having heritage values				
SERVICES AND INFRASTRUCTURE/PEOPLE AND COMMUNITIES				
The site is understood to be currently used for space weather monitoring and includes one building The following tenements exist on this site (NNTT, 2020): • Mining tenement (AUTH281) • Petroleum tenement (PPL1) No Native Title Claims exist over this site (NNTT, 2020)				

IMPACT ASSESSMENT

Direct impacts

Site 7 occurs wholly within the footprint of the OSO tunnel and may be directly impacted by construction of the tunnel. There will be no direct impacts to Site 7 due to other development under the Plan.

OSO tunnel

An assessment of the tunnel impacts on biodiversity values is provided in Chapter 36. This section provides a summary of the potential impacts of the tunnel in relation to the environment of Site 7.

It is not possible to determine at this stage the specific nature, extent and duration of the direct impacts of the OSO tunnel on Site 7. Development for the tunnels will generally occur within the tunnel footprints and direct impacts to the land surface will only occur within small areas of the footprint (see Part 2).

Disturbance to the land surface of Site 7 from the tunnel may occur due to:

- Construction activities
- Ancillary infrastructure, including ventilation systems
- Other infrastructure, such as entry and exit ramps and connection and tie in with existing roads and infrastructure
- Pedestrian and cyclist facilities
- Drainage work, pavement and finishing work

This may result in:

- Clearing of native vegetation and habitat
- Disturbance or destruction of the building on site and disruption of the weather services it provides
- Visual impacts from any permanent infrastructure, including ventilation shafts

The most important biodiversity values within the tunnel footprint of Site 7 that may be directly impacted are small amounts of Cumberland Plain Woodland. The potential for notable impacts to this TEC is low. While a patch of the TEC has the potential to be directly impacted, the amount of impact in the context of the amount remaining in the Strategic Assessment Area is not substantial and the patch is in thinned condition and is relatively isolated.

The Plan includes commitments that are expected to adequately address these potential direct impacts (see below).

POTENTIAL INDIRECT IMPACTS

Site 7 has the potential to be indirectly impacted by construction and operation of the OSO tunnel.

The nearest urban and industrial and infrastructure development is too distant (over 9 km) to be impacted by construction of the development. However, there may be indirect impacts on the site from increased populations in the area associated with urban development.

The potential indirect and facilitated impacts associated with this development and the key values of the environment of Site 7 that are potentially impacted are shown in Table 35-7.

Table 35-7: Potential indirect impacts on Site 7 associated with the development

Potential indirect impact	Extent within Site 7	Duration	Values potentially impacted
Construction			
Soil erosion and disturbance from vegetation clearing and earthworks	Whole of site	Generally short term	People and communities Biodiversity values
Changes to water quality from soil erosion or disturbance of contaminated soils			
Air quality, noise impacts, and visual or other			

Potential indirect impact	Extent within Site 7	Duration	Values potentially impacted
impacts to amenity			
Construction traffic causing disruption or reduced accessibility to the site			
Spread of weeds, disease, fauna disturbance and inadvertent impacts on adjacent habitat			
Disruption to land uses, services or infrastructure	Whole of site	Generally short term	People and communities
Operation			
Ground settlement and subsidence from tunnels due to the tunnel void or groundwater removal, leading to disturbance to the land surface	Whole of site	Short to long term	People and communities Biodiversity values

Biodiversity values

Construction of the tunnel may cause indirect impacts to biodiversity values in Site 7 from the spread of weeds, disease, and inadvertent impacts on adjacent habitat or vegetation. The tunnel also has the potential to cause ground settlement and subsidence due to the tunnel void or groundwater removal leading to disturbance to the land surface, as well as groundwater drawdown, both of which may impact biodiversity values.

The most important biodiversity values within the tunnel footprint of Site 7 that may be indirectly impacted are small amounts of Cumberland Plain Woodland. The potential for notable impacts to this TEC is low (as above for direct impacts).

The Plan includes commitments that are expected to adequately address these potential impacts on biodiversity values in Site 7 resulting from construction and operation of the tunnel (see below).

People and communities

Construction of the tunnel has the potential to disrupt the services provided at Site 7 – space weather monitoring – as a result of potential temporary closures to parts of the site to allow construction or provide for construction sites, disruption to traffic access to or within the site, and air quality and noise impacts. The Plan includes commitments that are expected to adequately address these potential construction impacts (see below).

Commitments and mitigation measures

The Plan includes commitments to mitigate direct and indirect impacts from construction and operation of the tunnel.

Direct impacts

The Plan includes a commitment to avoid and minimise impacts from the transport corridors outside the nominated areas (Commitment 4). This includes the following at Site 7 (Commitment 4.1):

- Avoiding and minimising impacts where possible to existing infrastructure
- Minimising disruption to existing services

This avoidance process will be undertaken during strategic planning and detailed design of the OSO tunnel project. The process will seek to avoid and minimise direct impacts of the tunnel to Site 7, including impacts to existing infrastructure and disruption to weather services, as well as biodiversity values.

This commitment is considered to adequately address the risks associated with the potential direct impacts of the OSO tunnel on Site 7. Note that each transport project will be subject to an environmental assessment process under the EP&A Act. While this assessment will not apply to tunnel activities on Site 7 (as Commonwealth land is outside the jurisdiction of NSW planning laws), the minimisation of impacts to infrastructure and disruption to existing services will occur in accordance with standard construction management processes.

Indirect impacts

The Plan includes a commitment to mitigate indirect impacts from transport corridors (Commitment 6). This commitment will be delivered through an environmental assessment process that will apply to each transport project under the EP&A Act (currently the State Significant Infrastructure approval process) to assess and manage the direct and indirect impacts of the project. A description of the process is provided in Chapter 15, section 15.6.3.

This process will assess the environmental impacts of the construction and operation of the tunnel project based on detailed design, in accordance with the standard requirements and policies applying to major infrastructure assessments in NSW (see Chapter 15, section 15.6.3). The current process requires an assessment of risks to the environment and the identification of avoidance and mitigation measures to manage these risks. This will include the assessment and management of indirect impacts of the tunnel project that may affect Site 7, including construction activities.

This assessment process therefore provides the mechanism to identify and implement mitigation measures to manage the potential indirect impacts on Site 7 from the transport development.

A detailed description of the assessment and approval process for transport, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.3.

35.3.8 SITE 8 (WESTERN SYDNEY (NANCY-BIRD WALTON) INTERNATIONAL AIRPORT)

PROFILE

SITE DETAILS	
Owner	The Commonwealth of Australia
Site name	Western Sydney (Nancy-Bird Walton) International Airport
Site ID number	8
Area	1,745.5 ha
Address	Badgerys Creek Road, Badgerys Creek NSW
Folio	101/123631, 11/226448, 9/226448, 3/611519, 7/3050, 8/3050, 2/C/1451, 11/1239207, 98/1236319, 99/1236319, 102/123631, 103/123631, 9/1233751, 14/1233751, 13/1233751, 8/1233751, 5/1233751, 32/259698, 108/123631, 107/123631, 23/259698, 17/258581, 6/1233751, 1/1233751, 3/1233751, 4/1233751, 1/129674
General description	Site 8 comprises the new Western Sydney (Nancy-Bird Walton) International Airport at Badgerys Creek. Construction of the airport is currently underway. The site has historically been used for agricultural purposes, consisting of stock grazing, cropping, orchards, dairying, and market gardening (DIRD, 2016a). Prior to commencement of airport construction works, native vegetation covered 25.0 per cent of the site. The site is located approximately 42 km west of the Sydney CBD
Site map	The location of Site 8 is shown in Map 54.9
DISTANCE FROM URBAN CAPABLE LANDS/ TRANSPORT CORRIDORS	
Site 8 shares its northern, western and south-western border with urban capable land in WSA	
LANDSCAPES AND LANDFORMS	
This site occurs in a landscape of gently undulating to rolling low hills and floodplains, valley flats and drainage depressions. As part of airport construction works, extensive landscaping will be undertaken on site to flatten the runway regions and provide suitable surfaces for airport infrastructure	
SOIL AND SUBSTRATES	
The soil landscape at Site 8 is made up of: • 1,478 ha Blacktown soil landscape – Blacktown soils are a hardsetting soils that have a shallow to moderately deep depth of > 100 cm (OEH, 2018a) • 79 ha Luddenham soil – Luddenham soils exist in varying forms depending on their location on a slope. Podzolic soils or earthy clays, yellow podzolic soils, and prairie soils are found on crests, upper slopes, and drainage lines respectively (OEH, 2018a) • 189 ha Wianamatta (South Creek) soil – Wianamatta (South Creek) soils are deep layered sediments that occur over bedrock or relict soils (minerals/structures that have not undergone metamorphic change while the surrounding rock has) (OEH, 2018a)	
WATER	
Site 8 occurs within the Hawkesbury-Nepean catchment. Water quality is variable throughout the area. The majority of the upper reaches of streams and rivers are healthy, while downstream reaches are affected by historical land uses (e.g. clearing, urbanisation) (GES, 2018). The site is located on the Bringelly Shale aquifer (DIRD, 2016d) There are several waterways within Site 8, including Badgerys Creek, Cosgroves Creek, Oaky Creek, and Duncans Creek. These will be significantly modified by the new airport (DIRD, 2016d)	
VEGETATION	
Most native vegetation that exists within the site will be removed for the new airport. While some areas of low vegetation (such as grass) will likely be retained within the airport layout (such as adjacent to the runways), such vegetation will be subject to ongoing management (such as mowing) and has little biodiversity value Environmental protection zones will be established along the riparian corridor of Badgerys Creek, and on the small site	

to the west of The Northern Road which is separated from the rest of Site 8. Existing vegetation within these areas will be protected from impacts associated with the airport development. Ecological communities within these areas include (DIRD, 2016b)

- Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain
- Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain
- Exotic grassland

BIO Map Priority Investment Areas

No BIO Map core or corridor areas have been identified on this site

ANIMAL SPECIES

Prior to the completion of the airport development, available fauna habitat on Site 8 included grassland, cropped areas, native woodland, riparian forest, and wetlands, and the site was known to support 173 fauna species known to occur at the site, including a number of threatened fauna species (DIRD, 2016b)

Following completion of the airport development, fauna habitat types at Site 8 will primarily include riparian forest and grassland and it is expected that fewer fauna species will have suitable habitat available on-site

CONSERVATION AND SPECIAL USE AREAS

Environmental protection zones will be established along the riparian corridor of Badgerys Creek, and on the small site to the west of The Northern Road which is separated from the rest of Site 8

HERITAGE PLACES AND ITEMS

Surveys were conducted for the Western Sydney Airport EIS that identified existing and new historic and indigenous heritage items (DIRD, 2016a, 2016c).

Identified indigenous heritage sites include numerous surface artefacts (including a grinding groove site), a modified tree, and subsurface artefacts. Higher artefact densities were found in close proximity to permanent water. The site was identified to be important as a place of cultural significance and continuing cultural connection by indigenous stakeholders consulted as part of the EIS process for Western Sydney Airport.

European heritage items reflect the historical development of the locality, including early efforts to develop agricultural economies and settled village communities. Examples of heritage items include early residential and commercial buildings, remains of early churches and associated graveyards, and infrastructure including historical wells.

As part of the airport development process, numerous strategies have been prepared and implemented to record, preserve and (where required) salvage heritage items on site to ensure that these items are protected from the impacts of the airport development

SERVICES AND INFRASTRUCTURE/PEOPLE AND COMMUNITIES

Site 8 is the future site for the new Western Sydney (Nancy-Bird Walton) International Airport, which is currently being constructed. The site will include

- Runways
- Taxiways and aprons
- Aviation rescue and fire-fighting services
- Air traffic control
- Airport terminals
- Utilities
- Road and rail access

The following tenement exists on this site (NNTT, 2020):

- Mining tenement (EL8429) – exploration lease
- Mining tenement (ML1771) – mining lease

No Native Title Claims exist over this site (NNTT, 2020)

IMPACT ASSESSMENT

Direct impacts

There will be no direct impacts to Site 8 due to the Plan (although note the GIS boundary error discussed in section 35.1, which wrongly suggests there are very small direct impacts).

Indirect and facilitated impacts

Site 8 has the potential to be indirectly impacted by construction and operation of the urban and industrial, and infrastructure development which occurs adjacent to the northern, western and southern boundaries of the site.

The potential indirect and facilitated impacts associated with these developments and the key values of the environment of Site 8 that are potentially impacted are shown in Table 35-8.

Table 35-8: Potential indirect impacts on Site 8 associated with the development

Potential indirect impact	Extent within Site 8	Duration	Values potentially impacted
Construction			
Soil erosion and disturbance from vegetation clearing and earthworks	Boundaries of the site	Generally short term	People and communities Biodiversity values
Changes to water quality from soil erosion or disturbance of contaminated soils			
Air quality, noise impacts, and visual or other impacts to amenity			
Construction traffic causing disruption or reduced accessibility to the site			
Spread of weeds, disease, fauna disturbance and inadvertent impacts on adjacent habitat			
Disruption to land uses, services or infrastructure	Whole of site	Generally short term	People and communities
Operation			
Changes to surface water flows due to additional runoff from urban areas	Waterways within the site	Long term	Water resources Biodiversity values
Disruption to land uses, services or infrastructure	Whole of site	Long term	People and communities

Biodiversity values

There is potential for indirect impacts from construction and operation of urban, industrial, and infrastructure development on the environmental protection zones to the west of The Northern Road, including spread of weeds and disease, fauna disturbance and inadvertent impacts on adjacent habitat, as well as potentially increased risk of human disturbance from public access. This area contains approximately 12 ha of mostly good condition Forest Red Gum - Rough-barked Apple grassy woodland, 4.9 ha of mostly poor condition Grey Box - Forest Red Gum grassy woodland, with the remainder of the site (approximately 3.5 ha) containing exotic grassland (DIRD, 2016b).

The OSO to the west of the site has the potential to reduce the connectivity of the environmental protection zones adjacent to The Northern Road. This area is currently connected to the riparian corridor of Duncan's Creek, which connects to patches of habitat and riparian corridors that link to the Nepean River to the west. The potential impacts of the OSO on the riparian corridor at Duncan's Creek may reduce the habitat values of the site for native species, and may decrease the viability of the vegetation communities on site.

The Plan includes commitments that are expected to adequately address these potential impacts on biodiversity values in Site 8 resulting from construction and operation of the development (see below).

Water resources

There is potential for runoff from urban industrial, and infrastructure development to impact surface water flows and water quality in Badgerys Creek, as this development is located adjacent to upstream tributaries of the creek. The Plan includes commitments that are expected to adequately address these potential impacts (see below).

The riparian corridor along Badgerys Creek is not considered to be at risk of other indirect impacts (such as noise or light) as a result of the Plan, as urban development is not planned to occur adjacent to the creek.

People and communities

Construction of the development has the potential to disrupt the airport services and facilities at Site 8 once the site is operating, as a result of potential temporary closures to parts of the site to allow construction or provide for construction sites, disruption to pedestrian or traffic access to the site, and air quality and noise impacts. The Plan includes commitments that are expected to adequately address these potential construction impacts (see below).

The urban, industrial, infrastructure, agribusiness and transport development within the vicinity of Site 8 will directly complement the use of the site as a major airport facility. The development will provide commercial and residential and agribusiness facilities in close proximity to the airport. This will allow for:

- The development of new commercial precincts in association with economic activity generated by the airport
- The provision of accessible and affordable housing close to the airport site to provide for employees of the airport and related commercial enterprises

The urban development and transport development under the Plan will therefore complement the operation of the airport at Site 8 and will subsequently produce a range of social and economic benefits.

Commitments and mitigation measures

The Plan includes commitments to mitigate indirect impacts from construction and operation associated with urban and industrial and infrastructure development. These commitments and processes to deliver these comments are different for each type of development.

Urban and industrial development

The Plan includes a commitment to mitigate indirect and prescribed impacts from development to best practice standards (Commitment 5). This commitment will be delivered through development controls specified in Development Control Plans (DCPs) and implemented through the standard development application process that occurs under the NSW planning system. A description of the process is provided in Chapter 15, section 15.6.1.

Relevant councils will prepare a DCP for each nominated area in collaboration with the Department and in accordance with standard processes for developing DCPs in NSW. The DCP will include development controls relevant to addressing the indirect and facilitated impacts of the urban and industrial development that may affect Site 8.

The general environmental controls likely to be included in DCPs are set out in Chapter 15, section 15.6.1, and include:

- Preparation of Construction Environmental Management Plans to manage on-site construction impacts
- Controls for managing impacts to hydrology and water quality

These development controls and the process for implementing them are expected to adequately address the potential indirect and facilitated impacts of the urban and industrial development that will occur adjacent to Site 8.

A detailed description of the development controls and implementation process, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.1.

Infrastructure development

The Plan includes a commitment to mitigate indirect and prescribed impacts from infrastructure development (Commitment 5.3). This commitment will be delivered through an environmental assessment and approval process that will be applied to detailed design of each infrastructure project at the time the project is brought forward for development. This will be undertaken under Part 4 or Part 5 of the EP&A Act (or equivalent at the time). State

Environmental Planning Policy (SEPP) (Infrastructure) 2007 provides a framework for determining how most types of infrastructure are assessed under the EPA Act.

This assessment process will assess and identify mitigation measures to manage the non-biodiversity related potential environmental impacts of the project. This will include the assessment and management of indirect impacts of any infrastructure projects that may affect Site 8, including impacts to hydrology and water quality.

This process therefore provides the mechanism to identify and implement mitigation measures to manage the potential indirect impacts on Site 8 from the infrastructure development.

A detailed description of the assessment and approval process for infrastructure, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.2.

