Phascolarctos cinereus (Koala)	V	Important Koala habitat occurs extensively on avoided lands in Wilton. The habitat is closely associated with the occurrence of Shale Sandstone Transition Forest in the Sydney Basin Bioregion and essential infrastructure projects have the potential to impact areas of Koala habitat. See Map 37 and Map 40 for mapped habitat and species records across the Strategic Assessment Area.	To constrain potential impacts to the species within avoided lands, the Guidelines: • Require efforts to avoid and minimise impacts to biodiversity (including Koala habitat) • Consider the connectivity of important Koala corridors within avoided lands in Wilton In addition, given the close association between important Koala habitat and Shale Sandstone Transition Forest in the Sydney Basin Bioregion the impact limit for the TEC (20 ha within Wilton) will help reduce any potential direct impacts to Koala habitat. Any residual impacts need to be offset.	It is possible that Koala habitat will be impacted by essential infrastructure projects. However, the Guidelines and Commitment 2.4 together will: • Constrain the scale of potential impacts • Prioritise avoidance of important Koala corridors in Wilton to maintain their integrity Where impacts occur they will be offset in accordance with the requirements of the BAM.
Pteropus poliocephalus (Grey-headed Flying-fox)	V	The species has been recorded on avoided lands in Wilton, and areas of foraging habitat (54.4 ha) for the Grey-headed Flying-fox are present. There are no known camps or important roosting sites for the species in these areas. Direct impacts to foraging habitat are possible, especially where it occurs near to urban capable lands. See Map 36.32 and Map 36.33 for mapped potential habitat and populations across the Strategic Assessment Area.	To constrain potential impacts to the species, the Guidelines require efforts to avoid and minimise impacts to biodiversity (including foraging habitat for the Grey-headed Flying-fox). In addition, given the extensive nature of Shale Sandstone Transition Forest in the Sydney Basin Bioregion on avoided lands, the impact limit for the TEC (20 ha within Wilton) will help reduce any potential direct impacts to foraging habitat for the species. Any residual impacts need to be offset.	It is possible that foraging habitat for the species will be impacted by essential infrastructure projects. However, the Guidelines will constrain the scale of potential impacts. Where impacts occur they will be offset in accordance with the requirements of the BAM.

Table 37-6: Potential direct impacts to biodiversity values in GMAC

EPBC matter	EPBC status	Occurrence and possible impacts	Application of the Essential Infrastructure Guidelines	Likely outcome
TECs				
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest	CE	Small areas of the TEC occur within avoided lands in GMAC (22.5 ha). Of the 22.5 ha, 10.3 ha is in good (intact) condition and 12.2 ha is in moderate (thinned) condition. Impacts to the TEC are possible from essential infrastructure as the majority of it occurs: • Between areas of urban capable lands • On flatter lands that have been avoided for biodiversity purposes See Map 48.4 for mapping of the TEC across the Strategic Assessment Area.	To constrain potential impacts to the TEC, the Guidelines require efforts to avoid and minimise impacts. Any residual impacts need to be offset.	Given the limited distribution of the TEC within avoided lands it is considered likely that avoidance of direct impacts will be possible. Where impacts occur they will be offset in accordance with the requirements of the BAM.
Shale Sandstone Transition Forest in the Sydney Basin Bioregion	CE	Significant areas of the TEC occur within avoided lands in GMAC (1,192.8 ha). Of the 1,192.8 ha, 981.9 ha is in good (intact) condition, 199.9 ha is in moderate (thinned), and 11 ha is in poor (scattered) condition. Given the extent of the TEC on avoided lands, it is probable that impacts from essential infrastructure will occur to the TEC. The likelihood of impact is reduced for those areas of the TEC that occur in riparian or steep areas (185.4 ha). See Map 48.6 for mapping of the TEC across the Strategic Assessment Area.	To constrain potential impacts to the TEC, the Guidelines: • Require efforts to avoid and minimise impacts to the TEC • Limit the maximum cumulative impact to 20 ha within avoided lands in GMAC The Guidelines require any residual impacts to be offset.	Commitment 2.3 specifies that a maximum of 20 ha of the TEC may be impacted by essential infrastructure projects within GMAC over the life of the Plan. Where impacts occur they will be offset in accordance with the requirements of the BAM.

EPBC matter	EPBC status	Occurrence and possible impacts	Application of the Essential Infrastructure Guidelines	Likely outcome
Western Sydney Dry Rainforest and Moist Woodland on Shale	CE	Small areas of the TEC occur within avoided lands in GMAC (15.4 ha). Of the 15.4 ha, 2.2 ha is in good (intact) condition and 13.2 ha is in moderate (thinned) condition. Impacts to the TEC are possible as it occurs on avoided lands in the centre of GMAC between urban capable land. The likelihood of impact is reduced where the TEC occurs in riparian corridors or on steep areas (4.2 ha). See Map 48.8 or mapping of the TEC across the Strategic Assessment Area.	To constrain potential impacts to the TEC, the Guidelines require efforts to avoid and minimise impacts. Any residual impacts need to be offset.	Given the limited distribution of the TEC within avoided lands it is considered likely that avoidance of direct impacts will be possible. Where impacts occur they will be offset in accordance with the requirements of the BAM.
Coastal floodplain eucalypt forest of eastern Australia	FPAL	Small areas of the potential TEC occur within avoided lands in GMAC (14.4 ha). Of the 14.4 ha, 9.9 ha is in good (intact) condition and 4.5 ha is in moderate (thinned) condition. Impacts to the potential TEC are possible as it occurs on avoided lands in the centre of GMAC between urban capable land. The likelihood of impact is reduced where the potential TEC occurs in riparian corridors or on steep areas (9.6 ha). See Map 48.5 for mapping of the EC across the Strategic Assessment Area.	To constrain potential impacts to the TEC, the Guidelines require efforts to avoid and minimise impacts. Any residual impacts need to be offset.	Given the limited distribution of the potential TEC within avoided lands it is considered likely that avoidance of direct impacts will be possible. Where impacts occur they will be offset in accordance with the requirements of the BAM.
THREATENED FLORA				
Genoplesium baueri (Yellow Gnat-orchid)	E	One known population of the species occurs within avoided lands in GMAC. Population 21 is important and contains 1 record comprising 1 individual. The whole population occurs within avoided lands. Without commitments to protect it, impacts to this population from essential infrastructure in this area could be possible although unlikely because the population occurs on the far eastern edge of GMAC approximately 400 m away from the nearest urban capable	To constrain potential impacts to the species, the Guidelines require efforts to avoid and minimise impacts to known locations and habitat. Any residual impacts need to be offset.	Commitment 2.4 specifies that avoidance of known populations of this species will be prioritised. Given the limited distribution of the species within avoided lands it is considered likely that avoidance of direct impacts will be possible. Where impacts occur they will be offset in accordance with the

EPBC matter	EPBC status	Occurrence and possible impacts	Application of the Essential Infrastructure Guidelines	Likely outcome
		land. See Map 36.9 for mapped potential habitat and populations across the Strategic Assessment Area.		requirements of the BAM.
Grevillea parviflora subsp. *parviflora* (Small-flower Grevillea)	V	One known population of the species occurs within avoided lands in GMAC. Population 519 is not important and contains 6 records comprising 6 individuals. Of these records, 1 (1 individual) occurs within avoided lands in GMAC. The area where the record occurs will be protected as part of the proposed Koala reserve. Based on this, direct impacts to the species will not occur. See Map 36.10 for mapped potential habitat and populations across the Strategic Assessment Area.	Once the Koala reserve is established, the Guidelines will not be applicable as essential infrastructure projects will not occur in the reserve.	No direct impacts to the species will occur as a result of essential infrastructure projects.
Pimelea spicata (Spiked Rice-flower)	E	One known population of the species occurs within avoided lands in GMAC. Population 533 is important and contains 1 record comprising 1 individual. The area where the record occurs will be protected as part of the proposed Koala reserve. Based on this, direct impacts to the species will not occur. See Map 36.21 for mapped potential habitat and populations across the Strategic Assessment Area.	Once the Koala reserve is established, the Guidelines will not be applicable as essential infrastructure projects will not occur in the reserve.	No direct impacts to the species will occur as a result of essential infrastructure projects.
Pomaderris brunnea (Rufous Pomaderris)	V	Seven known populations of the species occur within avoided lands in GMAC. Population 470 is not mapped as important and contains 1 record comprising 1 individual. Impacts to the population are possible as population occurs on avoided land in between and approximately 20 m from urban capable lands. Population 471 is not mapped as important and contains 3 records comprising 3 individuals. Impacts are possible as the entire	To constrain potential impacts to the species, the Guidelines require efforts to avoid and minimise impacts to known locations and habitat. Any residual impacts need to be offset.	Four populations of the species are at risk of direct impacts from essential infrastructure in GMAC. Commitment 2.4 specifies that avoidance of known populations of this species will be prioritised. Where impacts do occur they will be offset in accordance with the

EPBC matter	EPBC status	Occurrence and possible impacts	Application of the Essential Infrastructure Guidelines	Likely outcome
		population occurs on avoided lands in the south west of GMAC. Impacts are more likely where one record occurs 20 m from the development footprint. The likelihood of impacts to the other two records are reduced as they are located in steeper areas closer to the boundary of GMAC. Three populations occur to the east of Appin Road in the area proposed to be included in the George's River Koala Park. Impacts are unlikely to these populations. They are: • Population 513 - not important, 8 records comprising 8 individuals • Population 514 - not important, 2 records comprising 2 individuals • Population 515 - not important, 2 records comprising 2 individuals Population 586 is important and contains 7 records comprising 7 individuals. Of these records, 3 records (3 individuals) occur on avoided land in the centre of GMAC. Impacts to this population are possible as some records occur <100 m from urban capable land. Population 587 is important and contains 2 records comprising 2 individuals. The entire population occurs within avoided lands in the south-west of GMAC. Impacts to the population are possible as it occurs on the edge of urban capable land. See Map 36.22 for mapped potential habitat and populations across the Strategic Assessment Area.		requirements of the BAM.

EPBC matter	EPBC status	Occurrence and possible impacts	Application of the Essential Infrastructure Guidelines	Likely outcome
THREATENED FAUNA				
Chalinolobus dwyeri (Large-eared Pied Bat)	V	The species has been recorded on avoided lands in GMAC, and areas of potential foraging habitat (1,723.2 ha) for the Large-eared Pied Bat are present. It is important to note that there are no known roost or breeding sites for the species within the Strategic Assessment Area. The habitat is closely associated with the occurrence of Shale Sandstone Transition Forest in the Sydney Basin Bioregion and essential infrastructure projects have the potential to impact areas of the species. See Map 46.1 for mapped potential habitat and populations across the Strategic Assessment Area.	To constrain potential impacts to the species, the Guidelines require efforts to avoid and minimise impacts to biodiversity (including foraging habitat for the Large-eared Pied Bat). In addition, given the extensive nature of Shale Sandstone Transition Forest in the Sydney Basin Bioregion on avoided lands, the impact limit for the TEC (20 ha within GMAC) will help reduce any potential direct impacts to foraging habitat for the species. Any residual impacts need to be offset.	It is possible that foraging habitat for the species will be impacted by essential infrastructure projects. However, the Guidelines will constrain the scale of potential impacts. Where impacts occur they will be offset in accordance with the requirements of the BAM.
Dasyurus maculatus (Spot-tailed Quoll)	E	The species has been recorded on avoided lands to the east of Appin Road in GMAC, and areas of potential habitat (1,673.5) for the Quoll are present. Potential habitat is closely associated with the occurrence of Shale Sandstone Transition Forest in the Sydney Basin Bioregion and essential infrastructure projects have the potential to impact these areas. See Map 46.4 for mapped potential habitat and populations across the Strategic Assessment Area.	To constrain potential impacts to the species, the Guidelines require efforts to avoid and minimise impacts to biodiversity (including potential habitat for the Spot-tailed Quoll). In addition: • Given the extensive nature of Shale Sandstone Transition Forest in the Sydney Basin Bioregion on avoided lands, the impact limit for the TEC (20 ha within GMAC) will help reduce any potential direct impacts to potential habitat for the species • The requirement of the Guidelines to consider the connectivity of important Koala corridors within avoided lands in GMAC will help maintain any	It is possible that potential habitat for the species will be impacted by essential infrastructure projects. However, the Guidelines will constrain the scale of potential impacts. Where impacts occur they will be offset in accordance with the requirements of the BAM.

EPBC matter	EPBC status	Occurrence and possible impacts	Application of the Essential Infrastructure Guidelines	Likely outcome
			connectivity for the Spot-tailed Quoll Any residual impacts need to be offset.	
Lathamus discolor (Swift Parrot)	CE	The species has been recorded on avoided lands in GMAC, and areas of potential foraging habitat (1,811.6 for the Swift Parrot are present. Direct impacts to potential foraging habitat are possible, especially where it occurs near to urban capable lands. See Map 46.5 for mapped potential habitat and populations across the Strategic Assessment Area.	To constrain potential impacts to the species, the Guidelines require efforts to avoid and minimise impacts to biodiversity (including potential foraging habitat for the Swift Parrot). In addition, given the extensive nature of Shale Sandstone Transition Forest in the Sydney Basin Bioregion on avoided lands, the impact limit for the TEC (20 ha within GMAC) will help reduce any potential direct impacts to foraging habitat for the species. Any residual impacts need to be offset.	It is possible that foraging habitat for the species will be impacted by essential infrastructure projects. However, the Guidelines will constrain the scale of potential impacts. Where impacts occur they will be offset in accordance with the requirements of the BAM.
Petauroides volans (Greater Glider)	V	The species has been recorded on avoided lands to the east of Appin Road in GMAC, and areas of potential habitat (1,462.5) for the Greater Glider are present. Direct impacts to potential habitat are possible, especially where it occurs near to urban capable lands. Direct impacts to the location of the population on avoided lands are less likely because of its location to the east of Appin Road. See Map 36.30 for mapped potential habitat and populations across the Strategic Assessment Area.	To constrain potential impacts to the species, the Guidelines require efforts to avoid and minimise impacts to biodiversity (including potential habitat for the Greater Glider). In addition, given the extensive nature of Shale Sandstone Transition Forest in the Sydney Basin Bioregion on avoided lands, the impact limit for the TEC (20 ha within GMAC) will help reduce any potential direct impacts to foraging habitat for the species. Any residual impacts need to be offset.	It is possible that foraging habitat for the species will be impacted by essential infrastructure projects. However, the Guidelines will constrain the scale of potential impacts. Where impacts occur they will be offset in accordance with the requirements of the BAM.

EPBC matter	EPBC status	Occurrence and possible impacts	Application of the Essential Infrastructure Guidelines	Likely outcome
Phascolarctos cinereus (Koala)	V	Important Koala habitat occurs extensively on avoided lands in GMAC. The habitat is closely associated with the occurrence of Shale Sandstone Transition Forest in the Sydney Basin Bioregion and essential infrastructure projects have the potential to impact areas of Koala habitat. See Map 37 and Map 40 for mapped habitat and species records across the Strategic Assessment Area.	To constrain potential impacts to the species within avoided lands, the Guidelines: • Require efforts to avoid and minimise impacts to biodiversity (including Koala habitat) • Consider the connectivity of important Koala corridors within avoided lands in GMAC In addition, given the close association between important Koala habitat and Shale Sandstone Transition Forest in the Sydney Basin Bioregion the impact limit for the TEC (20 ha within GMAC) will help reduce any potential direct impacts to Koala habitat. Any residual impacts need to be offset.	It is possible that Koala habitat will be impacted by essential infrastructure projects. However, the Guidelines and Commitment 2.4 together will: • Constrain the scale of potential impacts • Prioritise avoidance of important Koala corridors in GMAC to maintain their integrity Where impacts occur they will be offset in accordance with the requirements of the BAM.
Pteropus poliocephalus (Grey-headed Flying-fox)	V	The species has been recorded on avoided lands in GMAC, and areas of foraging habitat (762.1 ha) for the Grey-headed Flying-fox are present. There are no known camps or important roosting sites for the species in these areas. Direct impacts to foraging habitat are possible, especially where it occurs near to urban capable lands. See Map 36.32 and Map 36.33 for mapped potential habitat and populations across the Strategic Assessment Area.	To constrain potential impacts to the species, the Guidelines require efforts to avoid and minimise impacts to biodiversity (including foraging habitat for the Grey-headed Flying-fox). In addition, given the extensive nature of Shale Sandstone Transition Forest in the Sydney Basin Bioregion on avoided lands, the impact limit for the TEC (20 ha within GMAC) will help reduce any potential direct impacts to foraging habitat for the species. Any residual impacts need to be offset.	It is possible that foraging habitat for the species will be impacted by essential infrastructure projects. However, the Guidelines will constrain the scale of potential impacts. Where impacts occur they will be offset in accordance with the requirements of the BAM.

Table 37-7: Potential direct impacts to biodiversity values in WSA

EPBC matter	EPBC status	Occurrence and possible impacts	Application of the Essential Infrastructure Guidelines	Likely outcome
TECs				
Coastal Swamp Oak (*Casuarina glauca*) Forest of New South Wales and South East Queensland ecological community	E	Small areas of the TEC occur within the avoided lands of WSA. Of the 29.1 ha, 27.9 ha is in moderate (thinned) condition and 1.2 is in low (scattered) condition. Impacts to the TEC are possible where it occurs within land avoided for biodiversity purposes (4.3 ha). The likelihood of impact is reduced where the TEC occurs in riparian corridors (24.8 ha). See Map 48.2 for mapping of the TEC across the Strategic Assessment Area.	To constrain potential impacts to the TEC, the Guidelines require efforts to avoid and minimise impacts. Any residual impacts need to be offset.	Given the limited distribution of the TEC within avoided lands it is considered likely that avoidance of direct impacts will be possible. Where impacts occur they will be offset in accordance with the requirements of the BAM.
Cooks River / Castlereagh Ironbark Forest in the Sydney Basin Bioregion	CE	Small areas of the TEC occur within the avoided lands of WSA. Of the 26.1 ha, 19.4 ha is in good (intact) condition and 6.7 ha is in moderate (thinned) condition. Impacts to the TEC are possible where it occurs between urban capable lands. See Map 48.3 for mapping of the TEC across the Strategic Assessment Area.	To constrain potential impacts to the TEC, the Guidelines require efforts to avoid and minimise impacts. Any residual impacts need to be offset.	Given the limited distribution of the TEC within avoided lands it is considered likely that avoidance of direct impacts will be possible. Where impacts occur they will be offset in accordance with the requirements of the BAM.
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest	CE	Small areas of the TEC occur within the avoided lands of WSA. Of the 20.1 ha, 0.2 ha is in good (intact) condition and 19.8 ha is in moderate (thinned) condition. Impacts to the TEC are possible where it occurs between urban capable lands. The likelihood of impact is reduced where the TEC occurs in riparian corridors (11.7 ha). See Map 48.4 for mapping of the TEC across the Strategic Assessment Area.	To constrain potential impacts to the TEC, the Guidelines require efforts to avoid and minimise impacts. Any residual impacts need to be offset.	Given the limited distribution of the TEC within avoided lands it is considered likely that avoidance of direct impacts will be possible. Where impacts occur they will be offset in accordance with the requirements of the BAM.

EPBC matter	EPBC status	Occurrence and possible impacts	Application of the Essential Infrastructure Guidelines	Likely outcome
Coastal floodplain eucalypt forest of eastern Australia	FPAL	Areas of the potential TEC occur within avoided lands in WSA (101 ha). Of the 101 ha, 12 ha is in good (intact) condition, 77.2 ha is in moderate (thinned) condition, and 11.7 ha is in poor (scattered) condition. Impacts to the potential TEC are possible where it occurs between urban capable lands. The likelihood of impacts are reduced where the TEC occurs in riparian corridors (68.1 ha). See Map 48.5 for mapping of the EC across the Strategic Assessment Area.	To constrain potential impacts to the TEC, the Guidelines require efforts to avoid and minimise impacts. Any residual impacts need to be offset.	Avoidance processes will be important to minimise the risk of impacts as essential infrastructure projects proceed. Where impacts do occur they will be offset in accordance with the requirements of the BAM.
THREATENED FLORA				
Persoonia nutans (Nodding Geebung)	E	One known population of the species occurs within avoided lands in WSA. Population 60 is mapped as important and contains 7 records comprising 7 individuals. Of these, 1 record (1 individual) occurs within avoided lands in the south east of WSA. Without commitments to protect it, impacts to this population could be possible as it occurs on the edge of urban capable land. See Map 36.19 for mapped potential habitat and populations across the Strategic Assessment Area.	To constrain potential impacts to the species, the Guidelines require efforts to avoid and minimise impacts to known locations and habitat. Any residual impacts need to be offset.	Commitment 2.4 specifies that avoidance of known populations of this species will be prioritised. Where impacts do occur they will be offset in accordance with the requirements of the BAM.
Pultenaea parviflora	V	One known population of the species occurs within avoided lands in WSA. Population 181 is not mapped as important and contains 78 records comprising 78 individuals. Of these, 11 records (11 individuals) occur within avoided lands in the south east of WSA (in a similar location to *Persoonia nutans*). Without commitments to protect it, impacts to this population could be possible as it occurs on the edge of urban capable land. See Map 36.24 for mapped potential habitat and populations across the Strategic Assessment Area.	To constrain potential impacts to the species, the Guidelines require efforts to avoid and minimise impacts to known locations and habitat. Any residual impacts need to be offset.	Commitment 2.4 specifies that avoidance of known populations of this species will be prioritised. Where impacts do occur they will be offset in accordance with the requirements of the BAM.

EPBC matter	EPBC status	Occurrence and possible impacts	Application of the Essential Infrastructure Guidelines	Likely outcome
THREATENED FAUNA				
Petauroides volans (Greater Glider)	V	The species has been recorded on avoided lands in the south of WSA. The record for population 585 (not mapped as important) occurs in a riparian corridor in an area where there is no mapped habitat for the species. See Map 36.30 for mapped potential habitat and populations across the Strategic Assessment Area.	To constrain potential impacts to the species, the Guidelines require efforts to avoid and minimise impacts to biodiversity. Any residual impacts need to be offset.	Given the limited mapped habitat for the species within WSA, it is considered unlikely that it will be impacted by essential infrastructure projects. Should any impacts occur they will be offset in accordance with the requirements of the BAM.

Table 37-8: Potential direct impacts to biodiversity values in GPEC

EPBC matter	EPBC status	Occurrence and possible impacts	Application of the Essential Infrastructure Guidelines	Likely outcome
TECs				
Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland ecological community	E	Very small areas (3.3 ha) of the TEC occur within the avoided lands of GPEC. It is all in moderate (thinned) condition. Impacts to the TEC are possible although relatively unlikely as 3 ha occurs in riparian corridors. See Map 48.2 for mapping of the TEC across the Strategic Assessment Area.	To constrain potential impacts to the TEC, the Guidelines require efforts to avoid and minimise impacts. Any residual impacts need to be offset.	Given the limited distribution of the TEC within avoided lands it is considered likely that avoidance of direct impacts will be possible. Where impacts occur they will be offset in accordance with the requirements of the BAM.
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest	CE	Small areas of the TEC occur within the avoided lands of WSA. Of the 51.1 ha, 7.4 ha is in good (intact) condition, 43.7 ha is in moderate (thinned) condition and 0.03 ha is in poor (scattered) condition. The TEC is located in the south of GPEC and impacts from essential infrastructure are possible. See Map 48.4 for mapping of the TEC across the Strategic Assessment Area.	To constrain potential impacts to the TEC, the Guidelines require efforts to avoid and minimise impacts. Any residual impacts need to be offset.	Avoidance processes will be important to minimise the risk of impacts as essential infrastructure projects proceed. Where impacts do occur they will be offset in accordance with the requirements of the BAM.
Coastal floodplain eucalypt forest of eastern Australia	FPAL	Areas of the potential TEC occur within avoided lands in GPEC (54.9 ha) Of the 54.9 ha, 11.7 ha is in good (intact) condition, 43 ha is in moderate (thinned) condition, and 0.2 is in poor (scattered) condition. Impacts to the potential TEC are possible where it occurs between urban capable lands. The likelihood of impacts are reduced where the TEC occurs in riparian corridors (31.8 ha). See Map 48.5 for mapping of the EC across the Strategic Assessment Area.	To constrain potential impacts to the TEC, the Guidelines require efforts to avoid and minimise impacts. Any residual impacts need to be offset.	Avoidance processes will be important to minimise the risk of impacts as essential infrastructure projects proceed. Where impacts do occur they will be offset in accordance with the requirements of the BAM.

EPBC matter	EPBC status	Occurrence and possible impacts	Application of the Essential Infrastructure Guidelines	Likely outcome
THREATENED FLORA				
Pultenaea parviflora	V	One known population of the species occurs within avoided lands in GPEC. Population 226 is not mapped as important and contains 1 record comprising 150 individuals. The whole population occurs within avoided lands in the south east of GPEC. Impacts to this population are possible as it occurs on the edge of urban capable land. See Map 36.24 for mapped potential habitat and populations across the Strategic Assessment Area.	To constrain potential impacts to the species, the Guidelines require efforts to avoid and minimise impacts to known locations and habitat. Any residual impacts need to be offset.	Commitment 2.4 specifies that avoidance of known populations of this species will be prioritised. Where impacts do occur they will be offset in accordance with the requirements of the BAM.
THREATENED FAUNA				
Lathamus discolor (Swift Parrot)	CE	The species has been recorded on avoided lands in GPEC, and areas of potential foraging habitat (153.8 ha) for the Swift Parrot are present. Direct impacts to potential foraging habitat are possible, especially where it occurs near to urban capable lands. See Map 46.5 for mapped potential habitat and populations across the Strategic Assessment Area.	To constrain potential impacts to the species, the Guidelines require efforts to avoid and minimise impacts to biodiversity (including potential foraging habitat for the Swift Parrot). Any residual impacts need to be offset.	It is possible that foraging habitat for the species will be impacted by essential infrastructure projects. However, the Guidelines will constrain the scale of potential impacts. Where impacts occur they will be offset in accordance with the requirements of the BAM.
Litoria aurea (Green and Golden Bell Frog)	V	One population of the species is potentially present on avoided lands associated with Ropes Creek within GPEC. The Plan includes a species-specific commitment to avoid, protect and enhance key habitat features identified within and adjacent to the Ropes Creek corridor if the population is confirmed present. Based on this commitment, direct impacts to the species will be avoided. See Map 36.31 for mapped potential habitat and populations across the Strategic Assessment Area.	Any essential infrastructure projects will need to meet both the requirements of the Guidelines and the species-specific commitment in the Plan.	No direct impacts to the species will occur as a result of essential infrastructure projects.

EPBC matter	EPBC status	Occurrence and possible impacts	Application of the Essential Infrastructure Guidelines	Likely outcome
Petauroides volans (Greater Glider)	V	The species has been recorded on avoided lands in GPEC. The record for population 584 (not mapped as important) occurs in an area where there is no mapped habitat for the species. See Map 36.30 for mapped potential habitat and populations across the Strategic Assessment Area.	To constrain potential impacts to the species, the Guidelines require efforts to avoid and minimise impacts to biodiversity. Any residual impacts need to be offset.	Given the limited mapped habitat for the species within GPEC, it is considered unlikely that it will be impacted by essential infrastructure projects. Should any impacts occur they will be offset in accordance with the requirements of the BAM.

POTENTIAL INDIRECT IMPACTS

Nature and extent of potential indirect impacts

It is not possible to determine at this stage the specific nature, extent and duration of the indirect impacts of essential infrastructure projects on biodiversity values. However, the main types of indirect impacts associated with essential infrastructure actions are shown in Table 37-9.

Table 37-9: Potential indirect impact types for essential infrastructure projects

Indirect impact type	Nature of indirect impact	Extent/general location of indirect impact and/or high risk areas	Duration of indirect impact
Hydrological disturbance	Changes to surface water and groundwater flows and quality	Waterways, wetlands, flood-prone areas within or downstream of essential infrastructure projects	Short term to long-term
Spread of infection/disease	Spread of pathogens from contaminated clothing and equipment or surface water runoff	Native vegetation retained within or adjacent to essential infrastructure projects	Likely long-term
Spread of weeds	Spread of invasive species due to edge effects, surface water run-off, or changed fire regimes	Native vegetation retained within or adjacent to essential infrastructure projects	Likely long-term
Predation / competition by pest / domestic fauna	Increased predation and competition of species by pest / domestic fauna	Habitat retained within or adjacent to essential infrastructure projects, including well-connected habitat corridors	Likely long-term
Altered fire regimes	Altered fire regimes as a result of increased burns for asset protection or reduced ability to burn due to risk to surrounding urban areas	Native vegetation retained within or immediately adjacent to essential infrastructure projects, particularly asset protection zones	Long-term
Fauna mortality, fauna displacement and barriers to fauna movement	Potential for mortality of threatened fauna species by vehicle strike and reduced movement and connectivity between habitat areas from barriers	Habitat intersected by essential infrastructure projects	Long-term
Fauna disturbance due to noise, dust or light	Noise, dust or light created by equipment during construction or by new structures during operation	Habitat retained within or immediately adjacent to essential infrastructure projects	Short-term to long-term
Inadvertent impacts on adjacent habitat or vegetation	Damage to adjacent habitat during construction activities or during ongoing management	Native vegetation immediately adjacent to essential infrastructure projects	Short-term to long-term

Commitments to address indirect impacts

In relation to indirect impacts, the Guidelines specify that each essential infrastructure project must:

- Apply an 'avoid and mitigate' process in considering the environmental impacts of the project under the EP&A Act
- If triggered, apply an 'avoid, mitigate, offset' process to biodiversity values under the BC Act
- Implement mitigation measures based on the outcomes of the environmental assessments of each infrastructure project based on detailed design of the project, in compliance with legislative requirements

The Plan also includes commitments to mitigate indirect and prescribed impacts from development on TECs, species and their habitat to best practice standards. They include:

- Commitment 5 which relates to the general mitigation of indirect and prescribed impacts from development on TECs, species and their habitat to best practice standards. This includes mitigation measures to address impacts during construction and operation of infrastructure projects, as prescribed in Appendix E of the Plan (Commitment 5.3). These commitments apply to both infrastructure and essential infrastructure under the Plan
- Commitment 7 which relates to the mitigation of indirect and prescribed impacts from urban, infrastructure and major infrastructure (transport) development on the Southern Sydney Koala population to best practice standards and in line with the Chief Scientist Koala Report

The future process of environmental assessment and approval for each essential infrastructure project will assess and identify mitigation measures to manage the potential indirect impacts of the project identified in Table 37-9 on biodiversity values, including Commonwealth-listed matters.

This process will, for example, assess the potential for the project to result in soil erosion and sedimentation, water quality impacts, the spread of weeds and disease, and disturbance to fauna in relation to relevant biodiversity values in the vicinity of the project, and will identify mitigation measures to address these risks.

In identifying mitigation measures, the commitments specify that measures meet best practice standards and mitigation measures prescribed in Appendix E of the Plan are implemented where relevant to addressing indirect impacts on the biodiversity values specified in the commitment, including Commonwealth-listed matters.

For infrastructure projects affecting biodiversity values, the BC Act and BAM process will generally be triggered. This process requires an assessment of the risks and consequences of indirect impacts on biodiversity values protected under the Act, and identification of mitigation measures to address these risks. Requirements to implement mitigation measures are typically incorporated into the approval, and the Act includes an enforcement and compliance framework for ensuring the mitigation measures are implemented in accordance with the approval.

The future process of environmental assessment and approval is considered adequate to effectively manage the risks of indirect impacts of essential infrastructure projects on biodiversity values identified in Table 37-5 to Table 37-8.

37.6.6 POTENTIAL IMPACTS TO OTHER MATTERS

No other protected matters will be potentially impacted by essential infrastructure projects. This is because:

- There is no important habitat for listed migratory species within the nominated areas (see Chapter 32)
- Development within the nominated areas will not affect any Ramsar sites (see Chapter 33)
- Development within the nominated areas will not affect any World or National Heritage sites (see Chapter 34)
- Essential infrastructure projects will not be able to be carried on Commonwealth land which is a type of excluded land

37.6.7 CONCLUSION

It is considered the Guidelines and supporting commitments 2.3 and 2.4, as they apply to essential infrastructure outside urban capable lands, will lead to acceptable outcomes for MNES as they:

- Provide for only a limited amount of development outside the urban capable lands, which has been assessed in this Assessment Report. This development must be necessary to support the urban and industrial development under the Plan. This limited scope reduces the potential for impacts to biodiversity values from the development
- Require implementation of assessment and ongoing environmental management processes, including:
  - An environmental impact assessment process to be applied prior to construction to assess and manage the impacts of the development. The assessment process is considered to be robust as it will be undertaken under NSW planning and assessment laws current at the time the development is proposed
  - An environmental management and compliance process to be applied during construction and operation to ensure activities comply with assessment requirements and mitigation measures are implemented effectively
- Will achieve avoidance and outcomes consistent with the Plan
- Will ensure mitigation measures are put in place to address all relevant indirect impacts

- Require unavoidable impacts to be offset in accordance with the BAM. As these impacts are not accounted for in terms of commitments under the Plan, these offsets would be additional to the offsets that are required for the development under the Plan. The process to determine the offset amounts and deliver the offsets is considered to be robust as it will be implemented:
    - Through existing offsetting processes under the BC Act or any subsequent legislative scheme, or
    - Consistent with the 'Implementation Strategy for Conservation Lands' to be established under the Plan
- Are supported by governance arrangements that will clarify roles and responsibilities, including for compliance, and ensure the development is consistent with the guidelines (these are set out in Appendix A of the Plan)

37.7 OVERALL OUTCOME UNDER THE PLAN

Urban capable land has generally avoided the vast majority of native vegetation and areas of high biodiversity values, including high condition vegetation, Commonwealth-listed TECs, species habitats, important populations and habitat connectivity. Within the nominated areas (not including excluded lands) this includes:

- 67.2 per cent of native vegetation
- 95.2 per cent of high condition (intact) native vegetation
- 87.5 per cent of critically endangered and endangered Commonwealth-listed TECs
- An average of 77.8 per cent of potential habitat for three species with a very high biodiversity risk weighting (>3), and an average of 78.6 per cent of potential habitat for 31 species with a high biodiversity risk weighting (>/=2)
- Of 14 species with important populations identified outside excluded land 12 have important populations represented (either wholly or partially) on land avoided for biodiversity purposes
- Approximately 88.3 per cent of Bio Map core areas and 86.0 per cent of Bio Map corridors

The detailed assessments for Commonwealth listed species and TECs concluded that despite the direct and indirect impacts of the transport corridors, the commitments under the Plan to address these impacts are adequate, and the Plan would be unlikely to reduce the long-term viability of these matters in the Cumberland subregion.

38 Cumulative Impact Assessment

38.1 INTRODUCTION

This Chapter provides an assessment of the cumulative impacts of development under the Plan with other current key major projects in the Cumberland subregion on MNES. The Chapter:

- Sets out the regulatory requirements for cumulative impact assessment
- Describes the assessment approach
- Assess cumulative impacts of the Plan on threatened species and TECs with other major projects
- Provides an overall conclusion and evaluation of these impacts to threatened species and TECs
- Addresses cumulative impacts on other MNES

The purpose of the cumulative impact assessment is to identify the MNES most impacted under the Plan that are also impacted by other major projects in the Cumberland subregion to:

- Assess the significance of cumulative impacts across the Plan and these major projects on these matters
- Determine whether the commitments under the Plan to address direct impacts to each matter are adequate in the context of the cumulative impacts on those matters

38.2 REGULATORY REQUIREMENTS

The terms of reference (ToR) requires:

- Identification of MNES that may be cumulatively impacted by the Plan (Section 3.2)
- An analysis of the likely adverse cumulative impacts to MNES (Section 4.5.3)

Due to the large spatial scale and long timeframes of the Plan, this Assessment Report itself is a form of cumulative impact assessment. The report considers in detail the potential impacts of urban and industrial, infrastructure, agribusiness, and transport development under the Plan, and the conservation benefits of the Plan on relevant MNES.

To support that analysis, this Assessment Report also takes a broader view and examines the cumulative impacts and conservation benefits of other current and reasonably foreseeable major development on the Cumberland Plain.

38.3 APPROACH TO THE ASSESSMENT

The approach to the cumulative assessment involved:

- Identifying current major projects within the Strategic Assessment Area
- Identifying key species and TECs most likely at risk of cumulative impacts across the Plan and major projects
- Evaluating the significance of the cumulative impacts and the adequacy of the commitments under the Plan in the context of these cumulative impacts for each key species and TEC

38.3.1 IDENTIFICATION OF MAJOR PROJECTS

The cumulative assessment considers impacts from current major projects in the Strategic Assessment Area:

- That have been approved for development or have been subject to impact assessment for pending approval
- Where clearing for development has not yet occurred or has only occurred over part of the project area to date. The assessment takes into account future impacts from December 2019. Where clearing has only occurred over part of the project area to date, these areas were excluded from the analysis
- Where data is available on impacts and offsets (the Sydney Metro EIS is still being prepared. Data on this project is therefore unavailable and has not been included in this assessment)

Table 38-1 identifies the major projects included in the cumulative impact assessment and data availability for each project. The location of each major project is shown in Figure 38-1.

CUMULATIVE IMPACTS FROM OTHER DEVELOPMENT

It is acknowledged that other major projects (such as the Sydney Metro – Western Sydney Airport) and many other types of development, including smaller scale residual areas and infrastructure, will be developed in the foreseeable future within the Cumberland subregion. It is not possible to estimate the cumulative impacts of these developments and the Plan on Commonwealth-listed species and TECs or other MNES due to either a lack of available data on biodiversity impacts (e.g. Sydney Metro – Western Sydney Airport is currently subject to early investigations) or uncertainty over the extent and location of development. However, future developments are likely to lead to:

- Additional cumulative impacts on MNES that are impacted by the Plan
- Increased demand for offsets that will compete with the demand created by the Plan

In this context, it is important to note that the Plan supports the delivery of the NSW Government nominated areas program, which consolidates future urban and industrial, infrastructure, agribusiness and transport development within defined areas. This consolidation of development through a process to avoid and minimise impacts to biodiversity contributes to reducing the risk of cumulative impacts from future development in Western Sydney.

38.3.2 IDENTIFICATION OF KEY SPECIES AND ECOLOGICAL COMMUNITIES MOST LIKELY AT RISK

The approach to identify the key species and TECs most likely at risk of cumulative impacts involved:

- Identifying the species and TECs directly impacted by the Plan in terms of impacts on total potential habitat (ha) or impacts on potential habitat relative to available potential habitat within the Cumberland subregion (per cent)
- Identifying the top 15 species and all TECs directly impacted by the Plan that are also being directly impacted by other major projects. Impacts were presented in terms of:
    - Impacts on habitat (ha) due to each major project and total impacts across all major projects
    - Total impacts on habitat relative to available potential habitat within the Cumberland subregion (per cent)
- Identifying cumulative impacts across the Plan and major projects. Impacts were presented in terms of:
    - Total cumulative impacts (ha)
    - Per cent additional impact due to major projects (%)
    - Total impact as per cent of subregion habitat
- Assessing the significance of cumulative impacts and determining whether the commitments under the Plan are adequate in the context of the cumulative impacts

Note that Coastal floodplain eucalypt forest of eastern Australia was not assessed as this TEC is currently FPAL and there was very little data on impacts in relation to the major projects.

The analysis was done based on habitat rather than impacts to records or populations because habitat was most widely available information to enable comparison between the Plan and across the major projects.

The species and TECs that are most likely at risk from cumulative impacts and that may need additional commitments under the Plan in the context of those impacts are those matters where:

- The Plan is having a notable impact (it is not within the scope of the Plan to address cumulative impacts from other projects on species/TECs that are subject to negligible or minor impacts under the Plan), and
- The major projects make a significant contribution to cumulative impacts (species/TECs not substantially impacted by major projects only need to be addressed in terms of the impacts of the Plan). This was considered to be where:
    - Major projects have a total impact greater than 100 per cent of the impact of the Plan, or
    - Major projects have a total impact greater than 2 per cent of remaining Cumberland subregion habitat, and
- There is a significant total cumulative impact from the Plan and major projects – this was considered to be where cumulative impacts were greater than 5 per cent of remaining Cumberland subregion habitat

Table 38-1: Major projects included in the cumulative impact assessment and data availability

Major project	Comments	Data source	Data used in the cumulative impact assessment			
			Impact data		Offset data	
			TEC	Species habitat	TEC	Species habitat
Western Sydney Airport	Clearing for development of the Western Sydney Airport commenced in November 2018. The project is predicted to be completed in 2024. No data is available on the clearing that has occurred to date	Western Sydney Airport Environmental Impact Statement (DIRD, 2016b)	Extent within development footprint	Known habitat within development footprint	Extent	Known habitat
Existing North West and South West Growth Areas	Clearing for development within the existing North West and South West Growth Areas has commenced. Impacts were determined for the precincts where clearing has not yet occurred or where clearing has commenced but not been completed.	Biodiversity Offset Program Annual Report 2017–18 (NSW OEH, 2018)	Extent within South West Growth Area precincts*	Extent within the South West* and North West** Growth Area precincts	Extent within and outside the Growth Areas	No data
M12 Motorway	Construction is expected to start in the 2022 and finish in 2025 (RMS, 2019).	M12 Motorway EIS (RMS, 2019)	Extent within development footprint	Known habitat within development footprint	Ecosystem Credits required for EPBC TEC impacts^	Species Credits required for EPBC species^
The Northern Road	Infrastructure approval was granted in May 2018.	The Northern Road Upgrade Mersey Road, Bringelly to Glenmore Parkway, Glenmore Park - NSW Environmental Impact Statement / Commonwealth Draft Environmental Impact Statement (NSW Government, 2017)	Extent within development footprint	Extent within development footprint	Ecosystem Credits required for PCTs associated with EPBC TEC impacts^	Species Credits required for EPBC species^

38.3.3 EVALUATION OF CUMULATIVE IMPACTS

The approach to the evaluation of cumulative impacts involved using information in conservation advices, recovery plans and threat abatement plans for each species or TEC to evaluate the significance of cumulative impacts across the Plan and major projects and determine whether measures should be undertaken under the Plan to reduce these impacts.

The evaluation was undertaken considering the following questions:

- What is the significance of the total cumulative impact across the Plan and major projects, taking into account:
  - Information in conservation advices, recovery plans and threat abatement plans for each species or TEC?
  - Distribution or spread of impacts across the Cumberland subregion?
- To what extent is the Plan contributing to cumulative impacts?
- To what extent are the impacts of the Plan known or likely?
- Do the current offset and mitigation measures under the Plan deal adequately with the cumulative impact?
- Whether additional mitigation measures are required to adequately address cumulative impacts?

38.3.4 LIMITATIONS

The cumulative impact assessment has the following key limitations:

- Data in relation to impacts or offsets was not always available for each major project
- Data was not always available in a form that allowed consistent comparison across major projects or the Plan. For example, the Plan assesses species habitat in terms of potential habitat, whereas some major projects assess species habitat in terms of known or likely habitat (as these assessments are done at a finer scale) or a combination of both
- Due to data availability, cumulative impacts were not considered in terms of indirect impacts
- Impact data on the existing North West and South West Growth Areas program was based on an assumption that the entire precincts covered in the analysis (see Table 38-1) were impacted, as development footprints were not available for the analysis. This is likely to greatly overestimate the impacts on potential habitat from this program
- A number of major projects have based their offset programs on acquiring biodiversity credits under the BBAM. Where conservation commitments are based on acquiring credits, a conversion factor was needed to describe the intended outcomes in terms of hectares of land conserved (see Table 38-2). This factor is an approximation only

Table 38-2: Offset credit conversion factors

Credit scheme	Number of credits	Equivalent number of hectares
BBAM	10	1

38.4 IMPACT ASSESSMENT

38.4.1 DIRECT IMPACTS

Table 38-3 and Table 38-4 identify the top 15 species and all TECs directly impacted by the Plan (in terms of impacts to potential habitat relative to available habitat within the Cumberland subregion) that are also impacted by major projects.

For each species and TEC, the tables show:

- Impacts from each major project in terms of hectares impacted and as per cent of subregion habitat, and the total impacts
- Total cumulative impacts across the major projects and Plan in terms of:
  - Total impact in hectares
  - 'Per cent additional impact due to major projects'
  - Total impact as 'per cent of remaining subregion habitat'

The table shows that the major projects make a significant contribution to cumulative impacts in relation to most of the top 15 species impacted by the Plan (the major projects have a total impact greater than 100 per cent of the impact of the Plan or greater than '2 per cent of remaining Cumberland subregion habitat') but only to one TEC – Cumberland Plain Woodland.

Of these species and this TEC, there is a significant total cumulative impact across the Plan and major projects (an impact on 'per cent of remaining Cumberland subregion habitat' of greater than 5 per cent) in relation to:

- Downy Wattle
- White-flowered Wax Plant
- *Micromyrtus minutiflora*
- Spiked Rice-flower
- *Pultenaea parviflora*
- Regent Honeyeater
- Swift Parrot
- Dural Land Snail
- Grey-headed Flying-fox
- Cumberland Plain Shale Woodland and Shale-Gravel Transition Forest

Table 38-3: Potential cumulative impacts to top 15 species impacted by Plan

38.4.2 OFFSETS FOR MAJOR PROJECTS

Table 38-5 and Table 38-6 show the offset commitments under major projects (ha) for the top 15 species and TECs impacted by the Plan. For each species and TEC, the tables show:

- Offsets from each major project (in hectares) and the total offsets from major projects
- Total cumulative offsets across the major projects and the Plan in terms of:
  - Total offsets in hectares
  - Total offsets as a per cent of remaining Cumberland subregion habitat

It is important to note that:

- Under the Plan some species have specific offset targets to secure either a certain number of offset locations or potential foraging habitat (see Chapter 8). Other species do not have targets, but are likely to benefit from the targets for NSW TECs/PCTs, as those PCTs provide potential habitat for the species. The amount of potential habitat (ha) for each species that will be secured in the SCAs because of the TEC/PCT targets is shown the table (see column 4)
- Some major projects included offsets involving securing of populations rather than known or potential habitat. This has not been included in the analysis, as the analysis was done based on habitat

Table 38-5: Offset commitments for top 15 species impacted by Plan

Matter	Total habitat in the SAA	Plan offsets		Major project offsets (ha)^							Cumulative offsets Plan and major projects	
		Specific target (ha or site locations)	Potential habitat secured through NSW TEC/PCT targets (ha)	Western Sydney Airport	Existing Growth Areas*	M12	Figtree Hill	The Northern Road	Bingara Gorge	Total - major projects	Total offset (ha)	Offsets as % of subregion habitat

*Note that the commitments under the existing North West and South West Growth Areas are for 1) At least 2400 hectares of Commonwealth-listed Cumberland Plain Woodland or other 'grassy woodland' communities, with preference given to Cumberland Plain Woodland, followed by White Box–Yellow Box–Blakely's Red Gum Grassy Woodland and Derived Native Grassland 2) At least 205 hectares of high quality Commonwealth-listed Cumberland Plain Woodland

38.5 EVALUATION FOR THREATENED SPECIES AND TECS

38.5.1 KEY MATTERS OF CONCERN

The purpose of the cumulative impact assessment is to identify the key species and TECs under the Plan that are also impacted by other major projects in the Cumberland subregion to:

- Assess the significance of cumulative impacts
- Determine whether the commitments under the Plan are adequate in the context of the cumulative impacts

The species and TECs that are most likely at risk from cumulative impacts and that may need additional commitments under the Plan in the context of those impacts are those matters where (see Section 38.3):

- The Plan is having a notable impact, and
- The major projects make a significant contribution to cumulative impacts, and
- There is a significant total cumulative impact from the Plan and major projects

The species and TECs that meet these criteria are:

- Species
    - Downy Wattle
    - White-flowered Wax Plant
    - *Micromyrtus minutiflora*
    - Spiked Rice-flower
    - *Pultenaea parviflora*
    - Regent Honeyeater
    - Swift Parrot
    - Dural Land Snail
    - Grey-headed Flying-fox
- TECs: Cumberland Plain Shale Woodlands and Shale Gravel Transition Forest

The significance of the cumulative impacts on each of these species and TECs is evaluated in Section 38.5.2.