35.3.9 SITE 9 (RAAF TELECOMMUNICATIONS UNIT)

Profile

SITE DETAILS	
Owner	The Commonwealth of Australia
Site name	RAAF Telecommunications Unit
Site ID number	9
Area	114.9 ha
Address	215 Badgerys Creek Road, Bringelly NSW
Folio	10/1235662
General description	The site is located 215 Badgerys Creek Road, Bringelly NSW. The site contains 16.2 per cent native vegetation cover. The site occurs in the Strategic Assessment Area, approximately 45 km south-west of the Sydney CBD
Site map	The location of Site 9 is shown in Map 54.10
DISTANCE FROM URBAN CAPABLE LANDS/ TRANSPORT CORRIDORS	
The site is located approximately 2 km from nearest development under the Plan – urban and industrial, infrastructure and agribusiness development in WSA. The land surrounding the site consists of low density, rural residential and commercial areas	
LANDSCAPES AND LANDFORMS	
This site occurs in a landscape of gently undulating rise and floodplains, valley flats and drainage depressions	
SOIL AND SUBSTRATES	
The soil landscape at Site 9 is made up of: • 85 ha Blacktown soil – Blacktown soils are a hardsetting soils that have a shallow to moderately deep depth of > 100 cm (OEH, 2018a) • 30 ha Wianamatta (South Creek) soil – Wianamatta (South Creek) soils are deep layered sediments that occur over bedrock or relict soils (minerals/structures that have not undergone metamorphic change while the surrounding rock has) (OEH, 2018a)	
WATER	
The site occurs within the Hawkesbury-Nepean catchment. Water quality is variable throughout the area. The majority of the upper reaches of streams and rivers are healthy, while downstream reaches are affected by historical land uses (e.g. clearing, urbanisation) (GES, 2018) The site is relatively flat. Moore Gully waterway passes through the southern part of the site. Two naturally occurring ponds are connected to this waterway. Five other drainage lines flow into Thompsons Creek and originate from varying locations on the site (DoI, 2019; DTA, DCA et al., 2019)	
VEGETATION	
Approximately 16.2 per cent (18.6 ha) of the site is covered by native vegetation. The eastern edge of the site borders on a narrow riparian corridor that follows Thompsons Creek in a south-north direction The native vegetation on the site, with the exception of the riparian corridor, is isolated from other substantial areas of vegetation and is in thinned (low) condition

CONSERVATION AND SPECIAL USE AREAS

There are no conservation or special use areas present on this site

The closest conservation or special use areas are:

- Area under a conservation agreement in Badgerys Creek (approximately 7.5km north)
- Kemps Creek Nature Reserve (approximately 5.5km northeast)
- Metro offset site (approximately 7km northeast)
- Biobanking agreement site in Mulgoa (approximately 8.5km north west)
- A number of biobanking agreement sites (approximately 8 northeast)
- A biobanking agreement site in Leppington (approximately 8.5km south east)
- Bents Basin and Gulguer Nature Reserves (approximately 8-10km west)
- A number of Metro offset sites (approximately 9km south)
- Edmondson Regional Park (approximately 10km south east)
- A Metro offset site (approximately 10.5km east)

HERITAGE PLACES AND ITEMS

It is not known whether the site has any historic or indigenous heritage values. The site is not listed in the Australian Heritage Database as having any heritage values

SERVICES AND INFRASTRUCTURE/PEOPLE AND COMMUNITIES

The site is an RAAF telecommunications unit. The telecommunications unit is no longer in use. The site is part of the future Aerotropolis Town Centre, within the South West Sydney Growth Centre

No Native Title Claims exist over this site (NNTT, 2020)

The following tenement exists on this site (NNTT, 2020): Mining tenement (EL8429)

IMPACT ASSESSMENT

Direct impacts

There will be no direct impacts to Site 9 due to the Plan.

Indirect and facilitated impacts

Site 9 occurs approximately 1.9 km from the nearest development under the Plan – urban and industrial, infrastructure and agribusiness development within WSA. The land surrounding Site 9 consists of low density, rural residential and commercial areas. The site is also located upstream of the nearest development and within a separate sub-catchment. The location of the site relative to the development and nature of the areas surrounding the site means:

- The site is very unlikely to be impacted by impacts typically associated with construction of the development in WSA such as air quality, noise, construction traffic, or the spread of weeds or disease
- The site will not be impacted by soil erosion of sedimentation, changes to surface and groundwater quantity and flows, or water quality impacts associated with the construction and operation of the development

Furthermore, the site no longer appears to be in use. If this is the case, the development would not disrupt any services or site operations or affect the health or safety of any person associated with the site.

The potential indirect or facilitated impacts associated with the development in WSA and the key values of the environment of Site 9 that are potentially impacted are shown in Table 35-9.

Table 35-9: Potential indirect impacts on Site 9 associated with the development

Potential indirect impact	Extent within site 1	Duration	Values of site potentially impacted
Construction			
Clearing of habitat during construction of the development that links the site to other areas of habitat, leading to impacts on biodiversity values	Whole of site	Long term	Biodiversity values

Biodiversity values

There are some areas of vegetation present on Site 9 which provide some habitat values for a number of native species. The habitat on Site 9 is primarily connected to the surrounding environment via a vegetated riparian corridor which continues to the north-east and south-west of the site.

The connectivity of this riparian corridor to the surrounding area will not be directly impacted by development under the Plan, and therefore the habitat values of the site are unlikely to be impacted indirectly by the Plan.

Commitments and mitigation measures

No commitments or mitigation measures are considered necessary to address the potential indirect impacts on the environment of Site 9 from the development under the Plan.

35.3.10 SITE 10

PROFILE

SITE DETAILS	
Owner	The Commonwealth of Australia
Site name	N/A
Site ID number	10
Area	10.5 ha
Address & Folio	221 Greendale Road, Greendale NSW
Folio	15/229293
General description	The site located at 221 Greendale Road, Greendale NSW. The site is potentially used for grazing. Approximately 19.1 per cent of the site is covered by native vegetation. The site occurs within the Strategic Assessment Area, approximately 45 km south-west of the Sydney CBD
Site map	The location of Site 10 is shown in Map 54.11
DISTANCE FROM URBAN CAPABLE LANDS/ TRANSPORT CORRIDORS	
The site is directly impacted by the footprint of the OSO under the Plan. The area of impact is approximately 4 ha, and occurs along the north-eastern corner of the site	
LANDSCAPES AND LANDFORMS	
This site occurs in a landscape of gently undulating rises to rolling low hills on Wianamatta Group shales	
SOIL AND SUBSTRATES	
The soil landscape at Site 10 is made up of: • 10 ha of Blacktown soil – Blacktown soils are a hardsetting soils that have a shallow to moderately deep depth of > 100 cm (OEH, 2018a) • < 1 ha of Luddenham soil – Luddenham soils exist in varying forms depending on their location on a slope. Podzolic soils or earthy clays, yellow podzolic soils, and prairie soils are found on crests, upper slopes, and drainage lines respectively (OEH, 2018a)	
WATER	
The site occurs within the Hawkesbury-Nepean catchment. Water quality is variable throughout the area. The majority of the upper reaches of streams and rivers are healthy, while downstream reaches are affected by historical land uses (e.g. clearing, urbanisation) (GES, 2018) The site contains a number of dams, which appear likely to be stock dams based on aerial imagery. The site is located at the headwaters of two drainage lines, which feed into Duncans Creek, and from there enter the Nepean River	
VEGETATION	
Native vegetation primarily occurs on the southern half of the site, with some scattered paddock trees occurring in the northern half of the site. Areas with trees occupy approximately 2 ha of the site The remainder of the site is cleared and may be used for grazing cattle The site is located within a wider agricultural landscape, which includes completely cleared areas, paddocks with scattered paddock trees and small vegetation patches, and larger, more connected areas of vegetation which tend to be associated with riparian corridors. Overall, the landscape is significantly fragmented, with riparian corridors and small patches of vegetation serving as 'stepping stones' through otherwise cleared paddocks

BIO Map Priority Investment Areas
No BIO Map core or corridor areas have been identified on this site

ANIMAL SPECIES
There are no threatened fauna records known from the site

Threatened fauna species			
Name	**EPBC Act or BC Act status**	**Area of habitat (ha)**	**Number of BioNet records**
Pommerhelix duralensis (Dural Land Snail)	Endangered (BC Act & EPBC Act)	1.8	0
Pteropus poliocephalus (Grey-headed Flying-fox)	Vulnerable (BC Act & EPBC Act)	1.8	0
Petauroides volans (Greater Glider)	Vulnerable (EPBC Act)	1.3	0
Anthochaera phrygia (Regent Honeyeater)	Critically Endangered (BC Act & EPBC Act)	2.0	0
Lathamus discolor (Swift Parrot)	Endangered (BC Act) Critically Endangered (EPBC Act)	2.0	0

CONSERVATION AND SPECIAL USE AREAS
There are no conservation or special use areas present on this site The closest conservation or special use areas are: • Biobanking agreement site in Mulgoa (approximately 5.5km north) • Bents Basin and Gulguer Nature Reserves (approximately 3.5-4.5km south west)
HERITAGE PLACES AND ITEMS
It is not known whether the site has any historic or indigenous heritage values. The site is not listed in the Australian Heritage Database as having any heritage values
SERVICES AND INFRASTRUCTURE/PEOPLE AND COMMUNITIES
The use of this site is unknown. There are several small buildings on the site. The site may be used for grazing The following tenement exists on this site (NNTT, 2020): • Mining tenement (EL8429) No Native Title Claims exist over this site (NNTT, 2020)

Impact assessment

Direct impacts

The OSO will directly impact up to 4.2 ha of Site 10 (39.8 per cent of the site).

Impacts to Site 10 will occur in the north-eastern corner of the site. This area includes pastures, some scattered paddock trees and a small area (approximately 0.1 ha) of Cumberland Plain Woodland. The south-west of the site, which contains approximately 2 ha of Cumberland Plain Woodland, will not be directly impacted.

The loss of a very small amount of Cumberland Plain Woodland (0.1 ha) is not considered notable. The landscape surrounding the site is significantly fragmented and the native vegetation on the site is isolated and provides little connectivity value to nearby areas of habitat.

The OSO will substantially disrupt any existing uses of the site. However, the use of the site is unknown, although it appears to be used for grazing. The grazing value of the site is very limited as the site is very small and any impacts on the use of the site for grazing are unlikely to be notable.

Indirect and facilitated impacts

Site 10 has the potential to be indirectly impacted by construction and operation of the OSO.

The nearest urban and industrial and infrastructure development is too distant (over 9 km) for the site to be impacted by the construction of this development.

The potential indirect and facilitated impacts associated with this development and the key values of the environment of Site 10 that are potentially impacted are shown in Table 35-10.

Table 35-10: Potential indirect impacts on Site 10 associated with the development

Potential indirect impact	Extent within Site 11	Duration	Values potentially impacted
Construction			
Soil erosion and disturbance from vegetation clearing and earthworks	Whole of site	Generally short term	People and communities Biodiversity values
Air quality, noise impacts, and visual or other impacts to amenity			
Construction traffic causing disruption or reduced			

Potential indirect impact	Extent within Site 11	Duration	Values potentially impacted
accessibility to the site			
Spread of weeds, disease, fauna disturbance and inadvertent impacts on adjacent habitat			
Disruption to land uses, services or infrastructure	Whole of site	Generally short term	People and communities
Operation			
Air quality, noise impacts, and visual or other impacts to amenity	Whole of site	Short to long term	People and communities

Biodiversity values

Construction of the OSO may cause indirect impacts to biodiversity values from the spread of weeds, disease, and inadvertent impacts on adjacent habitat or vegetation.

The most important biodiversity values within the tunnel footprint of Site 10 that may be indirectly impacted are small amounts of Cumberland Plain Woodland. The potential for notable impacts to this TEC is low (see above).

The Plan includes commitments that are expected to adequately address these potential impacts on biodiversity values in Site 10 resulting from construction and operation of the tunnel (see below).

People and communities

The OSO is likely to substantially disrupt any existing uses of the site from impacts such as air quality, noise impacts, and visual or other impacts to amenity associate with construction and operation, as well as construction traffic causing disruption or reduced accessibility to the site.

However, the use of the site is unknown, although it appears to be used for grazing. The grazing value of the site is very limited as the site is very small and any impacts on the use of the site for grazing are unlikely to be notable.

Commitments and mitigation measures

No commitments or mitigation measures are considered necessary to address any specific notable direct or indirect impacts on the environment of Site 10 from the development under the Plan.

However, the Plan includes commitments to avoid and minimise impacts from the transport corridors (Commitment 4) and mitigate indirect impacts from transport corridors (Commitment 6) and these are expected to adequately minimise impacts on the environment of Site 10.

35.3.11 SITE 11 (HOLSWORTHY DEFENCE BASE)

PROFILE

SITE DETAILS	
Owner	The Commonwealth of Australia
Site name	Holsworthy Defence Base
Site ID number	11
Area	18,826.0 ha
Address	Heathcote Road, Moorebank/Holsworthy NSW
Folio	100/104950, 1/1197707, 4/1130937, 2/1197707, 3/1197707, 4/1197707, 122/119451, 2/1186495, 2/1216308, 1/1216308
General description	Holsworthy Defence Base is located on Heathcote Rd, Moorebank in the Strategic Assessment Area. It is bounded on the south east by Heathcote National Park and by Georges River in the west. Native vegetation covers 95.8 per cent of the site. The site is part of two Commonwealth Heritage Listed sites and five areas listed on the NSW heritage list. The site contains high biodiversity values, supporting a range of threatened species and TECs. Holsworthy is located approximately 35 km south-west of the Sydney CBD
Site map	The location of Site 11 is shown in Map 54.12
DISTANCE FROM URBAN CAPABLE LANDS/ TRANSPORT CORRIDORS	
The nearest development under the Plan to Site 11 is urban capable land at the northern end of GMAC (near Glenfield), which is located approximately 1.4 km from the boundary of the site. The land in between the urban capable land and Site 11 in this area consists of existing urban development In the middle section of GMAC (between Glen Alpine and Rosemeadow), the urban capable land is located approximately 2.5 km from the boundary of Site 11 at its closest point to the site. The land between the urban capable land and Site 11 in this area consists of areas of urban development in the north west, agricultural fields in the south west and riparian vegetation associated with the Georges River in the east In the southern section of GMAC (between Gilead and Appin), the urban capable land is located approximately 4 km from the boundary of Site 11 at its closest point to the site. The land in between the urban capable land and Site 11 in this area consists of agricultural fields, low density rural residential areas and native vegetation	
LANDSCAPES AND LANDFORMS	
Site 11 is a large site that occurs across numerous of different landscape types. It occurs in a landscape of undulating rolling rises and low hills through to rugged, rolling to very steep hills on Hawkesbury Sandstone. It contains areas of disturbed terrain, most likely as a result of military activity on the site	
SOIL AND SUBSTRATES	
The soil landscape at Site 11 is made up of: • 680 ha Berkshire Park soil – Berkshire Park soil consists of heavy clays and clayey sands that are made up of less than a third of soil aggregates (OEH, 2018a) • 448 ha Blacktown soil – Blacktown soils are a hardsetting soils that have a shallow to moderately deep depth of > 100 cm (OEH, 2018a) • 220 ha Bundeena soil – no soil landscape report available • 19 ha Disturbed Terrain – areas where the original soil has been highly disturbed, buried or removed (OEH, 2018a) • 253 ha Faulconbridge soil – Faulconbridge soils are shallow (<50 cm) earthy sands and yellow earths with some siliceous sands associated with rock outcrops (OEH, 2018a) • 510 ha Gymea soil – Gymea soils are approximately 30-100 cm deep. The particular soil characteristic depends on the location. Gymea soils are made up of yellow earths and earthy sands, shallow siliceous sands, water logged and yellow podzolic sands, and siliceous and leached sands of < 100 cm in depth (OEH, 2018a)	

- 6,763 ha Hawkesbury soil – Hawkesbury soils are shallow (<50 cm). Rock outcrops, earthy sands, and shale lenses are associated with different aspects of Hawkesbury soils (OEH, 2018a)
- 9,806 ha Lucas Heights soil – Lucas Heights soils are moderately deep (50-150 cm). The soils are hardsetting and consist of yellow podzolic and yellow soloth soils
- 117 ha Richmond soil – Richmond soils consist of orange to red clay loams, clays, and sands that are poorly structured (OEH, 2018a)

WATER

Site 11 occurs within the Georges River catchment. The site has an undulating to dissected topography and is bounded on the west by the Georges River and on the east by the Woronora River. All waterways on the site are tributaries of these two rivers (DoI, 2019; DTA, DCA et al., 2019)

VEGETATION

Site 11 is heavily vegetated with 95.8 per cent (18,027.7 ha) of the site covered by native vegetation. The site includes large areas of several Commonwealth-listed TECs, including Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest, Castlereagh Scribbly Gum and Agnes Banks Woodlands and Cooks River/Castlereagh Ironbark Forest.

The site is well connected to large areas of habitat and protected lands. Three national parks occur adjacent to the boundaries of the site, including Dharawal National Park (adjacent to the southern boundary), Heathcote National Park (adjacent to the eastern boundary) and Georges River National Park (adjacent to the north eastern boundary). The site connects Heathcote National Park in the east to Dharawal National Park and other large areas of habitat in the west, particularly habitat in the vicinity of the Georges River, and the Nepean River further west

Plant Community Types (PCTs)/ NSW listed threatened ecological communities (TECs)

PCT number	PCT name	NSW TEC name	BC Act status	Area (ha)

BIO Map Priority Investment Areas

The site has been identified on BIO Map as containing over 1,115 ha of core areas and 59 ha of corridors

Type	**Area (ha)**
Core areas	1,114.9
State and Regional Biodiversity Corridors	58.6

ANIMAL SPECIES

The site contains records and habitat for a wide range of threatened fauna species, and is likely to contain habitat and populations of many common native fauna species (Eco Logical Australia, 2012; ERM, 2012)

Threatened fauna species			
Name	**EPBC Act or BC Act status**	**Area of habitat (ha)**	**Number of BioNet records**
Pommerhelix duralensis (Dural Land Snail)	Endangered (BC Act & EPBC Act)	895.1	0
Pteropus poliocephalus (Grey-headed Flying-fox)	Vulnerable (BC Act & EPBC Act)	7,883.4	27
Botaurus poiciloptilus (Australasian Bittern)	Endangered (BC Act & EPBC Act)	9.2	0
Hoplocephalus bungaroides (Broad-headed Snake)	Endangered (BC Act) Vulnerable (EPBC Act)	261.9	4
Heleioporus australiacus (Giant Burrowing Frog)	Vulnerable (BC Act & EPBC Act)	170.6	19
Petauroides volans (Greater Glider)	Vulnerable (EPBC Act)	781.9	0
Chalinolobus dwyeri (Large-eared Pied Bat)	Vulnerable (BC Act & EPBC Act)	1,084.8	2
Macquaria australasica (Macquarie Perch)	Endangered (BC Act & EPBC Act)	7.6	0
Anthochaera phrygia (Regent Honeyeater)	Critically Endangered (BC Act & EPBC Act)	1,199.1	0
Rostratula australis (Australian Painted Snipe)	Endangered (BC Act & EPBC Act)	4.2	0
Dasyurus maculatus maculatus (Spot-tailed Quoll)	Vulnerable (BC Act) Endangered (EPBC Act)	997.8	4
Lathamus discolor (Swift Parrot)	Endangered (BC Act) Critically Endangered (EPBC Act)	1,199.1	6
Artamus cyanopterus cyanopterus (Dusky Woodswallow)	Vulnerable (BC Act)	0.0	7
Burhinus grallarius (Bush Stone-curlew)	Endangered (BC Act)	0.0	2
Callocephalon fimbriatum (Gang-gang Cockatoo)	Vulnerable (BC Act)	0.0	3
Calyptorhynchus lathami (Glossy Black-Cockatoo)	Vulnerable (BC Act)	0.0	5
Cercartetus nanus (Eastern Pygmy-possum)	Vulnerable (BC Act)	0.0	3
Climacteris picumnus victoriae (Brown Treecreeper)	Vulnerable (BC Act)	0.0	2
Daphoenositta chrysoptera (Varied Sittella)	Vulnerable (BC Act)	0.0	19
Dasyornis brachypterus (Eastern Bristlebird)	Endangered (BC Act & EPBC Act)	0.0	2
Epthianura albifrons (White-fronted Chat)	Vulnerable (BC Act)	0.0	2
Falsistrellus tasmaniensis (Eastern False Pipistrelle)	Vulnerable (BC Act)	0.0	24
Glossopsitta pusilla (Little Lorikeet)	Vulnerable (BC Act)	0.0	41

Haliaeetus leucogaster (White-bellied Sea-eagle)	Vulnerable (BC Act)	0.0	1
Hieraaetus morphnoides (Little Eagle)	Vulnerable (BC Act)	0.0	3
Litoria aurea (Green and Golden Bell Frog)	Endangered (BC Act) Vulnerable (EPBC Act)	0.0	3
Litoria littlejohni (Littlejohn's Tree Frog)	Vulnerable (BC Act)	0.0	1
Lophoictinia isura (Square-tailed Kite)	Vulnerable (BC Act)	0.0	3
Meridolum corneovirens (Cumberland Plain Land Snail)	Endangered (BC Act)	0.0	43
Micronomus norfolkensis (Eastern Coastal Free-tailed Bat)	Vulnerable (BC Act)	0.0	9
Miniopterus australis (Little Bent-winged Bat)	Vulnerable (BC Act)	0.0	1
Miniopterus orianae oceanensis (Large Bent-winged Bat)	Vulnerable (BC Act)	0.0	9
Myotis macropus (Southern Myotis)	Vulnerable (BC Act)	0.0	10
Neophema pulchella (Turquoise Parrot)	Vulnerable (BC Act)	0.0	1
Ninox connivens (Barking Owl)	Vulnerable (BC Act)	0.0	1
Ninox strenua (Powerful Owl)	Vulnerable (BC Act)	0.0	9
Pachycephala olivacea (Olive Whistler)	Vulnerable (BC Act)	0.0	1
Petaurus australis (Yellow-bellied Glider)	Vulnerable (BC Act)	0.0	1
Petaurus norfolcensis (Squirrel Glider)	Vulnerable (BC Act)	0.0	2
Petrogale penicillata (Brush-tailed Rock-wallaby)	Endangered (BC Act) Vulnerable (EPBC Act)	0.0	1
Petroica boodang (Scarlet Robin)	Vulnerable (BC Act)	0.0	11
Petroica phoenicea (Flame Robin)	Vulnerable (BC Act)	0.0	1
Phascolarctos cinereus (Koala)	Vulnerable (BC Act & EPBC Act)	0.0	298
Pseudophryne australis (Red-crowned Toadlet)	Vulnerable (BC Act)	0.0	40
Saccolaimus flaviventris (Yellow-bellied Sheathtail-bat)	Vulnerable (BC Act)	0.0	20
Scoteanax rueppellii (Greater Broad-nosed Bat)	Vulnerable (BC Act)	0.0	22
Stagonopleura guttata (Diamond Firetail)	Vulnerable (BC Act)	0.0	2
Tyto novaehollandiae (Masked Owl)	Vulnerable (BC Act)	0.0	1
Varanus rosenbergi (Rosenberg's Goanna)	Vulnerable (BC Act)	0.0	4

CONSERVATION AND SPECIAL USE AREAS

The Moorebank Intermodal Terminal Biobanking Agreement site occurs in the north of the site.

The closest conservation or special use areas are:

- Dharawal National Park (adjacent to the southern boundary of the site)
- Heathcote National Park (adjacent to the eastern boundary of the site)
- Georges River National Park (adjacent to the north eastern boundary of the site)

HERITAGE PLACES AND ITEMS
The site partially contains two areas listed on the Commonwealth Heritage List for their outstanding cultural and natural value (DoEE, 2018a): • Old Army/ Internment Camp Group Holsworthy • Cubbitch Barta National Estate Area The site also contains areas listed by local government and state agencies on the NSW heritage list (OEH, 2019c): • Cubbitch Barta National Estate Area • Holsworthy (former) Corporals Club • Holsworthy (former) Officer's Mess • Holsworthy Group (Old Army/ Internment Camp Holsworthy) • Holsworthy Powder Magazine (Former Detention Block) Holsworthy Defence base contains two areas on the Register of the National Estate Area (non-statutory): • Cubbitch Barta National Estate Area – registered for its indigenous value • Defence National Storage and Distribution Centre – listed on the interim list for its historic value It is not known whether the site has any other historic or indigenous heritage values. The site is not listed in the Australian Heritage Database as having any other heritage values
SERVICES AND INFRASTRUCTURE/PEOPLE AND COMMUNITIES
The site is a defence base, including a training area and artillery range, for the Australian Army. Activities carried out on the base include the use of firing ranges, chemical weapons testing, fire training, vehicle maintenance, and bulk chemical storage and distribution from numerous above ground and underground storage tanks. Holsworthy Military Airport is also located in the site. The site exists under the Native Title Claim of the South Coast of NSW by the South Coast People (Tribunal file no. NC2017/003) (NNTT, 2020). The following tenements exist on this site (NNTT, 2020): • Mining tenement (AUTH6) • Mining tenement (AUTH432CCL724)

IMPACT ASSESSMENT

Direct impacts

There will be no direct impacts to Site 11 due to the Plan.

Indirect and facilitated impacts

At the closest point, Site 11 occurs approximately 1.4 km from the nearest development under the Plan – a relatively small area of urban capable land in the northern part of GMAC. The land in between this urban capable land and Site 11 consists of existing high density residential areas.

The location of the site relative to the development and near existing high density residual areas means:

- The site is very unlikely to be impacted by impacts typically associated with construction of the development in GMAC, such as air quality, noise, construction traffic, or the spread of weeds or disease
- The heritage values of the site will not be impacted by alterations to the setting of the place inconsistent with its values, such as through changes to the surrounding landscape causing visual or amenity impacts

The potential indirect and facilitated impacts associated with these developments and the key values of the environment of Site 11 that are potentially impacted are shown in Table 35-11.

Table 35-11: Potential indirect impacts on Site 11 associated with the development

Potential indirect impact	Extent within Site 11	Duration	Values potentially impacted
Construction			
Changes to water quality from soil erosion or disturbance of contaminated soils	Waterways within the site	Generally short term	Water resources
Clearing of habitat during construction of the development that links the site to other areas of habitat, leading to impacts on biodiversity values	Whole of site	Long term	Biodiversity values
Operation			
Changes to surface water flows due to additional runoff from urban areas		Long term	Water resources
Disruption to land uses, services or infrastructure	Whole of site	Long term	People and communities

Biodiversity values

Site 11 has been identified on BIO Map as containing large areas of core areas and corridors, and is therefore a significant site for habitat connectivity across the subregion.

Clearing of habitat in GMAC associated with urban capable land has the potential to lead to impacts on the biodiversity values of the site due to a reduction in habitat connectivity to and from the site.

The site is well connected to large areas of habitat and protected lands, including Dharawal National Park, Heathcote National Park and Georges River National Park. The site connects Heathcote National Park in the east to Dharawal National Park and other large areas of habitat in the west in the vicinity of the Georges River and Nepean River.

The development under the Plan will not disrupt these habitat connectivity links from the site to the surrounding area, and therefore the habitat values of the site are unlikely to be impacted indirectly by the Plan. While development in GMAC will reduce habitat connectivity across the nominated area to some extent, large habitat corridors that occur along riparian corridors and gullies, including BIO Map core areas and corridors, will generally be maintained.

Water resources

Construction and operation of urban, industrial and infrastructure development in GMAC may result in changes to surface water flows and impact the water quality of the Georges River, which forms the western boundary of Site 11.

These impacts are discussed below separately in relation to the different areas of urban capable land within GMAC that may affect the Georges River, as these different areas are likely to have different risks. The Plan includes commitments that are expected to adequately address these potential impacts on water resources (see below).

Development in GPEC northern section (near Glenfield)

Development in the northern section of GPEC will be partially located in the catchment of Bunbury Curran Creek and Glenfield Creek, both of which discharge into the Georges River. These potential impacts are considered to be minor. Both these catchments, as well as the Georges River catchment, are already subject to significant levels of urban development, which reduces the consequence of any water quality impacts.

Middle section (development between Glen Alpine and Rosemeadow)

The majority of this section of urban development under the Plan is located within the catchment of the Nepean River, with only a small area (approximately 19 ha) located within the upstream tributary catchments of Bow Bowing Creek, which discharges into Bunbury Curran Creek and then the Georges River. The length of watercourse between the development site and the discharge point into the Georges River is approximately 20 km.

The catchment of Bow Bowing Creek and Bunbury Curran Creek is already heavily developed, with the vast majority of the catchment area covered by urban development. Bow Bowing Creek has also been developed, including an area of impoundment and development of the creek corridor to form drainage channels. Overall, the environmental values of this catchment are very limited. Therefore, it is not considered that the comparatively small area of urban development within this catchment under the Plan will significantly degrade the water quality of the Georges River.

Southern section (development between Gilead and Appin)

The southern section of urban development within GMAC is located within the Nepean Catchment, and therefore there is no risk that urban development in this area will result in a decline in water quality of the Georges River.

People and communities

Population increases associated with urban development in GMAC may lead to increased pressure on roads, transport and other infrastructure that service the army base. However, the Plan intends to provide for future transport needs by supporting the delivery of major transport projects for Western Sydney. It is also expected that future transport and infrastructure needs of the army base will be provided for through existing local and regional planning processes.

As Site 11 is a military facility that is not open to the public, there is no risk that population increases associated with urban development will result in increased pressures associated with visitation or use of the site by the public.

Commitments and mitigation measures

The Plan includes commitments to mitigate indirect impacts from construction and operation associated with urban and industrial development, and infrastructure development. These commitments and processes to deliver these comments are different for each type of development.

Urban and industrial development

The Plan includes a commitment to mitigate indirect and prescribed impacts from development to best practice standards (Commitment 5). This commitment will be delivered through development controls specified in Development Control Plans (DCPs) and implemented through the standard development application process that occurs under the NSW planning system. A description of the process is provided in Chapter 15, section 15.6.1.

Relevant councils will prepare a DCP for each nominated area in collaboration with the Department and in accordance with standard processes for developing DCPs in NSW. The DCP will include development controls relevant to addressing the indirect and facilitated impacts of the urban and industrial development that may affect Site 11.

The general environmental controls likely to be included in DCPs are set out in Chapter 15, section 15.6.1, and include:

- Preparation of Construction Environmental Management Plans to manage on-site construction impacts
- Controls for managing impacts to hydrology and water quality

These development controls and the process for implementing them are expected to adequately address the potential indirect and facilitated impacts of the urban and industrial development that will occur adjacent to Site 11.

A detailed description of the development controls and implementation process, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.1.

Infrastructure development

The Plan includes a commitment to mitigate indirect and prescribed impacts from infrastructure development (Commitment 5.3). This commitment will be delivered through an environmental assessment and approval process that will be applied to detailed design of each infrastructure project at the time the project is brought forward for development. This will be undertaken under Part 4 or Part 5 of the EP&A Act (or equivalent at the time). State Environmental Planning Policy (SEPP) (Infrastructure) 2007 provides a framework for determining how most types of infrastructure are assessed under the EPA Act.

This assessment process will assess and identify mitigation measures to manage the non-biodiversity related potential environmental impacts of the project. This will include the assessment and management of indirect impacts of any infrastructure projects that may affect Site 11, including impacts to hydrology and water quality.

This process therefore provides the mechanism to identify and implement mitigation measures to manage the potential indirect impacts on Site 11 from the infrastructure development.

A detailed description of the assessment and approval process for infrastructure, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.2.

35.3.12 SITE 12

PROFILE

SITE DETAILS				
Owner	The Commonwealth of Australia			
Site name	N/A			
Site ID number	12			
Area	0.2 ha			
Address	Whittle Road, Edmondson Park NSW			
Folio	134/123070			
General description	The site located at the intersection of Whittle Road and Mckechnie Road. The site does not contain any native vegetation. The site occurs within the Strategic Assessment Area, approximately 35 km south-west of the Sydney CBD			
Site map	The location of Site 12 is shown in Map 54.13			
DISTANCE FROM URBAN CAPABLE LANDS/ TRANSPORT CORRIDORS				
The site is located approximately 1.8 km from the nearest development under the Plan – urban capable land in GMAC. The land between Site 12 and the nearest development primarily consists of existing urban development				
LANDSCAPES AND LANDFORMS				
The site is located in a suburban area and does not appear to have any landforms				
SOIL AND SUBSTRATES				
The soil landscape at Site 12 is made up of 0.2 ha of Blacktown soil – Blacktown soils are a hardsetting soils that have a shallow to moderately deep depth of > 100 cm (OEH, 2018a)				
WATER				
The site occurs within the Georges River catchment A minor non-perennial watercourse passes through the southern half of the site				
VEGETATION				
No native vegetation occurs on the site. However, a small area of potential habitat for three threatened flora species occurs on site.				
Plant Community Types (PCTs)/ NSW listed threatened ecological communities (TECs)				
PCT number	**PCT name**	**NSW TEC name**	**BC Act status**	**Area (ha)**
0	Cleared	N/A	N/A	0.2
Threatened flora species				
Name		**EPBC Act or BC Act status**	**Area of habitat (ha)**	**Number of BioNet records**
Acacia pubescens (Downy Wattle)		Vulnerable (BC Act & EPBC Act)	0.2	0
Micromyrtus minutiflora		Endangered (BC Act) Vulnerable (EPBC Act	0.2	0

Pimelea spicata (Spiked Rice-flower)	Endangered (BC Act & EPBC Act)	0.1	0
BIO Map Priority Investment Areas			
No BIO Map core or corridor areas have been identified on this site			
ANIMAL SPECIES			
No fauna species have been recorded on site			
CONSERVATION AND SPECIAL USE AREAS			
There are no conservation or special use areas present on this site The closest conservation or special use areas are: • Metro offset (approximately 1 km south and 2 km north-east) • Edmondson Regional Park (approximately 2 km south west)			
HERITAGE PLACES AND ITEMS			
It is not known whether the site has any historic or indigenous heritage values. The site is not listed in the Australian Heritage Database as having any heritage values			
SERVICES AND INFRASTRUCTURE/PEOPLE AND COMMUNITIES			
This site is a vacant block with no visible buildings or other infrastructure No tenement exists on this site (NNTT, 2020) No Native Title Claims exist over this site (NNTT, 2020)			

IMPACT ASSESSMENT

Direct impacts

There will be no direct impacts to Site 12 due to the Plan.

Indirect and facilitated impacts

Site 12 is located within an existing, heavily developed urban area, approximately 1.8 km from the nearest urban capable land associated with the Plan – urban capable land in GMAC. The land between Site 12 and the nearest development primarily consists of existing urban development. The site is also located upstream of the nearest urban development and within a separate sub-catchment.

The location of the site relative to the development and within a high density existing urban area means:

- The site is very unlikely to be impacted by impacts associated with construction of the development in GMAC, such as air quality, noise, construction traffic, or the spread of weeds or disease
- The site will not be impacted by soil erosion of sedimentation, changes to surface and groundwater quantity and flows, or water quality impacts associated with the construction and operation of the development

Furthermore, the site is unvegetated and has no or little biodiversity value and has no known heritage values. The site contains no buildings or other infrastructure and appears to be unused.

There are no potential indirect or facilitated impacts associated with the development considered relevant to the site.

Commitments and mitigation measures

No commitments or mitigation measures are considered necessary to address the potential indirect impacts on the environment of Site 12 from the development under the Plan.