38.5.2 EVALUATION OF EACH KEY MATTER

For each species and TEC, the evaluation considers:

- Extent, nature and risks of the impacts under the Plan. As potential habitat was used to assess cumulative impacts, this provides a better understanding of the significance of the likely or actual impacts of the Plan
- Significance of the cumulative impacts across the Plan and major projects, taking into account:
    - Cumulative impact as per cent of subregion habitat
    - Distribution of the species and likely importance of the Cumberland subregion for persistence
    - Amount of habitat in existing protected lands
- The overall outcome of the commitments made under the Plan and the offsets provided under the major projects that may address the cumulative impacts, taking into account:
    - Total offset amounts across the Plan and major projects
    - Per cent amount of increase in levels of protection in the subregion for the matter
    - The relative contribution of the Plan to total offsets and increasing levels of protection for the matter

ACACIA PUBESCENS (DOWNY WATTLE)

Nature and extent of impacts under the Plan

The Plan's contribution to cumulative impacts on potential habitat for *Acacia pubescens* is moderate compared to the other major projects (17 per cent of the total impact).

However, the risk of impacts to this species under the Plan is low. The Plan will not result in any direct impacts to records or important populations. There is a direct impact to 791.7 ha of potential habitat for this species, which amounts to 2.3 per cent of the mapped habitat in the Strategic Assessment Area.

This loss of potential habitat generally relates to small and scattered patches. The risk of impacts to higher quality larger patches of habitat within Wianamatta Regional Park are considered to be low because the species has never been recorded on this site, despite significant survey effort.

Significance of cumulative impacts

The significance of the cumulative impacts across the Plan and major projects on *Acacia pubescens* is considered to be moderate because:

- The total cumulative impact is moderate (greater than 10 per cent of total potential habitat in the subregion)
- The species is largely restricted to the Cumberland subregion
- The species is not well represented in existing protected lands (approximately 8 per cent of total potential habitat in the Strategic Assessment Area, or 13 of 97 important populations, occurs in existing protected lands)

Known records for *Acacia pubescens* are distributed across two core areas which have been identified for site management under the NSW Saving our Species (SOS) program:

- One area associated with the Hawkesbury SOS site, comprising approximately 3,736 ha in the north-east of the Strategic Assessment Area, including Windsor Downs, Pitt Town and Scheyville National Park
- The second associated with the Bankstown-Liverpool SOS site, comprising an area of approximately 5,842 ha that straddles the central-east boundary of the Strategic Assessment Area around Lansdowne

These areas are generally not impacted by the Plan or major projects.

It is also important to note that cumulative impact from other major projects are primarily due to the existing North West and South West Growth Areas, and the impacts associated with these areas are likely to be greatly overestimated (see Section 38.3). This reduces the significance of the total cumulative impacts.

Adequacy of the cumulative offsets

Offsets of potential habitat for *Acacia pubescens* are only provided under the Plan (and not under major projects).

Due to the risk of impacts being low, the Plan does not include a species-specific commitment to secure offset locations for *Acacia pubescens*. However, the Plan includes a commitment to protect 4,970 hectares of NSW TECs/PCTs that are associated with potential habitat for the species.

Given the low risk of impacts to the species under the Plan, it is considered that the Plan adequately contributes to addressing the cumulative impacts to this species. In particular, the Plan will:

- Lead to the protection of 5 per cent of the total potential habitat for the species in the Cumberland subregion
- Increase existing levels of protection of habitat for the species in the Strategic Assessment Area from 8 per cent to 13 per cent

CYNANCHUM ELEGANS (WHITE-FLOWERED WAX PLANT)

Nature and extent of impacts under the Plan

The Plan's contribution to cumulative impacts on potential habitat for *Cynanchum elegans* is low compared to the other major projects (7 per cent of the total impact).

The risk of impacts to this species under the Plan is medium. The Plan will not result in any direct impacts to records or important populations, however, one important population will be fragmented by the OSO at Cobbitty. There is a direct impact to 19.6 ha of potential habitat for this species, which amounts to 0.6 per cent of the mapped habitat in the Strategic Assessment Area. This impact generally relates to small and isolated areas.

Significance of cumulative impacts

The significance of the cumulative impacts across the Plan and major projects on *Cynanchum elegans* is considered to be low because:

- The total cumulative impact is relatively small (less than 10 per cent of total potential habitat in the subregion)
- The species is not restricted to the Cumberland subregion (the species occurs in eastern NSW from Brunswick Heads on the north coast to the Illawarra region south of Sydney) and therefore the cumulative impacts in the subregion are less likely to impact species persistence within NSW
- At least 40 populations of the species are known to occur within existing protected lands in NSW, and under the SOS program, current management is considered sufficient to protect *Cynanchum elegans* in NSW in the long-term

Adequacy of the cumulative offsets

Offsets of potential habitat for *Cynanchum elegans* are only provided under the Plan (and not under major projects).

The Plan includes a species-specific commitment to secure 2 offset locations for *Cynanchum elegans* to address the residual impacts of the development. The Plan also includes a commitment to protect 4,148 hectares of NSW TECs/PCTs that are associated with potential habitat for the species.

Given the low contribution of the Plan to cumulative impacts, it is considered that the Plan adequately contributes to addressing the cumulative impacts to this species. In particular the Plan will:

- Secure 2 offset locations for *Cynanchum elegans*
- Lead to the protection of 2 per cent of the total potential habitat for the species in the Cumberland subregion
- Increase existing levels of protection of habitat for the species in the Strategic Assessment Area from 13 per cent to 15 per cent

MICROMYRTUS MINUTIFLORA

Nature and extent of impacts under the Plan

The Plan's contribution to cumulative impacts on potential habitat for *Micromyrtus minutiflora* is low compared to the other major projects (7 per cent of the total impact).

Furthermore, the risk of impacts to this species under the Plan is very low. The Plan will not result in any direct impacts to records or important populations. The most notable impacts to potential habitat occur due to the OSO within Wianamatta Regional Park. The risk of impacts in this location is considered low because:

- The species has not been recorded in the area despite the area forming part of a Regional Park which is managed by the NSW National Parks and Wildlife Service and would be well traversed
- The species was not observed as part of surveys conducted through sections of suitable habitat within the OSO corridor as part of this Assessment Report

Significance of cumulative impacts

The significance of the cumulative impacts across the Plan and major projects on *Micromyrtus minutiflora* is considered to be moderate. Although less than 10 per cent of total potential habitat for the species in the Cumberland subregion is cumulatively impacted, the species:

- Is restricted to the north-western parts of the Cumberland Plain
- Not well represented in existing protected lands (only approximately 5 per cent of total potential habitat in the Cumberland subregion occurs in existing protected lands)

It is important to note that the cumulative impact from other major projects is primarily due to the existing North West and South West Growth Areas, and the impacts associated with these areas are likely to be greatly overestimated (see Section 38.3). This reduces the significance of the total cumulative impacts.

Adequacy of the cumulative offsets

Offsets of potential habitat for *Micromyrtus minutiflora* are only provided under the Plan (and not under major projects).

The Plan includes a commitment to protect 260 hectares of NSW TECs/PCTs that are associated with potential habitat for the species.

Given the low contribution of the Plan to cumulative impacts, and the very low risk of impacts to the species under the Plan, it is considered that the Plan adequately contributes to addressing cumulative impacts to this species. The Plan will increase existing levels of protection of habitat for the species in the Strategic Assessment Area from 5 per cent to 7 per cent.

***PIMELEA SPICATA* (SPIKED RICE-FLOWER)**

Nature and extent of impacts under the Plan

The Plan's contribution to cumulative impacts on potential habitat for *Pimelea spicata* is moderate compared to the other major projects (15 per cent of the total impact).

Furthermore, the risk of impacts to this species under the Plan is high. The Plan will result in direct impacts to one important population and 955.6 ha of potential habitat for the species, which is 2.7 per cent of potential habitat across the Strategic Assessment Area.

Significance of cumulative impacts

The significance of the cumulative impacts across the Plan and major projects on *Pimelea spicata* is considered to be high because:

- The total cumulative impact is moderate (greater than 10 per cent of total potential habitat in the subregion)
- The risk of impacts to this species under the Plan is high
- The species is relatively restricted in NSW, with the majority of known populations of the species occurring in the Cumberland subregion
- The species is not well represented in existing protected lands (only approximately 9 per cent of total potential habitat in the Strategic Assessment Area occurs in existing protected lands)

It is important to note that the cumulative impact from other major projects is primarily due to the existing North West and South West Growth Areas, and the impacts associated with these areas are likely to be greatly overestimated (see Section 38.3). This reduces the significance of the total cumulative impacts.

Adequacy of the cumulative offsets

Offsets for *Pimelea spicata* are only provided under the Plan (no offsets are provided through the major projects).

The Plan includes a species-specific commitment to secure 3 offset locations for *Pimelea spicata* to address the residual impacts of the development. In addition to this commitment, the Plan includes a commitment to protect 3,170.2 hectares of NSW TECs/PCTs that are associated with potential habitat for the species.

It is considered that the Plan adequately contributes to addressing cumulative impacts to this species. In particular, the Plan will:

- Secure 3 offset locations for *Pimelea spicata*
- Lead to the protection of 7 per cent of the total potential habitat for the species in the Cumberland subregion
- Increase existing levels of protection of habitat for the species in the Strategic Assessment Area from 9 per cent to 16 per cent

PULTENAEA PARVIFLORA

Nature and extent of impacts under the Plan

The Plan's contribution to cumulative impacts on potential habitat for *Pultenaea parviflora* is low compared to the other major projects (5 per cent of the total impact).

Despite this, the risk of impacts to this species under the Plan is high. The Plan will result in direct impacts to several important populations. There will be direct impacts on 188.4 ha of potential habitat for the species, which is 0.9 per cent of potential habitat across the Strategic Assessment Area. Habitat loss is generally to small patches exposed to edge effects, however, in Wianamatta Regional Park habitat loss will result in some fragmentation.

Significance of cumulative impacts

The significance of the cumulative impacts across the Plan and major projects on *Pultenaea parviflora* is considered to be moderate because:

- The total cumulative impact is moderate (greater than 10 per cent of total potential habitat in the subregion)
- The species is restricted to the Cumberland subregion
- The Strategic Assessment Area is the core location for the species. Records occur in the northern half of the Strategic Assessment Area, with the majority of records occurring in the locality of Londonderry/Marsden Park
- The species is not well represented in existing protected lands (only approximately 11 per cent of total potential habitat in the Strategic Assessment Area occurs in existing protected lands)

It is important to note that the cumulative impact from other major projects is primarily due to the existing North West and South West Growth Areas, and the impacts associated with these areas are likely to be greatly overestimated (see Section 38.3). This reduces the significance of the total cumulative impacts.

Adequacy of the cumulative offsets

The major projects provide total offsets of 141 hectares of potential habitat for *Pultenaea parviflora*.

The Plan includes a species-specific commitment to secure 2 offset locations for *Pultenaea parviflora* to address the residual impacts of the development. In addition to this commitment, the Plan includes a commitment to protect 260 hectares of NSW TECs/PCTs that are associated with potential habitat for the species.

It is considered that the Plan adequately contributes to addressing cumulative impacts to this species. In particular, the Plan, together with the major projects, will:

- Secure 2 offset locations for *Pultenaea parviflora* and 401 hectares of potential habitat for the species
- Lead to the protection of 3 per cent of the total potential habitat for the species in the Cumberland subregion
- Increase existing levels of protection of habitat for the species in the Strategic Assessment Area from 11 per cent to 15 per cent

REGENT HONEYEATER (ANTHOCHAERA PHRYGIA) AND SWIFT PARROT (LATHAMUS DISCOLOR)

Nature and extent of impacts under the Plan

The Plan's contribution to cumulative impacts on potential habitat for Regent Honeyeater and Swift Parrot is high compared to the other major projects (about 27 per cent of the total impact for both species).

The risk of impacts to these species under the Plan is low for Regent Honeyeater and medium for Swift Parrot. The Plan will result in the removal of 1,284.9 ha of potential foraging habitat for both these species, which amounts to 2.2 per cent of potential habitat across the Strategic Assessment Area.

Significance of cumulative impacts

The significance of the cumulative impacts across the Plan and major projects on Regent Honeyeater and Swift Parrot is considered to be low because:

- Total cumulative impact is relatively low (less than 10 per cent of total potential habitat in the subregion)

- The species are not restricted to the Cumberland subregion (both species have a broad range during their non-breeding seasons) and the Strategic Assessment Area is outside identified breeding locations for both species

It is important to note that the cumulative impact from other major projects is primarily due to the existing North West and South West Growth Areas, and the impacts associated with these areas are likely to be greatly overestimated (see Section 38.3). This reduces the significance of the total cumulative impacts.

Adequacy of the cumulative offsets

The major projects provide total offsets of 202 hectares of potential habitat for Regent Honeyeater and 143 hectares of potential habitat for Swift Parrot.

The Plan includes a species-specific commitment to secure 4,470 ha of potential foraging habitat for Regent Honeyeater and Swift Parrot to address the residual impacts of the development. The Plan also includes a commitment to incorporate a requirement in Development Control Plans to retain large trees (>50cm DBH) in urban areas, which are likely to provide high sources of nectar and therefore comprise primary foraging habitat for both these species.

It is considered that the Plan adequately contributes to addressing cumulative impacts to this species. In particular, the Plan together with the major projects, will:

- Lead to the protection of 8 per cent of the total potential habitat for the species in the Cumberland subregion
- Increase existing levels of protection of habitat for the species in the Strategic Assessment Area from 13 per cent to 21 per cent

Dural Land Snail (Pommerhelix duralensis)

Nature and extent of impacts under the Plan

The Plan's contribution to cumulative impacts on potential habitat for Dural Land Snail is small compared to the other major projects (1 per cent of the total impact).

Furthermore, the risk of impacts to this species under the Plan is very low. The Plan will not result in any direct impacts to records or important populations. There is a direct impact to 45.8 ha of potential habitat for this species, which amounts to 0.2 per cent of the potential habitat within the Strategic Assessment Area. Furthermore, this habitat is over 5 km from the nearest record, and over 30 km from the nearest important population.

Significance of cumulative impacts

The significance of the cumulative impacts across the Plan and major projects on Dural Land Snail is considered to be low because, while the total cumulative impact is moderate (greater than 10 per cent of total potential habitat in the subregion), records occur predominantly along the north-east fringes of the Cumberland subregion and generally outside areas that are cumulatively impacted, and the Strategic Assessment Area is not recognised as a key location for the species.

It is important to note that the cumulative impact from other major projects is primarily due to the existing North West and South West Growth Areas, and the impacts associated with these areas are likely to be greatly overestimated (see Section 38.3). This reduces the significance of the total cumulative impacts.

Adequacy of the cumulative offsets

Offsets for Dural Land Snail are only provided under the Plan (no offsets are provided through major projects).

Due to the risk of impacts being very low, the Plan does not include a species-specific commitment to offset known habitat or populations of Dural Land Snail. However, the Plan includes a commitment to protect 4,970.2 hectares of NSW TECs/PCTs that are associated with potential habitat for the species.

Given the very low risk of impacts to the species under the Plan, it is considered that the Plan adequately contributes to addressing cumulative impacts to this species.

GREY-HEADED FLYING-FOX (PTEROPUS POLIOCEPHALUS)

Nature and extent of impacts under the Plan

The Plan's contribution to cumulative impacts on potential habitat for Grey-headed Flying Fox is moderate compared to the other major projects (19 per cent of the total impact).

Despite this, the risk of impacts to this species under the Plan is low. The Plan will not result in any direct impacts to Grey-headed Flying-fox camps. There is a direct impact to 723.1 ha of potential foraging habitat, which amounts to 2.7 per cent of the potential habitat within the Strategic Assessment Area. The risk from this loss is considered to be low, because:

- Development will proceed in stages over the life of the Plan. Impacts will be at a rate of approximately 20 ha of habitat clearing per year. The annual loss of habitat will not be large
- There are large areas of habitat that support the highest nectar rank vegetation communities within 20 km of the nationally important and high priority camps (including large areas outside the Strategic Assessment Area)

Significance of cumulative impacts

The significance of the cumulative impacts across the Plan and major projects on Grey-headed Flying Fox is considered to be moderate because:

- Total cumulative impact is moderate (greater than 10 per cent of total potential habitat in the subregion)
- The Strategic Assessment Area supports a large number of Grey-headed Flying-fox camps (11 camps in total), including one nationally important camp in Bingara Reserve in Macquarie Fields
- 14 camps occur within 20 km of the Strategic Assessment Area, including three nationally important camps

The nationally important camp and high priority camp in the Strategic Assessment Area have significant mapped foraging resources (highest nectar rank) within 20 km. Much of this occurs outside the Strategic Assessment Area and is unlikely to be cumulatively impacted by the Plan or major projects as it largely comprises defence or protected lands.

Adequacy of the cumulative offsets

The major projects provide total offsets of 553 hectares of potential habitat for Grey-headed Flying Fox.

A species-specific commitment has been made under the Plan for Grey-heading Flying Fox to address potential impacts to foraging habitat from the development. The commitment is to incorporate a requirement in Development Control Plans to retain large trees (>50cm DBH) in urban areas, which are likely to provide high sources of nectar and therefore comprise primary foraging habitat for this species. In addition to this commitment, the Plan includes a commitment to protect 5,475.2 hectares of NSW TECs/PCTs that are associated with potential foraging habitat for these species.

Given the low risk of impacts to this species under the Plan, it is considered that the Plan adequately contributes to addressing cumulative impacts to this species. In particular, the Plan, together with the major projects, will:

- Lead to the protection of 8 per cent of the total potential habitat for the species in the Cumberland subregion
- Increase existing levels of protection of habitat for the species in the Strategic Assessment Area from 13 per cent to 21 per cent

CUMBERLAND PLAIN SHALE WOODLANDS AND SHALE GRAVEL TRANSITION FOREST

Nature and extent of impacts under the Plan

The Plan's contribution to cumulative impacts on Cumberland Plain Woodland is moderate compared to the other major projects (19 per cent of the total impact).

However, the Plan is not considered to have notable impacts on this TEC. The Plan will directly impact 154 ha of the TEC, which amounts to 1.6 per cent of the remaining TEC in the Strategic Assessment Area. The majority of the TEC impacted is in thinned condition and comprises small patches (less than 5 hectares). Most of the impacted TEC is of lower viability, and only 12 ha of higher viability TEC will be impacted (0.3 per cent of higher viability TEC in the Strategic Assessment Area).

Significance of cumulative impacts

The significance of the cumulative impacts across the Plan and major projects on Cumberland Plain Woodland is considered to be low because:

- The total cumulative impact is relatively low (less than 10 per cent of total potential habitat in the subregion):
- The TEC is relatively well represented in existing protected lands (approximately 21 per cent of total TEC in the Strategic Assessment Area occurs in existing protected lands). Note that this figure will significantly increase once the proposed offset in Orchid Hills for Stage 1 of the Western Sydney Airport is secured

Adequacy of the cumulative offsets

The major projects provide total offsets of 3,236 hectares of Cumberland Plain Woodland under the existing North West and South West Growth Areas program. It is important to note that the commitments under the program are for:

- At least 2,400 hectares of Commonwealth-listed Cumberland Plain Woodland or other 'grassy woodland' communities, with preference given to Cumberland Plain Woodland, followed by White Box–Yellow Box–Blakely's Red Gum Grassy Woodland and Derived Native Grassland
- At least 205 hectares of high-quality Commonwealth-listed Cumberland Plain Woodland

A species-specific commitment has been made under the Plan to address residual impacts on Cumberland Plain Woodland. The commitment is to secure 575 hectares of the TEC in conservation lands.

It is considered that the Plan adequately contributes to addressing cumulative impacts to this species. In particular, the Plan, together with the major projects (noting the qualification above), will:

- Lead to the protection of 39 per cent of the total TEC in the Cumberland subregion
- Increase existing levels of protection for the TEC in the Strategic Assessment Area from 20 per cent to 60 per cent

38.6 CONCLUSION IN RELATION TO THREATENED SPECIES AND TECS

While cumulative impacts to some species are considered to be moderate, the commitments under the Plan, together with the offsets through the major projects, are considered to adequately address these cumulative impacts. It is also considered that the Plan makes an adequate and substantial contribution to addressing these impacts.

38.7 CUMULATIVE IMPACTS ON OTHER MNES

The MNES that are most likely at risk from cumulative impacts and that may need additional commitments under the Plan in the context of those impacts are those matters where:

- The Plan is having a notable impact, and
- The major projects make a significant contribution to cumulative impacts, and
- There is a significant total cumulative impact from the Plan and major projects

Where the Plan is only having a minor or negligible impact on MNES, it is not within the scope of the Plan to address cumulative impacts from other major projects on those MNES.

Table 38-7 summarises the impacts of the Plan on other MNES and the potential for cumulative impacts resulting from additional urban or other development in the surrounding area.

Detailed assessments of the impacts of the Plan on each of these MNES are set out in Chapters 32, 33, and 34.

Table 38-7: Potential cumulative impacts from the Plan and major projects on other MNES

<table>
<tr><th>Other MNES</th><th>Summary of impact of Plan and potential for cumulative impacts from additional development in the Cumberland subregion</th></tr>
<tr><td>Migratory species</td><td>Migratory birds
Cumulative impacts are unlikely as potential impacts on migratory species from Plan are considered to be negligible.
Nine species listed in the migratory bird referral guidelines (DoE, 2015) have been observed within the Strategic Assessment Area. Potential impacts to the nine species from the Plan are considered to be negligible. No important habitat will be lost, and the risk of indirect impacts is considered to be negligible. Only one of the species (White-throated Needletail) has been observed in ecologically significant numbers in the Cumberland subregion. This species is almost exclusively aerial and found over a wide range of habitats including extensively modified and urban areas, and therefore the development under the Plan is considered unlikely to disrupt this species' use of the Strategic Assessment Area
See Chapter 32 for a detailed assessment of the impacts of the Plan on migratory birds
Migratory shorebirds
Cumulative impacts are unlikely as potential impacts on migratory species from Plan are considered to be negligible.
Twenty-one species of migratory shorebirds have been recorded in the Cumberland subregion. Two of those have been recorded at a site level in important numbers – Sharp-tailed Sandpiper and Latham's Snipe. No important habitat will be lost, and the risk of indirect impacts such as degradation of habitat and disturbance of birds is considered to be low
See Chapter 32 for a detailed assessment of the impacts of the Plan on migratory shorebirds</td></tr>
<tr><td>Ramsar</td><td>One Ramsar site is relevant to the Plan – Towra Point Nature Reserve. Towra Point Nature Reserve is located outside of the Strategic Assessment Area approximately 23 km from the nearest nominated area. A small part of the Strategic Assessment Area is located within the Georges River sub-catchment that flows directly into Botany Bay and the waters surrounding Towra Point Nature Reserve. This includes 170 ha of land for urban development within parts of GMAC and 9 ha of land within transport corridors
Potential cumulative impacts on Towra Point Nature Reserve from further development in the Cumberland subregion relate to:
• Increased number of visitors to Towra Point Nature Reserve due to increased populations in the surrounding area
• Further development in the Georges River sub-catchment and associated potential impacts on water quality due to urban run-off
Cumulative impacts from the Plan and other development in the surrounding area are unlikely to be notable.
The Botany Bay catchment currently supports an existing population of approximately 2 million people, and therefore has already experienced considerable levels of development (OEH, 2012; SMCMA, 2011). It is likely that additional development will continue to occur within this catchment over the next 36 years. However, it is not possible to predict the locations, nature or timing of these potential future developments, and as such the exact cumulative impact upon the hydrological character of the catchment cannot be quantified at this time
Despite this, the contribution of development within the Strategic Assessment Area to overall cumulative impacts on Towra Point Nature Reserve is likely to be small. The Plan provides for up to 179 ha of development within the Botany Bay catchment. The total size of the catchment is 1,165 km^2 (OEH, 2012; SMCMA, 2011). The urban capable land and transport corridors within the catchment therefore account for only 0.15 per cent of the total catchment area. It is unlikely that development across this small area of the catchment area will result in significant impacts to the wetland
Furthermore, development in the catchment area will not all occur at the same time, reducing the potential for a large increase in urban run-off carrying large quantities of sediment or pollutants into the catchment in any one event. Development under the Plan will occur over 36 years in stages,</td></tr>
</table>

Other MNES	Summary of impact of Plan and potential for cumulative impacts from additional development in the Cumberland subregion
	and other development in the catchment will also occur over many years. Most developments are subject to similar mitigation and management requirements under the EP&A Act that manage construction impacts, hydrological changes and water quality impacts The characteristics of Towra Point Nature Reserve also contribute to the resilience of the wetland and decrease its susceptibility to cumulative impacts. In particular, as the wetland is a tide-dominated estuary environment, the site is subject to regular flushing which significantly reduces the likelihood of build-up of pollutants at the site. Further, Towra Point Nature Reserve has a high level of adaptive site management consistent with best practice, which further protects the site from potential future impacts from wider landscape changes Pressures from increased visitor numbers to the Towra Point Nature Reserve are already occurring due to existing high population densities in proximity to the wetland. As a result, Towra Point Nature Reserve already implements a wide range of ongoing and comprehensive management measures to protect the reserve from disturbances associated with human visitation and recreational use. Therefore, the potential risk to the ecological character of Towra Point Nature Reserve as a result of an increased number of visitors is considered minimal See Chapter 33 for a detailed assessment of the impacts of the Plan on Towra Point Nature Reserve
World and National Heritage	There are three World and/or National Heritage listed sites in or near the Strategic Assessment Area that could potentially be impacted by development under the Plan. The Greater Blue Mountains World Heritage Area (GBMWHA) is located close to the nominated areas. The other heritage sites are further from the urban capable land and transport corridors and are unlikely to be impacted Potential cumulative impacts on GBMWHA from further development in the surrounding area relate to increased number of visitors to GBMWHA due to increased populations in the surrounding area. The potential impacts from increased visitors are: • Disturbance from people, vehicles and horses • Increased frequency of fires • Removal of bushrock and fallen timber • Introduced plants • Development or increased maintenance of visitor or management facilities or infrastructure The population of Sydney is already growing, and the overarching Strategic Plan and the plans of management for each individual reserve within the GBMWHA recognise the pressure from increasing visitors as a major management challenge. The management plans set out a range of management actions and monitoring programs that will support adaptive management of the threats related to increased visitors to GBMWHA over the life of the Plan (see Chapter 34). The protection arrangements for each of the reserves are considered adequate to manage potential cumulative impacts due to increased populations from further development in the surrounding area See Chapter 34 for a detailed assessment of the impacts of the Plan on World and National Heritage sites

Part 6B Attachment Contents

A. Ecological character of Towra Point

This section draws heavily on the ecological character description (ECD) for Towra Point (DECCW, SMCMA et al., 2010) and attempts to summarise the key points to facilitate impact assessment. As outlined in the ECD, wetlands are dynamic, changing, and interactive systems. Some components and interactions that contribute to the ecological character of Towra Point exist outside of the Ramsar site boundaries in the adjacent Towra Point Aquatic Reserve. Certain components of the Aquatic Reserve are therefore included in the following description although they may not occur within the Site boundary.

COMPONENTS AND PROCESSES

The components and processes that contribute to the ecological character of Towra Point are:

- Geomorphology
- Hydrology
- Physiochemical environment
- Biota
- Climate

GEOMORPHOLOGY

Towra Point was formed as a result of dynamic wind, wave, and tidal processes over time. The key drivers of geomorphology at Towra Point are:

- Geology and morphology
- Topography and microtopography
- Sedimentation

GEOLOGY AND MORPHOLOGY

The basis of Towra Point was formed from the dynamic movement of marine sand from Botany Bay and fluvial mud from the Georges River. Freshwater swamps formed in the lower lying areas as sea levels rose. River born sediments were deposited in areas with lower rates of water movement, such as Quibray and Woolooware bays. This provided the nutrient rich sediments necessary to support mangrove and salt marsh communities. Progressive erosion of Towra Beach followed by the accretion on the western side of Towra Point formed a sand spit.

Since its listing in 1984, there have been a range of anthropogenic and natural processes that continue to alter Towra Point's geomorphology. Towra Spit Island was formed in 1991 due to erosion by wind and waves. Accretion of sediment reconnected the island to the mainland in 1997, allowing land based predators access to important bird roosting and nesting habitat. The sediment connecting Towra Spit Island to the mainland was dredged in 2004 and needs to continuously be managed to maintain the ecological value of the Island.

TOPOGRAPHY AND MICROTOPOGRAPHY

Towra Point is generally a low-lying area. The elevation varies a little, providing environmental conditions that have led to the type and distribution of flora and fauna in the wetland depending on their tolerance to salt water. There are sand dunes located in the northern centre part of Towra Point. They surround terrestrial vegetation and reach a height of up to 5 m. Low lying areas and mudflats provide favourable environmental conditions for mangroves. Natural processes intensified by anthropogenic changes continue to change the topography, such as the erosion at Towra Beach.

SEDIMENTATION

The sediments in Botany Bay are made up of different sized marine sand, mud, and products of living organisms and biological processes. The erosion and accretion of sediments is caused by the natural processes of wind, waves, and currents. This movement depends on the size and type of sediment, the depth and velocity of water and vegetation cover. Most of the sediment from the Georges River is released into the ocean with a small amount entering the low energy systems of Woolooware and Weeney bays. A significant proportion of the sediment from Quibray bay has been moved around Towra Point to the Elephants Trunk.

Before Botany Bay underwent anthropogenic changes, sand transport in the bay occurred in a south-easterly direction. It now occurs in a westerly direction, causing increased erosion at Towra Beach.

The sedimentation processes of erosion and accretion facilitate the movement and colonisation of vegetation. It also creates mudflats that provide favourable habitat for migratory birds and mangroves.

LIMITS OF ACCEPTABLE CHANGE (LAC)

Maintaining the natural cycle of erosion and accretion has been identified as an aim for the limits of acceptable change for geomorphology. It focuses on maintaining the separation of Towra Spit Island from the mainland. The LAC for geomorphology is the same as those set for the little tern because the spit is an important breeding and roosting habitat for migratory birds including the little tern. The LAC is the 'successful annual breeding in one out of every two years' of the little tern.

HYDROLOGY

Towra Point Ramsar site and its surrounds are a dynamic system that rely on hydrological processes. The key components of hydrology at Towra Point are:

- Tides
- Wave action
- Groundwater

TIDES

Botany Bay is a tide dominated estuary that experiences semi-daily tides. Two high and low tides of equal size occur per lunar day, making it a well flushed system. Tidal movement is key to maintaining good water quality in the system.

The tidal currents are fairly slow and cannot solely cause sediment movement without the assistance of wave energy to suspend the sediments first.

The dynamic nature of hydrology means the tides have a direct influence on the following:

- Geomorphology: with the help of wave energy, tides facilitate sediment movement through the system by means of erosion and accretion
- Groundwater: tidal flooding determines groundwater properties such as salinity
- Physiochemical environment: the bay's physiochemical environment consists mostly of saltwater, with some freshwater on the surface from the river discharge and rainfall. Tides regulate the saltwater to freshwater ratio and consequently, the salinity levels. Tidal movement also ensures that excess nutrients, pollutants, and suspended sediment entering the system via the Georges river is flushed out and does not accumulate in the system
- Biota: tides facilitate the movement of phytoplankton and crab larvae. These are important food sources for zooplankton, invertebrates, fish, and birds. High tides help restock these food sources, while low tides expose mudflats that are important foraging habitat for birds at Towra Point. Tides also assist in seed disbursal

Anthropogenic changes prior to the listing of Towra Point under the Ramsar Convention have caused changes to tidal actions. These changes are included in the Site's baseline condition described in the ECD as they occurred prior to listing. These changes include a causeway that was built through the middle of Towra Point in 1952 that prevents undisturbed tidal flow through the wetland.

Further anthropogenic changes to parts of Botany Bay after the site's listing, such as dredging at the bay's entrance, have again impacted tidal speeds and water quality.

WAVE ACTION

Wave action is a product of the transfer of wind energy to surface water. Waves in Botany Bay are largely influenced by storms that originate from the south-east and enter the bay from the same direction. Wave direction entering into Botany Bay has shifted from impacting the north-west shore to impacting more to the southern shore. This is a result of the construction of Sydney Airport and Sydney Port on the northern shoreline and dredging that also occurred in that area of the bay in the 1960s. The change in direction and intensity of waves entering the bay have caused higher rates of erosion to occur in areas such as Towra Point Beach. These changes have also meant that storms have a greater impact, demonstrated by the intrusion of salt water into Towra Lagoon following severe storms in 1974.

Mudflats are created through the accretion of sediment in low energy areas. Increased wave energy entering the system has the potential to erode mudflats causing the resuspension of these sediments, and result in reduced light availability for seagrass.

GROUNDWATER

The groundwater table is fed by surface water filtering through the soil. Factors that influence water table levels are tides, rainfall, surface layer evaporation, transpiration from plants, and groundwater extraction. Groundwater is critical in providing plants with freshwater and nutrients, particularly during periods of low rainfall.

Towra Point is situated on the Botany Bay Sand Aquifer that extends from Centennial Park in the north, to Botany Bay and Kurnell Peninsula in the south, and west to Rockdale. It is a shallow aquifer, approximately two meters deep. Long term changes in ground water levels can impact the topography above the aquifer, reducing surface elevation. This would alter the extent of tidal inundation and therefore the extent and distribution of the flora and fauna that are supported at Towra Point.

The northern section of the aquifer is most frequently used for residential and industrial water extraction. Botany Bay Industrial Park is located in this section and drains into the aquifer. This has resulted in the contamination of groundwater by volatile chlorinated hydrocarbons in particular. The groundwater in the aquifer flows in a north-westerly direction. Towra Point is therefore unlikely to be directly affected by contamination in the northern zone but rather from the southern zone. The southern part of the aquifer covers a relatively small area, which includes Towra Point. The importance of Towra Point in the process of groundwater recharge and filtering of contaminants for the Botany Bay Sand Aquifer will grow as more of the surrounding area becomes developed with impermeable surfaces that prevent recharge. Other areas that have the potential to contaminate the aquifer are the Caltex oil refinery located east of Towra Point, Kurnell Landfill Company on Captain Cook Drive, and contaminated runoff from roads and industries in the sub-catchment.

Sandmining next to Towra Point at Kurnell Peninsula continued until 2005. This activity exposed the water table, which increased evaporation and the risk of contamination. It has since been filled with demolition waste.

LIMITS OF ACCEPTABLE CHANGE (LAC)

Limits of acceptable change for groundwater are determined by the relevant water quality guidelines (ANZECC & ARMCANZ, 2000; ANZG, 2018).

PHYSIOCHEMICAL ENVIRONMENT

At Towra Point the physiochemical environment determines water quality, which is vital for sustaining the diverse range of flora and fauna. There are some components that have a big impact on water quality such as chlorophyll-a, pH and dissolved oxygen and are critical to the upper parts of the Botany Bay catchment. However, these components are not considered critical for Towra Point due to the well-flushed nature of Botany Bay.

The key components of the physiochemical environment at Towra Point are:

- Salinity
- Nutrients
- Heavy metals
- Turbidity

SALINITY

The average ocean salinity is 35 parts per million (ppm). The salinity range in the water surrounding Towra Point is 20-35 ppm with an average of 33 ppm. Salinity reduces the risk of algal blooms. Botany Bay is less at risk of algal blooms than the upper parts of the catchment because it is well-flushed and has a high salinity level. The tidal flushing of Botany Bay means that freshwater from the Georges River only has an effect on Towra Point after long periods of rain or after heavy rainfall events in the catchments.

There are three named freshwater ponds at Towra Point. These include Towra Lagoon, Weedy Pond, and Mirrormere Pond. The salinity level of freshwater should be close to zero parts per million. In 1992 Towra Lagoon's salinity was 2 and 9.5 ppm in 2007 as a result of ongoing saltwater intrusion since a large storm event in 1974. This is well above the level of tolerance of many freshwater species. Attempts to restore the lagoon to a freshwater system continue to be made through a number of different means such as sandbagging and sand replenishment at Towra Beach.

The flora at Towra Point have varying levels of salt tolerance. There are distinct vegetation zones that can partially be attributed to soil salinity levels amongst other factors. The salt marsh vegetation zone is due to limiting factors such as light availability, rather than soil salinity levels. The distribution of mangroves has increased landward at Towra Point, indicating that salinity levels have changed since it became Ramsar listed.

NUTRIENTS

Nutrients that are important to ecosystems are nitrogen, phosphorus, carbon, silica and iron. Nutrients of particular importance to Towra Point are inorganic and organic forms of nitrogen and phosphorus. Forms of phosphorus that are readily available for plant uptake are inorganic orthophosphate and organic compounds containing phosphorus that are water soluble. Other forms of phosphorus are ionic phosphorus that are absorbed by sediment to settle onto seabeds for uptake by seagrass and other primary producers.

Towra Point wetland system has a high nutrient demand and plays an important role in the cycling of nutrients. The source of the majority of nutrients in Botany Bay is the Georges River, where it enters as runoff from the catchment. This includes agricultural runoff, stormwater and sewer overflows, runoff from urban and industrial areas, groundwater discharge, and decomposition of organic matter. Three sewage treatment plants exist in the catchment at Liverpool, Fairfield, and Glenfield. They treat waste water entering the Georges River during wet weather and are susceptible to occasional overflows for different reasons. In the instance of an overflow, high nutrient waste is discharged directly into the waterway and transferred into Botany Bay. Periods of high nutrient concentrations generally occur after recent rainfall.

Excess nutrients combined with a low energy system can result in algal blooms and eutrophication. This is unlikely to occur in Botany Bay due to the high energy nature of the system. However, Woolooware and Weeney bays that are adjacent to Towra Point are at a higher risk of eutrophication as they experience a lower rate of tidal flushing. Terrestrial weed growth increases with increased nutrient levels.

Insufficient data is available on the trend of total nutrient levels in Botany Bay. However, total nitrogen and phosphorus has decreased in Woolooware bay by 50-60% in Woolooware bay from 1984 to 2007.

HEAVY METALS

Wetlands play a critical role in absorbing and filtering heavy metals out of water. Some organisms need small amounts of heavy metals such as copper, iron, and zinc. Greater than trace amounts of these heavy metals can be toxic. Copper, lead and zinc are generally found close to residential and industrial areas. Heavy metals accumulate in organisms and are passed up the food chain. The cultivation of oysters at Woolooware and Quibray bays can be used as an indicator of the low concentration of heavy metals around Towra Point.

Changes in concentrations of heavy metals recorded in Woolooware Bay in 1977 and circa 2007 are displayed in Woolooware Bay is adjacent to Towra Point and along with Weeney Bay experiences less tidal flushing than other areas in Botany Bay. Concentrations of heavy metals recorded in 1977 in Woolooware Bay exceeded the current LAC.

TURBIDITY

Salinity reduces the presence of suspended particles in water, known as turbidity. The sodium and chloride ions bind suspended particles and metal ions causing them to settle. This increases water clarity and as a result water quality.

Seagrass beds in the Ramsar site occur at Weeney Bay. The majority of the seagrass occurs outside the Ramsar site in the Aquatic Reserve. It occurs below the low tide mark to a depth of 3 m in Woolooware Bay, around Towra Spit, off the shoreline from Towra Beach, and in Quibray Bay. Seagrass is a primary producer and has a high light requirement. It relies on high water quality to allow sunlight to filter through in order to photosynthesise. It also has a high nutrient requirement which it utilises from groundwater discharge areas. Too much turbidity and nutrients will cause the seagrass to dieback. The presence of seagrass at Towra Point therefore provides a good indicator of water quality.

Spikes in nutrient levels and turbidity occur following storm events that increase surface runoff from the catchment and wave action in the bay. These levels have been known to exceed the levels set by the water quality guidelines (ANZECC & ARMCANZ, 2000; ANZG, 2018). They are monitored when they exceed these levels and usually return to normal levels within a number of days.

LIMITS OF ACCEPTABLE CHANGE (LAC)

Water quality guidelines for marine water have been used to determine limits of acceptable change for the physiochemical environment (ANZECC & ARMCANZ, 2000; ANZG, 2018).

BIOTA

The biota at Towra Point is one of the components and processes that makes the wetland internationally significant. The key components of biota at Towra Point are:

- Flora
- Fauna

FLORA

Towra Point supports a number of regionally significant flora that occur as distinct vegetation zones across the wetland. The critical components of flora at Towra Point are:

- Seagrass
- Mangroves
- Saltmarsh

There are substantial areas of terrestrial vegetation at Towra Point that also play an important role in the wetland system.

Seagrass

Seagrass mostly occurs in the Towra Point Aquatic Reserve, next to Towra Point Ramsar site. Although seagrass exists mainly outside of the official boundary, it contributes to the ecological character of the Site. There are three seagrass species present in and around Towra Point. They are *Posidonia australis*, *Zostera capricorni*, and *Halophila ovalis*. At the time of listing in 1984, seagrass covered an area of approximately 516 ha along the southern shore of Botany bay.

Seagrass provides protection for fish at a critical stage in their life cycle, as well as crustaceans. It is also important in maintaining biodiversity at Towra Point and a critical link in the food chain. The organic matter produced by seagrass is an important food source for invertebrates and bacteria, and subsequently fish and birds. The loss of seagrass would mean the wetland is unable to continue to support the diversity and abundance of fauna present at Towra Point.

Light availability is important to the presence of seagrass. In Botany Bay, seagrass can be found in areas up to three meters deep. Water turbidity is a limiting factor for the distribution of seagrass in the bay. Turbidity determines light availability and is in turn regulated by rainfall and pollution levels.

Seagrass also have a high nutrient requirement. They acquire these nutrients from groundwater discharge and nutrients that have settled on the seabed. Seagrass is important in the cycling of nutrients and stabilising of sediment, which encourages accretion. This helps stabilise the geomorphology of the bay against waves and storms.

Anthropogenic changes to Botany Bay such as the construction of Sydney Airport's third runway have led to the decline of seagrass in the bay. The area of seagrass along the southern shore of Botany Bay was recorded as 458 ha in 2008.

Mangroves

Towra Point supports approximately 40% of the remaining mangroves in the Sydney region. They are also considered the largest and healthiest in the region. This is equivalent to 6% of the extent in NSW. There are two mangrove species present at Towra Point, *Avicennia marina* and *Aegiceras corniculatum.*

Mangroves trap and stabilise sediment as well as providing important nursery habitat for juvenile fish. Areas with seagrass, mangroves, and saltmarsh adjacent to one another (as is seen at Towra Point) support a larger diversity and abundance of species compared to other remnant patches of these flora types in the Sydney region.

Tidal inundation and salinity are determining factors for mangrove distribution. Mangrove distribution has increased since 1984 and is encroaching on the saltmarsh area at Towra Point.

Aerial photographs have been used to retrospectively calculate the area of mangroves at Towra Point at different points in time. In 1983 there was 395.2 ha of mangroves at Towra Point, which is around the time of the Site's listing. In 1999 470.5 ha was recorded using the same methodology. In 2008, 385 ha was recorded. However, this most recent number was generated using a different method and therefore cannot be reliably compared to the previous records.

Saltmarsh

Towra Point supports approximately 60% of saltmarsh areas in the Sydney region and 2% of the NSW extent. It is one of the largest remaining saltmarsh areas in NSW. Several saltmarsh species are found at Towra Point.

The key limiting factor for saltmarsh species is light. They prefer full light. The presence of mangroves and terrestrial trees limit their distribution seaward and landward respectively. The surface features at and around Towra Point combined with hydrological movement are critical for seed dispersal and distribution. Tides spread seeds to other suitable areas that are at an elevation to be influenced by tidal inundation.

Migratory shorebirds use the saltmarsh vegetation at Towra Point as roosting and foraging habitat. It is in close proximity to other foraging areas for these migratory species within Towra Point such as the mudflats. This means these areas are important for migratory birds to preserve energy on their migratory routes. Saltmarsh at Towra Point is also considered important habitat for other species that are regionally significant. For example, crab species that release larvae into the outgoing tides and certain fish species that are considered to be of commercial and economic significance that use these same tides to access this reliable food. The saltmarsh community provides habitat for crabs that release larvae in the outgoing tides that are a food source for birds and fish.

Aerial photographs have been used to retrospectively calculate the area of saltmarsh at Towra Point in 1983 and 1999. It was calculated at 141 ha and 88.1 ha respectively. A different methodology was used in 2008 which recorded saltmarsh over a 134 ha area. The main cause of loss of saltmarsh at Towra Point is mangrove encroachment. The spread of mangroves limits light availability for other plant species. This reduces the area of suitable habitat for saltmarsh.

Terrestrial vegetation

Over 150 species of terrestrial vascular plants are found at Towra Point. In 1983 the area covered by terrestrial vegetation was calculated at approximately 166 ha. This vegetation provides roosting and foraging habitat for fauna species such as the Masked Owl, Greater Broad-nosed Bat, Grey-headed Flying-fox, and a number of honeyeater species.

The magenta Lilly Pilly (*Syzygium paniculatum*) occurs at Towra Point and is one of the three threatened species listed under the EPBC Act for which the site was originally listed.

The plant community types found on the site are:

- Swamp oak forest
- Littoral strand
- Littoral rainforest
- Dune sclerophyll forest
- Bangalay forest with swamp oak (*Casuarina glauca*)

Surveys conducted around 2006 mapped 185 ha of terrestrial vegetation at Towra Point. The vegetation has been found to be in good to average condition with some areas dominated by weeds.

FAUNA

Towra Point is one of the last remaining wetlands of its type in the Sydney region and provides important habitat for a number of threatened and migratory species. The species present at the Site include:

- Macro-invertebrates
- Fish
- Reptiles and amphibians
- Mammals
- Birds

Macro-invertebrates

Macro-invertebrates are an important link in the food chain at Towra Point. Species such as molluscs, polychaetes, and crustaceans are a food source for fish and birds. These species also help to aerate the soil, improving the health of flora. Macro-invertebrates are associated with particular sediment types. They are therefore a good indicator of changes in sediment and disturbance.

Limited information is available about macro-invertebrates at Towra Point at the time of listing. This is still the case in the present day as no targeted studies have been conducted in the area. It has been identified as a knowledge gap.

Fish

Seagrass, saltmarsh and mangroves at Towra Point Ramsar site and the adjacent Aquatic Reserve are important in the provision of food and shelter for numerous fish species; most of which are in the juvenile stage of their life cycle.

75 species of fish were recorded in the seagrass surrounding Towra Point in 1981 and 46 species in the mangroves in 1984. Approximately 25 species of fish considered of economic and recreational importance use Towra Point.

Reptiles and amphibians

Studies at Towra Point in 1984 found 12 reptile and amphibian species. Amongst the amphibians recorded was the Green and Golden Bell Frog (*Litoria aurea)*. It is one of the three threatened species listed under the EPBC Act for which the site was originally listed. This population was identified as a key population in Sydney. The population at Towra Point has reduced as a result of loss of habitat from the intrusion of salt water into Towra Point Lagoon in 1974.

Mammals

A lack of historical data for mammals at Towra Point has been identified and robust surveys are still lacking. A Grey-headed Flying-fox *(Pteropus poliocephalus)* camp occurs on Kurnell Peninsula. The species has a foraging radius of 25 km and has been found in 14 different locations at Towra Point. It is one of the three threatened species listed under the EPBC Act for which the site was originally listed.

Birds

Towra Point supports at least 189 species of birds. This includes 34 migratory bird species listed under international agreements. In 1984 the Site supported at least 1% of the estimated international population of eastern curlew. The site no longer supports this proportion as an increase in the estimated population has occurred. Despite this, the number of visiting curlews recorded at Towra Point having increased.