36 Summary of transport program impacts

36.1 INTRODUCTION

This Chapter provides:

- A summary of the transport development
- A summary of the impacts of the transport program on MNES under the EPBC Act including:
  - Avoidance outcomes and commitments
  - Direct impacts and commitments to address these impacts
  - Indirect impacts and commitments to address these impacts
- An assessment of the direct and indirect impacts of the two transport corridor tunnels
- A conclusion about the overall outcome in relation to the transport corridors under the Plan

The summary draws on the detailed analysis of the impacts of the Plan and the adequacy of the commitments under the Plan to address these impacts on each MNES presented earlier in this Assessment Report.

These detailed impact assessments have shown that the direct, indirect and cumulative impacts of the transport (and urban) development under the Plan on MNES are acceptable and that the commitments under the Plan will adequately protect and conserve these matters in the context of these impacts.

Part 7 provides an evaluation of the overall adequacy and acceptability of the Plan in the context of the impacts of the development under the Plan and in accordance with the regulatory requirements of the BC Act and EPBC Act.

The transport program is described in Chapter 7.

Indicative locations of the transport corridors are shown in Figure 36-1.

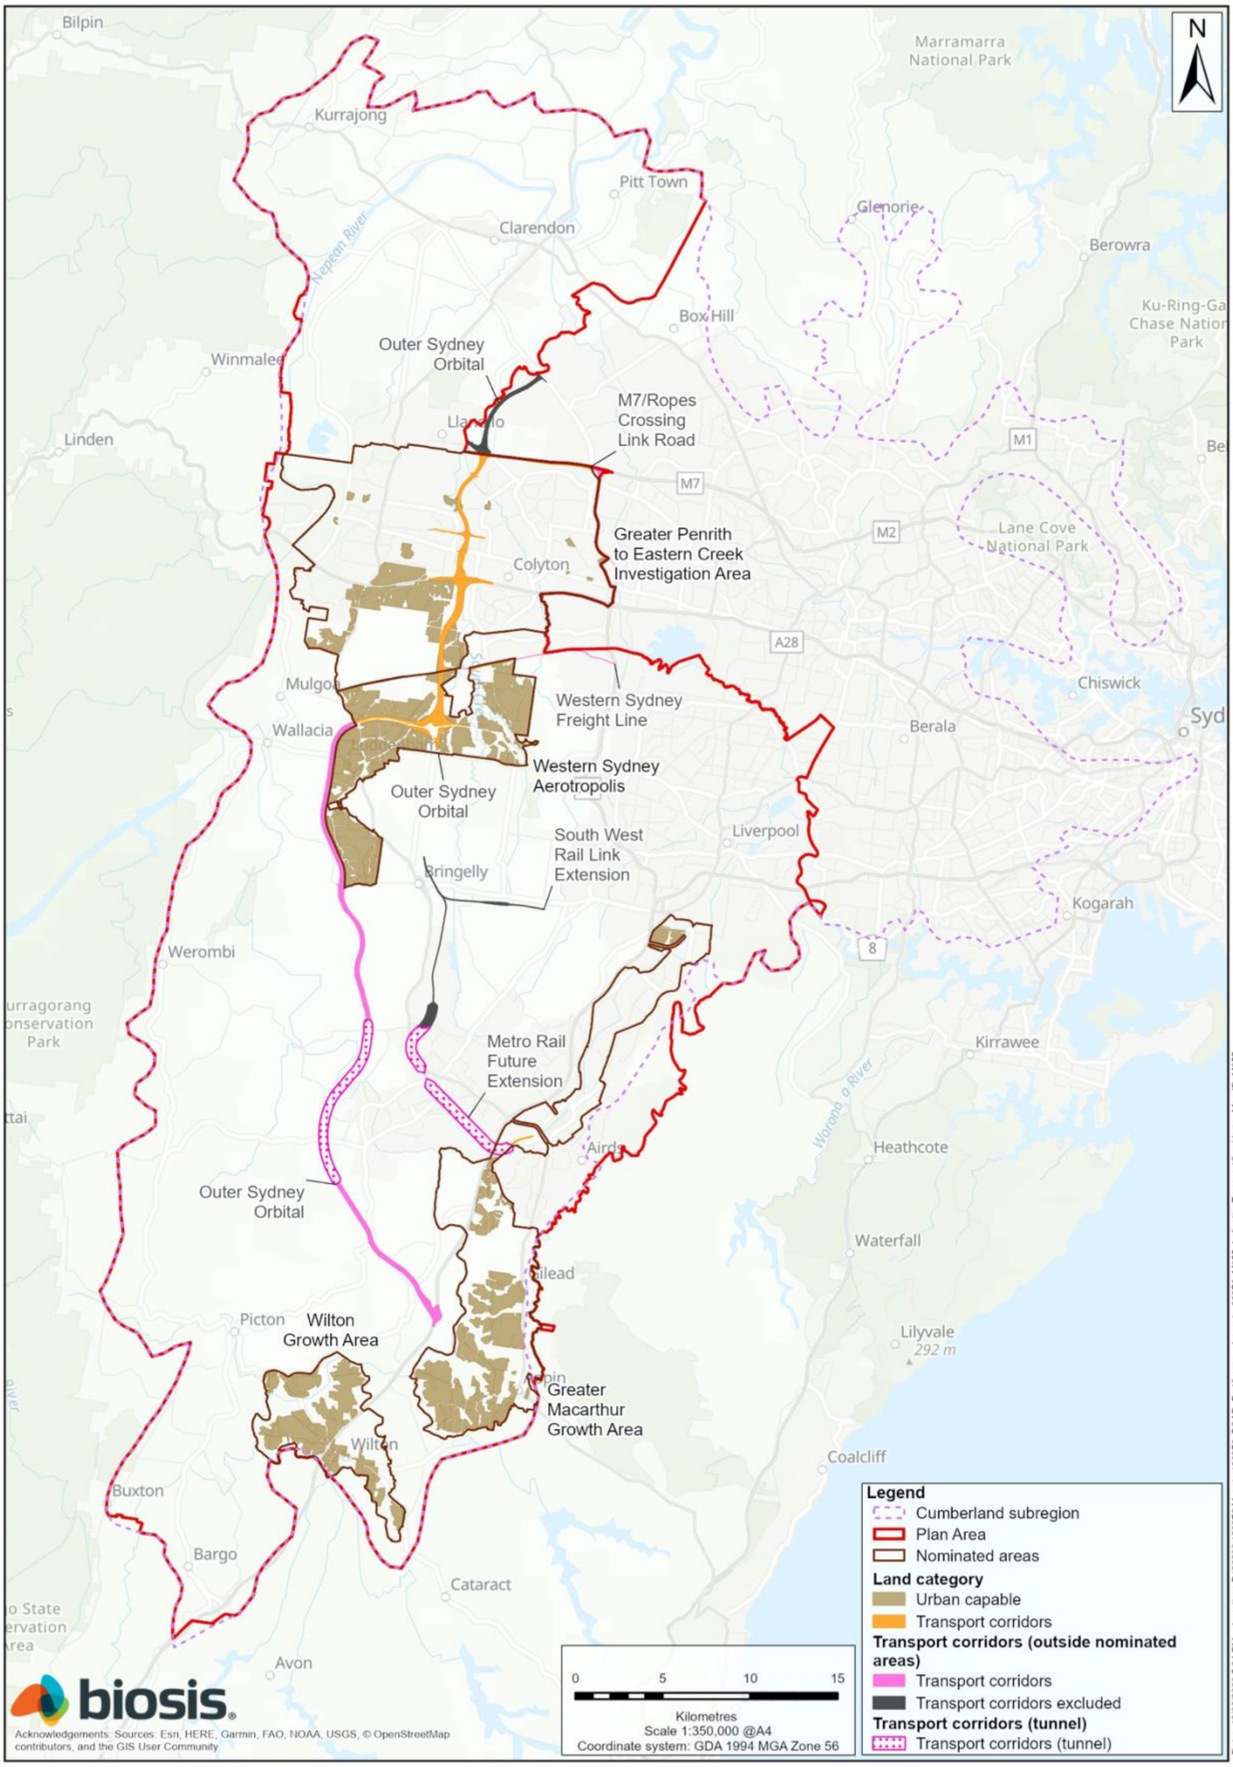

Figure 36-1: Indicative locations of transport corridors within the Strategic Assessment Area

36.2 SUMMARY OF THE TRANSPORT DEVELOPMENT

36.2.1 TRANSPORT CORRIDORS

The Plan includes the design, construction and operation of several major road and rail transport projects that will generally be located within the transport corridors shown in Figure 36-1. The transport projects are listed in Table 36-1.

Table 36-1: Transport projects covered under the Plan

<table>
<tr><th>Project</th><th>Description</th><th>Timing</th></tr>
<tr><td>Sydney Metro Greater West south from Western Sydney Aerotropolis to Macarthur (except for those areas within the existing South West Growth Area)</td><td>Provides for a commuter railway line</td><td>0 to 10 years</td></tr>
<tr><td>Western Sydney Freight Line corridor</td><td>Provides for a future freight rail line to connect Port Botany and Western Sydney</td><td rowspan="2">10 to 20 years</td></tr>
<tr><td>Outer Sydney Orbital (Stage 1) from Palmyra Avenue to the Hume Motorway</td><td rowspan="2">Provides for a future north south motorway and freight rail line</td></tr>
<tr><td>Remaining Outer Sydney Orbital 1</td><td rowspan="2">20 or more years</td></tr>
<tr><td>M7/Ropes Crossing Link Road</td><td>Provides for a future east-west motorway linking the M7 to the future Outer Sydney Orbital at Ropes Crossing</td></tr>
</table>

Development under the transport class of action includes all activities associated with the design, construction, and operation of the major road or rail projects. This includes any development on land within the transport corridors shown in the Plan (see Figure 36-1) or on any other land required for the transport project along these general alignments, as identified under the NSW environmental assessment and approval process for each project current at the time the project is brought forward (this is currently the State Significant Infrastructure approval process).

The transport activities included under the Plan include, but are not limited to:

- Vegetation clearing
- Earthworks
- Utility works
- Landscaping
- Erosion and sediment control
- Laydown areas
- Road and rail construction
- Tunnel construction
- Construction of supporting infrastructure such as stations, car parks and pedestrian access
- Electricity infrastructure
- Site offices and access roads
- Dust and noise suppression
- Stormwater management (including detention basins, ponds and dams)
- Vehicle and train movements
- Maintenance and upgrade activities
- Installation and maintenance of traffic control and safety infrastructure

As each transport project is brought forward for investigation, the project will be subject to:

- A process of strategic planning and detailed design, which will determine the final alignment of each transport project that will generally occur within each transport corridor

- NSW environmental assessment and approval process for each project current at the time the project is brought forward (this is currently the State Significant Infrastructure approval process under the EP&A Act)

The transport projects included in the Plan have not finalised implementing a process to avoid biodiversity values as the alignment for the corridors are not currently certain. Additional areas will be avoided during strategic planning and detailed design of the transport projects. The Plan includes commitments for further avoidance and minimisation of impacts to biodiversity values related to the transport corridors (see section 36.3).

36.2.2 TUNNELS

Development under the transport class of action includes tunnel construction and operation. Sections of two of the transport corridors are proposed to include tunnels. These are:

- Outer Sydney Orbital (OSO) tunnel – Cobbitty to Cawdor
- Metro Rail Future Extension (MRFE) tunnel – Oran Park to Narellan, and Narellan to Macarthur

The location of the tunnels are shown in Figure 36-1.

The activities associated with tunnelling may include but are not limited to the matters shown in Table 36-2.

Table 36-2: Construction activities and operational infrastructure associated with transport corridor tunnels

Project phase	Activities
Construction activities	• Site establishment and enabling work, including but not limited to utility work, fencing and hoarding, construction ancillary facilities and access, demolition of buildings and structures and clearance of vegetation where required • Erection of acoustic sheds (where relevant) over the temporary access tunnels and to contain noise and dust from tunnelling operations • Construction of temporary access tunnels • Construction of main tunnels, including but not limited to entry and exit ramps and associated tunnelled infrastructure • Spoil management and haulage • Finishing work in tunnel and provision of permanent tunnel services, including but not limited to mechanical and electrical fit out • Drainage work, including permanent water treatment facilities
Operational infrastructure	• Utilities infrastructure (including adjustments to, or relocation of, existing utilities infrastructure), electronic tolling facilities, signage, ventilation systems, emergency systems, systems for the control and management of roads, and tunnel control centre facilities • Entry and exit ramps (tunnel portals) • Connection to power, including construction of or connection to electrical substations • Connection and tie in with existing surface roads and infrastructure • Pedestrian and cyclist facilities • Drainage work, pavement and finishing work (including landscaping and urban design treatments)

As for the other parts of the transport corridors, development for the tunnels will generally occur within the footprints of the tunnels shown in Figure 36-1. In limited cases, development activities may be necessary adjacent to the footprint.

36.3 AVOIDANCE OF IMPACTS

36.3.1 SUMMARY OF AVOIDANCE PROCESSES

Avoidance and minimisation of impacts from the transport corridors is being undertaken in two stages:

- Processes to locate the transport corridors – this has already been undertaken
- Strategic planning and detailed design of each transport project within the transport corridors

Details of the processes to locate the transport corridors are provided in Chapter 14.

The future process to further avoid and minimise impacts through detailed design is summarised below.

36.3.2 COMMITMENTS FOR FURTHER AVOIDANCE

The transport corridors included in the Plan have not completed the process to avoid and minimise impacts to biodiversity values as the alignments of the transport projects within each corridor are not currently certain (see Part 2).

The Plan includes commitments for further avoidance and minimisation of impacts to biodiversity values related to the transport corridors. This will be undertaken through:

- A process of strategic planning and detailed design, which will determine the final alignment of each transport project that will generally occur within each transport corridor
- NSW environmental assessment and approval process for each project current at the time the project is brought forward (this is currently the State Significant Infrastructure approval process)

For the parts of the transport corridors within the nominated areas, the Plan commits to avoiding and minimising impacts to TECs, species and habitat (Commitment 3). This includes avoiding where possible:

- Areas of high biodiversity value (defined by the Plan's 'avoidance criteria' – see Chapter 14)
- Areas of potential habitat connectivity, particularly vegetation in riparian corridors, for specific species
- Known flora populations for specific species in specific locations

For the parts of the transport corridors outside the nominated areas, the Plan commits to avoiding and minimising impacts to species and TECs in accordance with the major infrastructure corridors class of action description and the BC Act, including the BAM (Commitment 4). This includes avoiding where possible:

- Known flora populations for specific species in specific locations
- Other specific locations of high biodiversity value
- Commonwealth land at three sites

The commitments for future avoidance relating to the transport corridors are considered adequate to ensure the corridors avoid and minimise the risk of unacceptable impacts on biodiversity values. The commitments ensure:

- Avoidance outcomes are achieved consistent with the Plan's 'avoidance criteria' (see Chapter 14) or are assessed in assessed and determined in accordance with the BAM (for the transport corridors outside the nominated areas)
- Impacts to known key biodiversity values within the corridors are avoided and minimised where possible, including specific species and habitat, and/or specific locations of high biodiversity value
- Avoidance of biodiversity values as well as the costs of offsets is taken into account in the evaluation of the route options (e.g. multi-criteria analysis) during the planning phase of each project

36.4 DIRECT IMPACTS

36.4.1 SUMMARY OF IMPACTS

The direct impacts that may occur due to the transport corridors are associated with construction and are:

- Habitat loss
- Habitat fragmentation and loss of habitat connectivity

The direct impacts of the transport corridors on MNES are assessed in Chapters 29 to 35.

A summary of the direct impacts on Commonwealth-listed species and TECs is provided in:

- Table 36-4 – transport impacts to threatened fauna
- Table 36-5 – transport impacts to threatened flora
- Table 36-6 – transport impacts to TECs

These tables identify impacts in relation to each transport corridor, as well as the total impact of the transport corridors and the contribution of the transport program to the total impacts of the development under the Plan.

Impacts are calculated on a worst-case scenario basis by assuming the entirety of each transport corridor will be impacted (as described above, in practice, these impacts will be reduced through future avoidance processes).

Table 36-3 provides the meaning of the acronyms used in the impact tables.

Table 36-3: Acronyms used in impact tables

Transport project acronym	Description
Metro	Sydney Metro Greater West south from Western Sydney Aerotropolis to Macarthur (except for those areas within the existing South West Growth Area)
WSFL	Western Sydney Freight Line corridor
OSO	Outer Sydney Orbital (Stage 1) from Palmyra Avenue to the Hume Motorway
M7 Link	M7/Ropes Crossing Link Road

The transport corridors will not have notable direct impacts on other MNES, including:

- Migratory species (see Chapter 32)
- Ramsar wetlands (see Chapter 33)
- World and National Heritage (see Chapter 34)

There are direct impacts from the transport corridors on one Commonwealth land site – this comprises 4.2 ha on Site 11 at 221 Greendale Rd, Greendale NSW. This impact is not considered notable. The use of the site is unknown, although it appears to be used for grazing, and impacts on biodiversity values are minor (see Chapter 35).

There may also be direct impacts on Commonwealth land from the tunnels. These impacts are assessed in section 36.6.

THREATENED FAUNA

The following outlines the magnitude of impact to each threatened fauna species solely with regards to development of the transport program. Chapter 30 provides a detailed assessment of each species as a result of all development (transport in addition to urban capable development) under the Plan, and produces a risk ranking for each fauna species with regards to their magnitude of direct impacts under the Plan. It is noted that the risk ranking relates to both urban capable and transport development, rather than just transport, and so it is possible for a species to have low transport impacts yet a high risk rating as a result of impacts due to urban capable development (and vice versa).

The transport corridors will directly impact potential habitat for 10 of the 20 fauna species, including: Regent Honeyeater (low risk), Australasian Bittern (low risk), Swift Parrot (medium risk), Australian Painted Snipe (very low risk), Large-eared Pied Bat (low risk), Spot-tailed Quoll (low risk), Greater Glider (very low risk), Grey-headed Flying Fox (low risk), Green and Golden Bell Frog (very low risk) and the Dural Land Snail (very low risk).

The most notable direct impacts occur to:

- Regent Honeyeater (low risk) and Swift Parrot (medium risk) in habitat along Wianamatta (South Creek), in Wianamatta Regional Park and in Cobbitty due to the OSO
- Grey-headed Flying-fox (low risk) in habitat along Wianamatta (South Creek), in Wianamatta Regional Park and in Cobbitty due to the OSO

The largest impacts to potential habitat will occur to:

- Wide ranging species such as the Grey-headed Flying-fox (low risk) (346.9ha of impact) and Spot-tailed Quoll (low risk) (239.9 ha of impact)
- Species with broad associations with woodland habitats primarily for foraging, such as the Swift Parrot (430.6 ha of impact) and the Regent Honeyeater (low risk) (430.6 ha of impact)

The species most impacted in terms of the percentage of total habitat in the Strategic Assessment Area is the Australasian Bittern (low risk), which will have 2.9 per cent of its potential habitat impacted.

The transport corridors will directly impact known important populations of some fauna species, including:

- Grey-headed Flying-fox (low risk) (1 population)
- Spot-tailed Quoll (low risk) (1 population)

THREATENED FLORA

The following outlines the magnitude of impact to each threatened flora species solely with regards to development of the transport program. Similar to fauna, Chapter 29 provides a detailed assessment of each species as a result of all development (transport in addition to urban capable development) under the Plan, and produces a risk ranking for each flora species with regards to their magnitude of direct impacts under the Plan. It is noted that the risk ranking relates to both urban capable and transport development, rather than just transport, and so it is possible for a species to have low transport impacts yet a high risk rating as a result of impacts due to urban capable development (and vice versa).

The transport corridors will directly impact potential habitat for 14 of the 23 flora species. These include: *Acacia bynoeana* (very low risk), *Acacia pubescens* (very low risk), *Allocasuarina glareicola* (very low risk), *Cynanchum elegans* (medium risk), *Eucalyptus benthamii* (low risk), *Grevillea parviflora* subsp. *parviflora* (low risk), *Micromyrtus minutiflora* (very low risk), *Persicaria elatior* (very low risk), *Persoonia bargoensis* (low risk), *Persoonia hirsuta* (low risk), *Persoonia nutans* (medium risk), *Pimelea curviflora* var. *curviflora* (very low risk), *Pimelea spicata* (high risk), *Pomaderris brunnea* (low risk), *Pultenaea parviflora* (high risk).

The most notable direct impacts occur to:

- *Pimelea spicata* (high risk) in habitat along Wianamatta (South Creek), near Orchard Hills, Shanes Park near Horsley Park due to the OSO, eastern end of the M7 link and WSFL
- *Acacia pubescens* (very low risk) in habitat along Wianamatta (South Creek), near Orchard Hills and near Horsley Park due to the OSO and WSFL

The largest impacts to potential habitat will occur to:

- *Pimelea spicata* (high risk) (241.3 ha of impact)
- *Acacia pubescens* (very low risk) (188.8 ha of impact)
- *Pomaderris brunnea* (low risk) (168.8 ha of impact)
- *Pultenaea parviflora* (high risk) (157.9 ha of impact)

The species most impacted in terms of the percentage of total habitat in the Strategic Assessment Area is *Persicaria elatior* (very low risk), which will have 2.8 per cent of its potential habitat impacted.

The transport corridors will directly impact known important populations of some flora species, including:

- *Persoonia nutan*s (medium risk) (1 population)
- *Pultenaea parviflora* (3 populations, including 2 populations in GPEC and one outside nominated areas

THREATENED ECOLOGICAL COMMUNITIES

The following outlines the magnitude of impact to each TEC with solely with regards to development of the transport program. Chapter 31 provides a detailed assessment of each species as a result of all development (transport in addition to urban capable development) under the Plan. The following outlines the area of each TEC impacted by transport development under the Plan, with the total impact of all development under the Plan (transport in addition to urban development) provided in brackets to provide additional context.

The transport corridors will directly impact 4 of the TECs. These include:

- Coastal floodplain eucalypt forest of eastern Australia (FPAL): 166.8 ha impacted by transport (210.2 ha impacted in total by the Plan)
- Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest: 51.5 ha impacted by transport (154.7 ha impacted in total by the Plan)

- Cooks River/Castlereagh Ironbark Forest of the Sydney Basin Bioregion: 14.9 ha impacted by transport (26.3 ha impacted in total by the Plan)
- Coastal Swamp Oak (*Casuarina glauca*) Forest of New South Wales and South East Queensland ecological community: 1.4 ha impacted by transport (1.8 ha impacted in total by the Plan)

The most notable direct impacts occur to:

- Coastal floodplain eucalypt forest of eastern Australia (FPAL) along Wianamatta (South Creek) due to the OSO
- Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest in habitat in Cobbitty and Shanes Park due to the OSO and M7/Ropes Crossing Link Road

The TEC most impacted by transport development in terms of the percentage of total TEC in the Strategic Assessment Area is Coastal floodplain eucalypt forest of eastern Australia (2.4 per cent) and Cooks River/Castlereagh Ironbark Forest of the Sydney Basin Bioregion (1.9 per cent).

* Proposed for listing under the EPBC Act

36.4.2 COMMITMENTS TO ADDRESS DIRECT IMPACTS

The Plan includes commitments to address the direct impacts of the transport corridors on Commonwealth listed species and TECs. The key commitments apply to both the transport and other impacts of the Plan, and include to:

- Secure a minimum of 5,475 hectares of native vegetation in the Cumberland subregion (Commitment 8) to conserve biodiversity values in perpetuity, including specific amounts of habitat for Commonwealth-listed species and TECs
- Undertake ecological restoration of up to 25% of the offset target for native vegetation in areas secured for conservation within the Cumberland subregion (Commitment 13)
- Secure priority habitat corridors within the Cumberland subregion in perpetuity, to support habitat connectivity (Commitment 12)

Note that these commitments cover the impacts of the transport corridors within the entire corridor footprint (excluding the tunnels). As described in section 36.3, not all these areas will be directly impacted and the Department will track impacts and adjust offset requirements through the Plan's reconciliation accounting process (see Part 2).

36.5 INDIRECT IMPACTS

36.5.1 SUMMARY OF IMPACTS

Potential indirect impacts are assessed in detail for each Commonwealth listed matter in Chapters 29, 30 and 31, and for other protected matters in Chapters 32, 33, 34 and 35. Chapter 15 summarises the commitments and mitigation measures and processes to implement them for the transport development.

Species and TECs with specific mitigation measures related to the transport development, and that are therefore considered most likely to be impacted by this development, are:

- Fauna:
  - Greater Glider
  - Green and Golden Bell Frog
  - Spotted-tailed Quoll
- Flora:
  - *Cynanchum elegans*
  - *Dillwynia tenuifolia*
  - *Grevillea juniperina* subsp. *juniperina*
  - *Persoonia nutans*
  - *Pultenaea parviflora*
  - *Eucalyptus benthamii*
  - *Pimelea spicata*
  - *Pomaderris brunnea*
- TECs:
  - Cooks River/Castlereagh Ironbark Forest

The transport corridors tunnels have the potential to indirectly impact several Commonwealth land sites (see Chapter 35). The commitment under the Plan (Commitment 6.2 relating to specific flora and fauna populations that are at risk of impacts) and the process to mitigate indirect impacts are considered to adequately manage this risk.

The transport development will not have notable indirect impacts on other EPBC Act protected matters, including:

- Migratory species (see Chapter 32)
- Ramsar wetlands (see Chapter 33)
- World and National Heritage (see Chapter 34)

36.5.2 COMMITMENTS TO ADDRESS INDIRECT IMPACTS

The Plan includes a commitment to mitigate indirect and prescribed impacts from transport corridors on species and habitat (Commitment 6). This includes implementing mitigation measures as prescribed in Appendix E of the Plan to address indirect impacts on biodiversity values.

The commitment to manage indirect impacts of the transport corridors will be delivered through NSW environmental assessment and approval processes. As described in Part 2, each transport project will be subject to future strategic planning and detailed design and a process of environmental assessment and approval:

- For the transport corridors within the nominated areas (where biodiversity impacts under both the EPBC Act and BC Act have already been assessed in this Assessment Report – see Part 1), this process will involve assessment under the State Significant Infrastructure approval process (or equivalent)
- For the transport corridors outside the nominated areas (where biodiversity impacts have not been assessed under the BC Act - see Part 1), this process will involve assessment under both:
    - State Significant Infrastructure approval process (or equivalent)
    - BC Act and BAM (or equivalent)

The process under the BC Act and BAM will address potential indirect impacts on biodiversity values. The process under the State Significant Infrastructure approval process (or equivalent) will assess the other environmental impacts and matters that need to be considered prior to construction and operation of the transport project. This will include an assessment of risks to the environment and the identification of mitigation measures to manage these risks, such as impacts related to hydrological disturbance, noise, air quality, and construction activities.

36.6 ASSESSMENT OF IMPACTS OF TUNNELS

This section assesses the likelihood of impacts to MNES due to the tunnel sections of the transport corridors. The impacts of tunnels were assessed separately to the rest of the transport corridors as only small areas of the footprints will be disturbed and it is not possible to determine at this stage the nature and extent of those impacts.

As for the other parts of the transport corridors, the tunnel footprints are generally wider than needed and the final alignment of the tunnels within the footprint (and associated surface impacts from construction and infrastructure) will be subject to future processes of refinement during the strategic planning and detailed design phase.

The impacts of the tunnels have not been included in the impact statistics for transport corridors in this Chapter or in the assessments for Commonwealth listed species and TECs (see Chapters 29 to 31). Where this assessment identified a risk of notable direct or indirect impacts from the tunnels, this has been noted in the assessments in Chapters 29 to 31.

36.6.1 POTENTIAL IMPACTS TO BIODIVERSITY VALUES

POTENTIAL DIRECT IMPACTS

Nature and extent of direct impacts

It is not possible to determine at this stage the specific nature, extent and duration of the direct impacts of the tunnels on biodiversity values. The tunnels will generally reduce the direct impacts of the transport corridors as tunnelling substantially reduces disturbance to the land surface required to construct the transport corridors.

Development for the tunnels will generally occur within the footprints of the tunnels shown in Figure 36-1. In some circumstances development may be necessary adjacent to the footprint. Direct impacts to biodiversity values will only occur within small areas of the tunnel footprints and the majority of the footprints will not be disturbed.

Activities associated with tunnels are described in section 36.2.2. In summary, disturbance to the land surface due to the tunnels, including vegetation clearing, may occur due:

- Construction activities
- Ancillary infrastructure, including ventilation systems
- Other infrastructure, such as entry and exit ramps and connection and tie in with existing roads and infrastructure
- Pedestrian and cyclist facilities

- Drainage work, pavement and finishing work

Biodiversity values potentially directly impacted

Most areas of high biodiversity value within and adjacent to the tunnel footprints occur within several areas already recognised for their environmental values. These areas include three protected lands (these cover a total of 120 ha within both tunnel footprints), as well as the Nepean River and associated riparian corridor within the OSO footprint, and the Mount Annan Botanic Gardens within the MRFE footprint.

Importantly, the Plan includes a commitment to avoid and minimise impacts to these areas. The Plan includes a commitment (Commitment 4.1**)** to avoid and minimise impacts to species and TECs from tunnel construction activities in transport corridors. This includes avoiding disturbance to the following locations where possible:

- The three areas of protected lands within and adjacent to the tunnel footprints:
  - Mater Dei BioBank site within the OSO footprint near Camden
  - Registered Property Agreement site within the OSO footprint at Camden Airport
  - Metro Offset site within the OSO and MRFE footprints near Harrington Park
- Nepean River and associated riparian corridor within the OSO footprint
- Camden Golf Club at Narellan adjacent to the MRFE footprint
- Mount Annan Botanic Gardens within the MRFE footprint
- Populations and habitat within or adjacent to the OSO and MRFE footprints for:
  - *Eucalyptus benthamii*
  - *Pomaderris brunnea*
  - *Pimelea spicata*
  - Cumberland Plain Land Snail
- Commonwealth land at:
  - Camden Airport
  - Western Sydney University (Campbelltown Campus)
  - 12 Werombi Road, Grasmere

This commitment is considered to adequately address the potential direct impacts of the tunnels on biodiversity values as it ensures impacts to most important biodiversity values within and adjacent to the tunnel footprints, including several species potentially subject to notable impacts (see Table 36-7) are avoided and minimised where possible.

Table 36-7 assesses the potential direct impacts to the biodiversity values that occur within the tunnel footprints outside these areas avoided under the Plan, and that may be directly impacted by the tunnels.

Table 36-7: Biodiversity values within the tunnel footprints outside areas to be avoided under Commitment 4.1

TEC or species name	Area of potential habitat (ha) outside areas to be avoided			Assessment of potential direct impacts
	MRFE tunnel	OSO tunnel	Total	
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest	15.3	25.2	40.5	Potential for notable impacts is low. Most impacts generally occur to smaller, generally isolated patches of the TEC in lower condition (thinned or scattered trees). The amount of impact that could potentially occur is very small in the context of the amount remaining in the Strategic Assessment Area. Commitment 4.1 ensure impacts are avoided and minimised to the largest and most intact patches of the TEC in the vicinity of the tunnels
Coastal floodplain eucalypt forest of eastern Australia* (currently being assessed for listing)	11.1	4.3	15.3	Potential for notable impacts is low. While there will be some impacts patches of the TEC in intact condition, impacts generally occur to smaller, generally isolated patches of the TEC. The amount of impact that could potentially occur is very small in the context of the amount remaining in the Strategic Assessment Area. Commitment 4.1 ensure impacts are avoided and minimised to the largest and most intact patches of the TEC in the vicinity of the tunnels, particularly along the Nepean River
Acacia bynoeana	1.7	0.6	2.3	Potential for notable impacts is low. Only small amounts of potential habitat are potentially impacted, and no populations are known to occur in the vicinity of the tunnels. Core areas for the species in the Cumberland subregion occur north and east of GPEC and WSA
Acacia pubescens	29.9	4.5	34.4	Potential for notable impacts is low. Only small amounts of potential habitat are potentially impacted, and no populations are known to occur in the vicinity of the tunnels. The species is concentrated around the Bankstown-Fairfield-Rookwood area and the Pitt Town area, with outliers occurring at Barden Ridge, Oakdale and Mountain Lagoon (OEH, 2019b)
Botaurus poiciloptilus (Australasian Bittern)	4.6	1.1	5.7	Potential for notable impacts is low. The tunnels will not impact areas known to support the species (freshwater or brackish swamps that are shallow and vegetated, with a preference for the presence of sedges, rushes, and reeds (Garnett, Szabo et al., 2011) and there will be only very small impacts to areas mapped as potential habitat
Meridolum corneovirens (Cumberland Plain Land Snail)	6.3	0.0	6.3	There is potential for notable impacts. Several records occur in the vicinity of the MRFE tunnel at Western Sydney University (Campbelltown Campus) suggesting a population may occur in the area (the notes attached to several of the records suggest the individuals recorded were not alive, however, there is potential for the population to occur at the site). The species is endangered and restricted to the Cumberland Plain. Little is known about its biology, including breeding biology and movement patterns (OEH, 2019a). Commitment 4.1 includes specifically avoiding and minimising disturbance to this species where possible, and is considered to adequately address these potential impacts

TEC or species name	Area of potential habitat (ha) outside areas to be avoided			Assessment of potential direct impacts
	MRFE tunnel	OSO tunnel	Total	
Cynanchum elegans	0.0	0.4	0.4	There is potential for notable impacts. While very little potential habitat and no populations are known to occur within the tunnel footprints, an important population of the species (#14) occurs about a kilometre to the north of the OSO tunnel. The species is associated with Forest Red Gum *Eucalyptus tereticornis* communities (OEH, 2018c), which occur along the Nepean River (as part of Coastal floodplain eucalypt forest of eastern Australia). Commitment 4.1 ensures that the largest and most intact areas of this community, which are most likely to provide habitat for the species in the vicinity of the tunnels, will be avoided and minimised, and is considered to adequately address these potential impacts
Cercartetus nanus (Eastern Pygmy Possum)	2.4	0.0	2.4	Potential for notable impacts is low. There are no records for the species within the vicinity of the tunnels and only very small amounts of potential habitat may be impacted. The species may disperse along creek lines within the Strategic Assessment Area (see Chapter 30), and may use the riparian corridor along the Nepean River. Commitment 4.1 includes specifically avoiding and minimising disturbance to the riparian corridor of the Nepean River, and is considered to adequately address these potential impacts
Eucalyptus benthamii	1.7	11.1	12.8	There is potential for notable impacts. A large important population of the species occurs within the OSO tunnel footprint. Species has a restricted distribution and individuals at Camden are important for genetic diversity of the species (DoE, 2014a). Commitment 4.1 includes specifically avoiding and minimising disturbance to this species where possible, as well as avoiding locations where the records for this species occurs (Registered Property Agreement site within the OSO footprint at Camden Airport and riparian corridor of the Nepean River), and is considered to adequately address these potential impacts
Petauroides volans (Greater Glider)	13.6	14.7	28.3	Potential for notable impacts is low. No records are known to occur in the vicinity of the tunnels. The species is associated with larger areas of eucalypt forest and woodlands and is typically found in highest abundance in taller, montane, moist eucalypt forests with relatively old trees and abundant hollows (TSSC, 2016a)
Chalinolobus dwyeri (Large-eared Pied Bat)	13.4	0.0	13.4	Potential for notable impacts is low. The area is unlikely to support breeding habitat (the site is not within one kilometre of areas likely to contain caves, crevices and cliffs - see Chapter 24) and only a small amount of potential foraging habitat has the potential to be impacted. There is one recent record (recorded in 2016) in the vicinity of the tunnels at the Mater Dei BioBank site (and an older record (from 2001) to the east of the OSO tunnel in an urban area). This area will be avoided and minimised under Commitment 4.1
Micromyrtus minutiflora	171.7	0.0	171.7	Potential for notable impacts is low. While it is possible the species occurs in potential habitat within the footprints, no populations are known to occur in the vicinity of the tunnels. The core area for the species within the Cumberland subregion occurs in the Londonderry area north of GPEC