Towra Point has been identified as part of one of the four most important migratory shorebird habitats in NSW. Migratory shorebirds use Towra Point as a critical stopover on migratory routes from Korea, Japan, China, Russia, Siberia and Alaska during September to April. Number of birds recorded at Towra Point fluctuate from year to year and depending on the season.

Towra Spit Island was formed in 1991 and has since been identified as the second most important little tern *(Sternula albifrons)* nesting site in NSW following the loss of nesting habitat at the location where Sydney Airport's third runway was built.

Loss of migratory shorebird habitat elsewhere in Botany Bay has placed increased pressure on Towra Point.

LIMITS OF ACCEPTABLE CHANGE (LAC)

Limits of acceptable change have been developed for biota where sufficient information is available.

These include hectare thresholds for:

- Seagrass
- Mangroves
- Saltmarsh
- Mixed mangrove and saltmarsh

The LACs for Magenta Lilly Pilly and the Grey-headed Flying-fox are no loss of the species.

The LAC for the green and golden bell frog is the species being recorded every year, or when surveys are undertaken.

The LACs for migratory shorebirds relate to net loss, percentage loss, or breeding success:

- In summer (December to February)
    - *Abundance*: no decline of more than 50% from the baseline condition for Botany Bay (1668 ± 472) in 5 consecutive years
    - *Diversity:* no net loss of species over 5 consecutive years
- In winter (June to August)
    - *Abundance:* no decline of more than 50% from the baseline condition for Botany Bay (604 ± 148) in 5 consecutive years
    - *Diversity:* no net loss of species over 5 consecutive years
- Eastern Curlew: no decline of more than 50% from the baseline condition for Botany Bay (133 ± 77) in 5 consecutive years
- Little tern (breeding numbers): successful annual breeding in one out of every two years

CLIMATE

Climate exists as an ecosystem regulator and plays an important role in maintaining equilibrium. The flora and fauna at Towra Point have adapted to the temperate climate of the region. Climate change and anthropogenic changes around Botany Bay are altering the intensity of climatic parameters. The key components that are regulated by climate are:

- Temperature
- Rainfall
- Storm events

TEMPERATURE

Temperature is a determining factor for species distribution at Towra Point. In 1977 the mean daily temperatures in winter varied from 6.2°C to 17°C and the mean daily temperature range in summer was 18.4°C to 26.2°C. Increases in temperature can increase the rate of evaporation, and as a result levels of soil salinity.

RAINFALL

Rainfall replenishes soil moisture content, offsets surface and soil salinity levels, and assists in the recharge of groundwater levels. It is the primary source of freshwater for Towra Point. In 1977 Towra Point received an average rainfall of 1,100 mm with the most rainfall usually occurring from March to June.

STORMS

Severe storm events have been key to the significant erosion at Towra Beach and the intrusion of salt water into Towra Point Lagoon, prior to 1984. Thunderstorms occurred once a month in winter and three times a month in summer around 1977. More intense storms with stronger winds and more rough, higher seas occur around five times a year. These are the storms that have the greatest detrimental impact on Towra Point as they cause increased rates of erosion.

These changes have the potential to place further stress on the system, forcing components and processes at Towra Point outside of their boundaries of natural variation.

LIMITS OF ACCEPTABLE CHANGE (LAC)

Parameters for climate cannot be managed at a local scale. It has therefore been identified that limits of acceptable change cannot be set for climate for Towra Point Nature Reserve Ramsar site.

SERVICES AND BENEFITS

Components and processes contribute to services and benefits. The services and benefits that are present at Towra Point Ramsar site and contribute to its ecological character as described in the ECD (DECCW, SMCMA et al., 2010) are:

- Provisioning services
- Regulating services
- Cultural services
- Supporting services

PROVISIONING SERVICES

Provisioning services of Towra Point Ramsar site include:

- Fisheries production: Towra Point and the adjacent Aquatic Reserve provide important habitat for the protection of juvenile fish, crustaceans, and molluscs and are of economic importance when they move to areas that are allowed to be commercially fished. This area also provides habitat for a small number of leases to cultivate Sydney rock oysters
- Trophic relay: the transfer of energy and nutrients at Towra Point to different parts of the estuary through a complex food web is critical to maintaining biodiversity

REGULATING SERVICES

Regulating services of Towra Point Ramsar site include:

- Maintenance of hydrological regimes: Towra Point plays an important role in maintaining the hydrological regimes of Botany Bay and the region. These hydrological processes include rainfall, ties, evapotranspiration, runoff, infiltration and groundwater flow
- Shoreline stabilisation and storm protection: vegetation at Towra Point such as mangroves and seagrass prevent erosion from tides, storms, and high rainfall
- Biological control of pests and disease: Towra Point provides habitat for native predators such as the masked owl, white-bellied sea eagle, and whistling kite that prey on introduced rodents
- Pollution control: mangroves at Towra Point act as sediment traps and contaminant filter. They contribute to the water quality and health of the waterway by providing a buffer between land and water. This helps filter contaminants before entering the waterway

CULTURAL SERVICES

Cultural services of Towra Point Ramsar site include:

- Recreation and tourism: Botany Bay and its tributaries are popular recreational areas for activities such as swimming, boating, and fishing due to their proximity to Sydney. The day-use area at Towra Point is the only publicly accessible area. It is only accessible by boat but is a popular recreational area
- Science and education: access to the majority of Towra Point Ramsar site is by permit only, which are granted for scientific and educational purposes
- Aesthetic amenity: the surrounds of Towra Point Ramsar site are highly developed and urbanised. Towra Point remains an example of the wetland types that used to be more common in the area and provides pleasant views of nature so close to Sydney's CBD
- Aboriginal heritage: the southern shore of Botany Bay is the country of the Gweagal clan of the Dharawal nation. This area is of significance to the Aboriginal people. Middens, rock shelters, engravings and burial sites can be found at Towra Point, indicating its importance to Aboriginal heritage

- Non-Aboriginal heritage: Captain James Cook and the crew of the *Endeavour* sailed into Botany Bay in 1770. Towra Point was the site of some of the first recorded botanical and zoological samples of Australia. The oyster industry in the water surrounding Towra Point is also a part of the cultural heritage of the area

SUPPORTING SERVICES

Supporting services of Towra Point Ramsar site include:

- Hydrological processes: Towra Point is key in maintaining hydrological processes including evapotranspiration, runoff, infiltration, and groundwater. These hydrological processes are also important in conserving the ecological character of the Ramsar site
- Food webs: the biodiversity at Towra Point is as a result of the interactions between organisms and the transfer of nutrients and energy. Critical links in the food chain include seagrass meadows and mangroves as they provide organic matter and detritus which is an important food source for invertebrates. Critical interactions include seed dispersal and pollination by the Grey-headed Flying-fox as well as export of crab larvae from the saltmarsh areas in outgoing tides. Tides play an important role in facilitation the transportation of organic and detritus matter and crab larvae export
- Physical habitat: Towra Point wetland provides particular habitat that can no longer be found elsewhere in the Sydney region. The suitable conditions support remnant habitats, threatened species, and endangered ecological communities. These include but are not limited to a diverse range of shorebirds, seagrass, mangroves, and saltmarsh
- Nutrient cycling: Maintaining a balance of nutrients is critical to the health of the ecosystem. Nutrients enters the system from the catchment in the form of runoff, sewage overflow and stormwater, and groundwater discharge. Flora and fauna found at Towra Point and the surrounding hydrological processes are critical to the cycling of nutrients. Primary producers such as phytoplankton, seagrass, mangroves, and saltmarsh have high nutrient requirements. They convert the nutrients to different forms that are more useable for other species. Botany Bay is a well flushed system, preventing the excess build-up of nutrients or sediment. This is maintained by the semi-diurnal tides
- Primary production: Towra Point supports primary producers such as phytoplankton, mangroves, saltmarsh, seagrass, and terrestrial vegetation. These in turn support a number of other processes
- Sediment trapping and stabilisation: seagrass, saltmarsh, and mangroves at Towra Point trap sediment and filter contaminants
- Biodiversity: the high level of biodiversity at Towra Point is supported by its size in relation to other areas of remnant vegetation in Sydney. Because of its size, the wetland supports a large variety of flora and fauna species. The importance of how the components at Towra Point contribute to its biodiversity are illustrated through the food web
- Special ecological, physical or geomorphic features: The Towra Point saltmarsh community is a threatened community listed under the BC Act. This community along with seagrass and mangroves are part of the features at Towra Point that provide habitat and nourishment for migratory shorebirds on their annual migration routes. This habitat also is an important nursery for fish and crustaceans. Oyster leases and other structures in the bays surrounding Towra Point (Quibray, Weeney, and Woolooware bays) provide additional roosting sites
- Threatened wetland species, habitats and ecosystems: The species and ecosystems supported at Towra Point include
  - 3 threatened species listed under the EPBC Act
  - 23 threatened species listed under the BC Act
  - 5 endangered ecological communities listed under the BC Act
- Priority wetland species: Towra Point Ramsar site and surrounding areas support 30 of the 80 migratory bird species listed a number of bilateral agreements including JAMBA, CAMBA, and ROKAMBA
- Ecological connectivity: Towra Point Ramsar site provides connectivity to other natural areas in the surrounding area that is otherwise highly urbanised. These natural areas include Kamay Botany Bay National Park, Royal National Park, Georges River National Park, Taren Point Shorebird Community, and Heathcote National Park. It also provides connectivity to foraging resources including shorebirds and the Grey-headed Flying-fox.

Part 7 List of Tables

39 Introduction

In considering approval of the Plan, the Commonwealth and NSW environment ministers must take into account various matters under the *Biodiversity Conservation Act 2016* (BC Act) and *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) in relation to the impacts and benefits of the Plan on biodiversity values and other protected matters.

This Part:

- Analyses the Plan against the principles of Ecologically Sustainable Development (ESD) (see Chapter 40)
- Evaluates the adequacy and acceptability of the Plan in the context of the impacts of the development and in accordance with the regulatory requirements of the BC Act and EPBC Act (see Chapter 41)

This Chapter sets out:

- The regulatory context for evaluating the Plan
- The overall approach to the evaluation

39.1 REGULATORY CONTEXT FOR THE EVALUATION

Under both the BC Act and EPBC Act processes, the Assessment Report must evaluate the overall outcomes and acceptability of the Plan on biodiversity values and other protected matters.

39.1.1 BIODIVERSITY CONSERVATION ACT

Under section 8.7 of the BC Act, the NSW Environment Minister may only confer biodiversity certification if satisfied that the 'approved conservation measures' adequately address the likely impacts on biodiversity values.

Under a strategic application for biodiversity certification, the BC Act does not require that the 'value' of the commitments be calculated in terms of credits and provides broad discretion around defining commitments. Commitments under strategic certification are not constrained by the offset rules (clause 6.2(5)(b) BC Regulation) and the NSW Environment Minister can determine any measure to be a commitment (section 8.3(2)(b) BC Act).

EES has prepared the *Draft Guidelines for planning authorities for proposing conservation measures in strategic applications for biodiversity certification* (draft version 6) ('draft guidelines for planning authorities') (EES, 2019). These provide guidance on how to evaluate whether the conservation measures adequately address the likely impacts on biodiversity values.

The 'draft guidelines for planning authorities' (EES, 2019) include a set of principles that must be considered in evaluating the Plan.

These principles are summarised in Table 41-1 and addressed in Chapter 41.

39.1.2 ENVIRONMENT PROTECTION AND BIODIVERSITY CONSERVATION ACT

Under the EPBC Act, the Commonwealth Environment Minister:

- May endorse a policy, plan or program if satisfied that the Impact Assessment Report 'adequately addresses the impacts' on protected matters to which the agreement (to undertake a strategic assessment) relates (s146(2)(f))
- May approve the taking of actions in accordance with the endorsed policy, plan or program (s146B(1)) subject to a range of considerations under Part 10 Division 1, Subdivision C, including:
    - General considerations under s 146F, including any matters relevant to MNES that the Minister considers is relevant to the approval, taking into account the principles of ecologically sustainable development
    - Constraints on decision-making discretion under ss 146 G, H, J, K, L and M, including that the Minister must not act inconsistently with the provisions of a recovery plan or threat abatement plan (s 146K)

The Agreement and Terms of Reference (ToR) require the Assessment Report to evaluate the commitments and outcomes for protected matters taking into account likely impacts on protected matters under the Plan. The ToR includes other matters that must be considered in evaluating the Plan. These matters are summarised in Table 41-1.

The ToR (section 5.2(4)) also requires the Assessment Report to evaluate the extent to which the Plan meets the endorsement criteria under clause 8 of the Agreement. The endorsement criteria specifies that, in determining whether the Assessment Report adequately addresses the impacts of the Plan, the Commonwealth Minister must have regard to the extent to which the Plan meets the objectives of the EPBC Act, including how the Plan:

- Protects the environment, particularly protected matters
- Promotes ESD through the conservation and ecologically sustainable use of natural resources
- Promotes the conservation of biodiversity
- Provides for the protection and conservation of heritage
- Promotes a co-operative approach to the protection and management of the environment
- Assists in the co-operative implementation of Australia's international environmental responsibilities

The matters required to be addressed by the Agreement and ToR are addressed in Chapter 40 and Chapter 41.

39.2 DEFINING 'ADEQUATE' IN THE CONTEXT OF THE PLAN

The commitments under the Plan are not driven solely by meeting the credit requirements of the Biodiversity Assessment Method (BAM), which is a key part of the definition of 'no net loss' under the BAM.

This recognises that strategic biodiversity certification supports development and planning priorities, and provides significant opportunities to maximise benefits to biodiversity and address landscape scale conservation challenges, which are not provided by site-by-site assessment processes.

The key commitments under the Plan have been developed in recognition of these potential benefits.

The biodiversity benefits of these types of commitments may not be realised, and are likely to be undervalued in an evaluation of the Plan, by focusing only on the credit balance of the Plan. This is recognised in the 'draft guidelines for planning authorities' (EES, 2019). While Principle 2 (see Section 41.5) requires consideration of the credit output of the Plan, this is only one of eight principles that the guidelines require to be taken into account in evaluating the Plan.

It is also important to note that due to the large scale of the Plan Area and the voluntary mechanisms proposed to secure conservation lands under the Plan, the location and boundaries of conservation lands are not yet final, and it has not yet been possible to undertake surveys within Strategic Conservation Areas (SCAs) to confirm biodiversity values. This means that it is not yet possible to determine the credits generated by securing conservation land under the Plan.

The Department developed an approach for defining offset targets to ensure that the commitments address the biodiversity values being impacted (see Chapter 8). The adequacy of these offset targets is evaluated in Section 41.5.

39.3 BROAD APPROACH TO THE EVALUATION

Evaluation of the overall outcomes and acceptability of the Plan was undertaken at three levels:

- In relation to the principles of Ecologically Sustainable Development (see Chapter 40)
- In relation to the overall adequacy of the Plan in accordance with the 'draft guidelines for planning authorities' (EES, 2019) and requirements of the Agreement and ToR (see Chapter 41)
- For individual Commonwealth protected matters under the EPBC Act. This analysis is provided in Chapters 29 – 35

Details of the approach to evaluating ESD and the overall adequacy of the Plan are set out in Chapters 40 and 41.

40 Ecologically sustainable development

40.1 INTRODUCTION

ESD is defined as:

> *'using, conserving and enhancing the community's resources so that ecological processes, on which life depends, are maintained, and the total quality of life, now and in the future, can be increased' (COAG, 1992).*

This Chapter:

- Sets out the legal and other requirements for assessing ESD
- Sets out the approach used to analyse the principles of ESD
- Provides an analysis of the Plan against each of the principles of ESD:
  - *Principle 1 – integration of social, economic and environmental considerations*
  - *Principle 2 – precautionary principle*
  - *Principle 3 – intergenerational and intragenerational equity*
  - *Principle 4 – conservation of biodiversity and ecological integrity*
  - *Principle 5 – valuation, pricing and incentive mechanisms*

In analysing the Plan, this Chapter describes how the principles of ESD have been considered and promoted in the development of the Plan, both in guiding the planning process and informing the commitments under the Plan.

40.2 REQUIREMENTS FOR ASSESSING ESD

The assessment of the Plan against the principles of ESD is a requirement under:

- Commonwealth and NSW legislation
- Commonwealth ToR
- 'Draft guidelines for planning authorities' (EES, 2019)

40.2.1 LEGISLATION

COMMONWEALTH LEGISLATION

The EPBC Act incorporates the promotion of ESD within the key objectives of the Act, which states (in Part 1, Section 3):

> *"The objects of this Act are … to promote ecologically sustainable development through the conservation and ecologically sustainable use of natural resources"*

The Act requires that the Commonwealth Environment Minister must consider economic and social matters, including taking the principles of ESD into account, when considering the approval of the taking of actions in accordance with an endorsed program or plan under the EPBC Act (section 146F).

The definition of ESD under Section 3A of the EPBC Act is:

Commonwealth definition of ESD – EPBC Act

Part 1 Preliminary

Section 3A Principles of ecologically sustainable development

The following principles are principles of ecologically sustainable development:

(a) decision-making processes should effectively integrate both long-term and short-term economic, environmental, social and equitable considerations;

(b) if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation;

(c) *the principle of inter-generational equity—that the present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations;*

(d) *the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision-making;*

(e) *improved valuation, pricing and incentive mechanisms should be promoted.*

NSW LEGISLATION

The principles of ESD underpin the central objectives of the BC Act. ESD is integrated into the purpose of the BC Act (section 1.3), which states:

> *"The purpose of this Act is to maintain a healthy, productive and resilient environment for the greatest well-being of the community, now and into the future, consistent with the principles of ecologically sustainable development (described in section 6 (2) of the Protection of the Environment Administration Act 1991)"*

The definition of ESD described in section 6(2) of the *Protection of the Environment Administration Act 1991* (POEA Act) is outlined below.

NSW definition of ESD – POEA Act

Part 3 Objectives of the Environment Protection Authority

6 Objectives of the Authority

…

2) *For the purposes of subsection (1) (a), ecologically sustainable development requires the effective integration of social, economic and environmental considerations in decision-making processes. Ecologically sustainable development can be achieved through the implementation of the following principles and programs:*

a) *the precautionary principle—namely, that if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation. In the application of the precautionary principle, public and private decisions should be guided by:*

i) *careful evaluation to avoid, wherever practicable, serious or irreversible damage to the environment, and*

ii) *an assessment of the risk-weighted consequences of various options,*

b) *inter-generational equity—namely, that the present generation should ensure that the health, diversity and productivity of the environment are maintained or enhanced for the benefit of future generations,*

c) *conservation of biological diversity and ecological integrity—namely, that conservation of biological diversity and ecological integrity should be a fundamental consideration,*

d) *improved valuation, pricing and incentive mechanisms—namely, that environmental factors should be included in the valuation of assets and services, such as:*

i) *polluter pays—that is, those who generate pollution and waste should bear the cost of containment, avoidance or abatement,*

ii) *the users of goods and services should pay prices based on the full life cycle of costs of providing goods and services, including the use of natural resources and assets and the ultimate disposal of any waste,*

iii) *environmental goals, having been established, should be pursued in the most cost effective way, by establishing incentive structures, including market mechanisms, that enable those best placed to maximise benefits or minimise costs to develop their own solutions and responses to environmental problems*

COMPARISON OF COMMONWEALTH AND NSW DEFINITIONS

There are some differences in the descriptions of ESD outlined under the EPBC Act and POEA Act. The EPBC Act includes additional detail to the definition of the principle of social, economic and environmental considerations, whilst the POEA Act includes additional detail to the definitions of the precautionary principle and the principle of improved valuation, pricing and incentive mechanisms. Despite this, the meaning of ESD under both Acts are generally consistent, and the following sections evaluate the Plan in accordance with the requirements of both Acts.

40.2.2 OTHER REQUIREMENTS

COMMONWEALTH TERMS OF REFERENCE

The ToR require the Assessment Report to: *"…describe how the principles of ecologically sustainable development (as set out in section 3A of the EPBC Act) are considered and promoted in the development of the Plan"*.

NSW STRATEGIC ASSESSMENT GUIDELINES

The EES draft *Guidelines for planning authorities for proposing conservation measures in strategic applications for strategic biodiversity certification* (EES, 2019) require the Assessment Report to explain how the commitments and actions under the Plan responds to ESD. The guidelines state:

> *"… the conservation measures and biodiversity certification as a whole must respond to the principles of ESD with reference to section 6(2) of the Protection of the Environment Administration Act 1991 … The biodiversity certification assessment report (BCAR) will explain how the conservation measures respond to ESD, particularly including but not limited to:*
>
> - *Bioregional and State scale conservation outcomes*
> - *Maintain diversity and quality of ecosystems and enhance capacity of change for future generations*
> - *Support biodiversity in a changing climate*
> - *Support conservation and threat abatement actions to slow the rate of biodiversity loss and conserve threatened species and ecological communities in nature*
> - *Support and guide prioritised and strategic investment in biodiversity conservation outcomes*
> - *Establish a framework to avoid, minimise and offset the impacts of proposed development and land use change*
> - *Support public consultation and participation in biodiversity conservation and decision-making about biodiversity conservation"*

40.3 APPROACH TO EVALUATION OF ESD

The evaluation of the Plan against each principle is undertaken by:

- Describing what the principle means
- Setting out the available legal and policy guidance to assist interpretation of the requirements of each principle
- Evaluating the Plan in accordance with the requirements of each principle

40.4 EVALUATION OF PLAN AGAINST THE PRINCIPLES OF ESD

This section provides an evaluation of the Plan against each of the principles of ESD.

40.4.1 PRINCIPLE 1: INTEGRATION OF SOCIAL, ECONOMIC AND ENVIRONMENTAL CONSIDERATIONS

Principle 1 requires decisions to integrate economic, environmental, social and equitable considerations.

Specifically, the EPBC Act defines Principle 1 of ESD as "decision-making processes should effectively integrate both long-term and short-term economic, environmental, social and equitable considerations" (Sec 3A(a)).

Principle 1 has a similar (although less comprehensive) definition in the POEA Act (Section 6(2)).

GUIDANCE TO ASSIST INTERPRETATION OF PRINCIPLE

There are several issues associated with balancing economic, environmental and social considerations (Preston, 2016):

- Environmental, economic, social and equitable considerations are interconnected and interdependent, such that changes in one can affect the capacity to achieve the goals of others
- It may not always be appropriate to accord equal weight to economic, environmental, social and equitable considerations. Doing this assumes that ecological processes can always sustain ongoing development. However, there are thresholds at which environmental processes may deteriorate

- Ecological, economic, social and equitable objectives cannot practically be balanced in all decisions made, or for each area of land. For example, some areas may be set aside completely for environmental objectives, whereas other parcels of land may be utilised for intensive economic development

EVALUATION OF PRINCIPLE

The Plan is considered to be consistent with Principle 1 of ESD as it:

- Supports the delivery of programs and regional strategic plans that integrate economic, social and environmental considerations and objectives and address key planning challenges facing Greater Sydney
- Has been developed through processes that integrate economic, social and environmental considerations, including:
  - A strategic assessment process
  - A Structured Decision Making process
  - A cost-benefit analysis

Supports delivery of programs and plans that address key planning challenges facing Greater Sydney

The Plan is needed to support the delivery of:

- Nominated areas program and the development of major transport infrastructure that deliver key social and economic objectives identified under the Greater Sydney Region Plan and Future Transport 2056
- Several key regional planning strategies and plans for Western Sydney that integrate economic, social and environmental considerations and address key planning challenges facing Greater Sydney

The need for the Plan is set out in Chapter 6.

The nominated areas program represents the strategic prioritisation and delivery of new development as part of the long-term growth of Greater Sydney. The nominated areas are the key focus for urban development over the coming decades and will be the centres of economic and social activity in Western Sydney. Major transport infrastructure is planned to be delivered to respond to the economic and social needs of Western Sydney over the next 40 years. This Plan includes key transport corridors that will generate economic activity and support employment opportunities in Western Sydney.

The key regional planning strategies and plans that the Plan supports the delivery of include:

- Western Sydney City Deal
- Greater Sydney Region Plan
- Western City District Plan
- NSW Koala Strategy in Western Sydney

These strategies and plans are the NSW Governments response to address several key economic, social and environmental planning challenges facing Greater Sydney, including:

- Population growth and housing needs, including housing affordability and choice
- Job opportunities
- Access to transport
- Protecting the natural environment and amenity

By supporting the delivery of programs and regional strategic, the Plan is supporting a planning process that integrates economic, social and environmental considerations and is addressing key planning challenges facing Greater Sydney.

Developed through processes that integrate economic, social and environmental considerations

The Plan was developed through three main processes that ensured economic, social and environmental considerations were effectively integrated in decisions relating to the Plan:

- A Structured Decision Making process
- A cost-benefit analysis

Furthermore, the Plan was developed through a strategic assessment process. Environmental impact assessment processes such as strategic assessments are a well-recognised mechanism to incorporate environmental considerations alongside economic, social and equitable considerations into policies, plans and programs (Preston, 2016). The strategic assessment processes is discussed further below under section 40.4.4.

Structured Decision Making

The Department applied a structured decision-making process during early development of the Plan to define a high-level biodiversity outcome for the Cumberland subregion that set the context and direction for the development of the Plan. The structured decision-making process provides a systematic method to identify and compare a range of conservation options available to the NSW Government, taking into account social, economic and environmental considerations.

The structured decision-making process is described in Chapter 6.

The key decision for the structured decision-making work integrated social, economic and environmental considerations, and was:

> *"What is the optimal biodiversity outcome for Western Sydney that will enable planned and existing development (including both in and beyond the nominated areas in the Cumberland Plain) to proceed in an affordable and sustainable way?"*

The process found that the best approach to achieving the optimal biodiversity outcome while balancing economic and social considerations is to apply a broad mix of commitments and actions to maximise the biodiversity values that are protected, maximise certainty of delivery and alleviate the pressure on offset supply and demand. This includes:

- Securing one or more new national parks in the Plan Area
- Investing in biodiversity stewardship in the best remaining vegetation in the Plan Area
- Restoring key parts of the landscape within the Plan Area
- Providing dedicated funding for a set of actions to protect Koalas
- Investing a smaller proportion of the funding on biodiversity stewardship outside the Plan Area, within the allowable variation rules under the BC Regulation

This mix of approaches is reflected in the conservation program for the Plan (see Chapter 8).

Cost-benefit analysis

In developing the Plan, the Department commissioned UTS (UTS Institute for Sustainable Futures, 2019) to undertake an indicative social cost-benefit analysis of two potential conservation scenarios under the Plan. The aim of the analysis was to assess whether the scenarios would bring net positive social and economic outcomes for Western Sydney.

A quantitative model was developed to undertake the analysis. The analysis assessed two potential conservation scenarios under the Plan against a base case that assumed ongoing site-by-site assessment and approval of development in Western Sydney through NSW Biodiversity Offsets Scheme (BOS) under the BC Act.

The two potential conservation scenarios reflected the wider array of conservation measures available through the strategic conservation planning option under the BC Act, including:

- Extensions or additions to the reserve system
- Private land conservation secured through Biodiversity Stewardship Agreements
- Restoration of degraded sites, incorporating landscape management
- Threat management measures, including pest and weed management

The results of the analysis indicated that the two potential conservation scenarios under the Plan would bring net positive outcomes for Western Sydney and would be a viable approach for the NSW Government to achieve the dual goals of delivering biodiversity outcomes and facilitating housing supply to support social and economic outcomes.

40.4.2 PRINCIPLE 2: PRECAUTIONARY PRINCIPLE

Principle 2 is articulated in Section 3A(b) of EPBC Act as: "if there are threats of serious or irreversible environmental damage, lack of full scientific certainty should not be used as a reason for postponing measures to prevent environmental degradation".

The POEA Act, (Section 6(2)(a)) further articulates how the precautionary principle should be interpreted by decision-makers, which applies in the administration of the BC Act:

> *"in the application of the precautionary principle, public and private decisions should be guided by:*
>
> *i. careful evaluation to avoid, wherever practicable, serious or irreversible damage to the environment, and*
>
> *ii. an assessment of risk-weighted consequences of various options."*

DEFINITION OF SERIOUS AND IRREVERSIBLE ENVIRONMENTAL DAMAGE

Definition under BC Act

Serious and irreversible impacts (SAII) have been specifically defined in NSW under 6.7(2) of the BC Regulation as:

> *An impact is to be regarded as serious and irreversible if it is likely to contribute significantly to the risk of a threatened species or ecological community becoming extinct because:*
>
> *(a) it will cause a further decline of the species or ecological community that is currently observed, estimated, inferred or reasonably suspected to be in a rapid rate of decline, or*
>
> *(b) it will further reduce the population size of the species or ecological community that is currently observed, estimated, inferred or reasonably suspected to have a very small population size, or*
>
> *(c) it is an impact on the habitat of the species or ecological community that is currently observed, estimated, inferred or reasonably suspected to have a very limited geographic distribution, or*
>
> *(d) the impacted species or ecological community is unlikely to respond to measures to improve its habitat and vegetation integrity and therefore its members are not replaceable.*

NSW Environment Energy and Science (EES) has developed further guidance for decision-makers on how to apply the principles to NSW-listed Threatened Ecological Communities (TECs) and species (DPIE, 2019). These guidelines identify a list of matters that may be subject to SAII – these matters are called 'SAII entities'. Table 40-1 identifies the relevant SAII entities that may be impacted by the Plan.

Under the BC Act, the consent authority (for the Plan, this is the NSW environment minister) makes the determination regarding SAII, based on:

- BC Regulation principles
- SAII guidance (DPIE, 2019) and the list of potential SAII entities
- Extent of the remaining impact after measures to avoid or mitigate have been taken

An assessment of the impacts of the development on NSW-listed SAII entities is provided in Chapter 25.

Definition under EPBC Act

Section 5.2(3) of the ToR requires that the evaluation of the overall outcomes of the Plan must consider whether there will be SAII on any protected matter.

SAII are not specifically defined at a Commonwealth level. For the purpose of this assessment, where a NSW-listed matter was also Commonwealth-listed Category 1 matter, it was also considered to be an SAII entity potentially subject to serious and irreversible impacts. However, seven Commonwealth-listed matters are not NSW-listed and so have not been considered in terms of the principles under 6.7(2) of the BC Regulation. These matters are:

- Red Knot (Endangered, migratory shorebird)
- Curlew Sandpiper (Critically Endangered, migratory shorebird)
- White-throated Needletail (Vulnerable)

- Bar-tailed Godwit (Vulnerable, migratory shorebird)
- Macquarie Perch (Endangered)
- Eastern Curlew (Critically Endangered, migratory shorebird)
- Greater Glider (Vulnerable)

The impacts of the Plan on these matters have been assessed in Chapter 32 (for migratory species) and Chapter 30 (for White-throated Needletail, Macquarie Perch, and Greater Glider). The risk of impacts to these species due to development under the Plan is considered to be negligible or low and therefore these species are not considered to be potentially subject to serious and irreversible impacts under the Plan.

WHEN AND HOW IS THE PRECAUTIONARY PRINCIPLE REQUIRED TO BE IMPLEMENTED?

Principle 2 is required to be applied when two conditions are met (Preston, 2017):

- There is a threat of SAII to the environment
- There is scientific uncertainty as to the environmental damage associated with the threat

Where both these conditions are met, the decision-maker must:

- Assume there will be impacts to the environment
- Put in place avoidance, mitigation and offset measures to manage these impacts

It is possible that SAII may be predicted to occur with a high degree of certainty as a result of a proposal. This may occur where systems are well understood, and causal links can be established with confidence. In these situations, Principle 2 is not triggered, as significant uncertainty is not present (Preston, 2017). While measures will still need to be taken to avoid and minimise damage in these cases, these measures are considered to be 'preventative' measures rather than 'precautionary' measures applied under the precautionary principle (Preston, 2017).

EVALUATION OF PRINCIPLE

The Plan is considered to be consistent with Principle 2 as the Plan or this Assessment Report:

- Identifies matters potentially subject to SAII entities
- Takes steps to avoid impacts to SAII entities to reduce the threat of SAII
- Considers the nature and extent of the threat of SAII by assessing the residual impacts to SAII entities
- For matters where there is some scientific uncertainty around residual impacts, assumes that impacts will occur and puts in place mitigation and offset measures to manage these impacts

Matters potentially subject to serious and irreversible impacts

Table 40-1 identifies the NSW and Commonwealth-listed SAII entities that may be subject to serious and irreversible impacts and that are potentially impacted by the development under the Plan. NSW-listed SAII entities are assessed in Chapter 25 and Commonwealth listed SAII entities are assessed in Chapters 29 to 31.

Table 40-1: NSW and Commonwealth matters that may be subject to serious and irreversible impacts

SAII entities
• Cooks River/Castlereagh Ironbark Forest (NSW/Cth) • Cumberland Plain Woodland (NSW)/ Cumberland Plain Shale Woodlands and Shale-Gravel Transition forest (Cth) • Shale Sandstone Transition Forest (NSW/Cth) • *Allocasuarina glareicola* (NSW/Cth) • *Hibbertia fumana* (NSW) • *Micromyrtus minutiflora* (NSW/Cth) • Large-eared Pied Bat (NSW/Cth) • Green and Golden Bell Frog (NSW/Cth)

SAII entities
• Three raptors; White-bellied Sea-Eagle, Little Eagle and Square-tailed Kite (NSW) • Red-crowned Toadlet (NSW)

Steps taken to avoid serious and irreversible impacts

The Department and Transport for NSW have undertaken a strategic planning process to locate and design the urban capable lands of the nominated areas and transport corridors to avoid and minimise impacts on biodiversity values. The highest priority for avoidance was critically endangered TECs and species, including SAII entities.

The steps taken to avoid and minimise impacts to biodiversity values is set out in Chapter 14. An evaluation of avoidance outcomes for NSW SAII entities is provided in Chapter 25 and for Commonwealth listed TECs and species in Chapters 29 to 31.

Assessment of threat of serious and irreversible impacts

An assessment of the nature and extent of the residual threat of serious and irreversible impacts on NSW SAII entities is provided in Chapter 25 and Commonwealth listed TECs and species is provided in Chapters 29 to 31.

For some NSW and Commonwealth matters potentially subject to SAII, the nature and extent of impacts cannot be predicted with a high degree of certainty. These matters are identified in Table 40-2. For these matters, the precautionary principle is triggered.

Table 40-2: NSW and Commonwealth TECs and species that trigger the precautionary principle

Matter	Reason for uncertainty
Allocasuarina glariecola	Some uncertainty about presence within urban capable land and the transport corridors
Hibbertia fumana	
Hibbertia puberula	
Micromyrtus minutiflora	
Green and Golden Bell Frog	
Raptors - White-bellied Sea-Eagle, Little Eagle and Square-tailed Kite	Some uncertainty about presence within urban capable land and the transport corridors
Koala	Some uncertainty about the nature and extent of the impacts, including the importance of various movement corridors and risks of indirect impacts

For the other SAII entities, impacts can be predicted to a relatively high degree of certainty because:

- Knowledge about presence of the TEC or species is relatively certain
- Nature and extent of the impacts are relatively well understood, including because the risk of impacts is clearly very low, or because the impacts can be relatively easily predicted

Although the precautionary principle is not triggered for these matters, a range of 'preventative' measures relevant to these matters will be implemented under the Plan to offset and mitigate the impacts of the development (see Chapter 25 for NSW SAII entities and Chapters 29 to 31 for Commonwealth listed TECs and species).

Mitigation of impacts where there is scientific uncertainty

For the SAII entities in Table 40-2, the Plan assumes that the potential impacts of the development under the Plan will occur and puts in place commitments and mitigation measures that mitigate and offset these impacts (see Chapter 25 for NSW SAII entities and Chapters 29 to 31 for Commonwealth listed TECs and species). This is consistent with the precautionary principle and is expected to adequately reduce the risk of impacts to these matters to an acceptable level.

40.4.3 PRINCIPLE 3: INTERGENERATIONAL AND INTRAGENERATIONAL EQUITY

Principle 3 is articulated in Section 3A(c) of EPBC Act as: "The present generation should ensure that the health, diversity and productivity of the environment is maintained or enhanced for the benefit of future generations".

The POEA Act provides the same definition for Principle 3.

GUIDANCE TO ASSIST INTERPRETATION OF PRINCIPLE

Principle 3 contains two key elements (Preston, 2016):

- Intergenerational equity – this relates to equity between current and future generations
- Intragenerational equity – this relates to equity within current generations

There are three sub-principles that inform the basis of intergenerational and intragenerational equity (Preston, 2016):

- Conservation of options – this provides that each generation should conserve the diversity and robustness of the resource base to ensure future generations have the same access to alternatives and options when solving problems
- Conservation of quality – this provides that the quality of natural and cultural environments should be maintained, so they are passed on in the same or better condition than they were received
- Conservation of access – this provides that each generation has the right to reasonable and equitable access to natural and cultural resources to improve their own social and economic wellbeing

EVALUATION OF PRINCIPLE

The Plan is considered to be consistent with Principle 3 of ESD as it conserves alternatives and options in relation to environmental resources, maintains the quality of natural and cultural environments, and conserves access to natural and cultural resources by establishing a conservation program (see Chapter 8 for details) that:

- Avoids and minimises impacts on high biodiversity value areas
- Mitigates indirect and prescribed impacts
- Conserves flora and fauna and associated habitat
- Manages landscape threats
- Builds knowledge and research to improve management of biodiversity

The purpose of the conservation program is to achieve the Plan's objective and conservation outcomes, and offset the impacts of the development on biodiversity values. The conservation program has been designed to maximise ecological function and resilience at the landscape scale in the Cumberland subregion.

The key focus of the conservation program (comprising 90 per cent of the program funding) is conserving 5,475 ha of flora and fauna and associated habitat in perpetuity by securing strategic conservation areas in the Cumberland subregion.

The outcomes of the conservation program are evaluated in Chapter 41. The evaluation suggests the Plan is consistent with Principle 3, as it will substantially increase the protection of high value biodiversity areas in the Cumberland subregion in perpetuity and therefore contribute to conserving the diversity and robustness of the resource base and maintaining the quality of natural environments in the subregion.

The Plan is proposing to establish a number of new reserves as part of the conservation program. These include the Georges River Koala Reserve, the Gulguer Reserve Investigation Area, and Confluence Reserve Investigation Area. Other areas within the SCAs have also been identified for further investigation as future reserves to provide greater landscape connectivity, such as the Bargo area.

Reserves provide the highest level of in-perpetuity biodiversity protection and a range of social benefits, such as enabling public access to natural areas and open space. This is consistent with Principle 3, because it provides increased opportunities for residents of Western Sydney to access natural resources and improve social wellbeing.

The conservation program also includes several other commitments that are consistent with Principle 3, including:

- Provide opportunities for the residents of Western Sydney to participate in biodiversity conservation

- Provide opportunities for Aboriginal communities of Western Sydney to participate in biodiversity conservation and related economic opportunities arising from the Plan

As part of developing the Plan, a 'trend analysis' was undertaken to model long-term changes in native vegetation extent and condition across the Cumberland subregion (see Supporting Document D).

The modelling examined various scenarios that approximate the development impacts of the nominated areas and the benefits of the conservation areas under the Plan. The analysis suggests generally that:

- Existing landscape scale threats across the Cumberland subregion, such as weed invasion, illegal activities, rubbish dumping, disturbance from recreational activities, are causing substantial declines
- The conservation areas to be established under the Plan have the potential to compensate for the impacts of the nominated areas and contribute to addressing the decline of native vegetation from existing landscape scale threats
- High intensity restoration of native vegetation provides significant potential for conservation outcomes

The trend analysis further suggests that the Plan is consistent with Principle 3 as it is likely to contribute to maintaining the health, diversity and productivity of the Cumberland subregion for future generations.

It is important to note that this Plan does not cover cultural resources other than areas of biodiversity value and matters of national environmental significance such as World Heritage and National Heritage sites. Other cultural resources, such as archaeological, built, and Aboriginal cultural heritage are regulated in NSW under other legislation and are subject to separate assessment and approval processes that are not part of this Plan (see Chapter 1).

40.4.4 PRINCIPLE 4: CONSERVATION OF BIODIVERSITY AND ECOLOGICAL INTEGRITY

Principle 4 is articulated in Section 3A(d) of EPBC Act as: *the conservation of biological diversity and ecological integrity should be a fundamental consideration in decision-making*.

The POEA Act provides the same definition for Principle 4.

GUIDANCE TO ASSIST INTERPRETATION OF PRINCIPLE

Section 528 of the EPBC Act provides the following definition of biodiversity:

> *Biodiversity means the variability among living organisms from all sources (including terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part) and includes:*
>
> *a) diversity within species and between species; and*
>
> *b) diversity of ecosystems.*

The Biodiversity Indicator Program for NSW (OEH, 2019b) defines ecological integrity as:

> *Ecological integrity is about maintaining the diversity and quality of ecosystems and enhancing their capacity to adapt to change and provide for the needs of future generations. It covers the extent, condition and connectivity of habitats; the effectiveness of on-ground conservation actions; and how well ecosystems respond to change, including climate change…*

As Commonwealth and NSW legislation articulates that Principle 4 should be a 'fundamental consideration' in decision making, courts have recognised that Principle 4 is one to which "significant weight should be assigned" (Preston, 2016). Although it is recognised that priority is to be given to the conservation of biodiversity and ecological integrity, this does not mean that a project must be refused if it is likely to impact on these matters (Preston, 2016).

EVALUATION OF PRINCIPLE

The Plan is considered to be consistent with Principle 4 of ESD as it:

- Has a conservation objective and strong conservation outcomes and establishes a comprehensive conservation program that is designed to achieve this objective and outcomes
- Has been developed through a strategic assessment process that ensured biodiversity was given fundamental consideration in decisions relating to the Plan

It is also important to note that the legislation regulating approval of the Plan requires decision-makers to provide significant consideration to biodiversity. For example:

- Under the BC Act, the NSW Environment Minister must be satisfied that the 'approved draft conservation measures' under the biodiversity certification adequately address the likely impacts on biodiversity values
- Under the EPBC Act, the Commonwealth Environment Minister can only approve the taking of actions in accordance with the endorsed Plan subject to a range of constraints on decision-making, including to not act inconsistently with a recovery plan or threat abatement plan for a protected matter (s 146K)

Conservation objective and conservation program

The Plan includes a conservation objective to "deliver biodiversity outcomes and support the ecological function of the Cumberland Plain" and strong conservation outcomes related to maintaining and enhancing biodiversity and other environmental values in the Cumberland subregion (see Chapter 8).

As described in section 40.4.3, the Plan establishes a conservation program to deliver this objective and these conservation outcomes. The outcomes of the conservation program are evaluated in Chapter 41.

The evaluation concludes that the Plan will:

- Avoid substantial areas of high biodiversity value and SAII entities
- Adequately offset the impacts of the development on biodiversity values
- Protect significant areas of high biodiversity value in the Cumberland subregion that are likely to maintain and enhance ecological function and processes, such as habitat connectivity
- Has the potential to contribute to addressing the decline of native vegetation from existing landscape scale threats

The evaluation suggests that biodiversity has been given fundamental consideration in decisions relating to the Plan, as the Plan will deliver substantial conservation outcomes for the Cumberland subregion.

Strategic assessment

The development of the Plan was informed by a strategic assessment process that ensured biodiversity was given fundamental consideration in decisions relating to the Plan.

A strategic assessment process provides an improved mechanism to address key landscape-scale conservation challenges over a site-by-site assessment and approval process. Strategic assessments can have the following benefits:

- Enable effort to be focused on the highest biodiversity value areas of the landscape
- Address ecological function and landscape-scale ecological processes, such as habitat connectivity
- Manage threats at a landscape scale that can maximise benefits to multiple species
- Be designed and implemented strategically, such as by consolidating offsets into large and more viable patches
- Be implemented ahead of impacts occurring from development, to help reverse any trend of decline

The strategic assessment process substantially informed the conservation program under the Plan by:

- Providing a comprehensive information base on biodiversity values to inform the development of the Plan
- Identifying key risks to biodiversity values from the impacts of the development
- Informing avoidance, mitigation and offset measures needed to adequately manage and offset impacts
- Informing conservation priorities, including offset priorities and targets

40.4.5 PRINCIPLE 5: VALUATION, PRICING AND INCENTIVE MECHANISMS

Principle 5 is articulated in Section 3A(e) of EPBC Act as: *improved valuation, pricing and incentive mechanisms should be promoted*.

The POEA Act (Section 6(2)(d)) further articulates how Principle 5 should be interpreted by decision-makers:

> *improved valuation, pricing and incentive mechanisms—namely, that environmental factors should be included in the valuation of assets and services, such as:*

i. *polluter pays—that is, those who generate pollution and waste should bear the cost of containment, avoidance or abatement,*

ii. *the users of goods and services should pay prices based on the full life cycle of costs of providing goods and services, including the use of natural resources and assets and the ultimate disposal of any waste,*

iii. *environmental goals, having been established, should be pursued in the most cost effective way, by establishing incentive structures, including market mechanisms, that enable those best placed to maximise benefits or minimise costs to develop their own solutions and responses to environmental problems.*

Preston (2016) notes that Principle 5 is designed to account for environmental damage caused by market failure. Market failure occurs where the output of one entity acts as a negative input into one or more other entities without accompanying payment of compensation. Negative outputs are referred to as negative externalities.

Principle 5 emphasises the promotion of mechanisms to internalise the costs of negative externalities. The rationale for this is if the real value of environmental resources is included in the total costs for using those resources, then environmental resources will be more sustainably used and the risk of exploitation will be reduced.

GUIDANCE TO ASSIST INTERPRETATION OF PRINCIPLE

The element in relation to Principle 5 subject to most guidance relates to the 'polluter pays' principle. This principle is the best-known means for internalising external environmental costs. The principle says that those who generate pollution and waste should bear the costs of containment, avoidance or abatement (Preston, 2016).

Under this principle, the polluter should pay for the costs of (Preston, 2016):

- Preventing pollution or reducing pollution to comply with relevant laws and standards
- Preventing, controlling, abating and mitigating pollution
- Making good any environmental damage caused by pollution
- Making reparation (including compensatory damages and compensatory restoration) for irremediable injury

Evaluation of the Plan in relation to Principle 5 is based on considering whether the Plan has developed mechanisms to achieve internalisation of negative externalities associated with the development under the Plan.

EVALUATION OF PRINCIPLE

The Plan is considered to be generally consistent with Principle 5 of ESD as environmental factors have been included in the valuation of assets and services. This has been achieved through:

- Applying the polluter pays principle
- Achieving environmental goals in cost-effective ways

Polluter pays principle

The conservation program under the Plan includes commitments to:

- Avoid areas of high biodiversity value (preventing or reducing 'pollution')
- Mitigate threats (controlling, abating and mitigating 'pollution')
- Offset impacts (making good any environmental damage caused by 'pollution')

The Plan is consistent with the polluter pays principle as funding to implement the conservation program involves substantive cost-recovery from developers through a Special Infrastructure Contribution (SIC) levy.

The SIC is broadly described in Chapter 9.

The SIC generally ensures that those who generate 'pollution and waste' bear the costs of 'containment, avoidance or abatement' by largely imposing the costs of the conservation program on developers.

It is important to note that the SIC may not account for the full cost of the conservation program, with any remaining shortfall to be funded by the NSW Government. In this case, the costs of avoiding, mitigating and offsetting impacts are not borne solely by developers but rather all NSW taxpayers. This approach ensures the Plan balances environmental objectives with economic and social objectives in 'facilitating urban development in Western Sydney' (such as through supporting housing supply and reducing pressure on housing affordability).

Cost-effective environmental goals

The Plan achieves environmental goals to minimise the costs of development and maximise benefits to biodiversity by:

- Using a strategic assessment process to assess and approve the Plan
- Using an existing market-based mechanism to help deliver the conservation program
- Identifying priority conservation areas to maximise benefits to biodiversity at least cost

Strategic assessment process

Strategic assessments provide a cost-effective mechanism to assess and seek approval for development. Access Economics undertook a cost-benefit analysis of seven strategic assessments based on net present value (NPV) over a 30-year period (2010-11 to 2039-40), comparing site-by-site assessment processes with the alternative strategic assessment process. The analysis (Access Economics, 2011) found that strategic assessments provide a net benefit of:

- $4.5 million for the Australian Government
- $0.57 million for State governments
- $5.92 billion for developers, reflecting the commercial benefits from reducing uncertainty, risk and delays

Across all entities, the NPV of the net benefit for the seven programs was estimated as $5.93 billion.

The cost benefit analysis undertaken for the Plan (UTS Institute for Sustainable Futures, 2019) also indicated that the two potential conservation scenarios under the Plan would bring net positive social and economic outcomes for Western Sydney when assessed against the base case of site-by-site assessments.

Use of market-based mechanisms

The Plan uses an existing market-based mechanism under the BC Act, the Biodiversity Offsets Scheme, to deliver a substantial part of the conservation program through Biodiversity Stewardship Agreements (BSAs).

BSAs are voluntary cooperative agreements between a private landholder and the NSW Government. BSAs are registered on the title of a property to provide in-perpetuity protection of biodiversity values. Landholders are responsible to ongoing management of the land using funding provided by the NSW Government. The Biodiversity Conservation Trust (BCT) will be responsible for the delivery and management of BSAs under the Plan.

By using the Biodiversity Offsets Scheme, the Plan ensures efficient delivery of conservation areas because:

- Land is not required to be purchased – land purchase is very expensive in Western Sydney
- The process is competitive – the BCT is more likely to enter into agreements with landholders who can deliver conservation outcomes at the least cost (where other factors are equal)
- BSAs are voluntary, meaning that only willing landholders, who may be more likely to deliver conservation outcomes effectively, will participate in the process and enter agreements with the BCT

Identifying priority conservation areas to maximise benefits

The Department developed a Conservation Priorities Method that was used to identify SCAs within which conservation areas will be secured under the Plan. The method is summarised in Chapter 8.

The priorities method combines spatial information about biodiversity values with an analysis of constraints and opportunities to identify an optimal mix of potential conservation areas to offset the impacts of the development. It builds strategic conservation planning in the Cumberland subregion over the last decade, including the Cumberland Plain Recovery Plan (DECCW, 2011) and Biodiversity Investment Opportunities Map (OEH, 2015).

Use of the method aims to ensure that the conservation areas secured under the Plan maximise biodiversity benefits for a given cost of implementing the conservation program. SCAs represent the areas in the Cumberland subregion containing habitat for biodiversity values impacted by the development that are considered most likely to be viable in the long-term and maximise ecological function and connectivity across the landscape.

41 Evaluation of the adequacy of the Plan

This Chapter:

- Identifies evaluation themes consistent with the regulatory requirements of the BC Act and EPBC Act
- Sets out the approach and assumptions involved in the evaluation
- Evaluates the adequacy and acceptability of the Plan against each theme
- Provides an overall conclusion about the adequacy and acceptability of the Plan

41.1 EVALUATION THEMES

The evaluation has been undertaken on the basis of a set of themes that are drawn from the 'draft guidelines for planning authorities' (EES, 2019) relevant to the BC Act and the ToR relevant to the EPBC Act (see Chapter 39).

The requirements of the 'draft guidelines for planning authorities' (EES, 2019) and ToR are similar or overlap in some cases. Where requirements are similar, they have been grouped and addressed together as a theme for this evaluation.

Table 41-1 identifies the requirements and how they have been grouped and addressed together.

Table 41-1: Summary of requirements and theme groupings for evaluating the adequacy of commitments in the Plan

Theme	**NSW requirements** ('draft guidelines for planning authorities')	**Commonwealth requirements (ToR)**
Theme 1: *Are serious and irreversible impacts avoided and minimised?*	SAII are avoided and minimised (Principle 1)	Whether there will be SAII on any protected matter (ToR, section 5.2(3))
Theme 2: *Do the commitments address the values being impacted?*	Commitments address the biodiversity values being impacted (Principle 2)	Extent to which commitments involving offsets meet the principles of the EPBC Environmental Offsets Policy, 2012 (ToR, section 4.6(3))
		Extent to which protected matters are represented in areas to be protected through the commitments or in existing protected areas (ToR, section 5.2(1))
Theme 3: *Do the commitments address the most important values?*	Commitments prioritise preservation of important conservation values (Principle 3)	-
Theme 4: *Do the commitments improve values and ecological function in the long-term?*	Commitments improve biodiversity values and ecological function in the long-term (Principle 4)	Extent to which the Plan maintains and improves landscape connectivity (ToR, section 4.6(4))
		Extent to which the areas to be protected through the commitments or existing protected areas ensure long-term viability of protected matters (ToR, section 5.2(2))

Theme	**NSW requirements** ('draft guidelines for planning authorities')	Commonwealth requirements (ToR)
Theme 5: *Are the commitments additional to existing requirements?*	Commitments are additional to existing requirements (Principle 5)	-
Theme 6: *Do development controls proposed as commitments conserve the environment?*	Development controls proposed as commitments conserve the environment (Principle 6)	-
Theme 7: *Are proposed new national parks consistent with the CAR reserve framework?*	Any proposed new national parks are consistent with the CAR reserve framework (Principle 7)	-
Theme 8: *Will the Plan be effectively implemented and will outcomes be certain?*	Delivery of commitments is timely and certain (Principle 8)	Extent to which the commitments are enforceable and achievable over the life of the Plan (Agreement, clause 8.2)
		Adequacy of the commitments in protecting protected matters, including the effectiveness of implementation and funding arrangements (ToR, section 4.6(2))
		Likely effectiveness of the commitments in protecting and managing protected matters (ToR, section 5.3(2))
		Key uncertainties and risks associated with implementing the Plan, including implementation effectiveness and capacity (ToR, section 6.1(4))
		Adequacy of the adaptive approach to implementation of the Plan (ToR, section 6.2)
		Adequacy of monitoring, reporting, review and auditing of the Plan (ToR, section 7.1)
Theme 9: *Does the Plan facilitate adaptation to climate change?*	-	Extent to which the Plan has considered adaptation to climate change (ToR, section 4.6(5))
		Extent to which the commitments facilitate adaptation of biodiversity to climate change (ToR, section 5.3(1))

41.2 APPROACH TO EVALUATION OF OVERALL ADEQUACY

The evaluation involved an analysis of the commitments and actions (including the implementation arrangements) under the Plan against each of the key themes identified in Table 41-1.

For each theme, the evaluation:

- Describes the context and method used to undertake the evaluation
- Provides an analysis of the theme
- Provides a conclusion in relation to the theme

41.3 ASSUMPTIONS AND LIMITATIONS

There are several assumptions and limitations of the analysis. The key ones are:

- The evaluation of themes was often based on biodiversity values contained in SCAs. Not all land within the SCAs will be secured for conservation. However, as the location and boundaries of conservation lands are not yet final due to the large scale of the Plan Area and the voluntary mechanisms proposed to secure conservation lands under the Plan, the analysis of SCAs is a feasible and appropriate approach for evaluating the themes
- Surveys have not been done within the SCAs – biodiversity values are based on broad scale mapping of TECs and species habitat, or existing native vegetation (PCT) maps for NSW matters that are not also Commonwealth matters
- BAM plot data has not been collected within the SCAs – calculations for theme 2 were based on BAM plot data within the nominated areas and the assumption that these represent the data in the SCAs
- The general limitations with the data used in the Assessment Report as described in Chapter 13

41.4 THEME 1: ARE SERIOUS AND IRREVERSIBLE IMPACTS AVOIDED AND MINIMISED?

41.4.1 CONTEXT AND METHOD

The ToR requires the Assessment Report to show how impacts to protected matters are avoided. The Plan must therefore demonstrate that suitable avoidance has taken place to minimise biodiversity impacts to protected matters.

Furthermore, the 'draft guidelines for planning authorities' (EES, 2019) (Principle 1) also requires that the Plan specifically avoid and minimise serious and irreversible impacts (SAII).

The steps taken and future processes to be implemented under the Plan to avoid and minimise impacts on biodiversity values are described in Chapter 14. This chapter also summarises overall avoidance outcomes for biodiversity values under the Plan. Avoidance outcomes for NSW-listed SAII entities are provided in Chapter 25, and for each Commonwealth listed species and TEC, in Chapters 29 to 31.

This section summarises these avoidance processes and outcomes, particularly in relation to SAII.

41.4.2 ANALYSIS

AVOIDANCE RELATING TO URBAN, INDUSTRIAL, AND INFRASTRUCTURE DEVELOPMENT

<u>Steps taken to avoid biodiversity values</u>

The Department has undertaken a strategic planning process to design and locate the urban capable lands within the nominated areas. Consistent with section 8.1.1.2 of the BAM, the process was iterative and began early in the assessment process before the final data on biodiversity values was completed. The process involved three phases:

- Strategic planning to locate the nominated areas
- Initial development of footprints through Land Use and Infrastructure Implementation Plans (LUIIP)
- Iterative refinement of the footprints through development of the Plan

The process is described in detail in Chapter 14.

Commitments for avoidance

The Plan includes a commitment (Commitment 2) to avoid and minimise impacts from urban and industrial, and infrastructure development, to at least 4,315 hectares of land within the nominated areas. This includes

- Avoiding 3,670 hectares of native vegetation comprising:
  - 2,735 hectares of native vegetation because of its biodiversity value
  - 935 hectares of riparian corridors and steep land
- Avoiding specific amounts of habitat for Commonwealth and NSW listed TECs
- Limiting cumulative direct impacts from essential infrastructure within non-certified land to the Commonwealth listed Shale Sandstone Transition Forest TEC and prioritising the avoidance of impacts from this infrastructure to specific known populations of flora species and important Koala corridors (see Chapter 37)

This commitment will be delivered through several actions, including:

- Introducing a planning provision to require that the urban capable lands in the precinct plans are consistent with the areas of certified land and avoided lands identified in the Plan
- Applying environment (E2) conservation zoning to avoided lands (see below)
- Applying further planning controls through the NSW planning system if the avoidance targets are not being met

The Plan will apply environment (E2) conservation zoning to land avoided for biodiversity purposes and other purposes (riparian corridors, steep land) to strengthen the protection of avoided lands from the impacts of development. Note that avoided land will have environment (E2) conservation zoning applied except for land owned by LALCs or under claim by LALCs. LALC owned land and land under claim represents 90 ha of the 4,795 ha of avoided land.[1]

Environment zoning will be implemented through the proposed State Environmental Planning Policy (SEPP) for strategic conservation planning or the relevant place based Environmental Planning Instrument (EPI), such as the Growth Centres SEPP or the draft Aerotropolis SEPP (see Part 2).

The Plan also includes several commitments related to mitigation of indirect impacts that would lead to avoidance and minimisation of impacts on key habitat features within or adjacent to urban capable land. These include:

- Retain large trees (≥50cm DBH) during precinct planning where possible and avoid impacts to soil within the dripline of these trees during construction
- Retain areas of high density proteaceae shrubs where possible, particularly along riparian corridors
- If Green and Golden Bell Frog is confirmed present along Ropes Creek, consult with land managers of the riparian corridor to ensure key habitat features are protected and enhanced

Avoidance outcomes

The planning process to avoid and minimise impacts has led to substantial avoidance outcomes for native vegetation, TECs, species habitats, and habitat connectivity.

Urban capable land has generally avoided the vast majority of native vegetation and key areas of high biodiversity values, including NSW and Commonwealth-listed TECs, species habitats, important populations and habitat connectivity. Within the nominated areas, total avoidance (not including excluded lands) includes:

- Approximately 67.2 per cent of all native vegetation, including 95.2 per cent of high (intact) condition native vegetation

[1] The total area of avoided land at the start of the Plan is 4,795 hectares. The avoidance target of 4,315 hectares has reduced this figure by 10% to allow for potential future development of essential infrastructure in non-certified land

- Approximately 87.5 per cent of critically endangered and endangered Commonwealth-listed TECs and 71.7 per cent of critically endangered and endangered NSW-listed TECs
- An average of 77.8 per cent of potential habitat for three species with a very high biodiversity risk weighting (>3), and an average of 78.6 per cent of potential habitat for 31 species with a high biodiversity risk weighting (≥2)
- Of 14 species with important populations identified outside excluded land, 12 have important populations represented (either wholly or partially) on land avoided for biodiversity purposes
- Approximately 88.3 per cent of Bio Map core areas and 86.0 per cent of Bio Map corridors

Note that these figures include the amount of land 'avoided' for other purposes and not just biodiversity purposes (i.e. the figures include land that is not suitable for urban development because it is steep land or riparian corridors).

It is considered these avoidance outcomes are adequate and generally consistent with the guidance under the BAM and requirements of the ToR. Furthermore, commitments under the Plan ensure:

- The amount of avoidance to be achieved is clear and transparent
- Precinct planning proceeds in a way that ensures avoided lands are clearly identified and avoided
- The protection of avoided lands from the impacts of development is strengthened through environmental zoning

AVOIDANCE RELATING TO THE TRANSPORT CORRIDORS

Steps taken to avoid biodiversity values

Avoidance and minimisation of impacts from the transport corridors is being undertaken in two stages:

- Processes to locate the transport corridors, which has already been undertaken
- Detailed design of the footprints within the transport corridors for each transport project to further avoid and minimise impacts – this will be undertaken through future environmental impact assessments for each transport project under NSW planning and assessment laws (see Chapter 7)

The process to locate the transport corridors is described in Chapter 14.

Commitments for avoidance

The transport corridors included in the Plan have not completed the process to avoid and minimise impacts to biodiversity values as the alignments of the transport projects within each corridor are not currently certain (see Part 2).

The Plan includes commitments for further avoidance and minimisation of impacts to biodiversity values related to the transport corridors. This will be undertaken through:

- A process of strategic planning and detailed design, which will determine the final alignment of each transport project that will generally occur within each transport corridor
- NSW environmental assessment and approval process for each project current at the time the project is brought forward (this is currently the State Significant Infrastructure approval process)

For the parts of the transport corridors within the nominated areas, the Plan commits to avoiding and minimising impacts to TECs, species and habitat (Commitment 3). This includes avoiding where possible:

- Areas of high biodiversity value (defined by the Plan's 'avoidance criteria' – see Chapter 14)
- Areas of potential habitat connectivity, particularly vegetation in riparian corridors, for specific species
- Known flora populations for specific species in specific locations

For the parts of the transport corridors outside the nominated areas, the Plan commits to avoiding and minimising impacts to species and TECs in accordance with the major infrastructure corridors class of action description and the BC Act, including the BAM (Commitment 4). This includes avoiding where possible:

- Known flora populations for specific species in specific locations
- Other specific locations of high biodiversity value

Avoidance outcomes

The commitments for future avoidance relating to the transport corridors are considered adequate to ensure the corridors avoid and minimise the risk of unacceptable impacts on biodiversity values. The commitments ensure:

- Avoidance outcomes are achieved consistent with the Plan's 'avoidance criteria' (see Chapter 14) or are assessed in assessed and determined in accordance with the BAM (for the transport corridors outside the nominated areas)
- Impacts to known key biodiversity values within the corridors are avoided and minimised where possible, including specific species and habitat, and/or specific locations of high biodiversity value
- Avoidance of biodiversity values as well as the costs of offsets is taken into account in the evaluation of the route options (e.g. multi-criteria analysis) during the planning phase of each project

AVOIDANCE RELATING TO ESSENTIAL INFRASTRUCTURE

Planning for essential infrastructure to support the nominated areas, such as water and electricity utilities, is in various stages of development, and this infrastructure may need to be located outside urban capable lands and on areas that are identified as avoided lands.

The Plan is seeking approval under the EPBC Act for certain essential infrastructure development to occur within the nominated areas outside urban capable lands (i.e. within avoided lands but not excluded lands).

Steps taken to avoid biodiversity values

The Plan specifies that:

- Every effort should be made to ensure that essential infrastructure development is limited to urban capable lands
- Where essential infrastructure occurs outside urban capable lands (i.e. within avoided lands), the development must comply with the 'Guidelines for essential infrastructure development' in Appendix A of the Plan. This includes a requirement (if necessary) to assess the biodiversity impacts of each project under the BC Act and BAM, which requires an avoid, mitigate and offset process to be applied

Commitments for avoidance

Under Commitment 2, the Plan will avoid and minimise impacts from urban, industrial and infrastructure development to at least 3,670 hectares of native vegetation on non-certified land.

As part of this, cumulative direct impacts over the life of the Plan from essential infrastructure to Shale Sandstone Transition Forest within non-certified land will be limited to no more than (Commitment 2.3):

- 20 ha in Wilton Growth Area (Wilton)
- 20 ha in Greater Macarthur Growth Area (GMAC)

Furthermore, avoidance of several known populations of flora and important Koala corridors within Wilton and GMAC will be prioritised to maintain their integrity (Commitment 2.4).

Avoidance outcomes

It is considered the Guidelines and supporting Commitment 2.3 and Commitment 2.4 will lead to acceptable avoidance outcomes for biodiversity values as they ensure:

- Avoidance outcomes are achieved consistent with the Plan
- Impacts to Shale Sandstone Transition Forest (which is widespread in avoided lands in Wilton and GMAC and has the potential to be notably impacted by essential infrastructure) are capped to 20 ha in each nominated area
- Impacts to known key biodiversity values within the corridors are avoided and minimised where possible
- The impacts of each project will be assessed under the BC Act and BAM (where triggered under the Act), which requires an avoid, mitigate and offset process to be applied to ensure avoidance outcomes are acceptable

AVOIDANCE OF SAII ENTITIES

The NSW and Commonwealth-listed SAII entities that may be subject to serious and irreversible impacts and that are potentially impacted by the development under the Plan are:

- Cooks River/Castlereagh Ironbark Forest (NSW/Cth)
- Cumberland Plain Woodland (NSW)/ Cumberland Plain Shale Woodlands and Shale-Gravel Transition forest (Cth)
- Shale Sandstone Transition Forest (NSW/Cth)
- *Allocasuarina glareicola* (NSW/Cth)
- *Hibbertia fumana* (NSW)
- *Micromyrtus minutiflora* (NSW/Cth)
- Large-eared Pied Bat (NSW/Cth)
- Green and Golden Bell Frog (NSW/Cth)
- Three raptors; White-bellied Sea-Eagle, Little Eagle and Square-tailed Kite (NSW)
- Red-crowned Toadlet (NSW)

Steps taken to avoid SAII entities

The planning process that the Department undertook to design and locate the urban capable lands within the nominated areas was also applied to SAII entities. The process gave priority to avoiding SAII entities as the criteria gave highest priority to the avoidance and minimisation of critically endangered matters (see Chapter 14).

Future avoidance processes for the transport corridors and essential infrastructure (see above) will also apply to SAII entities. Commitment 2.3 caps the cumulative direct impacts over the life of the Plan from essential infrastructure to Shale Sandstone Transition Forest to no more than 20 ha in Wilton and 20 ha in GMAC.

Avoidance outcomes for SAII entities

Table 41-2 and Table 41-3 summarise the avoidance outcomes for each SAII entity within the nominated areas (avoidance outcomes for the transport corridors outside the nominated areas and essential infrastructure in avoided lands is not identified as avoidance for these projects has not yet occurred).

Chapter 25 analyses avoidance outcomes for each SAII entity in more detail.

41.4.3 CONCLUSION

The avoidance outcome achieved through the process to design and locate the urban capable lands within the nominated areas is considered adequate and generally consistent with the guidance under the BAM and requirements of the ToR.

The avoidance process was detailed and robust and based on the best available data on biodiversity values, and achieved substantial avoidance outcomes for native vegetation, high (intact) condition native vegetation, the majority of Commonwealth-listed and NSW-listed TECs, including the most endangered TECs and potential habitat for species with a very high and high biodiversity risk weighting (>3).

As discussed for each TEC and species in Chapter 25 (SAII entities) and Chapters 29 to 31 (Commonwealth listed species and TEC), avoidance effort has generally focused on native vegetation and TECs in higher condition that are more likely to be viable in the long-term, with residual impacts from the development generally occurring to:

- Smaller patches
- Native vegetation or TECs in lower condition
- Only the edges of larger, contiguous patches associated with waterways and gullies and gorges, particularly in Wilton and GMAC, which minimises fragmentation and impacts on habitat connectivity

Despite this overall conclusion, for some SAII entities, about half or less of the TEC or potential species habitat was avoided and residual impacts remain. This includes:

- Cumberland Plain Woodland
- Cooks River/ Castlereagh Ironbark Forest

- *Allocasuarina glareicola*
- Green and Golden Bell Frog

For these TECs, the scale of impacts are relatively minor when considering the extent of these TECs across the Plan Area, and the majority of impacts are to lower viability areas. The offsets proposed by the Plan for these TECs (Commitment 8) will provide a substantial addition to the level of protection of these TECs and address key threats to the TECs identified in BioNet profiles and Conservation Advices.

For *Allocasuarina glareicola*, there are no impacts to records or important populations of the species (one important population occurs on excluded lands and will not be impacted).

While there will be direct impacts to small areas of Green and Golden Bell Frog habitat for a potential population in GPEC, it is not known whether this population still exists. Under Commitment 5, the Department will undertake surveys for this species along Ropes Creek, and if confirmed present, the Plan includes a species specific measure to consult with land managers of the riparian corridor to ensure key habitat features are protected and enhanced.

Table 41-2: Assessment of avoidance outcomes for SAII TECs within the nominated areas

SAII entity	Listing	Summary of TEC avoidance within nominated areas (without excluded lands)				Comment on avoidance outcomes within the nominated areas
		Total in nominated areas (ha)	Total avoided (ha / %)	Avoided for bio. reasons (ha / %)	Avoided for other reasons (ha / %)	
Cooks River/ Castlereagh Ironbark Forest	NSW	65 ha	27 / 43%	27 / 43%	0.2 / <1%	Between 43 - 50% of the TEC has been avoided For the NSW-listed TEC, of the 35 ha of intact condition TEC within the nominated areas (not including excluded land), the majority (19.4 ha or 55%) has been avoided (see Chapter 25) For the Commonwealth-listed TEC, of the 31 ha of intact condition TEC within the nominated areas (not including excluded land), the majority (19.4 ha or 62.6%) has been avoided (see Chapter 31)
	Cth	52 ha	26 ha / 50%	26 ha / 50%	0 ha / 0%	
Cumberland Plain Woodland	NSW	1,488 ha	474 ha / 32%	394 ha / 26%	80 ha/ 5%	Between 32 - 46% of the TEC has been avoided For the NSW-listed TEC, of the 147 ha of intact condition TEC within the nominated areas (not including excluded land), the majority (109 ha or 74%) has been avoided (see Chapter 25) For the Commonwealth-listed TEC, of the 26.8 ha of intact condition TEC within the nominated areas (not including excluded land), the majority (18.0 ha or 67.2%) has been avoided (see Chapter 31)
	Cth	204 ha	94 ha / 46%	74 ha / 36%	19 ha / 9%	
Shale Sandstone Transition Forest	NSW	2,623 ha	2,135 ha / 81%	1,865 ha / 71%	270 ha / 10%	Between 81% - 91% of the TEC has been avoided For the NSW-listed TEC, of the 1,511 ha of intact condition TEC within the nominated areas (not including excluded land), the vast majority (1,466 ha or 97%) has been avoided For the Commonwealth-listed TEC, of the 1,480 ha of intact condition and 1,379 ha of high viability TEC within the nominated areas (not including excluded land), 1,437 ha of intact condition (or 97.1%) and 1,346 ha of high viability (or 97.6%) TEC, have been avoided Furthermore, Commitment 2.3 caps the cumulative direct impacts over the life of the Plan from essential infrastructure to Shale Sandstone Transition Forest to no more than 20 ha in Wilton and GMAC
	Cth	2,138 ha	1,947 ha / 91%	1691 ha / 79%	255 ha / 12%	

Table 41-3: Assessment of avoidance outcomes for SAII species within the nominated areas

SAII entity	Summary of habitat avoidance (without excluded lands)				Comment on avoidance outcomes
	Total in nominated areas (ha)	**Total avoided (ha / %)**	**Avoided for bio. reasons (ha / %)**	**Avoided for other reasons (ha / %)**	
Allocasuarina glareicola	22 ha	10 ha / 46%	10 ha / 45%	0 ha / 0 %	About half the potential habitat has been avoided There are no impacts to records or important populations of the species (one important population occurs on excluded lands and will not be impacted).
*Chalinolobus dwyeri**	889 ha	882 ha / 99%	452 ha / 51%	429 ha / 48%	Almost all potential breeding habitat has been avoided An important population has been partially avoided. Population 424 occurs as a single important population across the Plan Area and surrounds. The majority of records lie outside of the nominated areas. Nine records occur within excluded lands and 2 records are located on avoided lands within central GMAC (see Chapter 14)
Hibbertia fumana	1,245 ha	1,207 ha / 97%	1,064 ha / 85%	143 ha / 11%	Almost all potential habitat has been avoided There are no impacts to records of the species
Litoria aurea	25 ha	11 ha / 46%	11 ha / 46%	0 ha / 0%	About half the potential habitat has been avoided. It is important to note that much of the potential habitat mapped comprises existing urban areas (houses and roads), as the mapping was done by applying a buffer to records along Ropes Creek (see Chapter 25) There will be direct impacts to habitat for a potential population in Greater Penrith to Eastern Creek Investigation Area (GPEC), although it is not known whether this population still exists If Green and Golden Bell Frog is confirmed present along Ropes Creek, the Plan includes a species specific measure to consult with land managers of the riparian corridor to ensure key habitat features are protected and enhanced
Micromyrtus minutiflora	50 ha	28 ha / 56%	28 ha / 56%	<1 ha / <1%	Over half the potential habitat has been avoided There are no impacts to records or important populations of the species (one important population occurs on excluded lands and will not be impacted).

SAII entity	Summary of habitat avoidance (without excluded lands)				Comment on avoidance outcomes
	Total in nominated areas (ha)	**Total avoided (ha / %)**	**Avoided for bio. reasons (ha / %)**	**Avoided for other reasons (ha / %)**	
*Haliaeetus leucogaster**	1,679 ha	1,661 ha / 99%	1,066 ha / 64%	596 ha / 35 %	Almost all potential breeding habitat has been avoided There are no impacts to known breeding sites (stick nests)
*Hieraaetus morphnoides**	3,026 ha	3,006 ha / 99%	2,311 ha / 76%	696 ha / 23%	
*Lophoictinia isura**	2,983 ha	2,955 ha / 99%	2,279 ha / 76%	676 ha / 23 %	
Pseudophryne australis	884	875 ha / 99%	652 ha / 74%	223 ha / 25%	Almost all potential habitat has been avoided There are no impacts to records of the species

*Impacts relate to potential breeding habitat only

41.5 THEME 2: DO THE COMMITMENTS ADDRESS THE VALUES BEING IMPACTED?

41.5.1 CONTEXT AND METHOD

NSW REQUIREMENTS

The BC Act requires an assessment of the impacts on biodiversity values of the development and the number and class of credits that would be required to be retired if the offset rules under the BC Act applied.

The Act does not require that the 'value' of commitments be calculated in terms of credits (see Section 39.1). However, the 'draft guidelines for planning authorities' (EES, 2019) specify that it should be explained how the biodiversity values that benefit from the commitments are relevant to the values impacted, and provides that commitments should aim to secure land that contains vegetation and species 'equivalent to the biodiversity values being impacted'.

The Plan includes offset targets (see Chapter 8) for each impacted NSW-listed TEC, which will be delivered within SCAs through a range of commitments, including reserves and biodiversity stewardship agreements.

The analysis of Theme 2 involved an assessment of the adequacy of the offset targets for each impacted NSW listed TEC by examining three key questions:

- Do all impacted TECs have offset targets?
- Are offset targets equivalent to the biodiversity values being impacted?
- Can the SCAs deliver the offset targets?

The question:

- 'Are the offset targets equivalent to the biodiversity values being impacted?' was addressed by undertaking an analysis of the credit requirements of the BAM
- Of whether the SCAs can deliver the offset targets was addressed by considering the available land within the SCAs for offsets and restoration actions, and the overall balance between impacts and offset availability

Both analyses used NSW TECs/PCTs as a surrogate for all biodiversity values and did not examine species outcomes in detail.

<u>Analysis of BAM credit requirements</u>

The purpose of this analysis was to examine whether the offset targets are equivalent to the biodiversity values being impacted. The analysis only covered the impacts within the nominated areas, as BAM plot data that is needed to calculate the credits required for impacts outside the nominated areas was not collected. The offset targets for this analysis were therefore reduced to only account for the nominated area impacts. The approach involved:

- Calculating the number of credits that would be required to be retired to offset the impacts per vegetation zone within the nominated areas. This was done as part of the Assessment Report in accordance with the BAM
- Estimating the number of credits generated within the SCAs per vegetation zone. As surveys of the SCAs have not been undertaken, this was done on the basis of the BAM plot data gathered in the nominated areas, which was input into the stewardship component of the BAM Calculator
- Determining the amount (ha) of each vegetation zone needed in the SCAs to meet the estimated credit requirements of the BAM and comparing this to the offset targets

There are several limitations to the analysis:

- The analysis was based on plot data collected within development lands rather than within SCAs. Plots completed within SCAs may change the results of the analysis (e.g. if high levels of African Olive is present within an offset site in the SCAs, credit generation is likely to decrease significantly)

- In estimating the number of credits potentially generated within the SCAs per vegetation zone, an assumption was made that active management would be undertaken on the offset sites to the highest standard allowed by the BAM Calculator. This is considered to be a reasonable assumption as landholders in NSW are often choosing to undertake active management at offset sites in order to generate the highest possible credits (and associated income from selling those credits). However, this may not be likely or possible on all offset sites

COMMONWEALTH REQUIREMENTS

The ToR requires an analysis of the extent to which commitments involving offsets meet the principles of the EPBC Act Environmental Offsets Policy (DSEWPC, 2012). The policy includes eight principles (see Table 41-4) and is accompanied by the EPBC offsets assessment guide (available on the DAWE website). The guide provides a 'balance sheet' approach to estimate the impacts and offsets for threatened species and ecological communities under the EPBC Act.

Offsets are defined as measures that compensate for the residual adverse impacts of an action on the environment (DSEWPC, 2012). Under the offsets policy and guide, suitable offsets must deliver an overall conservation outcome that improves or maintains the viability of the environment that is protected by national environmental law and affected by the proposed action (DSEWPC, 2012).

The analysis was undertaken by applying the EPBC offsets assessment guide to principles 1, 3 and 4 of the EPBC Act offsets policy. The other principles are addressed elsewhere in the Assessment Report as shown in Table 41-4.

Consistent with the approach used to analyse matters listed under the BC Act for this theme, the analysis of Commonwealth matters focused on EPBC Act TECs as a surrogate for biodiversity values more broadly and did not examine species outcomes in detail. The appropriateness of offsets for species are discussed in Chapters 29 and 30.

Table 41-4: Principles in the EPBC offsets policy

Principle Suitable offsets must…	Approach to analysis
1. Deliver an overall conservation outcome that improves or maintains the viability of the aspect of the environment that is protected by national environment law and affected by the development	Offsets assessment guide was applied to each Commonwealth listed TEC
2. Be built around direct offsets but may include other compensatory measures	This is described in Part 2
3. Be in proportion to the level of statutory protection that applies to the protected matter	Offsets assessment guide was applied to each Commonwealth listed TEC
4. Be of a size and scale proportionate to the residual impacts on the protected matter	Offsets assessment guide was applied to each Commonwealth listed TEC
5. Effectively account for and manage the risks of the offset not succeeding	Implementation arrangements for the conservation program under the Plan include a process to track delivery of offsets and implement an adaptive response if the delivery of offsets is not keeping pace with development impacts (see section 41.11) The Plan includes a monitoring, evaluation, reporting and improvement program (see Part 2 and section 41.11) that will monitor and evaluate the delivery of commitments and actions and the achievement of the Plan's outcomes and implement an adaptive response where necessary to ensure successfully

Principle Suitable offsets must…	Approach to analysis
	delivery of the conservation program, including offsets
6. Be additional to what is already required, determined by law or planning regulations or agreed to under other schemes or programs	This is evaluated under Theme 5
7. Be efficient, effective, timely, transparent, scientifically robust and reasonable	Implementation arrangements for the conservation program under the Plan include a process to track delivery of offsets and implement an adaptive response if the delivery of offsets is not keeping pace with development impacts (see section 41.11) The Plan includes a monitoring, evaluation, reporting and improvement program (see Part 2 and section 41.11) that will evaluate the efficiency and effectiveness of the delivery of commitments and actions, including offsets, and report on progress of delivery The method to determine the location of SCAs (the Conservation Priorities Method) where offsets will be secured was based on sound conservation planning principles and is set out in Part 2 and in Appendix D of the Plan. Confirmation of the values present at offset sites and the management of offset sites secured as BSAs under the conservation program will be undertaken in accordance with the requirements of the BAM (an agreed method underpinned by science)
8. Have transparent governance arrangements including being able to be readily measured, monitored, audited and enforced	This is evaluated under Theme 8

Applying the EPBC Act offsets assessment guide

An assessment using the offsets assessment guide was completed for the Commonwealth-listed TECs impacted by the development under the Plan, including:

- Coastal floodplain eucalypt forest of eastern Australia (FPAL)
- Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest
- Cooks River/Castlereagh Ironbark Forest
- Coastal Swamp Oak (*Casuarina glauca*) Forest
- Shale Sandstone Transition Forest

To complete the assessment the data entered into the offsets assessment guide was derived from a range of sources, most notably the plot data (and associated vegetation integrity score) captured for each vegetation zone assessed in the BAM assessment. The BAM vegetation integrity score data provides a robust data set and improves the reliability of the calculations completed within the offsets assessment guide.

Assessment of impacts

For the assessment of impacts under the offsets assessment guide (impact calculator), the impacts to each TEC (i.e. total quantum of impact) were calculated for each condition state impacted, including intact, thinned and scattered trees (where relevant). The results for each condition state were then summed to calculate a total quantum of impact for the TEC.

The data entered into the impact calculator is provided in Table 41-5 and includes:

- The status for each TEC (for Coastal floodplain eucalypt forest of eastern Australia a listing status of Endangered has been assumed)
- The area of impact for each TEC condition state consistent with the area calculated in this report
- The quality of the community entered as a score between 0 and 10. The quality data entered for each TEC condition state is based on the vegetation integrity score obtained through the application of the BAM and the associated BAM plots and vegetation integrity scores. As vegetation integrity is measure out of 100 for each TEC condition state the vegetation integrity score was divided by ten and then rounded (following standard rounding rules) to obtain a score out of 10

The total quantum of impact for each TEC condition state is also provided in Table 41-5. The highest total quantum of impact amounts relate to thinned Shale Sandstone Transition Forest and thinned Coastal floodplain eucalypt forest of eastern Australia due to the amount of clearing recorded and relatively high vegetation quality scores.

Assessment of offsets

As the exact location of offsets under the Plan is currently not known, and therefore the condition of vegetation protected is also unknown, it was not possible to conduct an assessment per condition state for the offset calculator. Therefore, a single assessment was conducted using the offset calculator for each TEC. As condition states on offset sites are likely to vary this approach is considered appropriate.

The data entered into the offset calculator is provided in Table 41-6 and includes:

- The area of proposed offset based on the targets defined under the Plan for each EPBC TEC
- A risk-related time horizon set at the maximum of 20 years and a time until ecological benefit of 10 years
- The start quality of the TEC based on the vegetation integrity score obtained through the application of the BAM and the associated BAM plots and vegetation integrity scores. As a single assessment was completed for each TEC the average vegetation integrity score calculated across the intact, thinned and scattered tree condition states was used to derive the start quality. Consistent with the impact calculator the score was divided by 10 and rounded (using standard rounding rules) to calculate a score out of 10
- The future quality (without offset) of the TEC. In all cases this was one less than the start quality calculated
- The future quality (with offset) of the TEC. To calculate the expected improvement of an offset site the BAM plot data was entered into the stewardship side of BAM credit calculator, as described in above. The improvement predicted by the BAM credit calculator was used to estimate the likely improvement of the EPBC TEC. Consistent with the impact calculator the score was divided by 10 and rounded (using standard rounding rules) to calculate a score out of 10. The analysis revealed that one EPBC TEC (Coastal floodplain eucalypt forest of eastern Australia) could achieve an average future quality (with offset) of 10/10 based on the data entered. As such a high condition level would be difficult to achieve within the Cumberland subregion this score was manually reduced to 9/10
- A risk of loss (without offset) of 20 per cent and a risk of loss (with offset) of 5 per cent
- The confidence in result for both the change in habitat quality and averted loss set to 85 per cent

Table 41-5: Attributes entered into EPBC offsets assessment guide – impact calculator

Threatened Ecological Community	Condition	EPBC Act Status	Quantum of impact (ha)	Quantum of impact (quality)	Justification	Total quantum of impact (adjusted ha)
Coastal floodplain eucalypt forest of eastern Australia*	Intact	Endangered	28.6	8 / 10	Impacts of 28.6 ha are calculated to intact condition CFEF. Average vegetation integrity of PCT 835 from BAM plots conducted in intact condition is 77/100, rounded to 8/10 for use in the EPBC offsets assessment guide	22.88
	Thinned		141.3	6 / 10	Impacts of 141.3 ha are calculated to thinned condition CFEF. Average vegetation integrity of PCT 835 from BAM plots conducted in thinned condition is 57/100, rounded to 6/10 for use in the EPBC offsets assessment guide	84.78
	Scattered trees		40.4	7 / 10	Impacts of 40.4 ha are calculated to scattered tree condition CFEF. Average vegetation integrity of PCT 835 from BAM plots conducted in scattered tree condition is 69/100, rounded to 7/10 for use in the EPBC offsets assessment guide	28.28
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest	Intact	Critically Endangered	22.6	6 / 10	Impacts of 22.5 ha are calculated to intact condition CPW. Average vegetation integrity of PCT 724, PCT 849 and PCT 850 from BAM plots conducted in intact condition is 57/100, rounded to 6/10 for use in the EPBC offsets assessment guide	13.56
	Thinned		128.1	4 / 10	Impacts of 129.9 ha are calculated to thinned condition CPW. Average vegetation integrity of PCT 724, PCT 849 and PCT 850 from BAM plots conducted in thinned condition is 43/100, rounded to 4/10 for use in the EPBC offsets assessment guide	51.24
	Scattered trees		4.1	2 / 10	Impacts of 4.0 ha are calculated to scattered tree condition CPW. Average vegetation integrity of PCT 724, PCT 849 and PCT 850 from BAM plots conducted in scattered tree condition is 24.7/100, rounded to 2/10 for use in the EPBC offsets assessment guide	0.82

Threatened Ecological Community	Condition	EPBC Act Status	Quantum of impact (ha)	Quantum of impact (quality)	Justification	Total quantum of impact (adjusted ha)
Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion	Intact	Critically Endangered	11.6	5 / 10	Impacts of 11.6 ha are calculated to intact condition CRCIF. Average vegetation integrity of PCT 725 from BAM plots conducted in intact condition is 49/100, rounded to 5/10 for use in the EPBC offsets assessment guide	5.80
	Thinned		12.9	4 / 10	Impacts of 12.9 ha are calculated to thinned condition CRCIF. Average vegetation integrity of PCT 725 from BAM plots conducted in thinned condition is 43/100, rounded to 4/10 for use in the EPBC offsets assessment guide	5.16
	Scattered trees		1.7	2 / 10	Impacts of 1.7 ha are calculated to scattered tree condition CRCIF. Average vegetation integrity of PCT 725 from BAM plots conducted in scattered tree condition is 20/100, rounded to 2/10 for use in the EPBC offsets assessment guide	0.34
Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland ecological community	Thinned	Endangered	1.7	4 / 10	Impacts of 1.3 ha are calculated to thinned condition CSOF. Average vegetation integrity of PCT 1800 from BAM plots conducted in thinned condition is 43/100, rounded to 4/10 for use in the EPBC offsets assessment guide	0.68
	Scattered trees		0.1	4 / 10	Impacts of 0.1 ha are calculated to scattered tree condition CSOF. Average vegetation integrity of PCT 1800 from BAM plots conducted in scattered tree condition is 41/100, rounded to 4/10 for use in the EPBC offsets assessment guide	0.04
Shale Sandstone Transition Forest in the Sydney Basin Bioregion	Intact	Critically Endangered	43.1	7 / 10	Impacts of 34.6 ha are calculated to intact condition SSTF. Average vegetation integrity of PCT 1395 from BAM plots conducted in intact condition is 73/100, rounded to 7/10 for use in the EPBC offsets assessment guide	30.17
	Thinned		135.7	6 / 10	Impacts of 126.7 ha are calculated to thinned condition SSTF. Average vegetation integrity of PCT 1395 from BAM plots conducted in thinned condition is 64/100, rounded to 6/10 for use in the EPBC offsets assessment guide	81.42

Threatened Ecological Community	Condition	EPBC Act Status	Quantum of impact (ha)	Quantum of impact (quality)	Justification	Total quantum of impact (adjusted ha)
	Scattered trees		13.0	3 / 10	Impacts of 13.1 ha are calculated to scattered tree condition SSTF. Average vegetation integrity of PCT 1395 from BAM plots conducted in scattered tree condition is 30/100, rounded to 3/10 for use in the EPBC offsets assessment guide	3.90

* Based on mapping for PCT 835

Table 41-6: Attributes entered into EPBC offsets assessment guide – offsets calculator

EPBC offsets assessment guide attribute	Value entered	Justification
Coastal floodplain eucalypt forest of eastern Australia*		
Time horizon – Risk-related time horizon (years)	20 years	The offset sites identified, conserved and managed under the Plan will either be dedicated as a reserve under the *National Parks and Wildlife Act 1974* or protected under a Biodiversity Stewardship Agreement (BSA). The longest possible risk-related time horizon of 20 years was therefore selected
Time horizon – Time until ecological benefit (years)	10 years	All offset sites will be funded and managed in perpetuity. The initial phase of active management is likely to lead to a reasonably rapid improvement in site condition in the short to medium term due to the implementation of up-front management activities such as fencing, weed management and supplementary planting. Over the longer term the level of improvement is likely to be more gradual as the sites enter a maintenance phase. Ten years has been entered as the time until ecological benefit as the initial phase of active management is expected to increase site condition noticeably in the short to medium term
Start area and quality - Start area (ha)	575 ha	The target committed to in the Plan for Coastal floodplain eucalypt forest of eastern Australia
Start area and quality - Start quality (scale of 0 – 10)	7 / 10	Average vegetation integrity of PCT 835 from BAM plots conducted in all condition states is 67/100, rounded to 7/10 for use in the EPBC offsets assessment guide
Future area and quality without offset – Risk of loss (%)	20%	The lands identified as potential offset sites within the SCA are generally located in western Sydney and are predominantly zoned for rural land uses. Should lands not be protected and managed as offset sites there will be an ongoing risk of loss of the biodiversity values of these lands due to ongoing agricultural practises and continued weed encroachment, grazing pressure and inappropriate access. A risk of loss of 20% is considered appropriate
Future area and quality without offset – Future quality (scale of 0 – 10)	6 / 10	If land is not protected and managed as a reserve or BSA it is highly likely that land will continue to degrade through weed encroachment, grazing pressure and inappropriate access etc. A reduction of 1/10 has been applied
Future area and quality with offset – Risk of loss (%)	5%	All offset land under the Plan will be protected as a reserve or BSA. The risk of loss is therefore considered to be low
Future area and quality with offset – Future quality (scale of 0 – 10)	9 / 10	Average vegetation integrity increase of PCT 835 from BAM plots conducted in all condition states (assuming active management is undertaken) is 26/100, rounded to 3/10 for use in the offsets assessment guide. This increase results in a future quality of 10/10 (i.e. increase from the current condition of 7/10 to 10/10). Assuming a condition of 10/10 may not be achievable in the context of the Cumberland subregion 9/10 was entered into the offsets assessment guide
Confidence in result (change in habitat quality and averted loss) (%)	85%	There is a relatively high level of confidence in the data entered into the offsets assessment guide. Much of the data entered is based on plot data collected and the calculations performed as part of the BAM. The BAM provides a scientifically robust and repeatable method to conduct biodiversity assessment. In

EPBC offsets assessment guide attribute	Value entered	Justification
		addition, offset sites are to be protected and managed through reservation or a BSA. The offset sites will be fully funded and managed through an approved management plan
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest		
Time horizon – Risk-related time horizon (years)	20 years	The offset sites identified, conserved and managed under the Plan will either be dedicated as a reserve under the *National Parks and Wildlife Act 1974* or protected under a Biodiversity Stewardship Agreement (BSA). The longest possible risk-related time horizon of 20 years was therefore selected
Time horizon – Time until ecological benefit (years)	10 years	All offset sites will be funded and managed in perpetuity. The initial phase of active management is likely to lead to a reasonably rapid improvement in site condition in the short to medium term due to the implementation of up-front management activities such as fencing, weed management and supplementary planting. Over the longer term the level of improvement is likely to be more gradual as the sites enter a maintenance phase. Ten years has been entered as the time until ecological benefit as the initial phase of active management is expected to increase site condition noticeably in the short to medium term
Start area and quality - Start area (ha)	575 ha	The target committed to in the Plan for Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest
Start area and quality - Start quality (scale of 0 – 10)	4 / 10	Average vegetation integrity of PCT 724, PCT 849 and PCT 850 from BAM plots conducted in all condition states is 42/100, rounded to 4/10 for use in the EPBC offsets assessment guide
Future area and quality without offset – Risk of loss (%)	20%	The lands identified as potential offset sites within the SCA are generally located in western Sydney and are predominantly zoned for rural land uses. Should lands not be protected and managed as offset sites there will be an ongoing risk of loss of the biodiversity values of these lands due to ongoing agricultural practises and continued weed encroachment, grazing pressure and inappropriate access. A risk of loss of 20% is considered appropriate
Future area and quality without offset – Future quality (scale of 0 – 10)	3 / 10	If land is not protected and managed as a reserve or BSA it is highly likely that land will continue to degrade through weed encroachment, grazing pressure and inappropriate access etc. A reduction of 1/10 has been applied
Future area and quality with offset – Risk of loss (%)	5%	All offset land under the Plan will be protected as a reserve or BSA. The risk of loss is therefore considered to be low
Future area and quality with offset – Future quality (scale of 0 – 10)	7 / 10	Average vegetation integrity increase of PCT 724, PCT 849 and PCT 850 from BAM plots conducted in all condition states (assuming active management is undertaken) is 33/100, rounded to 3/10 for use in the EPBC offsets assessment guide. This increase results in a future quality of 7/10 (i.e. increase from the current condition of 4/10 to 7/10)
Confidence in result (change in habitat quality and averted loss) (%)	85%	There is a relatively high level of confidence in the data entered into the EPBC offsets assessment guide. Much of the data entered is based on plot data collected and the calculations performed as part of the BAM. 41.5.2 ANALYSIS

NSW REQUIREMENTS

Do all impacted PCTs have offset targets?

Each impacted PCT has an associated offset target and therefore the commitments are addressing each value being impacted (see Table 41-8). The SCAs also contain substantial areas of each impacted PCT (see Table 41-8).

Are offset targets equivalent to the biodiversity values being impacted?

The Department developed an approach for defining offset targets to ensure that the commitments address the biodiversity values being impacted. The offset target method determined offset targets on the basis of the amount (ha) of each impacted matter, the conservation status of the impacted matter and the condition of the impacted matter.

Credit analysis

To determine whether the offset targets are equivalent to the biodiversity values being impacted, the Department undertook an analysis based on the estimated credit requirements of the BAM.

It is important to note that this analysis only took into account the impacts within the nominated areas, including the impacts from urban development and the transport corridors.