TEC or species name	Area of potential habitat (ha) outside areas to be avoided			Assessment of potential direct impacts
	MRFE tunnel	OSO tunnel	Total	
Persoonia bargoensis	0.1	0.0	0.1	Potential for notable impacts is low. Almost no potential habitat occurs in the tunnel footprints. The core area for the species within the Cumberland subregion occurs around Wilton, and south of Wilton
Pimelea spicata	261.5	49.1	310.6	There is potential for notable impacts. While no records occur within the footprint, it is considered that the species may occur within potential habitat. A very large population (of between 300 to over 1000 individuals) occurs immediately adjacent to the MRFE tunnel footprint at Camden Golf Club. The population at this location is of particular significance as it is one of the largest known populations and is covered by a conservation agreement between DAWE and Camden Golf Club (DEC, 2005). Commitment 4.1 includes specifically avoiding and minimising disturbance to this species where possible, and is considered to adequately address these potential impacts
Pomaderris brunnea	48.4	35.9	84.3	There is potential for notable impacts. A large important population of the species occurs within the OSO tunnel footprint. Only 10 to 14 populations of the species are known to occur in NSW (Sutter, 2011). Commitment 4.1 includes specifically avoiding and minimising disturbance to this species where possible, as well as avoiding locations where the records for this species occurs (Registered Property Agreement site within the OSO footprint at Camden Airport, and the riparian corridor of the Nepean River), and is considered to adequately address these potential impacts
Pommerhelix duralensis (Dural land snail)	9.7	28.8	38.5	Potential for notable impacts is low. No populations are known to occur in the vicinity of the tunnels. The core area for the species within the Cumberland subregion occurs north east of GPEC
Pteropus poliocephalus (Grey-headed Flying Fox)	30.6	35.1	65.7	Potential for notable impacts is low. There will be no impacts to known camps. There is potential for impacts to areas of potential foraging habitat. The scale of impacts to foraging habitat is small. The species is highly mobile, feeds on fruit and nectar from a variety of vegetation communities and has access to large areas of intact vegetation surrounding the Strategic Assessment Area
Pultenaea parviflora	0.0	0.4	0.4	Potential for notable impacts is low. No populations are known to occur in the vicinity of the tunnels. The core area for the species within the Cumberland subregion occurs north of the tunnels around WSA and GPEC, and particularly north of GPEC
Pultenaea pedunculata	0.1	0.0	0.1	Potential for notable impacts is low. One record for the species (3 individuals recorded in 2015) occurs at the north-eastern end of the OSO tunnel, in a disturbed area adjacent to a powerline. Although the species can be found in disturbed areas, there is almost no mapped potential habitat for the species within the tunnel footprints. Within the subregion, the main populations for the species are found at Villawood and Prestons, and north-west of Appin between the Nepean River and Devines Tunnel number 2 (OEH, 2018b)

TEC or species name	Area of potential habitat (ha) outside areas to be avoided			Assessment of potential direct impacts
	MRFE tunnel	OSO tunnel	Total	
Anthochaera phrygia (Regent Honeyeater)	34.9	53.2	88.1	Potential for notable impacts is low. There will be no impacts to known breeding habitat or key areas identified in the species Recovery Plan or Conservation Advice for the species. Any direct impacts to foraging habitat would be to more fragmented and degraded remnants unlikely to provide the ecological elements preferred or needed by the species. There is one old (1984) record of the species in the general vicinity of the tunnels (east of the MRFE tunnel). There are no areas mapped as important habitat by EES within the transport corridors (or nominated areas) (see Chapter 30)
Rostratula australis (Australian Painted Snipe)	6.0	2.4	8.4	Potential for notable impacts is low. There are no records for the species within the vicinity of the tunnels. Only very small amounts of potential foraging habitat may be impacted, and the Strategic Assessment Area is not recognised as a key location for the species (see Chapter 30)
Dasyurus maculatus maculatus (Spot-tailed Quoll)	9.4	5.2	14.6	Potential for notable impacts is low. There are no records for the species within the vicinity of the tunnels and only very small amounts of potential habitat may be impacted. The species may disperse along creek lines within the Strategic Assessment Area (Bruce Mullins, pers com), and may use the riparian corridor along the Nepean River. Commitment 4.1 includes specifically avoiding and minimising disturbance to the riparian corridor of the Nepean River, and is considered to adequately address these potential impacts
Lathamus discolor (Swift Parrot)	34.9	53.2	88.1	Potential for notable impacts is low. There are two records of the species recorded in 2014 and 2016 in the vicinity of the OSO tunnel footprint near Camden Airport. However, the higher number of records in coastal habitat to the east indicates a relatively lower reliance on the Cumberland subregion, and the scale of potential impacts on potential foraging habitat is very small. Commitment 4.1 includes specifically avoiding and minimising disturbance to locations where these records occur (the Registered Property Agreement site within the OSO footprint at Camden Airport and riparian corridor of the Nepean River), and is considered to adequately address these potential impacts

*Note that amounts of this TEC are likely to be overestimated as it has been mapped based on PCT 835 (see Part 3)

POTENTIAL INDIRECT IMPACTS

Nature and extent of indirect impacts

It is not possible to determine at this stage the specific nature, extent and duration of the indirect impacts of the tunnels on biodiversity values. The tunnels will generally reduce the risk of many indirect impacts associated with transport corridors on biodiversity values, as tunnelling substantially reduces the disturbance to the land surface required to construct the corridors. However, tunnelling will create larger risks associated with:

- Hydrological changes to groundwater
- Ground settlement potentially causing impacts to the land surface, including waterways
- Management of large quantities of spoil

Activities associated with tunnels are described in section 36.2.2. In summary, indirect impacts due to the tunnels may occur due:

- Construction activities
- Ancillary infrastructure, including ventilation systems
- Other infrastructure, such as entry and exit ramps and connection and tie in with existing roads and infrastructure
- Drainage work, pavement and finishing work

The main types of indirect impacts associated with these activities with the potential to indirectly impact biodiversity values within or adjacent to the tunnel footprints are shown in Table 36-8.

Table 36-8: Key activities associated with tunnels and associated potential indirect impacts

Type of indirect impact/threat	Description
Hydrological disturbance	Changes to surface water and groundwater flows and water quality. Potential for groundwater level drawdown into the tunnel void and water quality impacts from the disposal of poor quality groundwater and surface water drainage from the tunnel during operation
Soil erosion and sedimentation	Potential for soil erosion and sedimentation to lead to disturbance to vegetation and poor quality stormwater run-off, particularly associated with the management of spoil
Disturbance of contaminated soils	Potential for disturbance to contaminated sites, causing water quality impacts
Spread of weeds	Spread of invasive species due to edge effects, surface water run-off, or changed fire regimes
Spread of infection/disease	Spread of pathogens from contaminated clothing and equipment or surface water runoff
Fauna disturbance due to noise, dust or light	Noise, dust or light created by equipment during construction or generated through the tunnel ventilation system during operation
Fauna mortality and barriers to fauna movement	Potential for mortality of threatened fauna species by vehicle strike and reduced movement and connectivity between habitat areas from barriers
Inadvertent impacts on adjacent habitat or vegetation	Damage to adjacent habitat during construction activities
Ground settling or subsidence	Potential for the ground in the vicinity of the tunnels to settle or subside due to the tunnel void or groundwater removal, which may cause disturbance to the land surface

Biodiversity values potentially indirectly impacted

Table 36-9 identifies the biodiversity values that occur in the vicinity of the tunnel footprints that are most likely to be potentially indirectly impacted by the tunnels. These have been identified taking into account:

- The presence/abundance of species records, potential habitat and TECs in the vicinity of the tunnels
- Relevant threats to the species and TECs identified in Conservation Advices
- Proximity of the species and TECs to the tunnel footprints in the context of the indirect impact type (e.g. ground settling or disturbance is more likely to occur to biodiversity values within the tunnel footprint, weed invasion is a risk for values in proximity to construction sites that will generally be within the tunnel footprint)
- Importance of the location for the species and TEC at a local and regional scale

The Plan includes a commitment to mitigate indirect and prescribed impacts on species from the transport corridors (Commitment 6), including managing key threats to the following threatened species during construction of the tunnels (Commitment 6.2):

- *Eucalyptus benthamii*
- *Pimelea spicata*
- *Pomaderris brunnea*
- Cumberland Plain Land Snail

Key threats/indirect impacts that will be managed are:

- Hydrological/soil disturbance
- Spread of weeds
- Spread of infection/disease
- Ground settling or subsidence
- Disturbance to ground shelter habitat (e.g. removal of fallen logs, slashing)

As described above, this commitment will be delivered through the NSW environmental assessment and approval process. For the tunnels outside the nominated areas (where biodiversity impacts have not been assessed under the BC Act - see Part 1), this process will involve assessment under both:

- State Significant Infrastructure approval process (or equivalent)
- BC Act and BAM (or equivalent)

The process under the BC Act and BAM will address potential indirect impacts on biodiversity values. The process under the State Significant Infrastructure approval process (or equivalent) will assess the other environmental impacts and matters that need to be considered prior to construction and operation of the transport project. This will include an assessment of risks to the environment and the identification of mitigation measures to manage these risks, such as impacts related to hydrological disturbance, noise, air quality, and construction activities.

This commitment is considered adequate to address the potential indirect impacts of the tunnels as it:

- Includes a specific requirement to manage key threats to the species identified in Table 36-9 potentially indirectly impacted by the tunnels - *Eucalyptus benthamii*, *Pimelea spicata*, *Pomaderris brunnea* and Cumberland Plain Land Snail
- Specifies a process through these mitigation measures can be delivered and other broader risks to the environment relevant to these species, such as groundwater drawdown, are assessed and mitigated

Table 36-9: Key biodiversity values potentially indirectly impacted by tunnels

Biodiversity value	Key locations of TECs or species records	Relevant tunnel	Key relevant indirect impacts/threats	Assessment of potential indirect impacts
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest	Mater Dei BioBank site Sydney Metro offset site	OSO	• Hydrological/soil disturbance • Spread of weeds • Soil erosion and sedimentation • Spread of infection/disease • Ground settling or subsidence	Potential for notable impacts on these TECs is low. While several patches of these TECs, including several large (>20 ha) intact patches, have the potential to be indirectly impacted, particularly due to hydrological disturbance and ground settlement, the amount of impact that could potentially occur to these TECs is small in the context of the amount remaining in the Strategic Assessment Area. Commitment 6.1 is expected to adequately address the potential indirect impacts to these TECs
	Sydney Metro offset site Camden Golf Course, Narellan Mount Annan Botanic Gardens	MRFE		
Coastal floodplain eucalypt forest of eastern Australia	Mater Dei BioBank site Camden Airport Registered Property Agreement	OSO	• Hydrological/soil disturbance • Spread of weeds • Soil erosion and sedimentation • Spread of infection/disease • Ground settling or subsidence	
	Sydney Metro offset site Mount Annan Botanic Gardens Western Sydney University	MRFE		
Eucalyptus benthamii	Mater Dei BioBank site Camden Airport Registered Property Agreement Along the Nepean River in the vicinity of the OSO	OSO	• Hydrological/soil disturbance • Spread of weeds • Spread of infection/disease • Ground settling or subsidence	There is potential for notable impacts. As described above, a large important population of the species occurs within the OSO tunnel footprint. Commitment 6.1 includes specifically addressing key threats from the construction and operation of the tunnels on this species and is expected to adequately address potential indirect impacts

Biodiversity value	Key locations of TECs or species records	Relevant tunnel	Key relevant indirect impacts/threats	Assessment of potential indirect impacts
Pimelea spicata	Camden Golf Course, Narellan Mount Annan Botanic Gardens	MRFE	• Hydrological/soil disturbance • Spread of weeds	There is potential for notable impacts. As described above, a large important population of the species occurs at Camden Golf Club immediately adjacent to the MRFE tunnel footprint. Commitment 6.1 includes specifically addressing key threats from the construction and operation of the tunnels on this species and is expected to adequately address potential indirect impacts
Pomaderris brunnea	Camden Airport Registered Property Agreement Along the Nepean River in the vicinity of the OSO	OSO	• Spread of weeds • Soil erosion and sedimentation • Ground settling or subsidence	There is potential for notable impacts. As described above, a large important population of the species occurs within the Camden Airport Registered Property Agreement and within the riparian corridor of the Nepean River. Commitment 6.1 includes specifically addressing key threats from the construction and operation of the tunnels on this species and is expected to adequately address potential indirect impacts
Grey-headed Flying Fox	Mater Dei BioBank site	OSO	• Fauna disturbance due to noise	Potential for notable impacts is low. As described above, there are no known camps in the vicinity of the tunnels and potential indirect impacts relate to disturbance to individuals utilising foraging habitat only. The scale of impacts to foraging habitat is small. The species is highly mobile, feeds on fruit and nectar from a variety of vegetation communities and has access to large areas of intact vegetation surrounding the Strategic Assessment Area
	Mount Annan Botanic Gardens	MRFE		
Large-eared Pied Bat	Mater Dei BioBank site	OSO	• Fauna disturbance due to noise	Potential for notable impacts is low. As described above, the area is unlikely to support breeding habitat and potential indirect impacts relate to disturbance to individuals utilising foraging habitat only. Only one recent record of the species occurs in the area (at the Mater Dei BioBank site) and the scale of impacts to foraging habitat is small
Swift Parrot	Mater Dei BioBank site Camden Airport Registered Property Agreement	OSO	• Fauna disturbance due to noise	Potential for notable impacts is low. Potential indirect impacts relate to disturbance to individuals utilising foraging habitat only. The species is highly mobile, and the scale of impacts to potential foraging habitat is very small

Biodiversity value	Key locations of TECs or species records	Relevant tunnel	Key relevant indirect impacts/threats	Assessment of potential indirect impacts
Koala	Mount Annan Botanic Gardens	MRFE	• Hydrological/soil disturbance affecting feed trees • Fauna disturbance due to noise	Potential for notable impacts is low. While Koala has been recorded in the Botanic Gardens, the species is unlikely to be resident in the area. Habitat within the gardens is marginal, comprising supporting habitat only (see Chapter 30, Figure 38) and significant existing threats to Koalas are likely to exist in the area, including threats posed by roads, domestic dogs, barriers to movement (such as fences) and landscape hazards (such as swimming pools)

36.6.2 POTENTIAL IMPACTS TO OTHER MATTERS

Three areas of Commonwealth land occur within the tunnel footprints, including:

- Camden Airport within the OSO tunnel footprint
- Western Sydney University within the MRFE tunnel footprint
- 12 Werombi Road, Grasmere

The direct and indirect impacts of the tunnels on these matters are assessed in Chapter 35.

No other MNES occur in the vicinity of the tunnels or are likely to be directly or indirect impacted.

36.7 OVERALL OUTCOME UNDER THE PLAN

The detailed assessments for Commonwealth listed species and TECs and other protected matters have shown that the direct, indirect and cumulative impacts of the transport development under the Plan are acceptable and that the commitments under the Plan will adequately protect and conserve these matters in the context of these impacts.

37 Summary of urban program impacts

37.1 INTRODUCTION

This Chapter provides:

- A summary of the urban, industrial, infrastructure/essential infrastructure, and agribusiness development
- A summary of the impacts of the urban, industrial, infrastructure/essential infrastructure, and agribusiness development within urban capable lands on MNES under the EPBC Act including:
  - Avoidance outcomes and commitments
  - Direct impacts and commitments to address impacts
  - Indirect impacts and commitments to address impacts
- An assessment of the potential additional impacts of essential infrastructure within the nominated areas
- A conclusion about the overall outcome in relation to urban, industrial, infrastructure/essential infrastructure, and agribusiness development under the Plan

The summary draws on the detailed analysis of the impacts of the Plan and the adequacy of the commitments under the Plan to address these impacts on each MNES presented earlier in this Assessment Report.

These detailed impact assessments have shown that the direct, indirect and cumulative impacts of development within the nominated areas (and transport corridors) on MNES are acceptable and that the commitments under the Plan will adequately protect and conserve these matters in the context of these impacts.

Part 7 provides an evaluation of the overall adequacy and acceptability of the Plan in the context of the impacts of the development under the Plan and in accordance with the regulatory requirements of the BC Act and EPBC Act.

The urban, industrial, infrastructure/essential infrastructure, and agribusiness development is described in Chapter 7.

The locations of the nominated areas are shown in Figure 37-1.