Table 41-7 shows:

- The credits required to be retired to offset the impacts of each impacted PCT within the nominated areas
- The amount of offset land (ha) needed to generate the required credits to offset the impacts on each PCT under the high intensity management scenario. The range of values shown in the table (columns 4 and 5) reflect the different amounts of credits generated at the offset site for the different condition states of each vegetation zone that is part of a PCT (e.g. based on the BAM data collected within the nominated areas, the area to offset 1 ha of impact to 725 intact condition state requires 3.5 ha of 725 scattered trees, while the amount of thinned condition 725 is 2.5 ha)
- The offset targets (these account only for impacts within the nominated areas)
- The difference (ha) between the amount of offset land needed to generate the required credits to offset the impacts on each PCT and the current offset targets

The table shows that the total offset target for PCTs (5,475 ha) is estimated to be broadly within the range required to satisfy the BAM credit requirements (between 4,698 ha and 9,820 ha). However, the offset target is at the lower end of the range, which suggests that high intensity management for a proportion of offset sites may potentially be needed to ensure the Plan satisfies the BAM credit requirements (noting this is not a requirement of the BC Act).

The offset targets are estimated to generally satisfy the minimum credit requirements of the BAM for seven of the nine impacted PCTs (including for three of the nine impacted PCTs where there is a negligible shortfall (< 6 ha)). However, the offset targets are estimated not to meet the minimum credit requirements of the BAM for two PCTs:

- PCT 835: there is an estimated shortfall of about 167.4 ha
- PCT 1395: there is an estimated shortfall of about 134.1 ha

Table 41-7: Analysis of adequacy of offset targets for impacts within the nominated areas on the basis of credits

Impacted PCTs	Area impacted (ha)	Total credits required	Minimum amount of PCT needed to generate required credits (high intensity management scenario)^ (ha)	Maximum amount of PCT needed to generate required credits (high intensity management scenario)^ (ha)	Offset target (ha)*	Difference between offset target and minimum amount of PCT needed to generate required credits (ha)
724	52.2	1218	152.3	152.3	150.0	-2.3
725	36.9	809	80.9	115.6	110.0	29.1
781	2.1	65	8.1	8.1	5.0	-3.1
830	0.1	1	0.3	0.3	0.2	-0.1
835	165.1	4939	617.4	987.8	450.0	-167.4
849	729.8	14901	1,490.1	3,725.3	2,325.0	834.9
850	284.8	5575	619.4	1,393.8	845.0	225.6
1395	487.7	13393	1,674.1	3,348.3	1,540.0	-134.1
1800	19.2	446	55.7	89.1	50.0	-5.7
Total	**1,777.8**	**41,347**	**4,698.3**	**9,820.4**	**5,475**	**776.9**

^ High intensity management scenario assumes that all offset sites are subject to ongoing and intensive conservation management

*These offset targets account for development impacts within the nominated areas only (excluding transport corridors outside the nominated areas). Also, this figure represents the target that is proposed to be met through land-based measures (90 per cent of the total offset target). The other 10 per cent of the offset target will be met through other non-land based measures, such as threat management

Can the SCAs deliver the offset targets?

This question is addressed by analysing the available land within the SCAs for offsets and restoration actions, and the overall balance between impacts and offset availability for each impacted PCT.

Table 41-8 shows the offset targets for each PCT impacted by the nominated areas and transport corridors within the nominated areas and the overall balance between offset target and offset availability within the SCAs.

The table shows that the majority of PCTs (5 of 9) have enough PCT available within the SCAs to meet the offset targets. For 4 of those 5 PCTs, there is significantly more PCT available in the SCAs than needed to meet the targets.

For the 5 PCTs with enough PCT available in the SCAs, achieving the offset targets would require an average of only 25 per cent of the total amount of each PCT available within the SCAs to be secured (i.e. the SCAs contain an average of almost four times the amount of PCT needed to meet the offset targets for these PCTs).

Three PCTs have small shortfalls in availability in the SCAs:

- PCT 724 – there is a shortfall of about 44 ha
- PCT 725 – there is a shortfall of about 19 ha
- PCT 1800 – there is a shortfall of about 35 ha

One PCT (PCT 849) has a large shortfall of about 713 ha.

Addressing the shortfall through ecological restoration

The Plan aims to largely address the offset target shortfall for these four PCTs through ecological restoration.

Table 41-8 shows an initial estimate of restoration potential in the SCAs for each PCT. This is an initial estimate only, and was made by limited ground-truthing and intersecting a map of pre-1750 native vegetation (Tozer, Turner et al., 2010) with cleared or highly degraded land to identify cleared or degraded areas where PCTs may have previously occurred. The suitability of these areas for restoration will be confirmed during implementation of the Plan, including on the basis of site investigations.

The initial estimate of restoration potential in the SCAs indicates restoration has the potential to:

- Negate the shortfall for PCTs 725 and 849 in the SCAs
- Reduce the shortfall for PCT 724 to about 29 ha (see Table 41-8)

For PCT 1800, it is important to note the mapping within the Plan Area may be inaccurate as the PCT was not mapped by some regional vegetation maps being used in this assessment, and is likely to be mapped in the Cumberland subregion as part of other PCTs.

Potential shortfall in PCT 849

While restoration may negate the offset target shortfall for PCT 849, an additional option to address any residual shortfall for the PCT is by securing the excess amount of PCT 850 in the SCAs.

PCT 849 and PCT 850 are both part of Cumberland Plain Woodland, meaning that PCT 849 may be addressed through commitments that secure PCT 850 under the offset rules under the BC Regulation. This option is likely to be feasible as the SCAs contain over 2,800 ha of surplus PCT 850 (after the offset target for PCT 850 has been met (see Table 41-8)).

Availability of PCTs in SCAs estimated not to meet BAM credit requirements

Table 41-9 shows the two PCTs whose offset targets are estimated to not meet the minimum credit requirements of the BAM (see above) and whether there is enough PCT in the SCAs to potentially satisfy the BAM credit requirements.

The table shows that there are sufficient amounts of each PCT available in the SCAs to meet the estimated amount needed to satisfy the minimum BAM credit requirements. This suggests that the SCAs have the potential to achieve the minimum BAM credit requirements for these PCTs. As the Plan also has targets for TECs and species, there is the potential for the shortfall in these PCTs to be meet through these other targets.

Table 41-8: Availability of PCTs impacted by the nominated areas and transport corridors in the SCAs relative to offset targets, and showing restoration potential

Impacted PCTs	Area impacted^ (ha)	Offset target (ha)*	Area of PCT available in SCAs (ha)	Difference between offset target and available PCT in SCAs (ha)	Offset target as percentage of total area of PCT in SCA (%)	Initiate estimate of restoration potential in SCAs (ha)	Residual gap if restoration potential achieved (ha)

COMMONWEALTH REQUIREMENTS

Consistency with EPBC Act environmental offsets policy

The results of the EPBC Act environmental offsets policy analysis are provided in Table 41-10. Based on the requirements of the offsets assessment guide, all of the TECs meet the offset requirements needed to be consistent with the EPBC Environmental Offsets Policy by achieving a score greater than 100 per cent (the minimum required to meet the EPBC Environmental Offsets Policy is 90 per cent).

The highest of these is Coastal Swamp Oak (*Casuarina glauca*) Forest of New South Wales and South East Queensland (216.7 per cent), followed by Cooks River/Castlereagh Ironbark Forest (153.2 per cent), Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest (144.4 per cent).

The results for Shale Sandstone Transition Forest and Coastal floodplain eucalypt forest of eastern Australia are lower, but are still greater than 100 per cent (106.3 per cent and 114.8 per cent respectively).

Table 41-10: Results of EPBC offsets assessment

TEC	Condition	Listing Status	EPBC offsets assessment guide – impact calculator			EPBC offsets assessment guide – offsets calculator		
			Total impact (ha)	Total quantum of impact (adjusted ha)	Summed quantum of impact (adjusted ha)	Offset target (90%) (ha)	Total net present value of the offset (adjusted ha)	% of impact offset
Coastal floodplain eucalypt forest of eastern Australia*	Intact	Endangered	28.6	22.88	135.94	575	156.1	114.8
	Thinned		141.3	84.78				
	Scattered trees		40.4	28.28				
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest	Intact	Critically Endangered	22.6	13.56	65.62	575	94.8	144.4
	Thinned		128.1	51.24				
	Scattered trees		4.1	0.82				
Cooks River/Castlereagh Ironbark Forest	Intact	Critically Endangered	11.6	5.8	11.3	105	17.3	153.2
	Thinned		12.9	5.16

Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland	Thinned	Endangered	1.7	0.68	0.72	5	1.6	216.7
	Scattered trees		0.1	0.04				
Shale Sandstone Transition Forest	Intact	Critically Endangered	43.1	30.17	115.49	715	122.7	106.3
	Thinned		135.7	81.42				
	Scattered trees		13	3.9				

Availability of EPBC TECs in SCAs

A further assessment of Commonwealth-listed TECs was conducted to determine if the offset target for each TEC was present and feasible within the SCAs. The results are shown in Table 41-11.

The SCAs are estimated to have enough available habitat to broadly satisfy the offset required for four of the five TECs.

Coastal Swamp Oak (*Casuarina glauca*) Forest of New South Wales and South East Queensland has a negligible shortfall of 0.6 ha, and as discussed above is not broadly mapped outside the nominated areas. It is expected that this community has a wider distribution outside of the nominated areas and should therefore be available in the SCAs.

Cooks River/Castlereagh Ironbark Forest has a shortfall of 26 ha. As discussed above and displayed in Table 41-8, 47 ha of restoration potential for PCT 725 is available in the SCAs. This additional area of restoration would assist in meeting the offset requirement for Cooks River/Castlereagh Ironbark Forest.

Table 41-11: Area in SCAs of impacted Commonwealth-listed TECs

TEC Name	TEC offset target (ha)	Area of TECs in SCAs	Difference between offset target and area of TECs available in SCA (ha)
Coastal floodplain eucalypt forest of eastern Australia*	575	1,044.6	469.6
Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland	5	4.4	-0.6
Cooks River/Castlereagh Ironbark Forest	105	79.3	-25.8
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest	575	2,076.8	1,501.8
Shale Sandstone Transition Forest	715	4,063.1	3,348.1
Total	**1,975**	**7,268.1**	**5,293.1**

41.5.3 CONCLUSION

The analysis demonstrates that the commitments broadly address the values being impacted because:

NSW requirements

- Each impacted NSW TEC/PCT has an associated offset target
- The total offset target for NSW TECs/PCTs (5,475 ha) is estimated to be broadly within the range required to satisfy the BAM credit requirements (between 4,698 ha and 9,820 ha)
- The offset targets are estimated to generally satisfy the minimum credit requirements of the BAM for the majority (7 of 9) of the impacted NSW TECs/PCTs (for three of these seven PCTs, there is a negligible shortfall (< 6 ha))
- The majority of NSW TECs/PCTs (5 of 9) have enough PCT available within the SCAs to meet the offset targets. For 4 of those 5 PCTs, there is significantly more PCT available in the SCAs than needed to meet the targets
- For the 5 NSW TECs/PCTs with enough PCT available in the SCAs, achieving the offset targets would require an average of only 25 per cent of the total amount of each PCT available within the SCAs to be secured (i.e. the SCAs contain an average of almost four times the amount of PCT needed to meet the offset targets for these PCTs)
- For the four NSW TECs/PCTs with a shortfall of available PCTs in the SCAs:
  - Three of the PCTs – PCT 724, 725 and 1800 – have only small shortfalls (less than 45 ha)
  - An initial estimate of restoration potential in the SCAs indicates restoration has the potential to negate the shortfall for PCT 725 and reduce the shortfall for PCT 724 to about 29 ha
  - The offset for PCT 1800 is likely to be met as shortfall is generally a result of a lack of available mapping outside of the nominated areas

- While PCT 849 has a large shortfall:
  - An initial estimate of restoration potential in the SCAs indicates restoration can negate this shortfall
  - The SCAs contain over 2,800 ha of surplus PCT 850, which may be secured instead of PCT 849 to meet the shortfall, consistent with the offset rules under the BC Regulation

Commonwealth requirements

- The Commonwealth-listed TEC offset targets meet the requirements of the EPBC Act Environmental Offsets Policy when assessed on the basis of the requirements of the offsets assessment guide
- The SCAs contain enough Commonwealth-listed TECs to broadly satisfy the offset target for four of the five TECs. The shortfall for Cooks River/Castlereagh Ironbark Forest (26 ha) could potentially be negated through the restoration of PCT 725 within SCAs, which is estimated to be 47 ha

In concluding that the commitments broadly address the values being impacted, it is important to note that the Plan will implement several commitments to manage broad landscape threats in strategic locations in the Cumberland subregion, particularly to reduce threats to land secured in SCAs, including:

- Weeds (Commitment 16)
- Pest animals (Commitment 17)
- Fire (Commitment 18)
- Disease (Commitment 19)

These commitments are expected to substantially enhance the biodiversity benefits of securing land in the SCAs.

Furthermore, while only initial estimates of restoration potential in the SCAs have been made so far, the Plan includes a range of actions to ensure restoration is effective, including developing a Restoration Implementation Strategy (Commitment 13) in consultation with key stakeholders and delivery partners to:

- Provide a clear purpose for undertaking restoration, including how the Plan will meet its restoration target for impacted native vegetation communities
- Identify restoration potential of land within priority sites
- Provide guidance on restoration expectations at priority sites

Despite this overall conclusion that the commitments broadly address the values being impacted, there are several key risks with achieving the offset targets:

- A substantial proportion of private landholders within the SCAs must be willing to either voluntarily secure their land as offsets or sell their land to the NSW Government to establish reserves
- The SCAs cover large parts of the remaining native vegetation within the Cumberland subregion and there is likely to be demand from other development projects for offsets within these areas. This may reduce the actual availability of offsets within the SCAs for the development under the Plan
- Native vegetation mapping within the SCAs outside the nominated areas is based broadly on existing maps with rapid assessments conducted at key locations. Detailed site assessment of the SCAs may increase or reduce the actual amount of each TEC contained within the SCAs

Applying appropriate mechanisms for securing offsets within the SCAs will be critical in achieving the offset targets over the life of the Plan. Implementation arrangements for the conservation program are discussed in Section 41.11.

41.6 THEME 3: DO THE COMMITMENTS ADDRESS THE MOST IMPORTANT VALUES?

41.6.1 CONTEXT AND METHOD

The 'draft guidelines for planning authorities' (EES, 2019) (Principle 3) provide that commitments should prioritise the protection of important biodiversity values and set out a range of matters that commitments should be designed to protect, including:

- Habitat for threatened matters, particularly critically endangered matters

- Biodiversity values that are poorly represented in existing reserves within the subregion
- Areas identified as high priority by governments for conservation

The analysis of Theme 3 involved determining the extent to which the SCAs contain each of these categories of matters:

- Habitat for threatened matters within the SCAs was analysed using GIS on the basis of TEC, PCT and/or species habitat maps developed for this Assessment Report
- Biodiversity values poorly represented in existing reserves was analysed using GIS on the basis of data on the distribution of PCTs in the Cumberland subregion and the boundaries of existing reserves (including reserves under the *National Parks and Wildlife Act 1974* (NP&W Act), BioBank sites and Biodiversity Stewardship Agreements)
- Areas identified as high priority by governments for conservation were analysed using GIS on the basis of BioMap core and corridors (OEH, 2015) and the EES biodiversity values map (OEH, 2019a)

The analysis also included analysis of the potential feasibility of achieving the offsets targets for species with specific offset targets (see Part 2). This was done by compiling the following information for each species:

- Number of Biobank sites with 'issued' credits for the species
- Number of Biobank site Expressions of Interest (EOI) for the species (only EOIs since January 2017)
- Number of Biodiversity Stewardship sites with 'issued' credits for the species
- Number of Biodiversity Stewardship sites with credits 'pending' for the species
- Number of Biodiversity Stewardship sites site Expressions of Interest (EOI) for the species
- Number of BioNet and project records in SCAs
- Number of SCAs in which BioNet and project records occur

Note that searches of public registers for this analysis were limited to the Cumberland and adjacent subregions.

41.6.2 ANALYSIS

HABITAT FOR THREATENED MATTERS

The SCAs were designed to include Commonwealth and NSW-listed TECs and potential habitat for species to ensure the offset targets for matters impacted by the development can be met. Offset targets have been established for:

- The five Commonwealth-listed TECs directly impacted under the Plan
- The 9 PCTs/eight NSW-listed TECs directly impacted under the Plan
- The Commonwealth and NSW-listed species likely to be at risk of residual impacts from direct impacts

Threatened ecological communities

Table 41-12 and Table 41-13 show:

- Each impacted Commonwealth and NSW-listed TEC (critically endangered TECs are highlighted in blue)
- Amount (ha) of each TEC in the SCAs
- The offset target specific to the TEC

The tables show that the SCAs contain each impacted TEC, and that each TEC has an offset target.

Table 41-12: Area in SCAs of impacted Commonwealth-listed TECs

Associated PCTs	TEC	Cth status	Area of TEC in SCAs (ha)	Specific offset target (ha)
1800	Coastal Swamp Oak (*Casuarina glauca*) Forest of NSW and South East Queensland	E	4	5
725	Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion	CE	79	105
724, 849,	Cumberland Plain Shale Woodlands and Shale-	CE	2,077	575

Associated PCTs	TEC	Cth status	Area of TEC in SCAs (ha)	Specific offset target (ha)
850	Gravel Transition Forest			
792, 1281, 1395	Shale Sandstone Transition Forest in the Sydney Basin Bioregion	CE	4,063	715
835	River-flat Eucalypt Forest	FPAL	1,044	575

Table 41-13: Area in SCAs of impacted NSW-listed TECs

Associated PCTs	NSW TEC	NSW status	Area of TEC in SCAs (ha)	Specific offset target (ha)
724	Shale Gravel Transition Forest	E	106	150
725	Cooks River/Castlereagh Ironbark Forest	E	91	110
781	Freshwater Wetlands on Coastal Floodplains	E	63	5

849, 850	Cumberland Plain Woodland	CE	5,273	3,170
1395	Shale Sandstone Transition Forest	CE	4,930	1,540
1800	Swamp Oak Floodplain Forest	E	15	50

Threatened species

Amount of potential habitat for each species in SCAs

Table 41-14 shows:

- Each Commonwealth and NSW-listed species (critically endangered species are highlighted in blue) assessed in this Assessment Report and potentially impacted by the development under the Plan
- Amount (ha) of potential habitat for each species in the SCAs
- Any offset targets relevant to the species

In relation to offset targets, some species have specific offset targets to secure areas of known habitat or offset locations (see Chapter 8). Other species do not have specific offset targets, but are likely to benefit from the offset targets for NSW TECs/PCTs and Commonwealth-listed TECs, as those PCTs are identified in the Threatened Biodiversity Data Collection as being associated with that species and provide potential habitat for the species.

The amount of potential habitat (ha) for each species that will be secured in the SCAs because of the NSW TEC/PCT targets is shown in the last column of the Table 41-14.

The table shows that:

- The SCAs contain potential habitat for the vast majority of potentially impacted species
- Most species also either have a specific offset target or will benefit from the NSW TEC/PCT offset targets, which will lead to the securing of potential habitat in the SCAs for these species under the Plan

Table 41-14: Area of potential habitat in SCAs for Cth and NSW listed species assessed in the report

Scientific name	Common name	Cth status	NSW status	Area of potential habitat in SCAs (ha)	Offset target

Feasibility of achieving species-specific offsets targets

To further understand the potential availability of offsets for species with specific offset targets, the availability of each species in current offset locations was assessed, along with the presence of species records within the SCAs.

Table 41-15 provides the following information for each species:

- Number of Biobank sites with 'issued' credits for the species
- Number of Biobank site Expressions of Interest (EOI) for the species (only EOIs since January 2017)
- Number of Biodiversity Stewardship sites with 'issued' credits for the species
- Number of Biodiversity Stewardship sites with credits 'pending' for the species
- Number of Biodiversity Stewardship sites site Expressions of Interest (EOI) for the species
- Number of BioNet and project records in SCAs
- Number of SCAs in which BioNet and project records occur

The data in Table 41-15 indicates that offset sites for 9 of the 16 species with specific offsets are currently available (or are soon to be available) on Biobank or Stewardship sites and/or are represented within the SCAs. The data indicates that sourcing offsets for these species should be achievable under the Plan.

The 7 species highlighted in Table 41-15 are likely to be more difficult to secure on offset sites as they are currently not well represented on existing (or planned) Biobank or Stewardship sites and significant records for the species are not currently known within the SCAs. Further consideration of each of these species is provided in Table 41-16.

For these species, populations are known within and/or outside the Cumberland subregion and it is considered that securing the offset targets is possible, including outside the subregion if necessary. Furthermore, the Plan acknowledges that in some cases it may be challenging to meet some of the offset targets in the Plan. Rather than committing to a reduced offset target, the Plan allows for flexibility in reaching those targets through a set of conservation 'selection steps' and principles developed by the Department to guide implementation decisions (see section 41.11).

Table 41-15: Offset targets and potential availability on offset sites

Scientific name	Common name	Specific offset target	Number of Biobank Sites - current issued*	Number of Biobank EOIs (January 2017 - current)*	Number of Stewardship Sites*	Number of Stewardship Sites – Pending*	Number of Stewardship Sites – EOIs*	No. of BioNet and project records in SCAs	No. of SCAs in which BioNet and project records occur

* Cumberland subregion and surrounding subregions only

Table 41-16: Comment on species currently not well represented on Biobank/Stewardship sites and SCAs (as indicated by records)

Species	Comment
Cynanchum elegans	This species is widespread along coast and ranges north from the Illawarra. The offset target is likely to be achievable outside the Cumberland subregion if necessary
Hibbertia fumana	The species was known from 2 locations (Bankstown, Moorebank) but is cryptic and may have been confused with other *Hibbertia* species. As a result of recent surveys, populations have been detected over a wider range within greater Sydney stretching from Richmond to Mittagong (OEH, 2020)
Hibbertia puberula	Widely recorded in the Cumberland subregion, particularly within PCT 1081 south of Appin and through Wilton and in the northern and eastern (e.g. Simmos Beach) edge of the Cumberland subregion. Abundant in a local BSA site. Note that many known records are not yet in Bionet
Persoonia nutans	Species occurs in a number of locations in the Cumberland subregion, including at a local BSA site, Simmos Beach, Kemps Creek (bushland patch with *Dillwynia sp*. population) and in the general Castlereagh area
Pimelea spicata	Species occurs in a number of locations in the Cumberland subregion, including four populations (no.'s 31, 34, 534 and 51 – see Chapter 29) within excluded lands and one population (no. 533) within land avoided for biodiversity purposes (in GMAC)
Pultenaea parviflora	Species occurs in a number of locations in the Cumberland subregion, including around Luddenham and Kemps Creek, and also in areas of Llandilo/Castlereagh/Wianamatta. Several populations occur in excluded lands in GPEC and several populations occur in avoided lands
Pultenaea pedunculata	Known from sites at Villawood and Prestons, and north-west of Appin, although the species may be in the Kemps Creek and/or Luddenham/Orchard Hills area (lack of recent fire or soil disturbance in these areas will have reduced seed germination, which may be present in the seedbank). Species also occurs in the Southern Tablelands. The offset target is likely to be achievable outside the Cumberland subregion if necessary

VALUES THAT ARE POORLY REPRESENTED IN EXISTING RESERVES

Representativeness is a key goal of conservation planning. Representativeness refers to the extent to which reserves include a representative sample of the range of biodiversity values within a given area. Representativeness can be measured using surrogates such as habitat types (Margules & Pressey, 2000).

In Australia, the Comprehensive, Adequate and Representative (CAR) criteria is often considered when applying conservation targets (DECCW, 2010a). The CAR criteria include a representativeness target of 15 per cent of the pre-1750 distribution of each forest ecosystem included in conservation areas.

The Recovery Plan for the Cumberland Plain (DECCW, 2011) set representative targets for threatened ecological communities (TECs) of 15 per cent of remaining area of each TEC. This is equivalent to at least 5 per cent of the pre-1750 distribution of these TECs. These targets acknowledged that the subregion is a highly fragmented landscape and many of the existing vegetation types have been cleared to below 15 per cent of their pre-1750 extent.

This analysis used PCTs within the Plan Area to assess the representativeness of the SCAs.

Table 41-17 identifies:

- Total amount of each PCT in the Plan Area (PCTs impacted by the development are highlighted in blue)

- Amount/per cent of total amount in the Plan Area already represented in existing reserves (this includes reserves under the NP&W Act, BioBank sites and Biodiversity Stewardship Agreement sites)
- Amount/per cent of total amount in the Plan Area within SCAs
- Extent to which the SCAs contribute to existing levels of representation in the Plan Area

The table indicates that the SCAs have the potential to make a substantial contribution to existing levels of representation of PCTs in the Plan Area, including many PCTs that are currently under-represented in existing reserves.

The SCAs include all but 7 of the 39 PCTs (with an area greater than 1 ha) in the Plan Area. If these PCTs were secured for conservation, the SCAs would:

- Contribute to total representation within protected lands in the Plan Area of greater than 15 per cent for all but 5 PCTs
- Increase representation in protected lands in the Plan Area by greater than 50 per cent for 25 PCTs
- Increase representation in protected lands by greater than 75 per cent for the majority of PCTs (18 of 29) that have current levels of representation in existing reserves of less than 15 per cent
- Increase representation in protected lands by an average of 61 per cent for PCTs impacted by the development

For 12 PCTs, there are currently no areas protected in existing reserves. The SCAs include areas of 10 of these 12 PCTs and would therefore contribute to increasing representation by 83 per cent for these PCTs.

It is important to note that protection of land within SCAs will focus on PCTs impacted by the development under the Plan that have offset targets. However, in meeting these offset targets, it is likely that many PCTs not impacted by the development will also be included in conservation lands secured in the SCAs.

Table 41-17: Extent to which draft Plan contributes to protection of representative sample of PCTs in Cumberland subregion (impacted PCTs highlighted in blue)

PCT	Total amount in Plan Area (ha)	Amount in existing reserves* in Plan Area (ha)	Per cent in existing reserves* (%)	Amount in SCAs (ha)	Per cent in SCAs (%)	Per cent in SCAs or existing reserves* (%)	Per cent contribution of SCAs to existing levels of representation (%)

HIGH PRIORITIES FOR CONSERVATION

The NSW Government has developed several plans to identify priority areas for conservation or areas that are sensitive to biodiversity impacts in the Cumberland subregion. Two recent initiatives are:

- BIOMap core and corridors
- Biodiversity values map

BIOMap core/corridors

BIOMap identifies Priority Investment Areas (PIAs) where the protection and management of native vegetation is likely to maximise benefits to biodiversity within the Cumberland subregion. The PIAs comprise:

- Core areas: large areas of native vegetation and habitat where management will be of greatest benefit to the conservation of biodiversity values. These areas represent the habitat in the subregion most likely to support species persistence and interactions between species and landscape scale ecological processes
- Regional biodiversity corridors: linear areas that link core areas and play a crucial role in maintaining connections between species populations that would otherwise be isolated and at greater risk of local extinction

Table **41-18** and Table **41-19** show the amount of BIOMap core areas and corridors within the SCAs.

The tables indicate that the SCAs contain substantial amounts of BIOMap core and corridors – approximately 32 per cent of the total BIOMap core areas and 28 per cent of the total BIOMap corridors in the Cumberland subregion.

Table 41-18: BIOMap core areas within SCAs

Total area of BIOMap core in subregion (ha)	Area of BIOMap core in SCAs (ha)	Per cent of SCAs that is BIOMap core (%)	Per cent of total BIOMap core in subregion in SCAs (%)
24,196.8	7,819.8	28	32

Table 41-19: BIOMap corridors within SCAs

Total area of BIOMap corridors in subregion (ha)	Area of BIOMap corridors in SCAs (ha)	Per cent of SCAs that is BIOMap corridors (%)	Per cent of total BIOMap corridors in subregion in SCAs (%)
17,927.5	5,041.6	18	28

Biodiversity values map

The biodiversity values map identifies land with high biodiversity value that is particularly sensitive to impacts from development and clearing. The map forms part of the Biodiversity Offsets Scheme Threshold which is one of the triggers for determining whether the Biodiversity Offset Scheme under the BC Act applies to a clearing or development proposal.

Table 41-20 shows the amount of biodiversity values map areas within the SCAs.

The table indicates that the SCAs contain substantial amounts of biodiversity values map areas – approximately 27 per cent of the total biodiversity values map area in the Cumberland subregion.

Table 41-20: Biodiversity values map areas within SCAs

Total area of biodiversity values map in subregion (ha)	Area of biodiversity values map in SCAs (ha)	Per cent of SCAs that is within the biodiversity values map (%)	Per cent of total biodiversity values map in subregion within SCAs (%)
40,672.1	11,043.0	39	27

41.6.3 CONCLUSION

The analysis suggests that the commitments generally prioritise the protection of important biodiversity values as the SCAs within which the land-based commitments are intended to be delivered:

- Contain each impacted Commonwealth and NSW listed TEC
- Contain potential habitat for the majority of Commonwealth and NSW listed species
- Significantly contribute to increasing representation of PCTs in protected lands in the Cumberland subregion
- Include substantial areas of land identified by the NSW Government as priorities for conservation

Furthermore, it is likely that offset sites for the majority of species with specific offsets under the Plan are currently available (or are soon to be available) on Biobank or Stewardship sites and/or are represented within the SCAs. The data indicates that sourcing offsets for these species should be achievable under the Plan.

41.7 THEME 4: DO THE COMMITMENTS IMPROVE VALUES AND FUNCTION IN THE LONG TERM?

41.7.1 CONTEXT AND METHOD

The 'draft guidelines for planning authorities' (EES, 2019) (Principle 4) provide that commitments should ensure biodiversity values and ecological function are improved in the long term and set out a range of matters that commitments should be designed to protect, including:

- The size, shape and location of habitat in the landscape
- Habitat connectivity, such as corridors and riparian areas
- Management of key threatening processes and landscape scale threats
- Areas likely to provide significant potential for restoration

The analysis of Theme 4 involved determining the extent to which the SCAs contain each of these categories of matters. This included analysing:

- The size, shape and location of habitat in the landscape using GIS and by determining the extent to which large patches make up the total amount of native vegetation contained within the SCAs
- Habitat connectivity using GIS on the basis of BioMap core and corridors and other connected habitat elements
- Management of threats and restoration by discussing the commitments relating to these matters and drawing on the results of the trend analysis (see Supporting Document D)

41.7.2 ANALYSIS

SIZE AND LOCATION OF HABITAT PATCHES

Maximising the likelihood of viability or persistence of biodiversity values is a key goal of conservation planning (Margules & Pressey, 2000) and a key objective of the Cumberland Plain Recovery Plan (DECCW, 2011).

There are well established relationships between the size of a patch of native vegetation and the size and persistence of populations, with large patches generally supporting more persistent populations than smaller patches (Margules & Pressey, 2000). There are also relationships between the size of a patch and species richness, species dispersal, genetic diversity, persistence of large vertebrates, maintenance of near-natural disturbance regimes, and other important ecological functions (Hodgson, Thomas et al., 2009; Lindenmayer, Hobbs et al., 2008).

For this analysis, large patches are considered to be > 50 ha, and moderate patches are considered to be > 20 ha. This was based on findings by Parkes et al (2003) and recommendations of the Comprehensive, Representative and Adequate Advisory Group which suggest that in the Australian context, 50 hectares should be considered a minimum 'core' area of vegetation to prevent declines in biodiversity over time (Parkes, Newell, & Cheal, 2003; CARSAG, 2004).

The SCAs were designed to capture habitat patches in strategic locations in the landscape to maximise likely benefits to biodiversity values (see Chapter 8). This includes habitat patches adjacent to existing reserves or other large patches, or patches connecting or contiguous with other patches of habitat.

Table 41-21 shows the number of large and moderate patches in the SCAs and the extent to which large and moderate patches make up the total amount of native vegetation contained within the SCAs.

Table 41-22 shows the extent to which the SCAs contain the large and moderate patches that occur within the Plan Area.

The tables show that:

- Approximately 87 per cent of the total area of native vegetation in the SCAs comprises patches > 50 ha
- The SCAs contain about 35 per cent of the total area of patches > 50 ha in the Plan Area

Table 41-21: Extent to which large patches make up the total amount of native vegetation contained within the SCAs

	Total area of patches in SCAs (ha) > 50 ha or > 20 ha*	Per cent of total area of native vegetation in SCAs comprising patches > 50 ha or > 20 ha (%)*	Total number of patches in SCAs > 50 ha or > 20 ha*
Patches > 50 ha	16,000	87%	36
Patches > 20 ha	16,564	90%	70

*Note these figures may include smaller patches that are linked by contiguous areas of native vegetation, such as riparian corridors

Table 41-22: Extent to which the SCAs contain the largest patches within the Plan Area

	Total area of native vegetation patches in Plan Area (ha)	Per cent of total area of patches in Plan Area wholly or partially within SCAs (%)
Patches > 50 ha	45,947	35
Patches > 20 ha	49,372	34

HABITAT CONNECTIVITY

Habitat connectivity was a key factor influencing the location of the SCAs (see Chapter 8). In determining the SCAs, priority was given to including areas in the Cumberland subregion that were adjacent to and connecting other patches of habitat, including existing reserves, and that could form broad habitat corridors across the landscape.

The SCAs were also located to provide connectivity outside the Cumberland subregion. Figure 8-2 in Chapter 8 shows that the SCAs provide connectivity to existing reserves in the Blue Mountains to the west of the subregion, and to existing reserves and protected water catchments to the south-east and south-west of the subregion.

As part of the commitment to secure a minimum of 5,475 hectares of native vegetation in the Cumberland subregion, the Plan commits to securing priority habitat corridors within the subregion to support connectivity for ecological communities and species (Commitment 12). It is intended these priority habitat corridors will be secured within SCAs.

Actions to support the delivery of this habitat connectivity commitment include:

- Undertake ground-truthing within SCAs to confirm potential habitat corridors
- Secure priority habitat corridors and Koala movement corridors in accordance with the Conservation Lands Implementation Strategy under the Plan
- Protect avoided Koala habitat through environment (E2) conservation zoning in potential east-west Koala movement corridors between the Georges River and the Nepean River
- Through restoration, ensure at least one north-south corridor (the Georges River Koala Reserve) and one east-west corridor are each at least 390m wide, for Koala viability and movement
- Facilitate Koala movement for at least one east-west corridor by constructing a Koala crossing at Appin Road

The extent to which the SCAs contain areas important for habitat connectivity was analysed on the basis of BioMap core and corridors and other important connected habitat elements. These areas represent the most important area of habitat connectivity in the Cumberland subregion.

Section 41.6 shows that the SCAs contain substantial amounts of BIOMap core area and corridors, approximately 32 per cent of the total BIOMap core areas and 28 per cent of the total BIOMap corridors in the Cumberland subregion, and are therefore likely to make a substantial contribution to supporting habitat connectivity across the subregion.

It is also important to note that the urban capable lands under the Plan have avoided substantial areas of BIOMap core areas and corridors and other areas of connectivity, such as local corridors (see Chapter 24).

The parts of these areas within the nominated areas that are not included within SCAs, and that have been avoided for biodiversity or other purposes (riparian corridors, steep land) will be protected under the Plan by applying environment (E2) conservation zoning (see Chapter 8). Note that avoided land will have environment (E2) conservation zoning applied except for land owned by LALCs or under claim by LALCs. LALC owned land and land under claim represents 90 ha of the 4,795 ha of avoided land[2].

Key areas of habitat connectivity within the nominated areas that will be avoided are shown in Table 41-23.

Table 41-23: Key areas of habitat connectivity avoided in each nominated area and protected through environment zoning

Habitat connectivity type	Area in nominated areas (not including excluded lands)	Percentage avoided (not including excluded lands)
BIOMap regional corridor and core area	3,151 ha	89%
Connected vegetation	1,716 ha	52%
Isolated vegetation	14 ha	2%
Local corridor	217 ha	73%

LANDSCAPE THREATS

The Plan recognises that the effective management of landscape scale threats is critical to the success of the conservation program under the Plan and in managing the impacts of climate change on biodiversity (see Section 41.12). The Plan includes a range of commitments to reduce threats to conservation lands secured within SCAs, including:

- Weed and pest control programs to manage weeds and pests in conservation lands (Commitment 16 and 17)
- Support new or existing programs to control key diseases affecting species and TECs in the Cumberland subregion (Commitment 19)
- Fire management to support the maintenance of biodiversity values in conservation lands (Commitment 18)

Actions under these commitments generally include to:

- Establish working groups to advise on threat management
- Develop more detailed implementation strategies in consultation with working groups and other key stakeholders, including delivery partners, to set out:
    - Priorities for management of the threat
    - Guidance on management approaches
    - Any research needs
    - Delivery arrangements, including the provision of funding under the Plan

The Plan identifies a range of delivery partners to support implementation of these commitments and actions.

[2] The total area of avoided land at the start of the Plan is 4,795 hectares. The avoidance target of 4,315 hectares has reduced this figure by 10% to allow for potential future development of essential infrastructure in non-certified land

Trend analysis

The recognition under the Plan of the importance of managing landscape scape threats is supported by the results of the trend analysis (see Box 1 and Supporting Document D). The trend analysis examined the potential impacts of development and offsetting under various scenarios on PCT 849 in the Cumberland subregion.

Box 1: Trend analysis

Trend analysis for PCT 849

As part of the EPBC Act strategic assessment process for the nominated areas and transport corridors, a trend analysis looking at the extent and condition of PCT 849 over the life of the Plan was undertaken by RMIT University (Gordon & Peterson, 2019). The trend analysis examined the potential impacts of development and offsetting under various scenarios on PCT 849 in the Cumberland subregion. It considered a summed score across the landscape for the PCT of extent and ecological condition (the latter being based on an approximation of the BAM vegetation integrity score).

The project involved two major components:

- A formal expert elicitation to gather quantitative knowledge regarding how the condition of PCT 849 will change over time under:
  - High or low intensity management
  - The case where the PCT is exposed to typical ongoing private land activities
- Quantitative modelling to simulate the urban development within the designated nominated areas and compensation via managing areas as biodiversity offsets in a strategically defined offset region and the ecological response of the PCT. The modelling included eight scenarios exploring different options for implementing biodiversity offsets which varied:
  - The timing of when offsets are implemented
  - The total area of offsets implemented
  - The type of management implemented for the offsets (low or high intensity)

The analysis found that:

- Existing landscape scale threats (e.g. weed invasion, grazing, rubbish dumping, disturbance from recreational activities) across the Cumberland subregion are significant and will result in an approximate 5.8 per cent decline in the extent and condition of the PCT over the life of the Plan unless additional areas are managed
- The proposed impacts of development under the Plan will lead to approximately the same magnitude of losses (~5.8 per cent) to the PCT that will result due to existing landscape threats
- High intensity management and early offsetting will provide the greatest benefits to the outcomes of the PCT over the life of the Plan
- Securing approximately 1,600 ha of offsets for the PCT:
  - Will compensate for the impacts of development where earlier offsetting and higher intensity management is preferential by improving the extent and condition of the PCT over the life of the Plan
  - Has the potential to also contribute significantly to addressing the declines across the subregion due to existing landscape scale threats

The commitments under the Plan to manage landscape scale threats reflect a broad and holistic approach to conservation and aim to address the current level of existing landscape scale threats across the Cumberland subregion.

RESTORATION

The Plan includes a commitment to undertake ecological restoration of priority areas secured for conservation within the Cumberland subregion. The Plan intends to undertake up to 1,370 hectares of ecological restoration on conservation lands targeting the following TECs:

- Cooks River Castlereagh Ironbark Forest

- Cumberland Plain Woodland
- River-flat Eucalypt Forest
- Shale Gravel Transition Forest
- Swamp Oak Forest

The Plan includes a range of actions to ensure restoration is effective, including:

- Developing a Restoration Implementation Strategy in consultation with key stakeholders and delivery partners, to:
  - Set out how the Plan will meet its restoration target
  - Identify the restoration potential of land within priority sites
  - Provide guidance on restoration expectations at priority sites
- Entering into written agreements with delivery partners, and engaging specialist providers if necessary, to implement the restoration strategy

The recognition under the Plan of the importance of restoration is consistent with the Cumberland Plain Recovery Plan (DECCW, 2011), which highlights the importance of restoration in the context of the substantial degradation that has occurred in the Cumberland subregion due to agricultural and urban land uses.

Trend analysis

The emphasis on restoration under the Plan is also supported by the results of the trend analysis (see Box 1 and Supporting Document D). The expert elicitation process (involving experts on the management of Cumberland Plain Woodland) undertaken for the trend analysis indicates that high intensity management on conservation lands provides significant potential for providing restoration gains for PCT 849, even when starting from a low initial condition.

It is important to note that the trend analysis found that low intensity management has limited capacity to provide restoration gains for PCT 849 over time, especially when starting from a low initial condition.

41.7.3 CONCLUSION

The analysis suggests that the commitments broadly ensure biodiversity values and ecological function are improved in the long term as the SCAs within which the land-based commitments are intended to be delivered:

- Include many large patches > 50 ha that comprise over 87 per cent of the total native vegetation in the SCAs and contain 35 per cent of the total area of patches > 50 ha in the Plan Area
- SCAs contain substantial amounts of BIOMap core and corridors

Importantly the Plan has also committed to managing key landscape threats, including weeds, pest animals and fire, and restoring substantial areas of land in the SCAs as part of the conservation program.

41.8 THEME 5: ARE THE COMMITMENTS ADDITIONAL TO EXISTING REQUIREMENTS?

41.8.1 CONTEXT AND METHOD

The 'draft guidelines for planning authorities' (EES, 2019) (Principle 5) requires that commitments are additional to existing conservation obligations. Existing conservation obligations are actions that are legally required to be carried out on land. Consistent with BC Regulation clause 5.1, existing obligations include actions required to be carried out:

- Because of the reservation of land under the NP&W Act
- Under existing conservation agreements or offset arrangements
- Under a condition of approval or consent under the EP&A Act

The 'draft guidelines for planning authorities' (EES, 2019) also state that existing conservation obligations include those under plans of management for 'community' land, and voluntary obligations are not considered to be existing conservation obligations

The Plan intends to secure all conservation land within SCAs through either:

- Creation of reserves through acquisition of land
- Establishment of Biodiversity Stewardship Agreements (BSAs) with landholders

The Plan ensures that commitments are additional to existing conservation obligations through:

- Accounting for existing conservation obligations in the process to identify SCAs
- Securing land in SCAs in accordance with the rules and processes under the BC Act and BAM, which account for existing conservation obligations

The analysis of Theme 5 involved explaining these processes.

41.8.2 ANALYSIS

STRATEGIC CONSERVATION AREAS

The SCAs were identified through a Conservation Priorities Method (see Chapter 8). The method combines detailed spatial information about biodiversity values with an analysis of constraints and opportunities to identify an optimal mix of potential conservation sites to offset the impacts of the development on biodiversity values.

The method to identify SCAs excluded land that was unlikely to be suitable as an offset, including because the land was already subject to existing conservation obligations or controls. This included the following land:

- Land reserved under the NP&W Act
- Existing BioBank and Biodiversity Stewardship Agreement sites
- Existing offsets for other development projects

The method ensures that land clearly already subject to existing conservation obligations is not identified within SCAs.

PROCESS TO SECURE BIODIVERSITY STEWARDSHIP AGREEMENTS AND RESERVES

All BSAs under the Plan will be established in accordance with the requirements of the BC Act and BAM. The BC Act and BAM have rules and processes in place to ensure that the credits generated from establishing BSAs take into account existing conservation obligations. These include:

- Criteria under the BC Regulation (clause 5.1) that prevents several categories of land subject to existing conservation obligations from being eligible as a site for a BSA, including offset sites
- A process under the BAM (section 13.11) that ensures credits can only be created by management actions on a BSA site that are additional to existing conservation obligations. This includes a set of rules that reduce the credits generated according to either the tenure of the land (including land classed as 'community land' under the *Local Government Act 1993)* or the type of management action already required under existing obligations

This same rules and processes will be applied to land secured as reserves under the Plan, as the Plan intends that BSAs will be established prior to the acquisition of land by the Office of Strategic Lands. The land will then be transferred (along with the BSA, covenants on title and ongoing annual management payments) to a suitable long-term public land management authority such as National Parks and Wildlife Authority or Council.

ACCOUNTING FOR OFFSET TARGETS

The Plan includes an action to establish an accounting process to track progress in meeting offset targets. Offset targets will be tracked in terms of hectares of land secured, as well as credits where appropriate.

As part of the accounting process, a method will be established to reduce the number of hectares that are counted towards an offset target where existing conservation obligations apply to a site. This method will be developed to be consistent with the rule set in the BAM (section 13.11) for credits.

41.8.3 CONCLUSION

The Plan ensures that commitments are additional to existing conservation obligations consistent with the 'draft guidelines for planning authorities' (EES, 2019) (Principle 5) through:

- Accounting for existing conservation obligations in the process to identify SCAs
- Securing land in SCAs in accordance with the rules and processes under the BC Act and BAM, which account for existing conservation obligations
- Establishing an accounting process to track progress in meeting offset targets, including a method to reduce the number of hectares that are counted towards an offset target where existing conservation obligations apply to a site

41.9 THEME 6: DO DEVELOPMENT CONTROLS PROPOSED AS COMMITMENTS CONSERVE THE ENVIRONMENT?

41.9.1 CONTEXT AND METHOD

The 'draft guidelines for planning authorities' (EES, 2019) (Principle 7) requires that commitments involving the use of development controls conserve or enhance the natural environment. Consideration of this principle is guided by the following:

- Land use zoning is implemented following the biodiversity certification application
- Land use zone objectives are consistent with conservation/enhancement of the natural environment
- Permissible uses are consistent with conservation/enhancement of the natural environment
- There are specific local provisions put in place that set out the development controls that will apply to protect native vegetation and any other habitat for native species on the land
- Minimum lot sizes and/or options for lot averaging and lot clustering aim to preserve the integrity of native vegetation and any other habitat for native species on the land
- Management actions are proposed to enhance the natural environment
- Security of biodiversity values is improved (i.e. development controls are new or represent a significant upgrade)

41.9.2 ANALYSIS

The Department is proposing a new State Environmental Planning Policy (SEPP) for strategic conservation planning to implement the Plan's strategic conservation planning requirements. The proposed SEPP will include:

- Environmental conservation (E2) zoning that will be applied to areas that are identified in the Plan as non-certified because they are avoided for biodiversity purposes, or other purposes (riparian corridors, steep land). Note that avoided land will have environment (E2) conservation zoning applied except for land owned by LALCs or under claim by LALCs. LALC owned land and land under claim represents 90 ha of the 4,795 ha of avoided land[3]
- Planning controls for the SCAs to minimise impacts from development on areas of high biodiversity value, improve the management of biodiversity and help protect TECs and species in these areas. Note that planning controls will be applied across the SCAs except for land owned by LALCs or under claim by LALCs. Deerubbin owned land has been excluded from the SCAs at their request. Other LALC owned land and land under claim represents 1,700 ha of the 28,300 ha of the SCAs
- Consistency clause for urban development to ensure consistency between the urban capable land identified in precinct plans and areas of urban capable land identified by the Plan, to contain urban development to the urban capable lands and ensure avoided lands remain outside the development areas
- Acquisition clauses that allow the relevant acquisition authority to secure lands suitable for public reserves, such as national parks and council reserves

In addition to these planning controls, the Department also proposes to introduce a Ministerial Direction under section 9.1 of the EP&A Act. The direction will apply to avoided land and the SCAs as mapped in the proposed SEPP. It will restrict the ability to rezone avoided land, increase development or intensify land uses in the SCAs, and require a

[3] The total area of avoided land at the start of the Plan is 4,795 hectares. The avoidance target of 4,315 hectares has reduced this figure by 10% to allow for potential future development of essential infrastructure in non-certified land

relevant planning authority to ensure any planning proposals consider the land use objectives that apply to avoided land and, for the SCAs, the matters for consideration in the planning controls that apply to the area.

Note that, as for the other planning controls, this control will be applied across the SCAs except for land owned by LALCs or under claim by LALCs. Deerubbin owned land has been excluded from the SCAs at their request. Other LALC owned land and land under claim represents 1,700 ha of the 28,300 ha of the SCAs

It is considered the SEPP and other measures will improve the security of biodiversity values in avoided lands and the SCAs, and represent a significant upgrade to existing levels of protection in these areas, as they will:

- Include zoning objectives and permissible uses consistent with conservation (for avoided lands)
- Reduce the risk of rezoning avoided land or increasing development or intensifying land uses in the SCAs, which reduces the likelihood of potential impacts from future planning proposals within these areas
- Ensure planning authorities take into account the land use objectives that apply to avoided land or, if the development proposal is for the SCAs, the matters in the planning controls that apply to the area, when considering development and other planning proposals for avoided lands or SCAs
- Facilitate the acquisition of high biodiversity value land within the SCAs under the conservation program. The tenure of land across the Plan Area is mostly freehold, meaning land will need to be acquired from landowners over time. The proposed SEPP supports this important process over the life of the Plan

41.9.3 CONCLUSION

The proposed SEPP and associated zoning and planning controls, as well as other measures, are considered to provide substantial protection to avoided lands and the SCAs, consistent with the matters to be considered under the 'draft guidelines for planning authorities' (EES, 2019) (Principle 7). These measures represent a significant upgrade to existing levels of protection in avoided lands and the SCAs. These areas are the key locations of high biodiversity value identified to achieve the Plan's conservation outcomes, and the SEPP therefore increases certainty that the commitments and actions under the Plan relevant to the conservation program will be successfully delivered.

41.10 THEME 7: ARE PROPOSED NEW NATIONAL PARKS CONSISTENT WITH THE CAR RESERVE FRAMEWORK?

41.10.1 CONTEXT AND METHOD

The 'draft guidelines for planning authorities' (EES, 2019) (Principle 7) requires that any proposed new national parks are consistent with the CAR reserve system scientific framework (Commonwealth of Australia, 2010).

Specifically, the national parks must be:

- Comprehensive: the national parks must include regional-scale ecosystems impacted by the biodiversity certification in each subregion or bioregion
- Adequate: the national parks must include sufficient levels of each ecosystem to provide ecological viability and maintain the integrity of populations, species and communities
- Representative: the national parks must include the variability of habitat within ecosystems

The Department has identified initial locations for land that will be potentially reserved under the NP&W Act within the SCAs. This includes three new reserves proposed to be established within the first five years of the Plan's implementation to deliver upfront strategic offsets (see section 41.11).

These reserve locations are not final and are likely to be refined.

The analysis of Theme 7 involved analysing data on the initial locations of land that will be potentially reserved under the NP&W Act within the SCAs on the basis of PCTs (those impacted by the development), as follows:

- Comprehensiveness: the extent to which the potential reserve locations contain each impacted PCT
- Adequate: the extent to which the potential reserve locations contain large patches of native vegetation more likely to be viable in the long-term and more likely to support persistence of species and communities
- Representative: the extent to which the potential reserve locations contribute to the existing levels of protection of each impacted PCT in the Cumberland subregion

It is important to note that the reserve locations are not final and are likely to be refined. The final location of reserves will be determined during implementation of the Plan based on consultation with key stakeholders and guided by the Conservation Lands Implementation Strategy (see Chapter 8).

41.10.2 ANALYSIS

COMPREHENSIVE

Table 41-24 shows the extent to which the potential reserve locations within SCAs contain each impacted PCT.

The table shows that 8 of the 9 impacted PCTs are included in the potential reserve locations, with one of these PCTs (PCT 830) available in restoration lands only.

For the PCT not included in the potential reserve locations (PCT 1800) the lack of available mapping for this PCT is likely to be driving this result.

Table 41-24: Extent to which potential reserves component of SCAs contains each impacted PCT

Impacted PCTs	Area of PCT available in potential reserves (ha)	Restoration potential in potential reserves (ha)
724	10.0	3.7
725	50.7	15.1
781	51.1	0.3
830	0.0	11.4
835	84.7	339.0
849	384.5	556.6
850	164.7	277.4
1395	1949.0	567.8
1800	0.0	0.0
Total	**2,694.7**	**1,771.3**

ADEQUATE

Table 41-25 shows the number of large and moderate patches in the potential reserves and the extent to which large and moderate patches make up the total amount of native vegetation contained within the SCAs.

Table 41-26 shows the extent to which the SCAs contain the large and moderate patches that occur within the Plan Area.

The tables show that:

- Approximately 95 per cent of the total area of native vegetation in the potential reserve locations comprises patches > 50 ha
- The potential reserve locations contain about 14 per cent of the total area of patches > 50 ha in the Plan Area

Table 41-25: Extent to which large patches make up the total amount of native vegetation contained within the potential reserves component of SCAs

	Total area of patches in SCAs (ha) > 50 ha or > 20 ha*	Per cent of total area of native vegetation in SCAs comprising patches > 50 ha or > 20 ha (%)*	Total number of patches in SCAs > 50 ha or > 20 ha*
Patches > 50 ha	6,371.4	95%	36
Patches > 20 ha	6,425.6	96%	70

*Note these figures may include smaller patches that are linked by contiguous areas of native vegetation, such as riparian corridors

Table 41-26: Extent to which the potential reserves component of SCAs contain the largest patches within the Plan Area

	Total area of native vegetation patches in Plan Area (ha)	Per cent of total area of patches in Plan Area wholly or partially within SCAs (%)
Patches > 50 ha	45,947	13.9
Patches > 20 ha	49,372	13.0

Representative

Table 41-27 identifies:

- Total amount of each impacted PCT in the Plan Area
- Amount/per cent of total amount in the Plan Area already represented in existing reserves (this includes reserves under the NP&W Act, BioBank sites and Biodiversity Stewardship Agreement sites)
- Amount/per cent of total amount in the Plan Area within potential reserve locations
- Extent to which the potential reserve locations contribute to existing levels of representation in the Plan Area

The table indicates that the potential reserve locations contribute greater than 10 per cent to existing levels of representation for the majority (6 of the 9) of PCTs, including contributing about 70 per cent to existing levels of protection of the critically endangered TEC Shale Sandstone Transition Forest (PCT 1395).

Table 41-27: Contribution of potential reserve locations to existing levels of representation of impacted PCTs

PCT	Total amount in Plan Area (ha)	Amount in existing reserves* in Plan Area (ha)	Per cent in existing reserves* (%)	Amount in potential reserve locations (ha)	Per cent in potential reserve locations (%)	Per cent in potential reserve locations or existing reserves* (%)	Per cent contribution of potential reserve locations to existing levels of representation (%)
724	2,049.3	286.1	14.0	10	0.5	14.4	3.4
725	1,085.6	422.2	38.9	50.7	4.7	43.6	10.7
781	429.2	52.7	12.3	51.1	11.9	24.2	49.2
830	1,362.1	130.8	9.6	0	0.0	9.6	0.0
835	6,951.5	459.9	6.6	84.7	1.2	7.8	15.6
849	11,767.1	1,024.70	8.7	384.5	3.3	12.0	27.3
850	8,821.5	747.1	8.5	164.7	1.9	10.3	18.1
1395	12,475.8	852.8	6.8	1,949.0	15.6	22.5	69.6
1800	426.5	17.9	4.2	0	0.0	4.2	0.0

*This includes reserves under the NP&W Act, BioBank sites and Biodiversity Stewardship Agreement sites

41.10.3 CONCLUSION

The analysis suggests that the potential reserves are broadly consistent with the CAR reserve system scientific framework (after Commonwealth of Australia, 2010) as the reserves:

- Include the vast majority of PCTs impacted by the development (are comprehensive)
- Comprise patches > 50 ha for the vast majority of native vegetation in the reserves (are likely to be adequate)

- Contribute greater than 10 per cent to existing levels of representation for the majority of PCTs (are representative)

It is important to note that further consideration of the CAR reserve system scientific framework will be made in finalising the locations of the potential reserves during implementation of the Plan.

41.11 THEME 8: WILL THE PLAN BE EFFECTIVELY IMPLEMENTED AND WILL OUTCOMES BE CERTAIN?

41.11.1 CONTEXT AND METHOD

The 'draft guidelines for planning authorities' (EES, 2019) (Principle 9) and the ToR (Sections 4.6(2), 5.3 (2), 6.1(4), 6.2, and 7.1) require analysis of the extent to which the commitments are likely to be implemented effectively to achieve the outcomes.

Effective implementation is particularly important with strategic assessments because of the size and complexity of the programs, the long time frames over which they are implemented, the number of stakeholders and the diversity of their interests, the amount of money the programs cost, and the complexity of the legal frameworks they operate within.

Lessons learnt from other strategic assessments around Australia suggest that effective implementation requires:

- Clear and feasible outcomes that the Plan will deliver
- Clarity about the delivery framework and mechanisms to implement the Plan
- Appropriate flexibility within the Plan to ensure it remains relevant over time
- Clear governance arrangements, including certain funding
- Comprehensive processes to monitor and report on implementation, and adapt implementation as needed

The analysis of Theme 8 involved addressing each of these key factors in relation to the following questions:

- Why is this important for effective implementation?
- What is required to achieve this?
- Is the Plan consistent with what is required?

41.11.2 ANALYSIS

CLEAR AND FEASIBLE OUTCOMES

Why is this important for effective implementation?

Clear and achievable outcomes are critical for effective implementation to allow delivery partners to understand what they need to achieve, allow regulators and the public to understand what is intended to be delivered, and enable the Plan to be evaluated to determine if it is operating well, and ultimately if it has been a success.

What is required to achieve this?

To achieve this, the Plan needs to:

- Frame outcomes within a program logic
- Ensure outcomes are clear, measurable and achievable

Is the Plan consistent with what is required?

Frame outcomes within a program logic

The outcomes under the Plan have been framed within a program logic that underpins the Plan.

The program logic describes broadly how the Plan will be implemented and the relationships between outcomes and commitments and actions ('or 'outputs'), and how the commitments and actions are expected to lead to the outcomes. Key elements of the program logic are:

- Overall vision and objective of the Plan
- Outcomes – Environmental, social and economic outcomes of the Plan
- Commitments – How the outcomes are going to be delivered
- Actions – What will be done to deliver the commitments

By framing the outcomes within a program logic, the Plan provides a clear picture of why and how it is intended to be delivered and a chain of reasoning between achieving the vision and taking actions. The increasing level of detail from vision to actions provides a suitable way of articulating what success looks like (i.e. the vision/objectives and outcomes that the Plan will deliver) as well as the way that will be achieved (i.e. the commitments and actions).

The vision and objective of the Plan have three elements to them:

- Environmental – conservation of biodiversity to support ecological function in the subregion
- Economic – facilitating urban development to support growth
- Social – improving liveability

The outcomes are considered to be consistent with the program logic, as they:

- Cover the three elements of the vision and objective
- Articulate what is needed to achieve the vision and objective
- Articulate the results of delivering the commitments

Importantly, the outcomes clearly reflect the level of performance or intended impact or value resulting from the delivery of commitment and actions. Appropriately, the outcomes are clearly distinct from the commitments, which reflect what is delivered as a result of the implementation of the actions.

Ensure outcomes are clear, measurable and achievable

The key environmental outcomes of the Plan are that:

- Extent and condition of native vegetation increases and improves within areas of the Cumberland subregion most likely to support long-term viability and ecological connectivity
- TECs persist and their condition improves within areas of the Cumberland subregion most likely to support long-term viability
- Populations of targeted threatened species persist and the condition of suitable habitat improves within areas of the Cumberland subregion most likely to support long-term viability
- Condition of riparian corridors within the nominated areas improves

It is considered that these outcomes reflect best practice as they are:

- Specific in relation to scope – in the context of the commitments under the Plan, the area over which the outcome is intended to be achieved and the contribution of the Plan in achieving that outcome is clearly defined
- Measurable and able to be reported against – changes in extent and condition of native vegetation and persistence of species can be measured and reported against under the MER framework for the Plan
- Achievable – in the context of the commitments under the Plan, the outcomes are considered to be achievable

Flexibility within the Plan to ensure it remains relevant

Why is this important for effective implementation?

Given the spatial and temporal scope of the Plan, it is important that it retains sufficient flexibility to ensure that implementation can adapt over time to deliver the outcomes. This may be necessary for a range of reasons, including:

- Development priorities change necessitating minor changes to development areas
- New knowledge on biodiversity values identifies new conservation opportunities
- Ecological processes change over time (e.g. due to climate change) that require alternative conservation approaches
- Changes to technology mean there are better ways to achieve the outcomes than envisaged now

What is required to achieve this?

To achieve this, the Plan needs to:

- Build processes into the Plan that enable changes to development locations in appropriate circumstances
- Include mechanisms under the Plan for changing how outcomes are delivered where appropriate
- Ensure flexibility around how the conservation program is delivered

How well does the Plan address this requirement?

Build processes into the Plan that enable changes to development locations

The Plan includes an appropriate level of flexibility around development. In particular, the Plan provides for flexibility in relation to projects where planning has not yet begun or that are only at concept stage, including:

- Essential infrastructure to support the nominated areas, such as water and electricity utilities, which is in various stages of development and may need to be located outside urban capable lands
- Detailed design and location of the transport projects, which are also in various stages of development

The Plan includes commitments and a set of guidelines for essential infrastructure projects that allow for both flexibility in relation to future strategic planning and detailed design while also ensuring the projects avoid and minimise, mitigate and (where appropriate) offset the impacts of development consistent with the outcomes of the Plan.

The Plan also establishes governance arrangements to ensure the Department and regulators are provided oversight over these arrangements to ensure these projects proceed consistent with the requirements of the Plan (see below).

Mechanisms for changing how outcomes are delivered

The outcomes and commitments under the Plan are fixed and cannot be changed over time. This is appropriate as it ensures the Plan provides as much planning, development and conservation certainty as possible.

The actions that will be implemented under the Plan to deliver the commitments are able to be changed over time. This allows an appropriate level of flexibility to change implementation approaches based on monitoring and evaluation of the effectiveness of these actions through the MER framework and adaptive management approach (see below).

It is considered this ability to change actions in based on an evaluation process and in response to changes in circumstances is essential to the successful delivery of the outcomes and commitments under the Plan.

Flexibility around how the conservation program is delivered

The Plan acknowledges that in some cases it may be challenging to meet some of the offset targets in the Plan. Rather than committing to reduced offset targets, the Plan allows for flexibility in reaching those targets through a set of conservation principles and ‘conservation lands selection steps’.

The principles are broad and prioritise the protection of the best remaining large patches of vegetation, areas that provide ecological connectivity and landscape function, species adaptation needs under climate change, as well as the restoration of habitat corridors and areas that provide buffers to intact native vegetation.

The conservation lands selection steps will be used to identify and secure reserves or BSAs under the conservation program. The details of the steps are set out in Sub-Plan A. The selection steps:

- Set out priorities for securing offset targets in terms of locations within and outside the Cumberland subregion and the biodiversity values being targeted (TECs versus species)
- Identify the circumstances, including time periods, where offset targets can be substituted for alternative offsets for other biodiversity values or conservation measures in cases where those targets cannot be secured

The Biodiversity Conservation Trust will be required to follow these steps when implementing the BSA component of the conservation program, and the Department will be required to follow these steps when developing reserve proposals. In summary, the selection steps prioritise:

1. Securing offsets from priority areas within the SCAs, including the following preferences: (in order):

  - Targeted TECs that are most impacted under the Plan
  - Targeted TECs that have the highest percentage cleared status (as identified in BioNet)
  - Targeted TECs or species where there is a shortfall between impacts and the securing of offsets
  - Species offset locations or areas of potential foraging habitat
  - Areas that provide additional conservation benefits (e.g. habitat connectivity, riparian corridors, etc)
2. Securing offsets from elsewhere within the SCAs following the same priorities above

In securing BSAs under the conservation program, the following additional selection steps apply:

3. Secure target TECs outside the SCAs but within the Cumberland subregion or adjacent subregions, or as a last option, anywhere else they occur in NSW, following the same priorities above
4. Secure species offset locations or areas of potential foraging habitat in accordance with Box 4 of Sub-Plan A
5. Secure alternate native vegetation in accordance with Box 4 of Sub-Plan A

Box 4 of Sub-Plan A specifies separate priorities for TECs and species and sets out the circumstances, including time periods, where offset targets can be substituted for alternative offsets for other biodiversity values, or alternative conservation measures, in cases where those targets cannot be secured.

The rules in Box 4 specify, for example, that where offsets for a target TEC cannot be secured within or outside the Cumberland subregion after taking appropriate steps (including securing of credits), preference should be to secure alternative PCTs of the same Class first, then of the same Formation, to those of the target TEC.

The selection steps to guide the selection of conservation lands are considered to appropriately balance the need to provide certainty for achieving conservation outcomes in the Cumberland subregion while retaining enough flexibility to ensure successful delivery of the conservation program. In particular, the steps:

- Have been developed consistent with the offset rules under the BC Regulation 2016
- Prioritise securing of offsets within the SCAs, which represent the areas in the Cumberland subregion that are considered most likely to be viable in the long-term and to maximise ecological function and connectivity
- Prioritise securing the most impacted TECs under the Plan first
- Ensure TECs and species are given higher priority where progress in securing offsets is not keeping pace with impacts of the development on those matters (through an offset reconciliation accounting process – see below)
- Cap the amount of offsets that can be secured outside the Cumberland subregion through BSAs under the conservation program to 20 per cent of the total TEC offset target under the Plan
- Specify clear timeframes over the life of the Plan after which species offset targets can be achieved outside the Cumberland subregion, with greater flexibility provided for higher conservation status species to minimise the time between the impact of the Plan and conservation benefit achieved by the Plan for these matters

CLARITY ABOUT THE DELIVERY FRAMEWORK

Why is this necessary to ensure effective implementation?

The Plan is a high level framework for delivering urban and transport development consistent with regulatory requirements for biodiversity outcomes. This framework needs to be given effect through delivery mechanisms that turn the high level requirements of the Plan into specifics so that delivery partners and developers know exactly what they need to do at a site or project level to meet the requirements of the Plan.

What is required to achieve this?

To achieve this, the Plan needs to:

- Clearly set out how the Plan is intended to be delivered
- Ensure the delivery framework is legally robust
- Ensure delivery partners act consistently with the Plan
- Enable the NSW Government to take action to ensure compliance

Is the Plan consistent with what is required?

Set out how the Plan is intended to be delivered

The Plan sets out a clear delivery framework for implementation. The primary delivery framework for the Plan is the existing NSW planning system. The Department is proposing a new State Environmental Planning Policy (SEPP) as the key statutory mechanism to implement strategic conservation planning and to provide certainty that the Plan's commitments and actions to protect, enhance, maintain and restore biodiversity in Western Sydney will be met

The key parts of the planning system that will be used to implement the Plan are described in Chapter 9, and include:

- Strategic plans, such as LUIIPs
- Precinct plans
- Neighbourhood plans
- DCPs
- Development applications
- Environment (E2) conservation zoning
- Planning overlays
- Ministerial Directions

Ensure the delivery framework is legally robust

The Plan ensures the delivery framework is legally robust through:

- Utilising the NSW planning system as the primary delivery framework for the Plan
- Developing a SEPP to support delivery of the Plan

A SEPP is a statutory planning instrument made under the EP&A Act and will ensure development within the nominated areas is consistent with State and Commonwealth approvals for biodiversity. The SEPP will give statutory effect to relevant commitments and actions in the Plan and will:

- Facilitate appropriate development on certified lands in the nominated areas
- Identify and protect areas of high biodiversity value in the nominated areas
- Identify areas across the Plan Area with high biodiversity value that can support the ecological function of the Cumberland subregion and areas with important connectivity or ecological restoration potential
- Minimise impacts from future development on biodiversity values in areas of high biodiversity value
- Support the acquisition of priority areas of high biodiversity value in the Cumberland subregion as conservation lands in perpetuity
- Minimise impacts to biodiversity values on land secured for conservation from adjoining land uses

The SEPP will include a provision that requires Precinct Plans (made as part of the planning framework for nominated areas) and their corresponding land use zones are consistent with the biodiversity approvals under the Plan. The objective of this clause is to ensure that urban development in the nominated areas occurs on the certified land identified under the Plan, to protect land avoided for its high value biodiversity.

Ensure delivery partners act consistently with the Plan

The Plan will ensure delivery partners act consistently with the Plan by establishing service level agreements or memorandums of understanding as part of the process of engaging delivery partners. These will set out:

- Roles and responsibilities
- Processes for delivery
- Funding arrangements
- Stakeholder consultation arrangements
- Any monitoring and reporting requirements

The Department has commenced consultation and collaboration with delivery partners in relation to the Plan.

Enable the NSW Government to take action to ensure compliance

The Plan includes a commitment to implement a surveillance and compliance program to ensure compliance with the Plan and conditions of approval, and includes several actions to deliver this commitment, including:

- Establishing a compliance working group comprising the Department and other key stakeholders
- Preparing a compliance strategy under guidance of the working group

The compliance strategy will address the key elements of an effective compliance program, including:

- Identifying relevant compliance mechanisms used to ensure compliance
- Setting out compliance monitoring/auditing priorities and processes
- Developing a clear decision-making for taking compliance action
- Setting out procedures and protocols for taking compliance action
- Identifying roles and responsibilities for compliance, including monitoring and taking action

CLEAR GOVERNANCE ARRANGEMENTS AND CERTAIN FUNDING

Why is this necessary to ensure effective implementation?

Governance is a broad term and there are many definitions. Governance can be thought of as the systems and structures for implementing the Plan to ensure compliance, transparency and accountability. Robust governance arrangements are necessary to ensure the Plan is delivered efficiently and effectively, and complies with any conditions of approval.

What is required to achieve this?

To achieve this, the Plan needs to:

- Establish an organisational structure and define roles and responsibilities
- Establish assurance mechanisms for delivery of the conservation program
- Ensure funding certainty

Is the Plan consistent with what is required?

The Plan establishes an implementation and assurance framework to ensure the efficient and effective delivery of the Plan. The framework covers governance arrangements, including roles and responsibilities of key delivery partners, assurance mechanisms for delivery of the conservation program and offsets, and funding arrangements.

The Plan and sub-plans are high level documents providing an overarching framework and assurance processes for implementing the Plan. It is appropriate for further details about how key elements of the Plan will be implemented to be developed during early implementation of the Plan. This allows proper consideration of more complex issues, seeking of expert advice through working groups, and comprehensive engagement with key stakeholders. The Plan includes actions to prepare more detailed implementation strategies for all key elements of the Plan, including:

- Conservation program – the Conservation Lands Implementation Strategy
- Restoration – the Restoration Implementation Strategy
- Programs for managing landscape threats – the Weed Control Implementation Strategy, the Pest Animal Control Implementation Strategy, and Fire Management Strategy
- Community engagement and research programs – the Education and Engagement Implementation Strategy, Aboriginal Engagement Implementation Strategy, and Research Program Implementation Strategy
- Compliance program – the Compliance Strategy

These implementation strategies will set out further details about how each of these key elements of the Plan will be implemented, including criteria for decision-making, priorities for action, policy guidance for decision-making and implementation, procedures and protocols, and governance arrangements.

Establish an organisational structure and define roles and responsibilities

The Plan establishes a clear organisational structure for implementation of the Plan and broadly sets out roles and responsibilities for each part of the structure, including delivery partners. The structure includes all relevant organisational levels needed to effectively implement the Plan, including:

- Oversight bodies
- Co-ordinating bodies
- Delivery partners
- Agency partners
- Technical working groups
- Stakeholder groups

The Plan clearly identifies the Department as the responsible agency for delivering the Plan and meeting regulatory requirements as the Party to the strategic biodiversity certification (under s8.9 BC Act) and Approval Holder (under s146B EPBC Act). The Department's role under the Plan includes:

- Meeting statutory requirements (as a Party and approval holder)
- Centrally coordinating the Plan
- Coordinating delivery partners, including setting implementation and reporting requirements
- Preparing regular Plan progress reports for publication
- Identifying breaches and notifying the appropriate regulatory authority

The Plan also establishes a Steering Committee as a key oversight body to:

- Provide strategic direction and make key decisions in relation to implementation
- Ensure commitments and outcomes are monitored and reported on

The Steering Committee includes executive level representatives from the Department, approval/regulators including DAWE and EES, and partner agencies, including Transport for NSW. Working groups will be established where appropriate to advise the Steering Committee on specific issues, including Koala and weed and pest management.

Roles and responsibilities of each body within the organisation structure will be defined in detail during early implementation of the Plan. The Department has commenced consultation with key delivery partners and will finalise and agree roles and responsibilities through service level agreements or memorandums of understanding.

Establish assurance mechanisms for delivery of the conservation program

The Plan includes several processes to ensure offsets are secured in accordance with the Plan and in a timely manner consistent with the staging and impacts of the development. These are:

- A reconciliation accounting process to reconcile offsets secured through the Plan with development impacts
- Adaptive management steps to align the securing of offsets with development

The Plan includes an accounting process to track the impacts of the development on biodiversity values as clearing progresses and progress in securing the offset targets proceeds. If progress in securing offsets is not keeping pace with the impacts, the Plan sets out an adaptive management response that will triggered at a specific point to rectify the balance.

Offset targets will be tracked in terms of hectares of land secured, as well as credits where appropriate. This will be done by undertaking assessments using the BAM at each BSA and reserve to confirm the biodiversity values present, the credits generated at the site, and the contribution the site makes to the hectare targets (Commitment 8, action 7).

The impacts of the urban and industrial development will be tracked using housing data from the Department's existing Sydney Housing Monitor and the Greenfield Housing Monitor. The impacts of the transport development will be tracked by Transport for NSW as the transport projects are constructed, and will be reported regularly to the Department (Commitment 3, action 4 and Commitment 4, action 2). The Department will adjust the predicted impacts and offset requirements associated with the transport corridors through the reconciliation accounting process, and publish adjustments through the Plan's annual updates and five yearly reviews (see Part 2). This process ensures changes to impacts and offset requirements under the Plan because of the future avoidance and minimisation processes needed for the transport corridors is transparent and properly accounted for.

The offset liability of the Plan at any given point in time is determined using a ratio of 3.5:1 applied to the total area (ha) of native vegetation cleared in urban capable land. This ratio was determined based on the method for determining offset targets (see Part 2), which applied a higher ratio to impacted native vegetation of higher condition or threat status to determine the amount of offset target for each protected matter. The offset liability ratio is an average ratio to be applied across all the impacts of development in the urban capable land and would determine the liability in terms total amount of native vegetation (ha) to be offset, rather than a specific amount of impacted TEC or species. This is considered to be a practical and feasible approach to determining the offset liability at any given point in time, and consistent with the flexibility built into the 'conservation lands selection steps' (see above).

If progress in securing offsets is not keeping pace with the impacts of the development, the Plan specifies that:

- No action will generally be taken in the first 5 years of implementation to address any imbalance
- If the offsets secured are less than 80 per cent of the offset liability after Year 5, the executive implementation committee will consider a response. This will include, in order of priority:
  - Voluntary property acquisition
  - Compulsory property acquisition
  - Land use planning responses to development

The Office of Strategic Lands will prioritise voluntary acquisition of properties through several approaches, including market purchase, passive voluntary acquisition, or active and targeted voluntary acquisition . The Department will consider the use of compulsory acquisition only after voluntary options are not successful. The Department would consult with the community and key stakeholders before compulsory acquisition was undertaken.

The Plan specifies that land use planning responses may include:

- Pause rezoning of remaining precincts in the nominated areas, until sufficient offsets are secured
- If rezoning of all nominated areas has occurred, place a moratorium on development assessments being determined within the nominated areas via an amendment to the EP&A Regulation (2000).

These planning responses would be considered as a final option after at least 2 years of attempting to address the imbalance between offsets and impacts (i.e. not before Year 8). The planning response will remain in place until the amount of offsets secured are greater than 80 per cent of the offset liability at that point in time.

Ensure funding certainty

The NSW Government will establish a conservation fund to implement the Plan. Funding will be secured using a public-private funding model. The model involves upfront investment from the government and substantive cost-recovery through the biodiversity component of a Special Infrastructure Contribution (SIC) levy imposed on housing development in the nominated areas.

By using an existing process to collect the levy, the SIC, the Plan ensures clarity regarding:

- Legal robustness of the levy
- How the levy is collected
- When and over what land the levy is payable
- Whether the levy can be reviewed or challenged by a developer
- Compliance mechanisms to ensure the levy is paid

In addition to using a SIC, the Plan includes an additional level of accountability and transparency in relation to funding by establishing a Trust to administer funds on behalf of the Department. Furthermore, the Plan includes an action to prepare a funding framework in consultation with the Trust to set out how funding decisions will be made and administered.

Consistent with best practice, the funding arrangements under the Plan:

- Were supported by a robust process to estimate costs
- Include indexing developer contributions to ensure purchasing power is maintained over time
- Include a transparent and independent evaluation program to ensure conservation outcomes are delivered

It is important to consider the need for some upfront government contributions to ensure funding is available early during implementation. Funding tied solely to a levy on development creates the following risks:

- Delays at the start of implementation before adequate funds from a levy become available
- Delays later during implementation due to downturns in development
- Priority biodiversity values are lost or degraded prior to being secured under the conservation program

As demonstrated by the trend analysis (see Box 1 and Supporting Document D), the existing level of landscape threats in the Cumberland subregion is significant. This creates a substantial risk that biodiversity values degrade before land is secured, which may reduce the effectiveness or increase the costs of the conservation program.

This risk is addressed to a large extent under the Plan through the NSW Government committing to fund the first five years of implementation of the Plan, and prioritising the establishment of three new reserves to deliver upfront strategic offsets to protect TECs and species habitat. These are:

- The Georges River Koala Reserve – This is the most important north–south Koala movement corridor along the Georges River between Appin and Kentlyn, and contains around 1,500 hectares of native vegetation, including approximately 375 hectares of Shale Sandstone Transition Forest and 60 hectares of Cumberland Plain Woodland
- The Gulguer Reserve Investigation Area – This investigation area covers about 1,800 hectares and is located in the Warragamba area. A reserve in this area will support the east-west connection between Burragorang State Conservation Area and Gulguer Nature Reserve. TECs contained the potential reserve include approximately 600 hectares of Shale Sandstone Transition Forest and 200 hectares of Cumberland Plain Woodland
- The Confluence Reserve Investigation Area – This investigation area lies in the Hawkesbury LGA in the north of the Plan Area, to the east of Londonderry and covers about 600 hectares. It has been identified as a potential area for conservation and ecological restoration efforts due to its proximity to several existing nature reserves

These reserve locations are not final and are likely to be refined. Other areas within the SCAs have also been identified for further investigation as future reserves to provide greater landscape connectivity, such as the Bargo area.

COMPREHENSIVE MONITORING AND REPORTING ON IMPLEMENTATION, WITH ADAPTIVE RESPONSES AS NEEDED

Why is this necessary for effective implementation?

Monitoring, evaluation, reporting and improvement through adaptive management (MERI) is essential for ensuring implementation of the Plan is effective, transparent and accountable. MERI enables key stakeholder, such as regulators and the public, to understand:

- How efficiently and effectively the Plan is being implemented
- Whether the Plan's outcomes are being achieved
- Adaptive improvements in implementation to better achieve the outcomes

What is required to achieve this?

To achieve this, the Plan needs to include:

- A clear commitment to MERI
- A MERI framework underpinned by a program logic
- Clarity on scope and timing of monitoring, reporting and evaluations
- Evaluation of outcomes not just 'outputs'
- Clarity on when and how adaptive management will be implemented
- A plan for implementing the MERI framework supported by funding

Is the Plan consistent with what is required?

A clear commitment to MERI/adaptive management

The Plan includes a commitment to implement a monitoring, evaluation and reporting program consistent with an overall MERI framework described in Sub-Plan A (Commitment 27). This commitment is supported by several actions to ensure the MERI framework is implemented effectively. The MERI framework provides for:

- Monitoring of the delivery of actions and commitments and achievement of outcomes
- Evaluation of the Plan at annual and 5-yearly intervals to inform adaptive management responses
- Public reporting on progress in delivering the Plan

A MERI framework underpinned by a program logic

The MERI framework has been developed on the basis of the program logic underpinning the Plan (see Chapter 5). The program logic describes broadly how the Plan will be implemented and how the commitments and actions are expected to lead to the Plan's outcomes. Developing the MERI framework on the basis of the program logic helps to:

- Clearly articulate assumptions underpinning the Plan (e.g. that action X leads to the delivery of commitment Y, which leads to the achievement of outcome Z)
- Determine robust Key Evaluation Questions (for evaluations) and Key Performance Indicators (for monitoring)
- Inform evaluations and adaptive improvements to implementation of the Plan

Clarity on scope and timing of monitoring, reporting and evaluations

Sub-Plan A sets out the scope and timing of monitoring, reporting and evaluations (see also Chapter 9).

Monitoring will be undertaken regularly throughout implementation of the Plan to inform the evaluations and will include monitoring of commitments and actions as well as outcomes, including monitoring and assessment of changes to biodiversity values at specific locations to determine whether the commitments and actions are effective.

Evaluations will be undertaken on an annual and 5-yearly basis over the life of the Plan and not just at the end of implementation. This is important for effective MERI so there is scope for adaptive management of the Plan, if necessary, to ensure commitments and outcomes are met. The evaluations will aim to:

- Determine the effectiveness of commitments and actions to deliver outcomes
- Reconsider assumptions made as part of the program logic
- Determine the influence of external factors outside the control of the Plan
- Inform any necessary adaptive management decisions to the implementation of the Plan

Reporting will include:

- An annual update on the delivery of the commitments and actions, including program revenue and expenditure
- A fire-yearly independent review on the status of the Plan, its delivery and interim outcomes, based on evaluations

Evaluation of outcomes not just 'outputs'

The purpose of an evaluation is to determine how well the Plan is being delivered and to provide a trigger point and basis for adaptive management of the Plan. An evaluation should include analysis of the achievement of outcomes, as well as the delivery of commitments and actions, because outcomes are what key stakeholders, including regulators and the public, are most interested in understanding. Evaluating outcomes also enables:

- Assumptions underpinning the program logic to be tested
- Effectiveness of the delivery of commitments and actions to be evaluated

An evaluation should also go beyond merely determining whether commitments or actions are being delivered or outcomes are being achieved, and should ask:

- If outcomes are not being delivered, why?

- How efficiently and effectively are commitments and actions being delivered?

Consistent with best practice, the Plan includes two types of evaluations:

- Evaluation of program implementation (or delivery of commitments and actions)
- Evaluation of program impact (or effectiveness and efficiency of the achievement of outcomes)

The Plan will undertake these evaluations on the basis of Key Evaluation Questions. A set of draft evaluation questions have been prepared for each evaluation type (Sub-Plan A, Appendix F).

Clarity on when and how adaptive management will be implemented

Adaptive management is critical for effective implementation given the Plan is inherently subject to uncertainty and assumptions. Key elements of good adaptive management are:

- Clearly defining outcomes
- Undertaking regular data collection/monitoring to track progress
- Completing regular evaluations to investigate cause and effect, efficiency and effectiveness, and test assumptions
- Establishing programs of research to test and improve management interventions

The Plan includes each of these key elements to enable effective adaptive management (see above).

Adaptive management under the Plan will use data from monitoring and the findings of program evaluations to determine whether actions need to be revised to more effectively achieve the commitments and outcomes.

Where an evaluation indicates a commitment or outcome is not being effectively and efficiently delivered or achieved, the Plan specifies that this will trigger a detailed review of implementation. This will be carried out by the relevant delivery agency for that particular project or program, in partnership with the Department.

The Plan specifies that adaptive responses may be triggered where:

- Offset targets are not being met
- External factors arise that affect the assumptions, logic or delivery of the Plan

The adaptive management steps to be taken where offset targets are not being met are described above.

A plan for implementing the MERI framework supported by funding

The Plan includes an action under Commitment 26 to finalise the evaluation program in consultation with key stakeholders, including:

- Establishing governance arrangements for the evaluation program
- Developing a monitoring and data collection method
- Finalising evaluation questions including scope and frequency
- Finalising the reconciliation accounting process (see above)
- Developing templates for reporting quarterly to the executive implementation steering committee and annual updates over the life of the Plan. Identify key performance indicators for biodiversity conservation

This action will provide clarity about how the MERI program will be delivered, including important matters such as what Key Performance Indicators will be used for monitoring, how monitoring will be undertaken data collected, and the frequency and locations (where appropriate) of monitoring for each indicator.

The Plan includes a commitment to establish funding for implementation (see above). Details of how much funding will be set aside to implement the monitoring, evaluation and reporting program will clarified in consultation with the Trust administering the funds under the Plan during early implementation of the Plan.

41.11.3 CONCLUSION

The Plan includes the key elements that are considered to be important for effective delivery and to achieve its intended outcomes. In particular, the Plan provides:

- Clear and feasible outcomes
- Clarity about the delivery framework and mechanisms to implement the Plan
- Appropriate flexibility to ensure it remains relevant over time
- Clear governance arrangements, including certain funding
- Comprehensive processes to monitor and report on implementation, and adapt implementation as needed

It is important to note that the Plan and subplans are high level documents providing an overarching framework and assurance processes for implementing the Plan, and that successful implementation relies on considerable further work being done during the early stages of implementation to sort out details. This is appropriate because it allows detailed consideration of complex issues, seeking of expert advice, and comprehensive engagement with stakeholders.

The Plan provides a clear framework for this future implementation work by identifying a set of actions that will be undertaken to deliver each commitment within a program logic framework.

41.12 THEME 9: DOES THE PLAN FACILITATE ADAPTATION TO CLIMATE CHANGE?

41.12.1 CONTEXT AND METHOD

The ToR (Section 4.6(5) and 5.3(1)) requires analysis of the extent to which the Plan considers, and the commitments under the Plan facilitate, adaptation of biodiversity to climate change.

The extent and nature of the impacts of climate change on specific biodiversity values is difficult to predict. There is a lack of information about how specific matters are likely to respond to climate change, and there is debate and uncertainty over how to best facilitate adaptation. Given this, the evaluation was undertaken in two main ways:

- A qualitative evaluation using a set of broad principles derived from the scientific literature on how to best manage the impacts and facilitate adaptation of biodiversity to climate change
- A quantitative evaluation using a recent study by Macquarie University that modelled changes to future habitat suitability on the Cumberland Plain for some Commonwealth listed species under several climate change scenarios

The qualitative evaluation was done to complement the quantitative evaluation because quantitative data is not available for all Commonwealth listed TECs and species and there are limitations associated with this data.

MACQUARIE UNIVERSITY STUDY

Scope of the study

The quantitative evaluation was based on a study by Macquarie University (Macquarie University, 2019) that modelled how climate change will affect the suitability of habitat for 92 Cumberland subregion species, including 23 Commonwealth listed Category 1 matters, under several different climate change scenarios. The study:

- Assessed the change in extent and location (losses and gains) of currently suitable habitat for each species under future climate changes. This helps to:
  - Understand how the availability of suitable habitat for a species may change in the future
  - Identify the species particularly vulnerable to climate change in terms of loss of habitat
- Determined the extent to which currently suitable habitat will remain suitable under future climate changes for each species. These areas represent climate refugia for those species
- Identified localities that are likely to remain suitable for multiple species under future climate changes. These areas represent climate refugia likely to be most robust to climate change for multiple species

Species Distribution Models (SDMs) were used to predict habitat suitability for species. The SDMs were developed specifically for the Macquarie University Study and are different to the SDMs used in the species impact assessments in this Assessment Report. The SDMs were developed on the basis of seven climate and environmental variables relating primarily to temperature and precipitation. For some species, additional environmental variables were used relating to soils, weathering and topography.

Changes to suitable habitat are discussed in the study in terms of total and local suitable habitat:

- Local suitable habitat is the area of suitable habitat within an IBRA subregion that contains records for the species. This reflects an assumption that the ability for a species to disperse into areas of future suitable habitat is limited to within IBRA subregions that are already populated by the species
- Total suitable habitat is the total area of suitable habitat for a species (ignoring current records). This reflects an assumption that the ability for species to disperse into areas of future suitable habitat is unlimited

Climate scenarios modelled

The study was based on four NARCliM climate scenarios that were modelled on an assumed emissions scenario (SRES A2) (see Table 41-28). The project modelled climate scenarios over three time periods:

- Baseline climate (1990–2009)
- Near-future (2020–2039)
- Distant future (2060–2079)

Table 41-28: Climate scenarios projected by four Global Climate Models

Scenario	Global Climate Model	Summary of future climate
Warmer/Wetter	MIROC3.2(medres)	Warmer and wetter than present, particularly in north eastern NSW, although alpine regions are projected to become drier
Hotter/Little Change	ECHAM5/MPI-OM	Has the greatest increase in temperature of the four scenarios. Precipitation trend varies across the state (slightly wetter in the north eastern and coastal regions, slightly drier elsewhere)
Hotter/Wetter	CCCMA CGCM3.1(T47)	Warmer than MIROC, and wetter across most of the state, although areas in the northwest and southeast of the state may be slightly drier
Warmer/Drier	CSIRO-Mk3.0	Warmer than present, and the driest of the four models

Key limitations of the study

The study is subject to several limitations. A key limitation is that the SDMs were not informed by the current extent of native vegetation and habitat in the Cumberland subregion. This means they may predict that suitable habitat occurs in areas that no longer contain native vegetation or habitat because of land clearing or urban development.

The study is useful in providing a broad indication of the adequacy of the Plan in facilitating adaptation to climate change. However, the results, particularly in relation to predicting areas in the Cumberland subregion likely to remain suitable for species under future climate changes, must be considered in the context of actual on-ground circumstances.

41.12.2 ANALYSIS

QUALITATIVE ANALYSIS

This section outlines a general set of key principles drawn from the scientific literature on how to best facilitate adaptation of biodiversity to climate change and analyses the Plan against these principles to help evaluate the extent to which the Plan is likely to facilitate adaptation of biodiversity to climate change.

Principles for managing biodiversity under climate change

The goal of adaptation can be defined as reducing the risk of adverse impacts by enhancing the 'resilience' or 'resistance' of ecosystems to change. Resilience strategies attempt to enhance a systems ability to recover from change, while resistance strategies attempt to enhance a systems ability to resist change (Heller & Zavaleta, 2009).

Scientists and practitioners have proposed a wide range of principles or strategies to manage the impacts of climate change on biodiversity (Heller & Zavaleta, 2009). A set of commonly recommended key principles can be derived from the literature. These principles are:

- Ensure representativeness and replication
- Protect the largest and most viable patches
- Maintain and improve habitat connectivity
- Reduce the impacts of other threats
- Manage uncertainty through adaptive management

Most of these principles are consistent with general conservation planning principles, and scientists often argue that many conservation planning principles remain robust under a changing climate (e.g. see Hodgson, Thomas, Wintle and Moilanen, 2009). Despite this, in identifying this set of key principles, it is recognised that:

- There is considerable uncertainty about the how climate change will impact biodiversity and the best ways to facilitate adaptation of biodiversity to climate change
- Measures to facilitate adaptation of biodiversity to climate change are likely to be regional and species-specific
- There may not be scientific consensus on all of these key principles and the relative importance of each
- There is much uncertainty about how each of the key principles should be applied in practice

Ensure representativeness and replication

Representativeness and replication are well established principles of conservation planning. Representation refers to the need to protect the full range of biodiversity (e.g. vegetation types). Replication refers to the need to protect multiple examples of each unit of biodiversity to order to spread risk (Margules & Pressey, 2000).

These two principles will continue to be important in facilitating adaptation of biodiversity to climate change (Dunlop & Brown, 2008; Heller & Zavaleta, 2009). Dunlop and Brown argue:

> *By sampling a diversity of communities…[we] are also sampling the underlying geographic diversity of the landscape…Thus, a set of areas that samples a high diversity of communities now will probably also capture a high diversity of communities under future climates, even if the composition of the communities is different in the future*

The extent to which the SCAs include a representative sample of each PCT in the Plan Area (including PCTs impacted by the development), and contribute to total representativeness within protected lands in the Plan Area, is assessed in Section 41.6 (see Table 41-17). The analysis indicates that the SCAs:

- Include all but 2 of the 32 PCTs in the Plan Area
- Contribute to total representation within protected lands in the Plan Area of greater than 15 per cent for all but 3 PCTs
- Have the potential to make a substantial contribution to existing levels of representation of PCTs in the Plan Area, including to many PCTs that are currently under-represented in existing reserves

Protect the largest and most viable patches

Another well-established principle of conservation planning is to focus conservation efforts on protecting and restoring large patches. There are well established relationships between the size of a patch of native vegetation and the size and persistence of populations, species richness, species dispersal, genetic diversity, persistence of large vertebrates, maintenance of near-natural disturbance regimes, and other important ecological functions (Hodgson, Thomas, Wintle and Moilanen, 2009; Lindenmayer et al., 2008; Margules & Pressey, 2000).

Scientists argue this principle will continue to be important in facilitating adaptation of biodiversity to climate change. Because habitat loss remains the key threat to biodiversity and relationships between patch size and biodiversity value is well-established, protecting areas of high quality native vegetation and habitats should remain the primary focus of conservation efforts under climate change (Heller & Zavaleta, 2009; Hodgson, Thomas et al., 2009).

The extent to which the SCAs include large (> 50 ha) and moderate (> 20 ha) patches is assessed in Section 41.7 (see Table 41-21 and Table 41-22). The analysis indicates that the SCAs protect substantial areas of large patches, as:

- Approximately 87 per cent of the total area of native vegetation in the SCAs comprises patches > 50 ha
- The SCAs contain about 35 per cent of the total area of patches > 50 ha in the Plan Area

Habitat connectivity

Maintaining and improving habitat connectivity is often considered the most important strategy to manage the impacts of climate change on biodiversity (Dunlop & Brown, 2008; Heller & Zavaleta, 2009). Despite this, there is much uncertainty about the importance of habitat connectivity in managing the impacts of climate change. Some scientists argue that other, more certain strategies, such as protecting the largest patches of high quality native vegetation, should be prioritised over habitat connectivity (Hodgson, Thomas et al., 2009):

> *As uncertainties about connectivity tend to be high, and increases in habitat quantity and quality coincidentally improve connectivity, we conclude one should generally provide higher weight in decision-making to actions that increase area and quality [of habitat] Theoretically, we know that populations will sometimes benefit more from a small, well-connected piece of habitat than a larger, more isolated one, but the relative uncertainties and the probability of worse-than-expected outcomes [from improving habitat connectivity] should also affect our decision making…*

The extent to which the SCAs include the most important areas of habitat connectivity in the Cumberland subregion (BioMap core areas and BioMap corridors – see Section 41.7) is assessed in Section 41.6 and Section 41.7. The analysis indicates that the SCAs protect substantial areas of BioMap core areas and corridors, including:

- Approximately 32 per cent of the total BIOMap core areas in the subregion
- Approximately 28 per cent of the total BIOMap corridors in the subregion

The SCAs are therefore likely to make a substantial contribution to supporting habitat connectivity across the subregion.

It is also important to note that habitat connectivity was a key factor influencing the location of the SCAs (see Chapter 8). Priority was given to including areas that were adjacent to and connecting other patches of habitat, including existing reserves, and that could form broad habitat corridors across the landscape.

The SCAs were also located to provide connectivity outside the Cumberland subregion, including to existing reserves in the Blue Mountains to the west of the subregion, and existing reserves and protected water catchments to the south-east and south-west (see Chapter 8). This potentially enables more mobile species to shift to higher elevations (e.g. the Blue Mountains) or south to cooler climates in response to climate change. Large-scale corridors that span climatic gradients such as provided by the SCAs can enhance the capacity of species to shift to more favourable areas, allowing species to respond to shifting climates' (Adaptation Research Network Terrestrial Biodiversity, 2017).