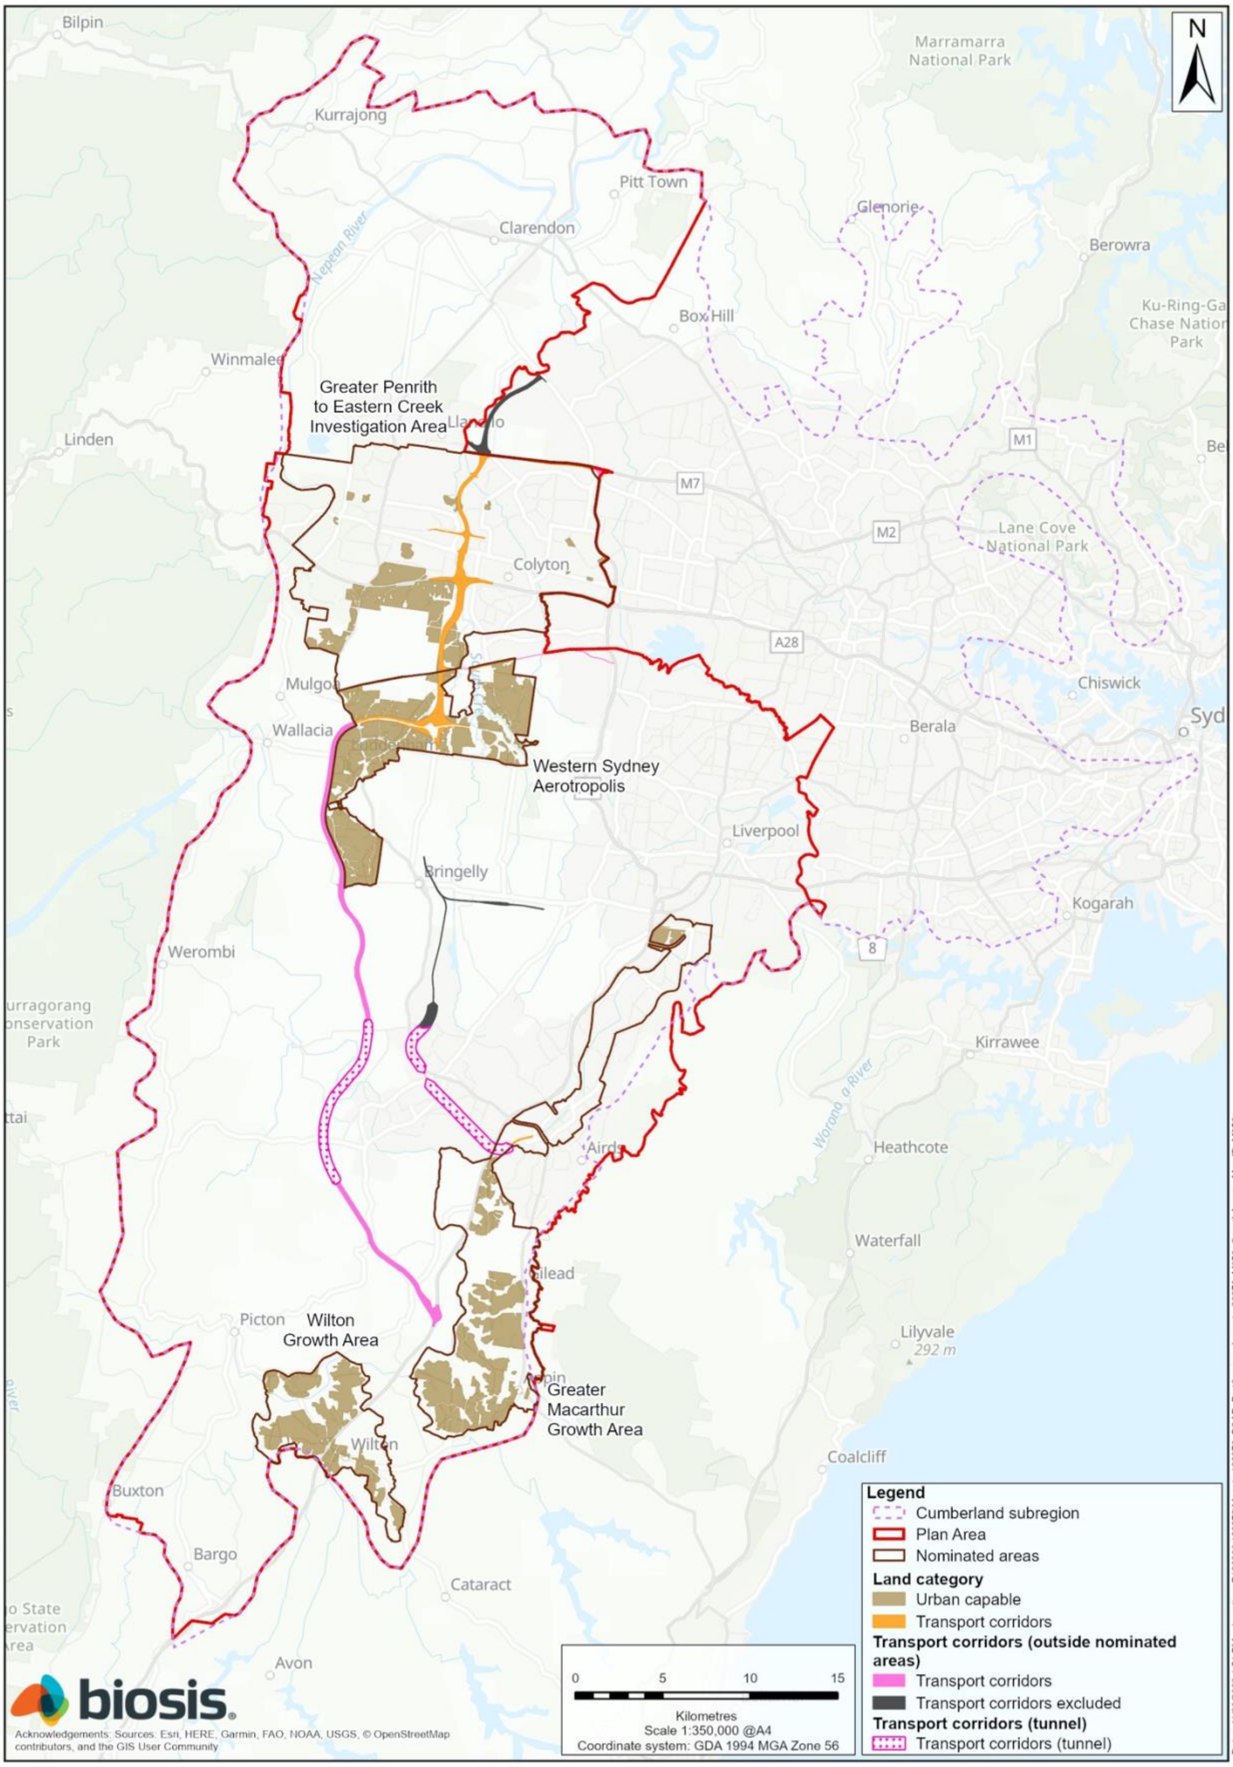

Figure 37-1: Locations of nominated areas within the Strategic Assessment Area

37.2 SUMMARY OF THE URBAN AND OTHER DEVELOPMENT

37.2.1 URBAN AND INDUSTRIAL DEVELOPMENT

Urban and industrial development will be confined to the urban capable lands within the nominated areas and includes any development permitted through residential, business, or industrial zones under relevant Local Environmental Plans, consistent with the structure plan and precinct plans for each nominated area.

Structure plans and precinct plans will be prepared for each nominated area by the relevant planning authority under the *Environmental Planning and Assessment Act 1979* (EP&A Act) and will map the boundaries of the urban capable land and the intended land use zones. Relevant planning authorities will rezone the land over time in stages.

37.2.2 AGRIBUSINESS

The Western Sydney airport presents an opportunity to invest in agriculture and agribusiness industries. The agribusiness precinct within WSA occurs on the northern and western edges of the airport and supports the long-term retention and growth of agriculture and agribusiness in the Western Parkland City.

Agribusiness will be confined to the agribusiness precinct within WSA and may include:

- Intensive plant agriculture, including protective structures used for production of fruit, vegetables or flowers
- Agribusiness – businesses associated with the production, processing, marketing and distribution of agricultural products, such as biotechnology research and development, food processing and export enabling infrastructure
- Advanced food manufacturing and logistics
- Wholesale markets, such as retail, distribution centres, cold stores, ripening rooms, and treatment facilities

37.2.3 INFRASTRUCTURE

Infrastructure development will generally be limited to urban capable land within the nominated areas and includes:

- Electricity transmission or distribution networks
- Gas pipelines
- Road or road infrastructure facilities, including public transport facilities (this is limited to local roads)
- Water reticulation systems, water storage facilities, water treatment facilities, or water supply systems
- Telecommunications facilities or telecommunication networks
- Supporting infrastructure for parks and public reserves (environmental facility, information and education facility, kiosk, recreation area, recreation facilities (outdoor), water recreation structure, road)

ESSENTIAL INFRASTRUCTURE

Certain essential infrastructure may be carried out by or on behalf of a public authority on land outside the urban capable land (not including land excluded from the Plan) within the nominated areas (i.e. on land avoided for biodiversity purposes or other reasons) provided specific requirements under the Plan are followed.

These requirements limit the scope of essential infrastructure development within these areas and will ensure that any infrastructure development in these areas avoids and mitigates and offsets any impacts to biodiversity values.

The potential impacts of essential infrastructure are assessed at Section 37.6.

37.3 AVOIDANCE OF IMPACTS

37.3.1 SUMMARY OF AVOIDANCE OUTCOMES

Consistent with Section 8.1.1.2 of the BAM, the process to identify the urban capable land boundaries within the nominated areas was an iterative one that began early in the assessment process before the final data on biodiversity values was completed. The urban capable land boundaries were identified in three phases:

- Strategic planning to locate the nominated areas
- Initial development of footprints through Land Use and Infrastructure Implementation Plans (LUIIP)

- Iterative refinement of the footprints through development of the Plan and assessment of impacts

Details of the process to design the urban capable land within the nominated areas are provided in Chapter 14.

Urban, industrial, infrastructure and agribusiness development in urban capable land within nominated areas has avoided the majority of native vegetation and key areas of high biodiversity values, including Commonwealth-listed TECs important populations and habitat connectivity.

Within the nominated areas, total avoidance (not including excluded lands) is summarised in Table 37-1.

Table 37-1: Avoidance outcomes for urban, industrial, infrastructure and agribusiness development within nominated areas

Biodiversity values	Summary of avoidance outcome in the nominated areas*
Native vegetation	67.2% avoided
High (intact) condition native vegetation	95.2% avoided
Commonwealth-listed TECs (critically endangered/endangered)	87.5% avoided
Commonwealth important populations	12 of the 14 species avoided (either wholly or partially)
Habitat connectivity (Bio Map areas)	88.3% of Bio Map core areas
	86.0% of Bio Map corridors

*Note that these figures include the amount of land 'avoided' for other purposes (e.g. riparian corridors and steep land) and not just biodiversity purposes. The figures do not include excluded land

37.3.2 COMMITMENTS FOR AVOIDANCE

The Plan includes a commitment (Commitment 2) to avoid and minimise impacts from urban and industrial, and infrastructure development, to at least 4,315 hectares of land within the nominated areas. This includes

- Avoiding 3,670 hectares of native vegetation comprising:
  - 2,735 hectares of native vegetation because of its biodiversity value
  - 935 hectares of riparian corridors and steep land
- Avoiding specific amounts of habitat for Commonwealth and NSW listed TECs
- Limiting cumulative direct impacts from essential infrastructure within non-certified land to the Commonwealth listed Shale Sandstone Transition Forest TEC and prioritising the avoidance of impacts from this infrastructure to specific known populations of flora species and important Koala corridors

37.4 DIRECT IMPACTS

37.4.1 SUMMARY OF IMPACTS

The direct impacts that may occur due to the nominated areas are associated with construction and are:

- Habitat loss
- Habitat fragmentation and loss of habitat connectivity

The direct impacts of the nominated areas on MNES are assessed in Chapters 29 to 35.

A summary of the direct impacts from urban development on Commonwealth-listed species and TECs is provided in:

- Table 37-2 – urban impacts to threatened fauna
- Table 37-3 – urban impacts to threatened flora
- Table 37-4 – urban impacts to TECs

These tables identify impacts in relation to each nominated area, as well as the total impact of the nominated areas and the contribution of the urban program to the total impacts of the development under the Plan.

The urban development will not have notable direct impacts on other EPBC Act protected matters, including:

- Migratory species (see Chapter 32)
- Ramsar wetlands (see Chapter 33)
- World and National Heritage (see Chapter 34)
- Commonwealth land (see Chapter 35)

THREATENED FAUNA

The following outlines the magnitude of impact to each threatened fauna species solely with regards to the urban capable development program. Chapter 30 provides a detailed assessment of each fauna species as a result of all development (urban capable in addition to transport development) under the Plan, and produces a risk ranking for each fauna species with regards to their magnitude of direct impacts under the Plan. It is noted that the risk ranking relates to both urban capable and transport development, rather than just urban capable development, and so it is possible for a species to have low urban capable development impacts yet a high risk rating as a result of impacts due to transport development (and vice versa).

Urban development within the nominated areas will directly impact potential habitat for 11 of the 20 fauna species. These include: Regent Honeyeater (low risk), Australasian Bittern (low risk), Swift Parrot (medium risk), Australian Painted Snipe (very low risk), Large-eared Pied Bat (low risk), Spot-tailed Quoll (low risk), Greater Glider (very low risk), Koala (high risk), Grey-headed Flying Fox (low risk), Giant Burrowing Frog (very low risk) and Green and Golden Bell Frog (very low risk).

The most notable direct impacts occur to:

- Regent Honeyeater (low risk) and Swift Parrot (medium risk) within GMAC and Wilton
- Grey-headed Flying-fox (low risk) within WSA
- Large-eared Pied Bat (low risk) in Wilton and GMAC

The largest impacts to potential habitat will occur to:

- Species with broad associations with woodland habitats primarily for foraging, such as the Swift Parrot (medium risk) (832.1 ha of impact) and the Regent Honeyeater (low risk) (832.1 ha of impact)
- Wide ranging species such as the Spot-tailed Quoll (low risk) (416.3 ha of impact) and Grey-headed Flying-fox (low risk) (364.8 ha of impact)

The species most impacted in terms of the percentage of total habitat in the Strategic Assessment Area is the Koala (high risk), which will have 1.7% of its potential habitat impacted.

THREATENED FLORA

The following outlines the magnitude of impact to each threatened flora species solely with regards to development of the urban capable land program. Similar to fauna, Chapter 29 provides a detailed assessment of each species as a result of all development (transport in addition to urban capable development) under the Plan, and produces a risk ranking for each flora species with regards to their magnitude of direct impacts under the Plan. It is noted that the risk ranking relates to both urban capable and transport development, rather than just urban capable development, and so it is possible for a species to have low urban capable impacts yet a high risk rating as a result of impacts due to transport development (and vice versa).

The nominated areas will directly impact potential habitat for 14 of the 23 flora species.

The most notable direct impacts occur to:

- *Pimelea spicata* (high risk) within Wilton and WSA
- *Acacia pubescens* (very low risk) within Wilton, GMAC, WSA and GPEC

The largest impacts to potential habitat will occur to:

- *Pimelea spicata* (high risk) (714.3ha)

- *Acacia pubescens* (very low risk) (602.9 ha)
- *Acacia bynoeana* (very low risk) (195.2 ha)

The species most impacted in terms of the percentage of total habitat in the Strategic Assessment Area is *Pimelea spicata* (high risk), which will have 2.0% of its potential habitat impacted.

The nominated areas will directly impact known important populations of some flora species, including: *Pimelea spicata* (high risk) (1 population).

THREATENED ECOLOGICAL COMMUNITIES

The following outlines the magnitude of impact to each TEC with solely with regards to development of the urban capable land program. Chapter 31 provides a detailed assessment of each species as a result of all development (transport in addition to urban capable development) under the Plan. The following outlines the area of each TEC impacted by urban capable development under the Plan, with the total impact of all development under the Plan (transport in addition to urban development) provided in brackets to provide additional context.

The transport corridors will directly impact 5 of the TECs. These include:

- Shale Sandstone Transition Forest of the Sydney Basin Bioregion 191.8 ha impacted by urban capable land (191.8 ha impacted in total by the Plan)
- Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest: 103.3 ha impacted by urban capable land (154.7 ha impacted in total by the Plan)
- Coastal floodplain eucalypt forest of eastern Australia (FPAL): 43.5 ha impacted by urban capable land (210.2 ha impacted in total by the Plan)
- Cooks River/Castlereagh Ironbark Forest of the Sydney Basin Bioregion: 11.3 ha impacted by urban capable land (26.3 ha impacted in total by the Plan)
- Coastal Swamp Oak (*Casuarina glauca*) Forest of New South Wales and South East Queensland ecological community: 0.4 ha impacted by urban capable land (1.8 ha impacted in total by the Plan)

The most notable direct impacts occur to:

- Shale Sandstone Transition Forest of the Sydney Basin Bioregion within Wilton and GMAC
- Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest within GMAC, WSA and GPEC

The TEC most impacted in terms of the percentage of total TEC in the Strategic Assessment Area is Shale Sandstone Transition Forest of the Sydney Basin Bioregion (2.3 per cent).

Table 37-2: Urban impacts to potential habitat for Commonwealth listed threatened fauna

37.4.2 COMMITMENTS TO ADDRESS IMPACTS

The Plan includes commitments to address the direct impacts of the nominated areas on Commonwealth listed species and TECs. The key commitments apply to both the urban and transport program and include to:

- Secure a minimum of 5,475 hectares of native vegetation in the Cumberland subregion (Commitment 8) to conserve biodiversity values in perpetuity, including specific amounts of habitat for Commonwealth-listed species and TECs
- Undertake ecological restoration of up to 25 per cent of the offset target for native vegetation in areas secured for conservation within the Cumberland subregion (Commitment 13)
- Secure priority habitat corridors within the Cumberland subregion in perpetuity, to support habitat connectivity (Commitment 12)

There are also a range of specific commitments for the species and TECs at the highest risk of adverse direct impacts.

37.5 INDIRECT IMPACTS

37.5.1 SUMMARY OF IMPACTS

Potential indirect impacts are assessed in detail for each Commonwealth-listed matter in Chapters 29, 30 and 31, and for other protected matters in Chapters 32, 33, 34 and 35. Chapter 15 summarises the commitments and mitigation measures and processes to implement them for the development in the urban capable lands.