Reduce the impacts of other threats

Some scientists argue that given the uncertainty about the impacts of climate change on biodiversity and how best to facilitate adaptation, focusing on reducing key existing threats to biodiversity provides a robust strategy to address climate change. For example, Steffen et al (Steffen, Burbidge et al., 2009) state:

> *A central strategy is giving ecosystems the best possible chance to adapt by enhancing their resilience. Approaches to building resilience include managing appropriate connectivity of fragmented ecosystems…* [and] *implementing more effective control of invasive species, and developing appropriate fire and other disturbance management regimes*

The Plan recognises that the effective management of landscape scale threats is critical to the success of the conservation program under the Plan and in managing the impacts of climate change on biodiversity. The Plan includes a range of commitments to reduce threats to conservation lands secured within SCAs. These are discussed in Section 41.7.

Address uncertainty through adaptive management

Adaptive management is an iterative process that seeks to improve management over time by testing hypotheses and learning from the results, and then incorporating lessons learnt into future management actions.

Many scientists argue that given the uncertainty about the impacts of climate change on biodiversity and how best to facilitate adaptation, management within an adaptive framework will be critical to facilitating adaption.

The Plan will be implemented adaptively to ensure the commitments and actions are delivered and the outcomes are achieved efficiently and effectively. Adaptive management will be triggered on the basis of the findings of the evaluations undertaken as part of the monitoring, evaluation and reporting program under the Plan.

The approach to adaptive management under the Plan is described in Chapter 9 and evaluated in Section 41.11.

QUANTITATIVE ANALYSIS

The quantitative analysis, based on the Macquarie University study (Macquarie University, 2019), was used to identify the Commonwealth listed species most vulnerable to climate change, as well as determine the extent to which the SCAs contain suitable habitat for these species and refugia for multiple species under future climate changes.

Species most vulnerable to climate change

The Macquarie University study modelled the change in the area of 'currently occupied' suitable habitat across the Cumberland subregion and NSW under the different climate scenarios. 'Occupied habitat' means the proportion of the climatically suitable habitat that is also found within a subregion for which there are records.

Table 41-29 shows the results of the study for the 23 Commonwealth listed Category 1 species. The table shows the area of 'occupied' suitable habitat remaining at 2030 and 2070 that is predicted to remain suitable under all climate scenarios (i.e. there is consensus across all climate scenarios that the area remains suitable).

The table also indicates that climate change may have substantial impacts on suitable habitat for the vast majority of Commonwealth listed Category 1 species. Of the 23 Category 1 species modelled:

- The majority are predicted to have no suitable habitat remaining in the Cumberland subregion at 2070
- The vast majority are predicted to be subject to substantial declines of greater than 50 per cent in suitable habitat within NSW by 2030 and by 2070

The species likely to be most vulnerable to climate change were defined for this assessment as species with less than 100 km^2 of 'occupied' suitable habitat remaining at 2030 across NSW. These species are highlighted in blue and are:

- *Eucalyptus benthamii*
- *Leucopogon exolasius*
- *Micromyrtus minutiflora*
- *Persoonia bargoensis*
- *Persoonia nutans*
- *Pomaderris brunnea*
- *Pultenaea parviflora*

Table 41-30 identifies the risk of impacts of the Plan on these seven species and the commitments under the Plan relevant to each species, drawing on the assessments in this Assessment Report (see Chapter 29).

The table shows that the risk of impacts of the Plan on these species is generally considered to be very low or low.

The Plan includes commitments to secure offset locations for *Personnia nutans* and *Pultenaea parviflora* and substantial areas of potential habitat for each of these seven species through meeting offset targets for Plant Community Types (PCTs) – see Section 41.5) in conservation lands within the SCAs.

Given the low risk of impacts to most of these species, the specific offsets being provided for the two higher risk species, and the consistency of the SCAs with adaptation principles (see above), it is considered that the commitments are adequate to facilitate adaptation to climate change for these species.

Table 41-29: Predicted impacts of climate change on currently 'occupied' habitat at 2030 and 2070 under all climate scenarios

Suitable habitat for species in Cumberland subregion

Table 41-31 shows the predicted area of 'occupied' suitable habitat within SCAs at 2070 under all climate scenarios for the 23 Commonwealth listed Category 1 species. The species likely to be most vulnerable to climate change (as defined above) are highlighted in blue in the table. The table shows that:

- The majority of species are predicted to not have any suitable habitat remaining in Cumberland subregion at 2070
- The SCAs are predicted to contain suitable habitat for five of the 23 Commonwealth listed Category 1 matters at 2070
- The SCAs do not contain any suitable habitat for the species most vulnerable to climate change (highlighted in blue). However, none of these species are predicted to have any suitable habitat remaining in the subregion at 2070

Table 41-31: Predicted area of 'occupied' suitable habitat within SCAs at 2070 under all climate scenarios

Refugia for multiple species in Strategic Conservation Areas

The study identified the localities in the Cumberland subregion that are likely to continue to have suitable climates for multiple threatened species under all climate scenarios. These are called 'high value' refugia and are particularly valuable for conservation as they represent the areas that are most likely to be robust to climate change.

High value refugia were identified in the study by combining maps for each species of 'occupied' suitable habitat that remains suitable under all climate scenarios, and calculating the number of species for which each map cell was suitable.

Table 41-32 show the extent to which the SCAs contain potentially suitable habitat for multiple species (of the 92 species modelled in the study) under all climate scenarios ('high value refugia'). The figures shown in the table are not additive (e.g. row 1 means that there is a total of 4,300 ha of habitat in the SCAs that is suitable for all 9 species).

The table shows:

- Some localities in the Cumberland subregion retain potentially suitable habitat (a total 100 ha) under all climate scenarios for up to a maximum of 22 of the 92 modelled species
- The SCAs include localities that retain considerable areas of potentially suitable habitat (a total of 4,300 ha) under all climate scenarios for multiple species (a maximum of 9 species)

Table 41-32: Extent to which SCAs contain habitat for multiple species under all climate scenarios

Number of species	Area of habitat in Cumberland subregion suitable for that number of species (ha)	Area of habitat in SCAs suitable for that number of species (ha)	Percentage of total habitat in Cumberland subregion included in SCAs (%)
9	34,800	4,300	12%
15	18,300	700	4%
22	100	0	0%

41.12.3 CONCLUSION

The extent and nature of the impacts of climate change on specific biodiversity values is difficult to predict. There is a lack of information about how specific matters are likely to respond to climate change, and there is debate and uncertainty over how to best facilitate adaptation of biodiversity to climate change.

- Protect the largest and most viable patches
- Maintain and improve habitat connectivity
- Reduce the impacts of other threats
- Manage uncertainty through adaptive management

The quantitative analysis, which was based on the Macquarie University study, suggests that climate change will significantly impact the availability of suitable habitat in the Cumberland subregion for the vast majority of the 92 modelled Commonwealth-listed species.

The risk of impacts of the Plan on the seven species identified as being most vulnerable to climate change is generally considered to be low. In the context of this risk, and given the consistency of the SCAs with adaptation principles, it is considered that the commitments under the Plan are adequate to facilitate adaptation to climate change for these species.

While the SCAs are predicted to only contain suitable habitat for five of the 23 Commonwealth listed Category 1 matters at 2070, the majority of species are predicted to not have any suitable habitat remaining in Cumberland subregion.

It is important to note that the Macquarie University study is subject to several key limitations. This means the results must be considered in the context of actual on-ground circumstances, including whether areas predicted to retain suitable habitat under future climate changes have not been cleared and still contain habitat.

41.13 CONCLUSION

It is considered that the Plan will deliver substantial conservation outcomes for the Cumberland subregion and adequately addresses the likely impacts of the urban, industrial, infrastructure, agribusiness and transport development on biodiversity values and other protected matters under the BC Act and EPBC Act.

The Plan is broadly consistent with the 'draft guidelines for planning authorities' (EES, 2019) and the requirements in the Commonwealth Terms of Reference relating to evaluating the commitments. In particular, the Plan:

- Is broadly consistent with the principles of ESD
- Has achieved substantial avoidance outcomes for biodiversity values, including avoiding 95 per cent of all high (intact) condition) native vegetation, and has adequately avoided SAII entities
- Includes commitments that:
    - Adequately address the biodiversity values being impacted
    - Address the most important biodiversity values, particularly the most threatened matters
    - Are considered likely to improve values and ecological function in the long-term
    - Are additional to existing requirements
    - Involve development controls that conserve the environment
    - Involve new reserves generally consistent with the CAR reserve framework
    - Are likely to be effectively implemented and ensure outcomes are certain
    - Are consistent with key principles for facilitating adaptation of biodiversity to climate change

In concluding that the Plan adequately addresses the impacts of the development, it is important to note that the Plan's commitments are not driven solely by meeting the biodiversity credit requirements of the BAM, which is a key part of the definition of 'no net loss' under the BAM. This is consistent with the BC Act. For strategic biodiversity certifications such as the Plan, the Act does not require the value of commitments be calculated in terms of credits. This recognises that strategic biodiversity certification provides significant opportunities to maximise benefits to biodiversity and address landscape scale conservation challenges that are not provided by site-by-site assessment processes.

The key commitments under the Plan have been developed in recognition of these potential benefits, including:

- Focusing the conservation program, including offsets, on the areas of the landscape considered most likely to be viable in the long-term and maximise ecological function and connectivity across the landscape
- Addressing ecological function and landscape-scale ecological processes through improving habitat connectivity and undertaking ecological restoration in priority parts of the landscape
- Implementing programs to manage threats at a landscape scale that can benefit multiple species and TECs

- Focusing the conservation program, including offsets, on the areas of the landscape considered most likely to be viable in the long-term and maximise ecological function and connectivity across the landscape
- Addressing ecological function and landscape-scale ecological processes through improving habitat connectivity and undertaking ecological restoration in priority parts of the landscape
- Implementing programs to manage threats at a landscape scale that can benefit multiple species and TECs
- Consolidating offsets into larger patches that are likely to be more viable in the long term

Furthermore, modelling work undertaken as part of the Assessment Report that looked at trends in native vegetation extent and condition in the subregion (see Supporting Document D) demonstrated that the existing level of landscape threats is significant and is likely to lead to substantial declines in native vegetation over time unless action is taken. The Plan's commitments will help to address this ongoing decline by ensuring large areas in the landscape are secured and managed in perpetuity and through programs to manage landscape threats.

A key implication of the modelling work for the Plan is that offsets should be established as early as possible to help reverse the trend of decline. This is addressed to a large extent under the Plan through the NSW Government committing to fund the first five years of implementation of the Plan and prioritising the establishment of three new reserves (the Georges River Koala Reserve, the Gulguer Reserve Investigation Area, and the Confluence Reserve Investigation Area) to deliver early strategic offsets to protect TECs and species habitat.

CUMBERLAND PLAIN ASSESSMENT REPORT

PART 8: SUPPORTING DOCUMENTS

PREPARED FOR THE NSW GOVERNMENT DEPARTMENT OF PLANNING, INDUSTRY AND ENVIRONMENT

Part 8 – Contents

AUGUST 2020

CUMBERLAND PLAIN ASSESSMENT REPORT

Supporting document A – EPBC agreement and ToR

THE HON MELISSA PRICE MP
MINISTER FOR THE ENVIRONMENT

MS18-001422

The Hon Anthony Roberts MP
NSW Minister for Planning
52 Martin Place
SYDNEY NSW 2000

12 NOV 2018

Dear Minister Roberts

Thank you for your letter of 18 October 2018, providing the statutory Agreement to undertake a strategic assessment under Part 10 of the *Environment Protection and Biodiversity Conservation Act 1999* for Western Sydney, signed by yourself and Minister Upton.

I am writing to inform you that I have counter-signed the Agreement and have enclosed a copy for your records. I understand that you and Minister Upton will now invite public comments on the draft Terms of Reference for the assessment.

I look forward to the assessment proceeding, and to working with you to ensure good environmental outcomes from this important commitment under the Western Sydney City Deal.

Yours sincerely

MELISSA PRICE

CC: Minister for Cities, Urban Infrastructure and Population, the Hon Alan Tudge MP

ENVIRONMENT PROTECTION AND BIODIVERSITY CONSERVATION ACT 1999 (Cth)

Part 10 Strategic Assessment

Section 146 agreement

Strategic Assessment of the impacts of actions taken under
the *Cumberland Plain Conservation Plan*
on matters protected by Part 3 of the EPBC Act

between

THE COMMONWEALTH MINISTER FOR THE ENVIRONMENT

and

THE STATE OF NEW SOUTH WALES

Table of Contents

1. Parties

1.1 The parties to this agreement are:

the Commonwealth Minister for the Environment

and

The State of New South Wales, represented by the Minister for Planning and the Minister for the Environment.

2. Definitions

2.1 Unless the context indicates otherwise in this agreement, the definitions, meanings and terms in the EPBC Act apply to this agreement including its attachments.

2.2 In this agreement:

agreement means this strategic assessment agreement entered into between the **parties** on the date the last party executes this agreement, and includes any attachments.

attachment means an attachment to this agreement.

Commonwealth Environment Department means the Commonwealth Department with responsibility for administering the EPBC Act from time to time.

Commonwealth Minister means the Commonwealth Minister with responsibility for administering the EPBC Act, and includes a delegate of the Minister.

DPE means the New South Wales Department of Planning and Environment.

EPBC Act means the *Environment Protection and Biodiversity Conservation Act 1999* (Cth).

Impact means an impact as defined under section 527E of the EPBC Act and includes impacts from an event or circumstance as a result of implementation of the Plan on areas outside the strategic assessment area.

Impacts to which this agreement relates means the impacts of actions under the Plan on any matter protected by a provision of Part 3 of the EPBC Act.

OEH means the New South Wales Office of Environment and Heritage.

Parties means the parties to this agreement as set out at clause 1.

Plan means the *Cumberland Plain Conservation Plan* which will be prepared pursuant to clauses 4 and 6 of this agreement and which constitutes a 'policy, plan or program' pursuant to section 146 of the EPBC Act. The actual name of the Plan may change prior to submission for endorsement under the EPBC Act.

Protected matter means a matter protected under Part 3 of the EPBC Act.

State means the State of New South Wales.

Strategic assessment area means the indicative area of the Cumberland Plain as shown in the map at **Attachment 1**. The final strategic assessment area will be agreed between the State and Commonwealth.

Strategic Assessment Report means the report describing and assessing the impacts of actions under the Plan on protected matters, as contemplated by section 146(2)(a) of the EPBC Act, and prepared under clauses 5 and 6 of this agreement.

Supplementary Report means a report which includes:

a) a summary of all the public comments received; and

b) sets out how comments have been addressed through modification/s to the Plan or Strategic Assessment Report, if any, following public exhibition of the draft Strategic Assessment Report and draft Plan.

Terms of Reference means the terms of reference for the Strategic Assessment Report prepared under clause 5 of this agreement.

In this agreement references to the singular include the plural.

3. Context and scope

3.1 Under the Western Sydney City Deal, the Commonwealth, the State of NSW and a number of local councils have committed to working together to improve the lives of the people of Western Sydney through better transport, improved housing supply and affordability, better access to jobs and improved environmental outcomes.

3.2 The Parties acknowledge that the Cumberland Plain of Western Sydney has important environmental values that must be considered alongside the economic and social benefits of development of the region, and that a landscape approach to planning may benefit the environment.

3.3 The Parties agree to reduce duplication and streamline regulatory processes through alignment of a strategic assessment under Part 10 of the EPBC Act with an application for biodiversity certification under the NSW *Biodiversity Conservation Act 2016*. This may include conducting parallel public consultation periods and producing consolidated assessment documentation that satisfies regulatory processes of both jurisdictions.

3.4 The Parties agree to undertake a strategic assessment of the impacts of actions under the *Cumberland Plain Conservation Plan* (the Plan), currently being prepared by the State of NSW, on all matters protected under Part 3 of the EPBC Act.

3.5 The Plan will aim to provide for development over approximately 38 years within the boundary of the strategic assessment area. The Plan may include consideration of residential, commercial and industrial developments, and supporting infrastructure including major transport corridors for future roads.

3.6 The Parties agree to share information and work collaboratively throughout the strategic assessment.

4. Development of the Plan

4.1 The Parties agree that the State will develop a Plan that will seek to maximise conservation of protected matters that occur within, or adjacent to, the agreed strategic assessment area through a landscape approach to environmental conservation.

4.2 The Plan will include, but is not limited to, the identification of areas for development and commitments and outcomes for conservation of protected matters in the agreed strategic assessment area.

4.3 The Plan will include an implementation framework that describes how the commitments for conservation of protected matters set out in the Plan will be achieved. This implementation framework will address the following:

a) how outcomes and commitments for protected matters will be documented, delivered and adequately resourced throughout the life of the Plan; and

b) a framework for adaptive management, review of the effectiveness of the implementation in meeting the objectives for protected matters over time, and provision of a 5 yearly assurance report.

4.4 The Plan may include additional content relating to other responsibilities of the State.

4.5 The Plan will clearly identify and address protected matters separately from other State matters and ensure that, to the extent consistent with applicable NSW laws, the 'avoid, mitigate and offset' hierarchy of principles has been applied.

4.6 The State agrees to consult with interested stakeholders on the development of the draft Plan.

5. Terms of Reference for the Strategic Assessment Report

5.1 Pursuant to section 146(1B)(b) of the EPBC Act, the Parties agree to the preparation of Terms of Reference for a Strategic Assessment Report on the impacts of actions under the Plan on protected matters.

5.2 The State must make available for public comment, by notice, the draft Terms of Reference for the Strategic Assessment Report. The State must ensure that, at a minimum, the notice:

a) is posted on the DPE or OEH website;

b) is published in a national newspaper and a state daily newspaper circulating in NSW;

c) mentions:

i. that the draft Terms of Reference are available for public comment;

ii. the provision of the EPBC Act that requires the draft Terms of Reference for the Strategic Assessment Report to be published (i.e. section 146(1B)(b)(ii));

iii. where and how copies may be obtained in an electronic and hard copy form without charge or at a reasonable cost;

iv. contact details for obtaining further information, including reasonable access for persons with special needs; and

d) invites public comment on the draft Terms of Reference for the Strategic Assessment Report for a period of at least 28 calendar days that is specified by the Commonwealth Minister and set out in the notice.

5.3 The Commonwealth Environment Department will make the notice and draft Terms of Reference available electronically on the Commonwealth Environment Department's website.

5.4 The Parties may directly notify any party they think may have an interest in the draft Terms of Reference of the notice in clause 5.2.

5.5 Following consideration by the State of the public comments on the draft Terms of Reference and the making of any revisions by the State, the State will submit to the Commonwealth Minister:

a) any revised draft Terms of Reference; and

b) a copy of all public comments relating to the draft Terms of Reference; and

c) a document summarising whether and how the public comments have been taken into account in the revised draft Terms of Reference.

5.6 If the Commonwealth Minister is satisfied that the revised draft Terms of Reference will provide for a strategic assessment report that adequately addresses the impacts to which this agreement relates, the Commonwealth Minister will notify the Parties that the Terms of Reference can be finalised.

5.7 On receipt from the Commonwealth Minister of a notification under clause 5.6, the Parties must finalise the Terms of Reference.

6. Publication of the Plan and Strategic Assessment Report

6.1 Once the Terms of Reference for the Strategic Assessment Report have been finalised in accordance with clause 5.7, the State must prepare a draft Strategic Assessment Report in accordance with this agreement and the finalised Terms of Reference.

6.2 The State will provide the draft Plan and draft Strategic Assessment Report to the Commonwealth Environment Department for comment prior to both documents being released for public comment under clauses 6.4 - 6.6.

6.3 The Commonwealth Environment Department will assist the State toward ensuring that the draft Strategic Assessment Report adequately addresses the impacts to which this agreement relates by providing comments on the draft Plan in a timely manner.

6.4 Following the completion of the process set out in clauses 6.2 - 6.3 of this agreement, the State must, by notice, make the draft Strategic Assessment Report and draft Plan available for public comment. The State must ensure that, at a minimum, a notice:

a) is posted on the DPE or OEH website;

b) is published in a national newspaper and a state daily newspaper circulating in NSW

c) mentions:

i. that the draft Plan and draft Strategic Assessment Report are available for public comment;

ii. where and how copies may be obtained in an electronic and hard copy form without charge or at a reasonable cost;

iii. contact details for obtaining further information, including reasonable access for persons with special needs;

iv. the address to which public comments should be provided; and

d) invites public comment for a period of at least 28 calendar days that is specified by the Minister in the notice.

6.5 The Parties may separately notify any person, of the notice under clause 6.4 and of the availability of the draft Plan and draft Strategic Assessment Report.

6.6 The Commonwealth Environment Department will make the draft Plan and draft Strategic Assessment Report available electronically on its website.

6.7 Following consideration of any public comments received, the State will prepare, and then submit to the Commonwealth Environment Department for further comment:

a) a copy of all public comments;

b) a revised draft Strategic Assessment Report that takes account of the public comments received (if any);

c) a revised draft Plan that takes account of the public comments received (if any); and

d) a Supplementary Report.

6.8 The Minister is to direct the Commonwealth Environment Department to assist the State in ensuring that the revised draft Strategic Assessment Report adequately addresses the impacts to which this agreement relates by providing comments in a timely manner. The comments provided by the Commonwealth Environment Department may include recommended modifications to the draft Strategic Assessment Report, the draft Plan or both.

6.9 Following consideration of the Commonwealth Environment Department's comments, the State must finalise the revised draft Strategic Assessment Report and the revised draft Plan.

6.10 The State must then submit the following documents to the Commonwealth Minister:

a) the Strategic Assessment Report; and

b) the Plan; and

c) the Supplementary report.

7. Consideration of the Strategic Assessment Report and the Plan

7.1 Following receipt of the Strategic Assessment Report and the Plan in accordance with clause 6 of this agreement, the Commonwealth Minister may make recommendations to the State about the Plan (including recommendations for modification of the Plan).

7.2 The Commonwealth Minister may request any additional information he or she considers necessary in order to consider whether the Strategic Assessment Report adequately addresses the impacts to which this agreement relates.

7.3 If the Commonwealth Minister makes recommendations about the Plan, the State may:

a) seek clarification from the Commonwealth Minister on the recommendations;

b) modify the Plan to give effect to the Commonwealth Minister's recommendations; or

c) modify the Plan in a manner that has the same effect as the modifications recommended by the Commonwealth Minister.

7.4 If the State modifies the Plan in response to the Commonwealth Minister's recommendations, the State must submit to the Commonwealth Minister for consideration:

a) the modified Plan; and

b) a summary of how the Minister's recommendations were given effect.

7.5 Following receipt of the modified Plan, the Commonwealth Minister may request any additional information he or she considers necessary in order to consider whether the impacts of actions under the Plan on protected matters have been adequately addressed.

8. Endorsement of the Plan

8.1 The Commonwealth Minister may endorse the Plan if satisfied that:

a) the Strategic Assessment Report adequately addresses the impacts to which this agreement relates (that is, impacts of actions under the Plan on protected matters); and

b) either the recommended modifications to the Plan, or modifications having the same effect, have been made.

8.2 In determining whether or not to endorse the Plan, the Commonwealth Minister may consider the extent to which the commitments for the protection and management of protected matters are enforceable and achievable over the life of the Plan.

8.3 In determining whether he or she is satisfied that the Strategic Assessment Report adequately addresses the impacts to which the agreement relates, the Commonwealth Minister must have regard to the extent to which the Plan meets the objectives of the EPBC Act, including how the Plan:

i. protects the environment, especially those aspects of the environment that are protected matters under Part 3 of the EPBC Act;

ii. promotes ecologically sustainable development through the conservation and ecologically sustainable use of natural resources;

iii. promotes the conservation of biodiversity;

iv. provides for the protection and conservation of heritage;

v. promotes a cooperative approach to the protection and management of the environment; and

vi. assists in the co-operative implementation of Australia's international environmental responsibilities.

8.4 If the Plan is endorsed by the Commonwealth Minister, the State must make the Strategic Assessment Report, Plan and (if relevant) Supplementary Report, publicly available electronically through an official website for the life of the Plan.

8.5 The Parties acknowledge that the endorsement of the Plan itself does not constitute any approval for the taking of actions under Part 10 of the EPBC Act.

9. Approval of actions

9.1 If the Commonwealth Minister endorses the Plan, the Commonwealth Minister may then approve the taking of an action, or class of actions, in accordance with the Plan. The effect of this approval decision is that any actions or class of actions approved under section 146B would not need further approval by the Minister under the EPBC Act if taken in accordance with approval and any conditions attached to the approval decision.

9.2 The Parties agree that an approval holder (or holders) will be named for any approval of actions, or classes of actions, granted under section 146B of the EPBC Act.

10. Environmental information management

10.1 The Parties agree to work cooperatively and share information, to the fullest extent practical, so as to avoid duplication of work in undertaking the strategic assessment pursuant to this agreement, subject to meeting requirements under the EPBC Act. To deliver upon this objective the Parties commit to the following open access requirements:

a) Information is accessible and reusable by the community, business, government and other stakeholders.

b) Information is published under an Open Licence (preferably Creative Commons Attribution licence), and available in the public domain.

c) Information is published and described in a way that maximises discovery and reuse, preferably online, and in open formats.

d) Information is published at the highest resolution and accuracy available.

e) Information is released electronically at no cost to users or, if other formats are required, at minimal cost.

f) The Parties agree to restrict information access only where necessary to adequately manage sensitive or confidential information.

10.2 The Parties agree to develop and maintain a Data Management Plan to record the key pieces of data and information generated to support the decision for this strategic assessment.

10.3 Parties will endeavour to jointly explore new approaches and internationally recognised standards to inform the strategic assessment to achieve best practice environment impact assessment and effective and transparent monitoring and reporting.

11. Governance arrangements and dispute resolution

11.1 The Parties agree to use best endeavours to establish agreed timelines within one month of the signature of this agreement for deliverables and arrangements to ensure adequate communications to progress the strategic assessment. This may include preparation of joint or individual project plans. The Parties agree to use reasonable efforts to resolve by negotiation any problem that arises between them in the course of carrying out this agreement (dispute).

11.2 A party will not terminate this agreement as a result of a dispute until the following process has been exhausted:

a) If there is a dispute between the Parties concerning this agreement, either party may give written notice of the Dispute to the other party which will state that it is a notice under this clause and will specify the details of the dispute concerned.

b) Management representatives of each of the Parties will endeavour in good faith to agree upon a resolution of the dispute.

c) Should management representatives fail to reach a resolution within 14 business days of receipt of a notice of dispute (or another timeframe agreed in writing between the Parties), the dispute will be taken to senior executive service (SES) or equivalent representatives of each of the Parties.

d) SES representatives will endeavour in good faith to agree upon a resolution of the dispute.

e) Should the SES representatives fail to resolve the dispute within 10 business days (or other time frame agreed in writing between the Parties), the dispute will be taken to the:

i. relevant Deputy Secretary of the Commonwealth Environment Department, and

ii. relevant Deputy Secretary, DPE; and

iii. Chief Executive, OEH,

who will endeavour to reach agreement regarding the dispute.

12. Variation

12.1 The Parties may vary this agreement by written agreement only to the extent that the varied agreement is consistent with the provisions of the EPBC Act.

12.2 Any variation to this agreement shall be published on the DPE or OEH website.

13. Termination

13.1 This agreement may be terminated at any time by written notice from either Party, except where the termination relates to a Dispute and the procedure at clause 11 has not been followed.

14. General

14.1 Any notice given by a party under this agreement must be in writing and hand delivered or sent by pre-paid post or email to the appropriate representative at the specified address. The appropriate representative for each Party is:

i. relevant Deputy Secretary, DPE (Deputy Secretary, Policy and Communications, GPO Box 39, Sydney NSW 2001) and Chief Executive, OEH (PO Box A290, Sydney South 2000), and

ii. Assistant Secretary of the Branch managing the strategic assessment within the Australian Government Department of the Environment and Energy (Assistant Secretary, Assessments and Waste, Environment Standards Division, GPO Box 787 Canberra ACT 2601).

14.2 Notwithstanding any other provision of this agreement, the Parties may disclose information about this agreement, including personal information, where required or permitted to be disclosed by law.

Draft Terms of Reference for the Strategic Impact Assessment Report for the Cumberland Plain Conservation Plan

1. PURPOSE OF THE STRATEGIC IMPACT ASSESSMENT REPORT

   1.1. The purpose of the Report is to assess the impacts of actions taken under the Cumberland Plain Conservation Plan (Plan) on all matters protected by Part 3 of the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) ('protected matters').

2. DESCRIPTION OF THE PLAN BEING ASSESSED

   2.1. The Report must describe the Plan:

      1. The Report must provide a summary outlining its overall purpose, key elements, spatial extent, and timeframes, including how long the Plan will be in effect.
      2. The Report must provide details about the key elements, including:
         a. The conservation commitments and outcomes to be delivered for protected matters.
         b. The actions likely to be taken under the Plan over the short, medium and long term.
         c. The legal and administrative frameworks to implement the Plan and the persons and authorities responsible for implementation, including:
            i. How the Plan has been developed and its legal standing under New South Wales law.
            ii. The relationship of the Plan to other relevant policies, plans, guidelines, commitments, regulations and legislation including existing approvals under Commonwealth legislation for the Western Sydney Airport and the Western Sydney Growth Centres.
            iii. Management, approval and funding arrangements for implementing the Plan.
      3. The Report must describe the need and justification for the Plan including the environmental, social and economic drivers for its development.
      4. The Report must describe the decision-making framework used in considering alternatives and developing conservation outcomes of the Plan. It should identify where alternative options that have been evaluated to reach the final Plan have been published.
      5. The Report must describe how the principles of ecologically sustainable development (ESD) (as set out in section 3A of the EPBC Act) are considered and promoted in the development of the Plan.

3. DESCRIPTION OF THE PROTECTED MATTERS IMPACTED BY THE PLAN

   3.1. The Report must describe the nature of the environment within the strategic assessment area, and other areas outside the strategic assessment area that may be impacted by actions taken under the Plan. This must include (at a minimum):

      1. A description of historical and current land use.
      2. The extent and quality of native vegetation present including detailed mapping of ecological communities and habitat for threatened species listed under the EPBC Act.
      3. The nature of the environment, including ecosystem processes and threatening processes.
      4. A description of the landscape context for key environmental matters, including connectivity, habitat fragmentation and ecological processes.
      5. A spatial map of areas that are already protected for environmental purposes, including Bio-banking and Biodiversity Stewardship sites.

3.2. The Report must identify and describe each protected matter that may be impacted directly, indirectly and cumulatively by actions taken under the Plan, including (at a minimum):

1. Key sites, and where relevant, key habitats for protected matters.
2. Important populations of protected matters, including the consideration of the importance of both small and large areas of habitat, and their position within the landscape.
3. Areas likely to be important for maintaining ecological processes (for example, habitat connectivity) for protected matters.
4. Condition of protected matters, including where relevant, seasonal and annual variability, and their likelihood to alter over time.
5. Key threatening processes.

4. ASSESSMENT OF THE IMPACTS OF THE PLAN ON PROTECTED MATTERS

4.1. The Report must describe and assess the likely impacts of actions taken under the Plan on all protected matters.

4.2. The Report must describe the method used to understand likely impacts on all protected matters of actions taken under the Plan. The level of the assessment will be proportionate to the level of likely risk to each protected matter. The method must:

1. Be appropriate for assessment at a strategic scale.
2. Rely on the best available information.
3. Discuss uncertainty, including reference to the technical data and information relied upon.

The Report must identify the data used in the assessment, any limitations it may have, where (or if) the data is available and where it can be accessed, including publicly accessed.

4.3. Describe and assess separately the likely impacts (if any) of actions taken under the Plan on the environment on Commonwealth land (as defined in section 528 of the EPBC Act).

4.4. The Report may also consider protected matters that are potentially eligible for listing as a result of inclusion in a final priority assessment listing held by the Commonwealth, or a recommendation to the Commonwealth Minister for listing by the Threatened Species Scientific Committee prior to the Report being submitted.

4.5. The Report must include an analysis of the likely adverse impacts of actions of the Plan on protected matters. This must include (at a minimum) consideration of:

1. Information on the following :
   a. Number and size of populations/important populations.
   b. Extent (in hectares) of suitable habitat.
   c. Extent (in hectares) and condition of protected matters.
   d. Landscape connectivity and ecological processes.
   e. Heritage listing and values.
2. How impacts on protected matters will be avoided through land use planning and other measures, and what mitigation measures will be implemented to reduce impacts, including a description of the mitigation measures and how unavoidable impacts will be offset.
3. Potential indirect and cumulative impacts.

4.6. The Report must include an analysis of the conservation benefits (beneficial impacts) of the Plan, including:

1. How protected matters will be conserved, protected and managed within the Strategic Assessment Area and other areas related to the Plan.
2. The adequacy of the conservation measures under the Plan in protecting and managing protected matters, including the effectiveness of implementation and funding arrangements and who will be responsible for delivering on commitments.
3. How proposed conservation measures involving environmental offsets meet the principles of the *Environment Protection and Biodiversity Conservation Act, Environmental Offsets Policy, 2012.*

4. How landscape connectivity has been maintained and improved, which may include opportunities for strategic restoration of key corridors and areas adjacent to sites with high biodiversity values.
5. How adaptation to reasonable climate change scenarios has been considered.

4.7. The Report must consider the extent to which the impacts on protected matters of actions taken under the Plan meet legislative obligations under the EPBC Act, including but not limited to:

1. Consistency with Australia's international obligations, including the Ramsar Convention.
2. Consistency with recovery plans (section 146K of the EPBC Act).
3. Regard to objectives, conservation actions and other relevant information in conservation advices (section 146K of the EPBC Act).
4. Consistency with World Heritage management plans (sections 316 and 321 of the EPBC Act) and National Heritage place management plans (sections 324S and 324X of the EPBC Act).

The Report may also consider other Commonwealth policy guidelines on protected matters.

4.8. The Report must include justification for key methods used in the assessment, including summaries of independent peer review processes and where the review/s are available to the public.

5. EVALUATION OF THE OVERALL OUTCOMES OF THE PLAN

5.1. The Report must evaluate the overall commitments and outcomes for protected matters taking into account likely impacts on protected matters from actions taken under the Plan.

5.2. The evaluation must include:

1. The extent to which protected matters are represented in areas to be protected or managed under the Plan or in existing protected areas in the IBRA bioregion/subregion.
2. The extent to which the areas to be protected or managed under the Plan or existing protected areas in the IBRA bioregion/subregion will ensure the long-term viability of each protected matter.
3. Whether there will be serious and irreversible impacts on any protected matter.
4. An assessment of how the Plan meets the endorsement criteria set out in the Agreement at clause 8.

5.3. The evaluation may also include consideration of:

1. The extent to which the conservation measures under the Plan facilitate adaptation of biodiversity to climate change and address any significant vulnerabilities of protected matters under reasonable climate change scenarios.
2. The likely effectiveness of the conservation measures under the Plan in protecting and managing protected matters and any risks and uncertainties.

6. ADDRESSING UNCERTAINTY AND ADAPTIVE MANAGEMENT

6.1. The Report must identify key uncertainties and risks associated with implementing the Plan, responses to these and proposed adaptations to changing circumstances. Key uncertainties may include:

1. Knowledge gaps in scientific understanding and responding to new knowledge.
2. Assumptions made in assessing potential impacts and benefits.
3. How changes to State and Commonwealth legislation, policies, plans and advice is to be accounted for in the management of the areas impacted by the Plan.
4. Effectiveness or capacity to ensure the Plan is implemented.

6.2. The Report must describe and assess the adequacy of the procedures proposed in the Plan to ensure an adaptive approach to implementation of the Plan. This must include:

1. How the results of monitoring will be used to understand the effectiveness of conservation outcomes for protected matters and improve implementation.
2. How new information relating to protected matters and biodiversity, including legislative changes, may be assessed and accounted for in implementation of the Plan.

7. MONITORING AND REPORTING AND AUDITING

7.1. The Report must describe and assess the adequacy of the monitoring programs, regular review, public reporting and independent auditing processes proposed in the Plan to:

1. Ensure conservation commitments and outcomes for protected matters contained in the Plan are delivered.
2. Enable implementation of the Plan to adapt where monitoring demonstrates delivery of the conservation actions are not leading to the predicted conservation outcomes.
3. Enable implementation of the Plan to adapt to changed circumstances, where there are risks to protected matters.

7.2. The Report must identify and analyse the likely circumstances and procedures that may result in the review or modification of implementation plans proposed to deliver on commitments and outcomes for each protected matter as described in the Plan, or abandonment of the Plan.

8. INFORMATION SOURCES

8.1. The Report must identify the sources of information and data relied upon including the reliability and currency of the data.

1. Introduction

Niche Environment and Heritage Pty Ltd (Niche) have been commissioned by NSW Department of Planning and Environment (DPE) to undertake an independent peer review of the Western Sydney Strategic Assessment. Specifically Niche were engaged to address Section 4.8 of the EPBC Terms of Reference, which requires that:

> *The Report must include justification for key methods used in the assessment, including summaries of independent peer review processes and where the review/s are available to the public.*

1.1 Background

The NSW Government has identified four Growth Areas and approximately 200 kilometres of Transport Corridors to support planned future growth in Western Sydney over the next 38 years (see

Figure 1). These initiatives are identified under a number of strategies including:

- A Metropolis of Three Cities - The Greater Sydney Region Plan (Greater Sydney Commission, 2017b)
- Future Transport 2056 (Transport NSW, 2017)
- Western Sydney City Deal (2018).

The four Growth Areas are:

- Wilton Growth Area
- Greater Macarthur Growth Area
- Western Sydney Aerotropolis Growth Area
- Greater Penrith to Eastern Creek Urban Release Investigation Area.

The NSW Department of Planning and Environment (DPE) is pursuing the relevant State and Commonwealth statutory environmental approvals required for development of the Growth Areas and Transport Corridors. As part of this approval process, DPE is preparing the Draft Cumberland Plain Conservation Plan (the Plan). The Plan will outline both the program of development works proposed for authorisation under relevant legislation, and commit to environmental measures that will contribute to the maintenance or return of ecological function on the Cumberland Plain in response to the proposed development.

The Plan is being drafted to meet State and Commonwealth statutory requirements for assessment of impacts on threatened species and ecological communities. DPE will seek approval for the Plan under the:

- Biodiversity certification provisions (Part 8) of the NSW *Biodiversity Conservation Act 2016* (BC Act)
- Strategic assessment provisions (Part 10) of the Commonwealth *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act).

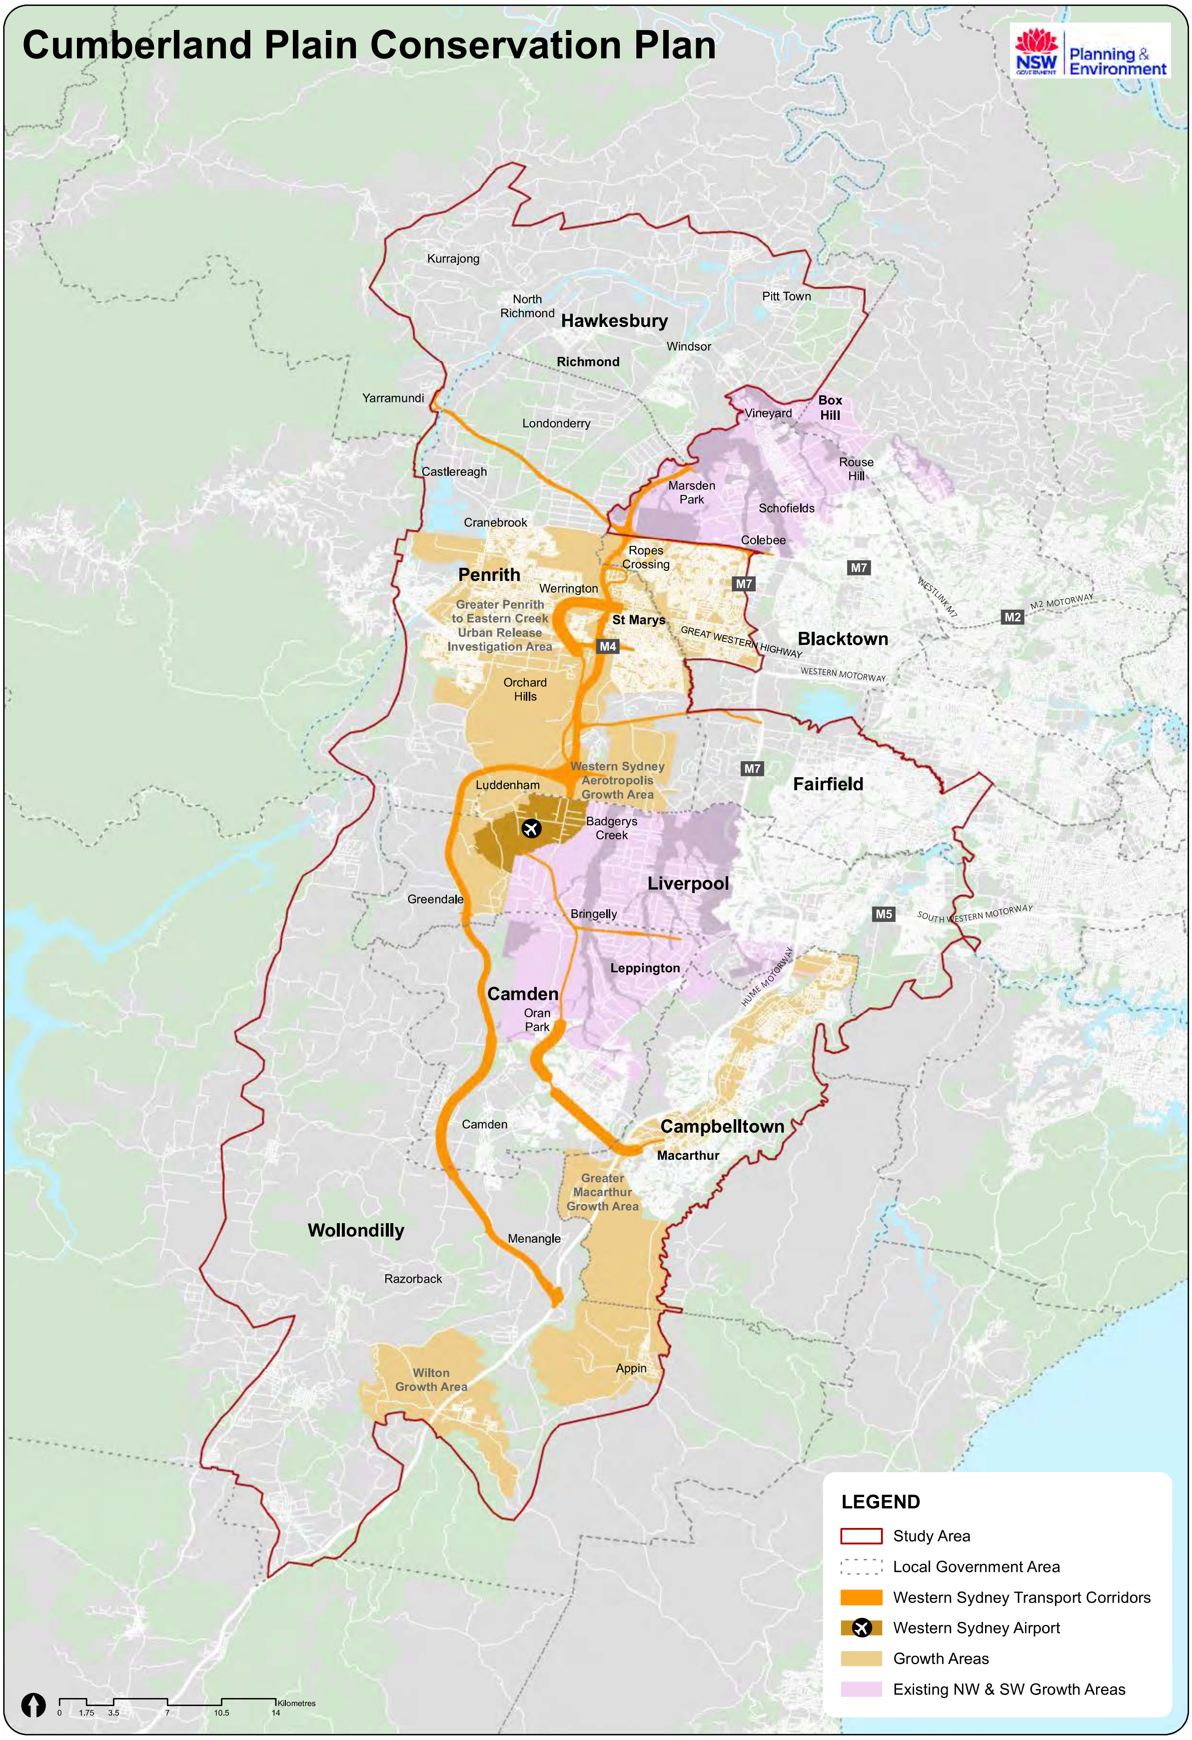

Figure 1. Map of the strategic assessment area

1.2 Scope of impact assessment within the Draft Cumberland Plain Conservation Plan

The scope of impact assessment within the Plan under the BC Act and EPBC Act is different (see Table 1). This relates to both:

- The components of the proposed development that is being assessed for approval
- The impact assessment requirements under each piece of legislation.

Table 1. Impact assessment requirements of the BC Act and the EPBC Act

Legislation	Impact assessment requirement	Comments
BC Act	Address provisions of the legislation and regulations under the relevant approval pathway within the Act.	The Plan is being assessed as a strategic application for biodiversity certification under Part 8 of the BC Act. The relevant regulatory provisions need to be met.
	Use of the Biodiversity Assessment Methodology (BAM)	The BAM is the detailed impact assessment method that is required under the BC Act
	Consider the guidelines for planning authorities for proposing conservation measures in strategic applications for biodiversity certification (Draft Version 7)	The Guidelines "*provide guiding principles for demonstrating that the conservation measures proposed for a strategic application for biodiversity certification adequately address impacts on biodiversity values under section 8.7 of the BC Act*" The Guidelines need to be addressed
EPBC Act	Address and meet relevant provisions of the legislation and regulations	The Plan is undergoing strategic assessment under Part 10 of the EPBC Act.
	Address the terms of Reference for the Strategic Impact Assessment Report for the Cumberland Plain Conservation Plan	The Terms of Reference specify the requirements for the Strategic Assessment Report
	Consider relevant statutory documents in the impact assessment process.	The EPBC Act requires that certain statutory documents be considered in the impact assessment process. For example, these include recovery plans, threat abatement plans, and conservation advices
	Consider EPBC Act policies and guidelines	The Australian Government has published a range of EPBC Act policies and guidelines which need to be considered in the impact assessment process

The assessment approach under Part 10 of the EPBC Act is different for the Transport Corridors that occur outside the Growth Areas compared with the other proposed development components. Table 2 shows the assessment approach for the proposed development components under Part 10 of the EPBC Act.

Table 2. Assessment approaches under Part 10 of the EPBC Act

Proposed development component	Assessment approach
Four growth areas	Detailed assessment of impacts on Commonwealth protected matters on the basis of the BAM and in accordance with the Terms of Reference
Sydney Metro Stage 1	
Transport Corridors within the growth areas	
Transport Corridors outside the growth areas	High level, risk-based assessment of protected matters and likely effectiveness of proposed avoidance, mitigation and offset measures to meet an improve or maintain scenario

1.2.1 EPBC Act Terms of Reference

The Terms of Reference for the Strategic Impact Assessment Report (SIAR) are part of the Strategic Assessment Agreement between the NSW and Australian Governments. They set out the information requirements that the impact assessment component of the Plan needs to address for matters protected under the EPBC Act.

The Terms of Reference broadly require the impact assessment to:

- Describe the Plan being assessed (clause 2)
- Describe the protected matters impacted by the Plan (clause 3)
- Assess the impacts of the Plan on protected matters (clause 4)
- Evaluate the overall outcomes of the Plan (clause 5)
- Address how uncertainty and adaptive management are considered in the Plan (clause 6)
- Describe the monitoring, reporting and auditing that will be implemented under the Plan (clause 7)
- Identify the information sources used to inform the impact assessment report (clause 8).