Species and TECs and other protected matters with specific mitigation measures related to the urban and other development in the urban capable land, and that are therefore considered most likely to be impacted by this development, are:

- Fauna:
  - Koala
  - Macquarie Perch
  - Green and Golden Bell Frog
  - Grey-headed Flying Fox
  - Regent Honeyeater
  - Swift Parrot
  - Spotted-tailed Quoll
  - Greater Glider
- Flora:
  - *Persoonia nutans*
  - *Pimelea spicata*
  - *Pultenaea parviflora*
  - *Grevillea parviflora* subsp. *parviflora*
  - *Persoonia bargoensis*
  - *Genoplesium baueri*
  - *Melaleuca deanei*
  - *Pterostylis saxicola*
- TECs:
  - Cooks River Castlereagh Ironbark Forest
  - Cumberland Plain Woodland
  - Coastal floodplain eucalypt forest
  - Shale Sandstone Transition Forest
  - Coastal Swamp Oak Forest

Development within the nominated areas will not have notable indirect impacts on other EPBC Act protected matters, including:

- Migratory species (see Chapter 32)
- Ramsar wetlands (see Chapter 33)
- World and National Heritage (see Chapter 34)

37.5.2 COMMITMENTS TO ADDRESS IMPACTS

The Plan includes a commitment to mitigate indirect and prescribed impacts on TECs and species from development within the nominated areas to best practice standards (Commitment 5), including implementing development controls in the nominated areas to protected species, as prescribed in Appendix E of the Plan (Commitment 5.1)

Two broad types of development controls will be implemented:

- General environmental controls that will benefit the environment generally, including biodiversity values
- Specific controls that apply to specific species and TECs in specific locations or broader nominated areas. These controls have been identified through this Assessment Report and are needed to address residual risks to species or TECs that remain after implementation of the general environmental controls

The commitment to manage indirect impacts of urban, industrial and agribusiness development within the nominated areas will be delivered primarily through the NSW planning system, and specifically, the nominated areas planning delivery framework. The overarching planning delivery framework is described in Chapter 9.

The key mechanism to implement the general environmental controls and the specific controls in the nominated areas is Development Control Plans (DCPs). DCPs will be prepared for each nominated area and set out the controls that need to be addressed by neighbourhood plans and development applications to mitigate indirect impacts.

37.6 ASSESSMENT OF POTENTIAL ADDITIONAL IMPACTS OF ESSENTIAL INFRASTRUCTURE

37.6.1 INTRODUCTION

This section assesses the potential additional impacts to protected matters under the EPBC Act due to essential infrastructure projects within non-certified lands avoided lands in the nominated areas.

Planning for essential infrastructure to support the nominated areas, such as water and electricity utilities, is in various stages of development, and this infrastructure may need to be located outside urban capable lands.

The Plan is seeking approval under the EPBC Act (but not the BC Act) for certain essential infrastructure development to occur within the nominated areas outside urban capable lands (i.e. within avoided or non-certified land but not excluded lands).

The Plan specifies that:

- Every effort should be made to ensure that essential infrastructure development is limited to urban capable lands
- Where essential infrastructure occurs outside urban capable lands (i.e. within avoided lands), the development must comply with the 'Guidelines for essential infrastructure development' in Appendix A of the Plan. This includes a requirement (if necessary) to assess the biodiversity impacts of each project under the BC Act
- Cumulative impacts from essential infrastructure on EPBC Act-listed Shale Sandstone Transition Forest is capped and avoidance of impacts is prioritised for certain species (Commitment 2.3 and Commitment 2.4)

This Section:

- Provides definitions of the different land types in the nominated areas
- Sets out the scope of essential infrastructure development
- Describes the planning, assessment and implementation processes set out in the guidelines for essential infrastructure development (the Guidelines) and relevant commitments
- Analyses the potential impacts to EPBC Act threatened species and TECs

- Analyses the potential impacts to other matters protected by the EPBC Act
- Provides a conclusion about the likely outcomes for protected matters arising out of essential infrastructure development

37.6.2 DEFINITIONS OF LAND TYPES IN THE NOMINATED AREAS

There are different land types in the nominated areas. These are relevant to the scope of the essential infrastructure process.

CERTIFIED LANDS

Certified lands within the nominated areas are referred to as 'certified-urban capable land'. These areas are proposed to be approved under both the EPBC Act and BC Act and include the development footprints for urban development.

Essential infrastructure that occurs within the urban capable lands is assessed (in relation to the EPBC Act) as part of Chapters 27-35.

NON-CERTIFIED LANDS

Not all of the nominated areas are proposed for urban development. These areas are non-certified lands and comprise land that has been avoided and land that is excluded from the assessment.

Avoided lands

The definition of what constitutes avoidance has been adopted from the BCAR process. Under the BAM, avoidance refers to land that is suitable for development and included in the area proposed for development or biodiversity certification, but has been avoided because of its biodiversity value. This is referred to as avoidance for 'biodiversity purposes' in this assessment.

Land not impacted because it is not suitable for development or biodiversity certification, or land that has been excluded from the area proposed for development is not considered to have been avoided under the BAM. This land is referred to as avoidance for 'other purposes' and includes:

- Riparian corridors consistent with the *Water Management Act 2000*:
  - Strahler stream order 2 - buffer 20 m either side
  - Strahler stream order 3 - buffer 30 m either side
  - Strahler stream order 4 and above - buffer 40 m either side
- State protected land (>18 degrees slope, considered too steep for urban development)

The assessment in this section considers the potential impacts of essential infrastructure on avoided lands in the nominated areas.

Excluded lands

Some land within the nominated areas was not considered for inclusion in the area proposed for development and has therefore been identified as 'excluded' land. These lands include:

- Existing protected land, including reserves and established offset sites
- Council owned land which is zoned for environmental conservation, environmental management or recreation
- Commonwealth land, such as Defence Establishment Orchard Hills
- Lands within the nominated areas already assessed as part of another development approval (Bingara Gorge), or lands progressing through an alternate assessment (Mount Gilead, Menangle Park, Sydney Metro Stage 1)
- Lands already developed (existing urban areas, urban land zones and roads)

Other non-certified land

This relates to land in WSA that has been identified as 'Environment and Recreation' lands within the updated Western Sydney Aerotropolis Stage 1 Structure Plan. These lands have not been included in urban capable lands. However, it is proposed that the lands may be used for public open space or passive recreation, including supporting infrastructure such as information facilities, kiosks, or recreational areas.

37.6.3 SCOPE OF ESSENTIAL INFRASTRUCTURE

The spatial scope, types of actions and activities, and criteria that must be met for essential infrastructure projects that are assessed in this report are described below. These are largely taken from the Guidelines in Appendix A of the Plan.

SPATIAL SCOPE

The spatial scope of essential infrastructure that is assessed here applies to projects that occur on avoided lands within each of the four nominated areas.

The assessment does not address the potential impacts of essential infrastructure projects that occur:

- On excluded lands within the nominated areas
- Outside of the nominated areas
- On other non-certified land in WSA which has not been included in the assessment of essential infrastructure at this point due to a late change in the Plan that did not provide sufficient time for a detailed assessment to be carried out. The potential implications of essential infrastructure on these lands will be considered after public comment

It is important to note that the potential impacts of essential infrastructure projects on EPBC Act protected matters within the urban capable lands of each nominated area are assessed in Chapters 27-35.

It is also important to note that the Guidelines make reference to essential infrastructure projects that occur "wholly or mostly within the nominated areas". Given the uncertainty about the scale, nature and extent of potential impacts outside the nominated areas, the spatial scope of the assessment within this report is restricted to activities that occur within the nominated areas (on avoided lands). Potential impacts of activities that might occur outside the nominated areas have not been assessed.

TYPES OF ACTIONS AND ACTIVITIES

Actions

The Guidelines define essential infrastructure as including the following types of actions:

- Electricity generating works or solar energy systems
- Electricity transmission or distribution
- Pipelines and pipeline corridors
- Roads and traffic
- Sewerage systems
- Stormwater management systems
- Telecommunications and other communication facilities
- Waste or resource management facilities
- Water supply systems
- Recreation works (environmental facility, information and education facility, kiosk, recreation area, recreation facilities (outdoor), water recreation structure and other supporting development) only on non-certified land in the Western Sydney Aerotropolis

Activities

Development of the essential infrastructure projects includes all activities associated with the design, construction and operation of the actions listed above.

Specific activities that may be carried out under the Plan for these projects include, but are not limited to:

- Vegetation clearing
- Earthworks

- Utility works
- Landscaping
- Erosion and sediment control
- Laydown areas
- Road construction
- Construction of supporting infrastructure such as stations, car parks and pedestrian access
- Electricity infrastructure
- Site offices and access roads
- Pipelines
- Construction of buildings that form part of the permitted actions
- Dust and noise suppression
- Stormwater management (including detention basins, ponds and dams)
- Maintenance and upgrade activities

CRITERIA

The Guidelines constrain the types of actions that may be undertaken through a set of criteria that must be met. Any essential infrastructure project that is included in the list of possible projects above must also be a development by a public authority which includes:

- Local development
- Part 5 activities (5.1) under the EP&A Act (except for Road Activities)

Projects may not include:

- State significant development
- State significant infrastructure
- Classified Roads
- Division 5.1 Road Activities (EP&A Act) which are subject to an existing Part 10 approval under the EPBC Act.

In practice, these criteria restrict the scope of essential infrastructure development to smaller scale projects that are carried out by public authorities to facilitate growth in the nominated areas where the activities cannot be accommodated within the urban capable lands.

37.6.4 PLANNING, ASSESSMENT AND IMPLEMENTATION PROCESSES FOR ESSENTIAL INFRASTRUCTURE

GUIDELINES

The Guidelines set out what is required to protect biodiversity in terms of planning, assessment and implementation as each essential infrastructure project is brought forward.

Each project will be managed through the NSW planning and approvals framework as current at the time of the project. This process will be critical to adequately avoiding, minimising, mitigating and offsetting any impacts to MNES as a result of essential infrastructure projects on avoided lands.

The Guidelines state that:

Essential infrastructure may be carried out by or on behalf of a public authority on non-certified land, if:

- *Environmental impacts of the activities are considered under the Environmental Planning and Assessment Act, and an 'avoid and mitigate' process is applied*
- *MNES are considered through the 'avoid and mitigate' process and any relevant MNES-specific requirements of the Plan are applied* [Commitment 1, Commitment 2, Commitment 5 and Commitment 7; Appendix C – Plan Commitments]
- *The biodiversity impacts of the activities will be assessed under the Biodiversity Conservation Act, if triggered, and an 'avoid, mitigate, offset' process will be applied*
- *The public authority has notified the department of the development.*

The Guidelines also require the following procedures to be applied:

- ***Environmental impact assessment*** *(pre-construction) - the impacts of proposed activities on the environment must be considered along with identified mechanisms to deliver environmental solutions. The environmental assessment process aims to:*
  - *Identify environmental impacts at the earliest possible stage in project development*
  - *Take steps to avoid or minimise potential impacts as the first priority*
  - *Assess the unavoidable impacts of a proposed activity on the environment before making a decision on whether it should proceed, including consideration of cumulative impacts*
  - *Ensure the community is appropriately consulted and that their input is taken into account in decision-making*
  - *Provide appropriate offset measures to ensure that any residual impacts that cannot be avoided or minimised do not have an unacceptable environmental impact*
- ***Environmental management and compliance*** *(during construction and operation) – to ensure that activities comply with legislative requirements and deliver effective implementation of identified safeguards and mitigation measures during project construction and future on-going maintenance*

These future impact assessment and environmental management processes will be undertaken in accordance with NSW planning and assessment laws current at the time the development is proposed.

The Guidelines also set out what is required for essential infrastructure projects to meet the Plan's commitments. This includes but is not limited to:

- *Avoid land for biodiversity or other environmental purposes within the nominated areas where possible; this includes specific consideration of nationally threatened species, ecological communities and their habitats. These areas will be zoned for environmental purposes and should be avoided where possible*
- *Where an action cannot feasibly or practicably avoid impacts on non-certified land, the public authority shall ensure the impacts are minimised as far as possible. This includes by refining design elements to reduce the overall impact*
- *Fulfil biodiversity offset requirements under the Biodiversity Conservation Act 2016 or any subsequent legislative scheme in place at the time*
- *Implementing impact mitigation measures based on the outcomes of environmental assessment of detailed designs, including consideration to Plan Commitments 4 and 6.*

Finally, the Guidelines also set out a number of specific constraints around potential impacts to MNES in relation to essential infrastructure projects on avoided lands. These constraints are:

- *Limit the total cumulative direct impacts within avoided lands to Shale Sandstone Transition Forest in the Sydney Basin Bioregion over the life of the Plan to no more than 20 ha in Wilton and 20 ha in GMAC*
- *Consider the of connectivity of important Koala corridors within avoided lands in Wilton and GMAC*

COMMITMENTS

The Plan also includes commitments related to essential infrastructure that support the Guidelines. These are:

- Commitment 1: Development will be undertaken in accordance with the Plan and any conditions of approval.
- Commitment 1.1: Essential infrastructure in non-certified land will be implemented consistent with the Plan's Essential Infrastructure Guidelines.
- Commitment 2.3: Limiting cumulative direct impacts over the life of the Plan from essential infrastructure to Shale Sandstone Transition Forest in avoided lands to no more than:
  - 20 ha in Wilton
  - 20 ha in GMAC

- Commitment 2.4: Prioritising the avoidance of impacts from essential infrastructure in avoided lands to:
  - Known populations of the following threatened flora species:
    - *Grevillea parviflora* subsp. *parviflora* (Small-flower Grevillea)
    - *Persoonia bargoensis* (Bargo Geebung)
    - *Persoonia nutans* (Nodding Geebung)
    - *Genoplesium baueri* (Yellow Gnat-orchid)
    - *Pimelea spicata* (Spiked Rice-flower)
    - *Pultenaea parviflora*
  - Important Koala corridors within Wilton and GMAC to maintain their integrity

37.6.5 POTENTIAL IMPACTS TO THREATENED SPECIES AND TECS

POTENTIAL DIRECT IMPACTS

The potential direct impacts to threatened species and TECs due to essential infrastructure projects include habitat loss and fragmentation. Given that it is not possible at this stage to know the location, scale and nature of specific projects, the following approach was used to understand the potential direct impacts to threatened species and TECs. For each nominated area:

- The presence of known populations of threatened species (i.e. where records exist) and mapped TECs on avoided lands was determined. This was based on the baseline data that was prepared for each species and TEC (see Chapters 29-31 for details)
- The potential for direct impacts to these species and TECs due to essential infrastructure was assessed. This included consideration of:
  - The location, extent and sensitivity of MNES values and judgement about the likelihood that impacts could occur. For example, flora populations occurring within corridors away from the urban capable lands may be less likely to be directly impacted than flora populations on flat land near the edge of urban capable lands
  - How the requirements of the Guidelines may apply to each relevant MNES
- The likely outcome for each MNES following the application of the criteria in the Guidelines and the NSW planning and approvals framework was determined

The following tables set out the analysis for each nominated area:

- Table 37-5 - Wilton
- Table 37-6- GMAC
- Table 37-7 - WSA
- Table 37-8 - GPEC

Table 37-5: Potential direct impacts to biodiversity values in Wilton

EPBC matter	EPBC status	Occurrence and possible impacts	Application of the Essential Infrastructure Guidelines	Likely outcome
TECS				
Shale Sandstone Transition Forest in the Sydney Basin Bioregion	CE	Significant areas of the TEC occur within avoided lands in Wilton (753.7 ha). Of the 753.7 ha, 455.5 ha is in good (intact) condition, 292.8 ha is in moderate (thinned) condition, and 5.4 ha is in poor (scattered) condition. Given the extent of the TEC on avoided lands, it is probable that impacts from essential infrastructure will occur to the TEC. The likelihood of impact is reduced for those areas of the TEC that occur in riparian or steep areas (69.8 ha). See Map 48.6 for mapping of the TEC across the Strategic Assessment Area.	To constrain potential impacts to the TEC, the Guidelines: • Require efforts to avoid and minimise impacts to the TEC • Limit the maximum cumulative impact to 20 ha within avoided lands in Wilton The Guidelines require any residual impacts to be offset.	Commitment 2.3 specifies that a maximum of 20 ha of the TEC may be impacted by essential infrastructure projects within Wilton over the life of the Plan. Where impacts occur they will be offset in accordance with the requirements of the BAM.

EPBC matter	EPBC status	Occurrence and possible impacts	Application of the Essential Infrastructure Guidelines	Likely outcome
THREATENED FLORA				
Grevillea parviflora subsp. *parviflora* (Small-flower Grevillea)	V	Two known populations of the species occur within avoided lands in Wilton. Population 104 is important and contains 13 records comprising 339 individuals. Of these 13 records, 8 (331 individuals) occur within avoided lands in the north of Wilton approximately 300 m from urban capable land. Without commitments to protect it, impacts to this population from essential infrastructure in this area could be possible. Population 518 is important and contains 1 record comprising 1 individual. Without commitments to protect it, impacts to this population from essential infrastructure in this area could be possible although unlikely because the population occurs on the western edge of Wilton, approximately 600 m from the nearest urban capable land, and close to steep areas and sandstone cliffs. See Map 36.10 for mapped potential habitat and populations across the Strategic Assessment Area.	To constrain potential impacts to the species, the Guidelines require efforts to avoid and minimise impacts to known locations and habitat. Any residual impacts need to be offset.	Commitment 2.4 specifies that avoidance of known populations of this species will be prioritised. Given the limited distribution of the species within avoided lands it is considered likely that avoidance of direct impacts will be possible. Where impacts occur they will be offset in accordance with the requirements of the BAM.
Persoonia bargoensis (Bargo Geebung)	V	One known population of the species occurs within avoided lands in Wilton. Population 114 is important and contains 343 records comprising 1,461 individuals. Of these records, 3 (8 individuals) occur within avoided lands in the north west and east of Wilton. Without commitments to protect it, impacts to this population from essential infrastructure in this area could be possible. See Map 36.16 for mapped potential habitat and populations across the Strategic Assessment Area.	To constrain potential impacts to the species, the Guidelines require efforts to avoid and minimise impacts to known locations and habitat. Any residual impacts need to be offset.	Commitment 2.4 specifies that avoidance of known populations of this species will be prioritised. Given the limited distribution of the species within avoided lands it is considered likely that avoidance of direct impacts will be possible. Where impacts occur they will be offset in accordance with the requirements of the BAM.