Clause 4.2 of the Terms of Reference outlines how the Plan should describe the methods used in the assessment:

"*The Report must describe the method used to understand likely impacts on all protected matters of actions taken under the Plan. The level of the assessment will be proportionate to the level of likely risk to each protected matter. The method must:*

1. *Be appropriate for assessment at a strategic scale*
2. *Rely on the best available information*
3. *Discuss uncertainty, including reference to the technical data and information relied upon*

The Report must identify the data used in the assessment, any limitations it may have, where (or if) the data is available and where it can be accessed, including publicly accessed."

The SIAR is designed to meet all of the Terms of Reference.

1.2.2 Key steps in the impact assessment

Despite the differences between the BC Act and EPBC Act processes, there are three common and key steps in the impact assessment:

- Step 1 – understand the environment
- Step 2 – understand impacts (and identify avoidance and mitigation measures)
- Step 3 – evaluate the outcome of the plan to adequately mitigate for any impacts and assess the benefits to the environment from the conservation measures.

1.3 Scope of the peer review

1.3.1 Peer review requirement

The peer review relates only to the strategic assessment under the EPBC Act. Section 4.8 of the EPBC Terms of Reference requires:

> *The Report must include justification for key methods used in the assessment, including summaries of independent peer review processes and where the review/s are available to the public.*

It is agreed that the term 'key methods' refers to technical methods for describing the protected matters impacted by the plan, such as methods used to collect data on protected matters and map or model the known or predicted occurrence of protected matters. The methods to be reviewed in this report include the assumptions underpinning all analyses and modelling, and the decisions about what datasets to include or exclude in the mapping and/or modelling processes.

We have been advised by DPE that the term 'key methods' does not include approaches to understand the likely impacts on protected matters of actions taken under the Plan, such as the approach to assessing direct impacts, indirect impacts, or cumulative impacts, or demonstrating how adaptation to climate change has been considered.

While the peer review is only required for the EPBC Act process, the results of the review will be of interest to the NSW Office of Environment and Heritage as part of the BC Act strategic biodiversity certification.

1.3.2 Methods for review

The following methods have been reviewed:

- The approach to determining the relevant Commonwealth matters for assessment ("the categorisation approach")
- The methodology for mapping EPBC Act-listed TECs, including any assumptions about correlations/ alignment between NSW Plant Community Types and EPBC Act TECs
- The knowledge-based method applied to mapping Category 1 EPBC listed threatened species
- The appropriateness and representativeness of the variables and datasets used for mapping habitat for 19 EPBC listed species using species distribution modelling
- The methods for identifying important populations of listed flora and fauna across the strategic assessment area for each species, and the application of the method for each species
- The evaluation method for determining the viability of the Southern Sydney koala population
- The Conservation Priorities Method, which is being used to identify priorities for offsetting.

1.4 Approach to the peer review

Niche was provided with details of the methods used to identify the range of protected matters prior to attending a workshop facilitated by Open Lines, which aimed to provide further information and opportunity for consultation with personnel involved. The workshop was held at DPE's Sydney office (Pitt Street) on 18th February 2019 and included detailed presentations by the lead author of each method:

- Tom Holden (Open Lines) – Chair and overview of EPBC impact assessment

- James Shepard (Biosis) - EPBC TEC mapping
- Rebecca Dwyer (Biosis) – Knowledge based mapping for EPBC Category 1 species
- Callan Wharfe (Biosis) - EPBC population mapping
- Peter Hemphill (Open Lines) - EPBC categorisation approach and Koala evaluation method
- Ascelin Gordon (RMIT) - Species distribution modelling
- Darren James (DAJ Environmental) and Ophelie Tinel (DPE) - Conservation priorities method

Dr Rhidian Harrington and Evelyn Craigie of Niche Environment and Heritage attended the workshop in their capacity as peer reviewers. CVs for Rhidian and Evelyn are provided in Annex 1.

Open Lines provided a detailed summary of the methods of each element in an agenda for the workshop but, apart from the *Western Sydney Strategic Plan – Species distribution Modelling* report (RMIT) and a section of the *Conservation Priorities Method for the Cumberland Plain Conservation Plan* report (DPE), no other reports were provided to the peer reviewers.

The workshop provided an opportunity to clarify any sections of the method that were unclear. Further information was provided following the workshop including updates to the method descriptions and GIS data. Where further information or clarification was required to inform the review, this was obtained directly from the creators/authors of the method.

2. Determining the relevant Commonwealth matters for assessment

2.1 Overview of method

Relevant Commonwealth matters for assessment within the Plan were determined by applying the 'categorisation method'. This involved identifying all matters with potential to be affected by the proposal within a 10 kilometre buffer around the boundary of the strategic assessment area, using the Protected Matters Search Tool, NSW Bionet, Atlas of Living Australia and the Commonwealth's Finalised Priority Assessment List (FPAL). Each matter identified on the list was then assigned to Category 1 (to undergo detailed assessment), or Category 2 (no further assessment).

If a threatened species or community met any of the following criteria, it was assigned to Category 1:

- The BAM process for the Growth Areas identified the species may be impacted
- The species was subject to a commitment in the Sydney Growth Centres Strategic Assessment Program Report
- A known important population occurs in the strategic assessment area
- The strategic assessment area contains >5% of all known records in NSW of a species since 1990 according to the Atlas of NSW Wildlife dataset
- The strategic assessment area comprises >5% or more of the mapped distribution of the species according to DoEE's current distribution mapping
- It is an FPAL species, and available information suggests it occurs in the strategic assessment area.

If a migratory species met any of the following criteria, it was assigned to Category 1:

- The strategic assessment area supports important habitat or an ecologically significant proportion of modelled habitat for a species
- The strategic assessment area contains >5% of all known records in NSW of a species since 1990 on the Atlas of NSW Wildlife.

The results of the threatened and migratory species categorisation were reviewed by two senior ecologists familiar with the area to confirm its accuracy.

All Ramsar Wetlands downstream of the study area and all world and national heritage and Commonwealth land in the study area were assigned to Category 1.

2.2 Data collection and categorisation

The approach is considered appropriate for determining matters for assessment at a strategic scale as it:

- Uses a precautionary approach, with the initial step aiming to capture all matters that may be of relevance within the strategic assessment area and within 10 kilometres of its boundary
- Uses appropriate criteria to categorise the matters for further assessment
- Aligns with standard methods used in ecological assessment for identification of matters for assessment
- Includes analysis and cross-checking that is independent of the source data and method outputs.

2.3 Details of the approach

2.3.1 Data collection/manipulation

The methods used to identify potential Threatened Ecological Communities (TECs) is considered appropriate as an initial filter as it captures all Plant Community Types in the strategic assessment area that may be TECs.

2.3.2 Assumptions

The categorisation method includes information from sources that are not specific to the area, e.g. EPBC Act recovery plans and conservation advice. In some cases, these sources may not include information relevant to the assessment area. This should be identified as a limitation, however, it is noted that area specific information was also used and results were reviewed by ecologists familiar with the area of investigation.

2.3.3 Datasets

The method uses the ecological databases that are commonly used in ecological assessment, supplemented by the results of recent studies undertaken in the Growth Areas and review by ecologists familiar with the area. This is considered to be appropriate as it:

- Incorporates the most up to date databases that are available at the required scale
- Is conservative and unlikely to exclude matters that require further assessment.

2.4 Components that require improvement

The reviewed methods are considered appropriate for the strategic assessment and no components requiring improvement have been identified. However, any limitations associated with the information sources should be identified within the strategic assessment, including whether they incorporate up to date information and the scale at which they are relevant.

3. Mapping for EPBC Act TECs

3.1 Overview of method

This section summarises the methods used to prepare the general vegetation map and the EPBC Act TEC map. The methods used to prepare the general vegetation map is not the subject of this review, however, as it underlies the EPBC Act TEC mapping, a brief summary is provided.

3.1.1 General vegetation mapping

Due to the different requirements for the BAM and the EPBC Terms of Reference, two methods were used to prepare the general vegetation map as follows:

- Within the Growth Areas, vegetation mapping commenced with a desktop study and subsequent updates based on data collected in the field in accordance with the BAM
- Within the Cumberland sub-region (outside the Growth Areas) vegetation mapping was based on the vegetation maps prepared by OEH:
    - *Remnant Vegetation of the Western Cumberland Subregion: 2013 update* (OEH 2013)
    - *The Native Vegetation of the Sydney Metropolitan Area: Version 3.0* (OEH 2016).

The desktop study included analysis of:

- Recent Nearmap imagery at 15 centimetre resolution
- NSW Landuse polygons from DPI
- NSW soils datasets at 1:100,000 from the OEH data portal
- NSW geology datasets at 1:250,000 from the DPE data portal
- Processing multispectral aerial imagery at 60 centimetre resolution into NDVI imagery
- Amalgamating previous native vegetation mapping undertaken by Biosis and others across the Growth Areas
- Combining two existing OEH maps of native vegetation within the Cumberland sub-region (OEH, 2013, 2016b) into a single layer and clipping the layer to the Growth Area boundaries
- Creating a Canopy Height Model using 1 metre LiDAR data from various projects contained within Biosis' GIS database (data ranged from six years to nine years old)
- Processing the Canopy Height Model into amalgamated canopy polygons for vegetation over 1 metre in height.

The draft maps were then updated based on the results of field survey (in the Growth Areas only), which included rapid assessment ground-truthing and plots in accordance with the BAM.

It is considered the datasets, methods for data collection and assumptions associated with the general vegetation mapping are appropriate and provide the most suitable base for mapping of EPBC Act TECs.

3.1.2 EPBC Act TEC mapping

All TECs with the potential to occur in the strategic assessment area were identified based on the Protected Matters Search Tool and Plant Community Types (PCTs) identified during the general vegetation mapping.

The method used to map EPBC Act TECs within the Growth Areas is summarised as follows:

1. Identify PCTs that correlate with an EPBC Act TEC and thereby identify specific areas that may comprise an EPBC Act TEC
2. For each potential area of EPBC Act TEC, apply criteria related to:
    a. distribution and patch size class
    b. projected foliage cover (where relevant to the TEC threshold criteria)
    c. elevation (where relevant)

3. Map vegetation polygons that meet the above criteria as candidate TEC polygons
4. Apply condition class criteria to candidate polygons within which BAM plots have been undertaken, and assign the polygon as the TEC, or remove it as the TEC
5. Apply condition class criteria to candidate polygons within the Growth Areas but external to the development footprint, i.e. areas within the Growth Area were BAM plots were not undertaken, and assign a potential category to the polygon (high, moderate and low potential and not TEC)
6. The methods and outputs were reviewed by the DoEE.

The method used to map EPBC Act TECs external to the Growth Areas is summarised as follows:

1. Identify PCTs that correlate with an EPBC Act TEC and thereby identify specific areas that may comprise an EPBC Act TEC
2. Apply distribution and patch size criteria and remove polygons that did not meet the criteria
3. Apply condition class criteria, based on condition classes associated with the two source maps (OEH 2013 and OEH 2016)
4. Analyse draft maps to remove areas with discrepancies such as cleared land and assign a potential category to the polygon (high, moderate and low potential and not TEC).

3.2 General Approach

3.2.1 Data collection/manipulation

The general approach is considered appropriate for assessment of EPBC Act TECs at a strategic scale as it:

- Incorporates all TECs that have potential to occur in the strategic assessment area, including one TEC that is proposed for listing
- Is repeatable across the entire strategic assessment area
- Has established rule sets that incorporate all relevant attributes for each TEC, as described in the DoEE's Species Profile and Threats Database (SPRAT) and discussion with DoEE
- Relies on the best available information, including the most recent iterations of all input data
- Allows for updates to be incorporated
- Is adjusted to account for the different levels of accuracy in vegetation mapping available across the strategic assessment area
- Includes analysis and cross-checking that is independent of the source data, model outputs and other input information.

3.2.2 Assumptions

The method incorporates numerous assumptions, largely associated with the data used in the GIS model. This is necessary in the absence of field collected data and has been adequately discussed and justified for each point where an assumption is made. Where it was possible to reduce the level of uncertainty involved, for example through a cross check of results by GIS and ecology practitioners, this has been undertaken and explained.

It is considered that further details of all datasets used in the project are required. Information such as whether the data is based on a desktop study or field verification, and methods used to capture the data.

3.2.3 Datasets

The method has incorporated the best available information as it:

- Incorporates the results of extensive recent field survey where possible
- Incorporates the most up to date datasets that are available at the required scale
- Has updated the data where possible
- Has considered a wide range of data and its suitability to the assessment.

3.3 Details of the approach

3.3.1 Data collection/manipulation

The methods used to identify potential TECs is considered appropriate as an initial filter as it captures all PCTs in the strategic assessment area that may be TECs.

TEC mapping in the Growth Areas

Further filtering by patch size, canopy cover, native vegetation patch size, soil and elevation (in areas for which field data is available) is appropriate as it incorporates the factors that determine whether vegetation meets the criteria to be a TEC (as described in SPRAT) and for which data is available and can be accurately interrogated. The GIS interrogation of the data, coupled with independent review by an ecologist, is considered appropriate and would achieve as much accuracy as possible without field verification.

For patches where BAM data is not available, the method does not identify areas of TEC but rather, categorises the candidate TEC polygons according to their potential to be a TEC (High, Moderate, Low and Not TEC). This is appropriate as it accounts for greater uncertainty in the model and is likely to overestimate the areas of potential TEC, rather than underestimate. This conservative approach is appropriate for a strategic level assessment where comprehensive field surveys have not been conducted.

TEC mapping – Cumberland Plain

The reduced filtering undertaken for TECs in the Greater Cumberland Plain (patch size and condition only) is appropriate as it accounts for the increased reliance on data that has not been validated in the field.

This method also categorises the candidate TEC polygons according to their potential to be a TEC (High, Moderate, Low and Not TEC). This is appropriate as it accounts for the reliance on data that has not been validated in the field and is also likely to provide a conservative estimate of the TECs in the area. This is appropriate for a strategic level assessment where comprehensive field surveys have not been conducted.

3.3.2 Assumptions

The assumptions associated with the method are clearly stated and considered appropriate. They comprise factors that can reasonably be assumed based on known data, such as presence of hollows and species composition. The assumptions are also inclusive, i.e. the required features for a polygon to be a TEC are assumed to be present (for polygons that remain after the filtering process), rather than absent, thereby resulting in an approach that is likely to provide a conservative estimate of the TECs in the area. This is appropriate for a strategic level assessment.

3.4 Components that require improvement

The method is considered appropriate for the strategic assessment and components requiring improvement have not been identified. However, further details associated with the input data should be included to provide the reader a more complete understanding of the limitations of the method. This includes details of the extent and dates of field validation undertaken for the source mapping.

4. Mapping of EPBC species

Section 3.2 of the Terms of Reference requires the SIAR to describe for the strategic assessment area the protected matters that may be impacted directly, indirectly and cumulatively by actions taken under the Plan. Habitat for Commonwealth listed Category 1 species was mapped within the Cumberland sub-region using either:

- Species Distribution Modelling (SDM) where species data is adequate, or
- Assumed presence using a knowledge-based method (KBM)

In some cases, a map was prepared for a Commonwealth listed Category 1 species within the Growth Areas in accordance with the BAM because the Commonwealth species is also a NSW listed candidate species credit species. Under the BAM, candidate species credit species were mapped within the Growth Areas using:

- An expert report in accordance with section 6.5.2 of the BAM, or
- Assumed presence using a knowledge-based method (KBM)

Where a map was prepared for a Commonwealth listed Category 1 species within the Growth Areas in accordance with the BAM, that Growth Areas map was integrated into the Cumberland sub-region map and formed the basis of the assessment of impacts on that species within the Growth Areas.

4.1 Species Distribution Modelling

Species Distribution Modelling (SDM) was undertaken for Commonwealth listed Category 1 species within the Cumberland subregion where adequate species records were available to develop a model. SDMs were developed for 19 Commonwealth listed Category 1 species (6 fauna species and 13 flora species). The assessment will use SDMs for 15 of those species.

SDMs are statistical models used to estimate the relationship between species records at sites and the environmental and/or spatial characteristics of those sites. Once this relationship has been estimated, the statistical model can be used to predict other locations in the landscape where the species is likely to occur.

The models were developed using the software 'Maxent'.

Data required for the modelling included:

- Species records obtained from BioNet. During a review of the records, various errors were identified. Ecologists were engaged to review the records and exclude those with errors.
- Twenty-one environmental predictors that were used to establish the relationships between species records at sites and the environmental and/or spatial characteristics of those sites. These included:
  - Native vegetation (PCTs)
  - Soil type
  - Mean annual temperature
  - Mean annual radiation
  - Number of days per year with minimum temperature less than 2 degrees
  - Latitude
  - Distance to streams
  - Topographic position.

An approach was developed to account for the different levels of bias likely to be present in the species records. This resulted in the development of three maps for each species with different assumptions regarding bias in the records, depicting the likelihood of occurrence for each species. These three maps were then combined to produce a single Species Distribution Model for each species with three classes of occurrence for each species:

- Unlikely to occur – none of the three models predicted the species to occur
- Potential to occur – at least one of the three models predicted the species to occur
- Likely to occur – all three of the models predicted the species to occur.

It is considered that the datasets and their interrogation, which was used to feed into the SDM, are the most appropriate and suitable of methods available at this spatial scale for predicting species distribution. The covariates (environmental predictor layers) used in the modelling were reviewed for each species and are considered to be appropriate.

4.1.1 Details of approach

Data collection/manipulation

The general approach is considered appropriate for modelling species distribution at a strategic scale as:

- The way in which the BioNet species record data was interrogated by an ecologist and filtered based on a 100 metre accuracy criteria would have adequately excluded records that were spatially inaccurate
- The environmental predictors used for each species were appropriate and used appropriate data and the best data available
- Biases in data (i.e. BioNet data is not random) is accounted for as best is possible by using three different models with different assumptions regarding bias
- Interpretation of the model's outputs (i.e. "unlikely to occur", "potential to occur" and "likely to occur") provide a very conservative approach which is likely to overestimate species occurrence
- Includes analysis and cross-checking that is independent of the source data, model outputs and other input information.

The exclusion of Koala records from within the 10 kilometre buffer region due to a large number of records in the buffer region skewing the model to predict reduced occupancy within the Cumberland Subregion appears appropriate. As is exclusion of records not within native vegetation due to them representing dispersing males.

The report rightly notes that the predicted distribution for the Green and Golden Bell Frog should be approached with caution. The fact that the model excluded areas without vegetation means that small waterbodies within the Subregion would not be captured, even if frogs had been recorded there.

Assumptions

The method appears to incorporate numerous assumptions, and although some of these are referred to throughout the report, it is considered that further details are required. It is recommended that a separate section of the report list all assumptions and discuss their implications to the modelling.

Datasets

The method has incorporated the best available information as it:

- Incorporates the most up to date datasets that are available at the required scale, although it is recognised that vegetation and soil data contained errors that could not be rectified and that vegetation data did not extend across the whole buffer area
- Has interrogated the data and excluded it when inaccurate
- Has considered a wide range of data and its suitability to the assessment.

4.1.2 Summary

In general, the approach used for generating the species distribution models would over-predict the habitat for a species. Errors in data (particularly vegetation and soil) may have resulted in associations with these variables that were artefacts, thus over-predicting species distribution. However, the use of "likely to occur" and "potential to occur" regions limits the likelihood of over-prediction in this regard.

Other factors that may have resulted in over-prediction include the highly fragmented and modified habitat within the Subregion, which means patches of habitat that contain the appropriate predictors for a species may be too isolated or degraded for that species to occur.

Although over-predicting a species distribution is acceptable from a precautionary approach care must be taken that this approach is not transposed to offset sites, as it will predict false occurrence. It is noted though that all offset sites would be surveyed prior to being secured. Consideration must also be made of the offsetting requirements from over-predicting species distribution as this will have significant cost implications, and could result in offsets being provided unnecessarily. Over-prediction may also prevent development in areas of limited conservation value.

Despite the potential issues with data error and over-prediction of species distribution, the interrogation of the data, coupled with independent review by an ecologist, is considered appropriate and would achieve as much accuracy as possible without field verification.

4.1.3 Components that require improvement

The approach is considered appropriate for the strategic assessment and components requiring improvement have not been identified. However, further details associated with the assumptions of the model should be included to provide the reader a more complete understanding of the factors affecting the outcomes of the model.

The *Western Sydney Strategic Plan – Species Distribution Modelling* report has numerous typographical errors, but these have not been detailed in this report.

4.2 Knowledge-based mapping method

Where adequate species records were not available, Commonwealth listed Category 1 species within the Cumberland subregion were mapped on the basis of assumed presence using a knowledge-based method. The method is the same method applied to NSW-listed candidate species credit species within the Growth Areas. It was based on the following steps:

STEP 1: IDENTIFICATION OF POTENTIAL HABITAT

Potential habitat for each species was identified and mapped using the Western Sydney Strategic Assessment Vegetation Mapping undertaken by Biosis for the project. Each species polygon was initially mapped using the relevant PCT and condition class identified in BioNET.

The potential habitat was then refined using scientific literature, including the following spatial and non-spatial data resources:

- Atlas of NSW Wildlife (BioNet)
- Commonwealth SPRAT database
- OEH Threatened Biodiversity Data Collection
- Cumberland Plain Recovery Plan (OEH 2011)
- Other recovery plans/conservation advices
- NSW Threatened Species Profiles Database
- BirdLife Australia shorebird data
- Hydrological modelling derived from LiDAR data
- Topographic information, including height and slope, obtained from LiDAR data
- The altitude above sea level and slope
- Soils data digital atlas of Australian soils

STEP 2: UNDERTAKE FIELD SURVEYS

Letters were sent by DPE to all landholders within the development footprints of the Growth Areas to request access. Due to a limited response, Biosis also undertook door knocking to request access for targeted surveys.

Targeted surveys for threatened flora and fauna were undertaken within the 'development footprint' where access was provided by landholders. Due to time restrictions of the project, it should be noted that targeted fauna surveys were not undertaken in accordance with the relevant survey guidelines, and were only used to identify potential habitat for relevant species.

STEP 3: INTEGRATE RESULTS FROM TARGETED SURVEYS

The results from the targeted surveys were incorporated in two ways:

- Any areas where a species was not recorded (and where surveys were considered sufficient) were removed from the potential habitat polygons
- Any areas where a species was recorded were integrated into the mapping.

STEP 4: ASSUMED PRESENCE IN POTENTIAL HABITAT

Given the limitations in access and survey, species were assumed to be present in all areas of potential habitat.

4.2.1 Details of approach

Data collection/manipulation

The general approach is considered appropriate for mapping of EPBC Act species habitat at a strategic scale as it:

- Interrogated species record data using an expert ecologist and removed any inaccurate records

- Used appropriate data and the best data available, including updated Western Sydney Strategic Assessment Vegetation Mapping undertaken by Biosis for the project
- Assumed presence of a species if potential habitat was present and survey of the habitat patch was insufficient to determine presence
- Used an appropriate approach for determining candidate species that would be impacted
- Used appropriate assumptions and criteria for determining potential habitat
- Includes analysis and cross-checking that is independent of the source data and other input information
- Used a conservative approach so that despite insufficient survey effort compared with the government guidelines species habitat would be over-estimated.

More details and justification are required on the exclusion of habitat based on patch size, particularly for species where a patch size of 1,000 hectares was used (i.e. Spotted-tailed Quoll, Satin Flycatcher, Oriental Cuckoo, Horsfield's Cuckoo, Spectacled Monarch and Rufous Fantail). It is considered that use of such a large patch size, particularly for highly mobile species such as birds, will exclude areas of potential habitat that could be utilised by these species.

More details and justification is required with respect to the exclusion of records for some species that are earlier than the lifespan of the species. For example, records for the Regent Honeyeater were restricted to those post 2008 to account for the 10 year lifespan of the species. It is considered that the exclusion of these records, particularly for highly mobile species, will exclude areas of potential habitat that could be utilised by those species.

Assumptions

The assumptions associated with the method are clearly stated and considered appropriate for a strategic level assessment, except for the issues discussed above in the *Data collection* section.

It’s important these assumptions are presented in the report.

Datasets

The method has incorporated the best available information as it:

- Incorporates the most up to date datasets that are available at the required scale, including updated vegetation mapping
- Has interrogated the data and excluded it when inaccurate
- Has considered a wide range of data and information relevant to the species habitat requirements, and its suitability to the assessment.

4.2.2 Summary

In general, the approach used for the knowledge based method would over-predict the habitat for a species. However, it is considered that some data refining approaches, such as exclusion of habitat based on patch size and the exclusion of records older than the lifespan of the species, may result in suitable habitat being excluded for some species.

Although over-predicting a species distribution is acceptable from a precautionary approach care must be taken that this approach is not transposed to offset sites, as it will predict false occurrence. It is noted though that all offset sites would be surveyed prior to being secured. Consideration must also be made of the offsetting requirements from over-predicting species distribution as this will have significant cost implications, and could result in offsets being provided unnecessarily. Over-prediction may also prevent development in areas of limited conservation value. However, it is noted that detailed surveys would be completed prior to areas being developed.

Despite the potential issues with data error and over-prediction of species distribution, the interrogation of the data, coupled with independent review by an ecologist, is considered appropriate and would achieve as much accuracy as possible without significantly more effort with respect to field verification.

4.2.3 Components that require improvement

The approach is generally considered appropriate for the strategic assessment. However, the exclusion of habitat based on patch size needs to be explained and justified in detail and, where it might result in suitable habitat being excluded for some species, an alternative approach used.

4.3 Important populations

The term 'important populations' refers to a concept applied under the EPBC Act to inform the assessment of impacts of actions, such as urban development, on matters of national environmental significance. Important populations are defined in the Commonwealth's Significant Impact Guidelines (Policy Statement 1.1) (DoE, 2013) as:

> *Any population of a vulnerable species which meets the definition of an important population in the Commonwealth's Significant Impact Guidelines (Policy Statement 1.1) as follows:*
>
> *'A population that is necessary for a species' long-term survival and recovery. This may include populations identified as such in recovery plans, and/or that are:*
>
> - *key source populations either for breeding or dispersal*
> - *populations that are necessary for maintaining genetic diversity, and/or*
> - *populations that are near the limit of the species range'*.

For the purposes of the SIAR, important populations are also defined as including any population of an endangered or critically endangered species. Under the EPBC Act, all populations of an endangered or critically endangered species are considered to be important for the survival and recovery of the species.

The following steps were undertaken to identify and map important populations for critically endangered, endangered and vulnerable Commonwealth listed Category 1 matters:

- Step 1: Development of criteria for defining important populations for vulnerable Commonwealth listed Category 1 matters. The criteria and rationale for each criteria is provided in Table 3
- Step 2: For each species, BioNet records were analysed to define biological populations of the species. This analysis was undertaken by ecologists at Biosis with knowledge and expertise in the ecology of each species. Where gene flow between two records is considered likely, the records were assigned to the one population. The ecologists took the following factors into account in determining whether gene flow is likely between records:
    - Distance between individual flora records
    - The presence of features or barriers that might limit demographic or genetic exchange
    - Pollinator type and seed dispersal mechanism (where known)

    - The continuity of patches of vegetation.
- Step 3: For critically endangered and endangered Category 1 matters:
    - Describe and map each population (including identifying population sizes).
- Step 4: For vulnerable Category 1 species:
    - Collate the required data on each species as per the data sources in Table 3
    - Apply the criteria in Table 3 to each species, using GIS analysis where necessary
    - Describe and map each population (including identifying population sizes).

Table 3. Criteria for identifying and mapping important populations of vulnerable Commonwealth listed Category 1 species

	Criteria	Rationale	Data sources
1	Any population of a species identified as potential Serious and Irreversible Impacts (SAII) entity under the NSW BC Act	SAII entities have been identified under the NSW BC Act and meet one or more of the following principles: • Species in rapid rate of decline • Very small population size • Very limited geographic distribution • Unlikely to respond to management and therefore irreplaceable • Populations of SAII entities therefore make a significant contribution to the conservation of the species.	• Threatened Biodiversity Data Collection
2	A population identified or inferred in a Commonwealth conservation advice, recovery plan, final determination, or other relevant policy document as being important	Consistent with the EPBC Act Policy Statement 1.1 (DoE, 2013).	• Recovery plans • Conservation advices • Final determinations
3	A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program	Species targeted by the Saving our Species program have been prioritised for conservation effort under a program that aims to maximise the chance of securing the greatest number of species in the wild. Therefore populations targeted under the NSW Saving our Species program could comply with the following EPBC important population criteria: • Key source populations either for breeding or dispersal • Populations that are necessary for maintaining genetic diversity, and/or • Populations that are near the limit of the species range'.	• Save our Species program conservation projects database
4	A population associated with a commitment made under the Sydney growth	These populations have been previously identified for conservation, have had significant resources attributed to their conservation and are subject to existing commitments under the Sydney growth centres	• Sydney Growth Centres Strategic Assessment: Program Report (DOP, 2010)

	centres conservation program	conservation program and should therefore be considered important.	• NSW *Threatened Species Conservation Act 1995* Order to confer biodiversity certification on the State Environmental Planning Policy (Sydney Region Growth Centres) 2006
5	Any population of a species that contains more than 20% of the total population (total number of mature individuals in the species) or 20% of the Area of Occupancy (AOO)* of that species	Significant contribution to the conservation of the species. Loss of any population that contains 20% or more of the total population or Area of Occupancy is justification for change in status from Vulnerable to Endangered under IUCN and EPBC Act criteria (IUCN 2012).	• BioNet, site specific surveys
6	Any population of a species where the species has less than 10 known subpopulations	These are species that have very few populations. All known populations therefore make a significant contribution to the conservation of the species. Loss of any population of such a species would be significant.	• BioNet, site specific surveys
7	Any population of a species that is a large population in the context of the ecology of that species, in the opinion of expert ecologists	Large populations are important from a genetic perspective. They typically will have sufficient genetic diversity, increased evolutionary potential, reduced inbreeding effects and increased probability of long term viability and persistence.	• BioNet, site specific surveys
8	Any population of a species within a conservation reserve (regardless of the number of plants or size, etc)	These populations are important because they are more likely to be effectively managed and have a greater chance of persistence due to their occurrence in a conservation reserve, and therefore make a significant contribution to the conservation and recovery of the species. Conservation reserve refers to those that meet IUCN protected area categories I-IV.	• BioNet, site specific surveys • National parks estate data • BioBank site data
9	Any population of a species that is important for maintaining the Extent of Occurrence (EOO)^ of that species	Maintaining the full range of a species has a greater chance of retaining the variation within the species (a primary aim of biodiversity conservation). Populations at the extent of occurrence or that are outliers to the more general distribution are likely to contain genetic difference or capacity to persist in different environmental conditions that will provide the species ability to cope and respond to changes in the environment, such as climate change.	• BioNet, site specific surveys • Commonwealth database profiles/distribution mapping

*AOO is defined as the area within a species 'extent of occurrence' which is occupied by a taxon, excluding cases of vagrancy. The measure reflects the fact that a taxon will not usually occur throughout the area of its extent of occurrence, which may contain unsuitable or unoccupied habitats.

^Extent of occurrence is defined as the area contained within the shortest continuous imaginary boundary which can be drawn to encompass all the known, inferred or projected sites of present occurrence of a species, excluding cases of vagrancy.

4.3.1 Details of approach

Data collection/manipulation

The general approach is considered appropriate for determining important populations at a strategic scale as it:

- Interrogated species record data using an expert ecologist and removed any inaccurate records
- Used appropriate data and the best data available
- The criteria used for identifying and mapping important populations was appropriate and comprehensive
- Used appropriate assumptions for determining populations of individual species
- Includes analysis and cross-checking that is independent of the source data and other input information
- Used a conservative approach so that despite quality of data methods for determining populations were unlikely to be overlooked.

More details and justification is required with respect to the exclusion of populations for some species that are earlier than the lifespan of the species. For example, records for the Regent Honeyeater were restricted to those post 2008 to account for the 10 year lifespan of the species. It is considered that the exclusion of these records may exclude records that could contribute towards a population of that species not being considered. However, it is noted that only three species were not considered to have important populations within the Subregion.

Assumptions

The assumptions associated with the method are clearly stated and considered appropriate for a strategic level assessment, except for the issues discussed above in the *Data collection* section.

It's important these assumptions are presented in the report.

Datasets

The method has incorporated the best available information as it:

- Incorporates the most up to date datasets that are available at the required scale
- Has interrogated the data and excluded it when inaccurate
- Individual records have been interrogated by an expert ecologist.

4.3.2 Summary

In general, the approach used for determining important populations is adequate and conservative. However, it is considered that some data refining approaches, such as the exclusion of records older than the lifespan of the species, may exclude records that could contribute towards a population of that species not being considered.

4.3.3 Components that require improvement

The approach is generally considered appropriate for the strategic assessment. However, for the species that have been determined not to have important populations within the subregion AND have had records excluded based on the lifespan of the species, a detailed discussion of the implications of the approach needs to be provided.

5. Southern Sydney Koala population viability evaluation method

5.1 Background and context

There are a significant number of koalas within and adjacent to the southern portion of the strategic assessment area.

These koalas are thought to be in recovery, with research indicating clear increases in the area of habitat occupied by koalas in the locality over recent years. The koalas in the area are subject to a range of existing threats, in particular increasing road kill along Appin and Picton Roads. They will also be subject to direct impacts as a result of development within the Greater Macarthur and Wilton Growth Areas (noting that significant avoidance of impacts has occurred), and potential indirect impacts associated with proximity to new urban areas and roads.

However, the Cumberland Plain Conservation Plan (the Plan) also provides a significant opportunity to:

- Protect and manage large areas of habitat for the population
- Restore and improve key habitat corridors
- Manage and reduce threats
- Improve the information base for the population to assist in ongoing adaptive management

5.1.1 Terminology

The koalas within and adjacent to the southern portion of the strategic assessment area are currently being referred to as the "Southern Sydney koala population".

However, it is noted that koalas within this locality may in fact comprise two ecologically and genetically distinct koala populations (the Southern Tablelands koala population, and the Campbelltown koala population).

It is known that the Campbelltown koala population is important as it is free from Chlamydia. Conversely, the Southern Tablelands population is known to contain virulent strains of Chlamydia.

It is thought that these two koala populations may have originally been separated due to low population numbers, yet as populations expand, they may now be increasingly exposed to contact with each other.

The locations of the boundaries between each population are difficult to determine and further research is required as part of this assessment to identify them. It is noted that the true locations of the boundaries between the populations may be unknown and therefore there is a potential that the assessment approach may need to account for uncertainty in this regard.

Therefore, the terminology "Southern Sydney koala population" may be subject to change in the future, depending upon further consideration of whether the assessment area encompasses one or two koala populations, the likely location of the boundaries between the koala populations (if known), or whether the boundaries of the koala populations are unknown.

The Plan defines a [draft] outcome for the Southern Sydney koala population that it aims to deliver. It is:

> *"Key areas of habitat for iconic and distinctive threatened species such as koala are protected and managed".*

5.1.2 Regulatory context

Koalas are listed as vulnerable under both the EPBC and BC Acts. The key instruments considered for the assessment included:

- Approved Conservation Advice for *Phascolarctos cinereus* (DSEWPC, 2012)
- EPBC Act referral guidelines for the vulnerable koala (Department of the Environment, 2014)
- Recovery plan for the koala (*Phascolarctos cinereus*) (DECC, 2008)
- State Environmental Planning Policy No 44 – Koala Habitat Protection
- Securing the koala in the wild in NSW for 100 years: Saving Our Species Iconic Koala Project 2017-2021 (OEH, 2017)
- NSW Koala Strategy (OEH, 2018)
- Conserving koalas in Wollondilly and Campbelltown LGAs (OEH, 2018).

5.2 Overview of approach

This section summarises the approach to the evaluation methods for determining the viability of the Southern Sydney koala population.

Open Lines is preparing a detailed impact assessment for the Southern Sydney koala population. This is based on addressing the terms of reference for the EPBC strategic assessment through:

- Understanding the background to koalas and the regulatory context for the assessment
- Understanding the baseline information for the species within the strategic assessment area
- Analysing the efforts to avoid and minimise impacts
- Analysing the direct and indirect impacts to koalas as a result of development under the Plan
- Assessing the proposed mitigation and management measures within the Plan
- Assessing the proposed conservation measures within the Plan
- Assessing potential cumulative impacts on koalas within the strategic assessment area
- Carrying out a detailed evaluation of the outcome for the species against the statutory and policy requirements. This will be done using the method that is the subject of this peer review (described below)

Open Lines are working with Associate Professor Mathew Crowther who is providing expert advice on the assessment.

5.2.1 Information sources

In addition to the documents listed above, the information sources in Table 4 were considered.

Table 4: Information sources for the impact assessment

Source	Description
Literature on the ecology of the population	The ecological characteristics of the koala population in the locality have been intensively studied over the last few decades. Research efforts have included government research (conducted by the Saving Our Species program administered by OEH), numerous academic publications and a PhD thesis.

	From this body of research, information specifically about the Southern Sydney koala population is available regarding: • Koala home range sizes and densities (OEH, 2018a; Ward, 2002) • Potential population size (Biolink, 2016; OEH, 2018a; Ward, 2002) • Population trends (Biolink, 2016, 2018b) • Preferred feed tree species (OEH, 2018a; Phillips & Callaghan, 2000; Sluiter, Close, & Ward, 2002; Ward, 2002) • Habitat connectivity requirements (Biolink, 2018a) • Population genetics (Kjeldsen et al., 2018; Lee, Zenger, Close, Jones, & Phalen, 2010) • Key threats (Phillips, 2016) This targeted literature is complemented by a broader body of research relating to koala populations and ecological characteristics across the range of the species. The available literature and resources provide a solid foundation with which to understand the key characteristics and conservation needs of the Southern Sydney koalas.
Species records	Koala records within and adjacent to the study area have been accessed from the NSW BioNet Atlas database. The BioNet Atlas contains species records within the study area which were obtained during recent research conducted by the Saving Our Species program, and therefore is considered a resource containing contemporary knowledge of koala distributions within the area. BioNet records have been used in research to assess population trends (Biolink, 2016, 2018b) and identify koala roadkill locations and hotspots (OEH, 2018a). BioNet records have also been used to conduct Species Distribution Model mapping as part of the current assessment process.
Cumberland Plain wide species distribution model	A Species Distribution Model (SDM) has been prepared to predict the occurrence of koala habitat within the Cumberland subregion. The SDM supports environmental impact analysis within the Growth Areas, such as through providing information about the relative importance of habitat within each Growth Area, and providing indicative information about the availability of habitat for offsetting.
Habitat and corridor mapping	Comprehensive mapping of koala habitat within the study area has been undertaken, first by OEH within the Greater Macarthur and Wilton GA, with the methodology then replicated by Biosis for the whole of the Cumberland subregion. This habitat mapping is based upon: • Mapping Plant Community Types (PCTs) to a fine resolution across the study area, and using coarser resolution data across the wider subregion • Classifying each PCT as either 'high', 'medium' or 'low' quality habitat for koalas, and from this identifying 'principal' and 'supporting' koala habitat • Identifying movement corridors, and categorising corridors into 'primary', 'secondary' and 'tertiary' corridors • Identifying important koala habitat based on species polygons Habitat mapping provides insight into the relative importance of vegetation areas for supporting koalas, and enables avoidance, mitigation and conservation measures to be appropriately targeted to ensure the best possible outcomes for koalas within the locality.
Mapping of habitat critical to the survival of the species	Mapping of habitat critical to the survival of the species is currently being undertaken in accordance with the *EPBC Act referral guidelines for the vulnerable koala* (Department of the Environment, 2014). The mapping process is based on scoring

	criteria and considers the following key parameters in determining the value of koala habitat: • Koala occurrence • Vegetation composition • Habitat connectivity • Existing threats • The value of the potentially impacted koalas to the recovery of the wider koala community Each attribute is assigned a score based on whether or not certain parameters are met for each of the above attributes. If an area of habitat equals or exceeds a score of 5, then the habitat considered to be habitat critical to the survival of the species. The purpose of this mapping is to identify the presence of habitat which is of significant conservation value to koalas, such that appropriate avoidance, mitigation and conservation measures may be taken during environmental assessment.
Habitat connectivity analysis around Greater Macarthur and Wilton	Biolink Ecological Consultants were engaged by OEH to conduct an analysis of habitat connectivity across the Wilton Growth Area and the southern portion of the Greater Macarthur Growth Area. The purpose of the assessment was to assess the current habitat connectivity of the area, and then model the projected changes in habitat connectivity following development within the Growth Areas and upgrading of Appin Road. The results of this assessment provide insight into relative the accessibility of different patches of koala habitat within the Growth Areas, and enables assessment of the potential fragmentation impacts of different development scenarios.

It is considered that the datasets and literature considered as part of the assessment are appropriate and comprehensive, and provide the most suitable base for meeting the objectives. Although only in draft form, the Campbelltown City Council Comprehensive Koala Plan of Management should be considered.

5.2.2 Key gaps

Open Lines identify two key knowledge gaps which remain for koalas within the assessment area, which may impact upon the environmental assessment methodologies used to determine the viability of the Southern Sydney koala population, and whether the outcome in the Plan has been met. These gaps are as follows:

Demographic statistics for the koalas within the study area

Key demographic information (such as the birth rates, mortality rates, and mortality causes) are currently not available for the Southern Sydney koala population. This lack of information is considered to impede the capacity to immediately conduct an accurate Population Viability Analysis (PVA) model, which is a well-recognised methodology to assess a population’s viability.

Open Lines consider it may be possible for a PVA to be conducted in the future, once further background work has been undertaken to consolidate all available information for the koalas within the study area, and then further survey work is undertaken to obtain information which is otherwise not available.

Boundaries of koala populations within the study area

Open Line identify that further work is required as part of the assessment process to ensure that the best available knowledge has been accessed, to identify the locations (and porosities) of boundaries between the Campbelltown and Southern Tablelands koala populations.

It is noted that the Campbelltown koala population is currently free of Chlamydia, whereas the Southern Tablelands population is known to contain virulent strains of Chlamydia.

It is noted that potential proximity and subsequent connectivity between the Campbelltown and Southern Tablelands koala populations is of conservation concern, and that it has the real potential to significantly impact upon the projected the viability of the Campbelltown koala population.

5.2.3 The evaluation method for review

The evaluation method is based on posing a series of evaluation questions:

1. Will the Plan deliver the desired outcome of the Plan and ensure viability of koalas?
2. How does the Plan address the OEH principles?
3. How does the Plan consider the EPBC Act referral guidelines?
4. Has the Plan had regard for the Conservation Advice?

Question 1: Will the Plan deliver the desired outcome of the Plan and ensure viability of koalas?

The current draft koala outcome in the Plan is:

> *Key areas of habitat for iconic and distinctive threatened species such as koala are protected and managed.*

In addition to analysing this outcome, Open Lines considered it important to look at the current and future viability of the Southern Sydney Population. Predicting the performance of the Plan against this framework has its challenges. In particular, the assessment relies upon a clear and measurable definition of viability.

Viability has been defined as the ability of the koala population to persist and avoid extinction. There are a number of key factors which have been identified as influencing a population's viability:

- Extent and quality of habitat
- Landscape connectivity
- Level of threat
- Genetic variation
- Population size and demographics
- Stochastic events.

Population Viability Analysis was not used as much of the input data was not available and it was considered that the model's predictions might be inaccurate and result in inappropriate conservation actions. Further it was considered that if the Koala population responded in ways not predicted this would undermine scientific and public confidence in the process.

Instead population viability will be analysed through considering the factors which influence a population's viability, and through assessing whether any of these factors will be negatively affected in a significant manner such that the viability of the population could be undermined.

To this end, the following approach is proposed by Open Lines to analyse whether the Plan will achieve the desired outcome. It is based on considering each of the factors that drive viability and includes:

- Step 1 avoidance of impacts: Calculate the avoidance of impacts to koala habitat as a result of planning decisions in the Greater Macarthur and Wilton Growth Areas through:
  - Calculating available habitat in each Growth Area broken down by primary, secondary and tertiary corridors
  - Calculating avoidance of habitat for biodiversity reasons
  - Calculating avoidance of habitat for other reasons (e.g. topography).
- Step 2 extent and quality of habitat: Calculate the net change in the extent of quality of habitat as a result of development, restoration and offsetting through:
  - Calculating the total current extent of habitat broken down by primary, secondary and tertiary corridors
  - Calculating the future extent of habitat once the Plan has been implemented. This will include areas to be restored.
- Step 3 landscape connectivity: Analyse changes to landscape connectivity through:
  - Reviewing the findings of the GIS-based GAPCLoSR undertaken by Biolink
  - Analysing the projected changes to primary corridors.
- Step 4 level of threat: Analyse changes to the level of threat to the population through:
  - Roadkill:
    - Assessing current roadkill records
    - Assessing projected decline of roadkill events with proposed wildlife fencing and/or crossing structures
    - Assessing changes in koala movement patterns as a result of proposed wildlife fencing
  - Dogs:
    - Assessing the likely increase in dog density and associated dog predation of koalas under projected development scenarios
  - Disease:
    - Assessing the likely current and projected connectivity between the Campbelltown (disease free) and Southern Tablelands (diseased) koala populations, under current conditions ('do nothing' approach) and under projected development scenarios.

- Step 5 genetic variation: consider possible changes to the genetic variation of the population through:
    - Assessing current available literature regarding the genetic diversity of the local koala populations
    - Assessing the likelihood of koala populations or sub-populations becoming genetically isolated as a result of the proposed development
    - Assessing the severity of the risk posed by low genetic diversity to koala population viability, noting that some of the most heavily populated and expanding koala populations within Australia are populations with very low genetic diversity.
- Step 6 population carrying capacity: analyse possible changes to the carrying capacity of the population through:
    - Habitat loss (either through land clearing, or through isolation of otherwise viable habitat patches)
    - Alteration of habitat quality through long-term environmental changes such as climate change.

Given the lack of data available to feed in to the PVA it is agreed that using PVA at this time may provide inadequate or false outputs and that it should not be used. It is considered the proposed approach to assessing Koala viability through measuring changes to the extent and quality of Koala habitat, connectivity, threats, genetic variation and carrying capacity is appropriate and the best possible approach, in light of the absence of suitable data for PVA. It is agreed that the use of carrying capacity rather than Koala numbers is a better approach as it takes into consideration habitat loss and alteration, whereas measuring Koala numbers would be time consuming expensive and potentially of low accuracy, and may not reflect true carrying capacity due to delayed changes to populations from changed habitat.

Question 2: How does the Plan address the OEH principles?

The following outlines the evaluation approach for determining how well the Plan addresses the principles outlined by OEH.

- Principle 1: Avoid new residential development within core koala habitat and primary corridors:
    - As per Step 1 for Question 1
- Principle 2: Separate residential development and koala populations to minimise ongoing threats from domestic dogs and vehicles:
    - Assessing the suite of management measures which are proposed to separate residential developments from koala populations in terms of:
        - Which measure/s will be implemented
        - Where each measure will be implemented

        - Whether there are any areas or gaps in which no measures are implemented at the interface of koala-urban habitat, and whether the localised lack of mitigation measures represents a significant threat to koalas
        - Whether there are sufficient provisions for long-term monitoring and maintenance for each measure
        - Whether the proposed measures to be implemented are supported by appropriate scientific data to indicate their effectiveness in achieving their desired outcomes

- Principle 3: Identify critical revegetation zones that will augment and strengthen core habitat and corridors:
    - Assessing the location/s of proposed rehabilitation and/or revegetation areas with regards to the locations of important habitat
    - Assessing whether proposed revegetation areas contribute to strengthening important habitat, and/or widening/filling in gaps within existing corridors
    - Assessing whether revegetation targets key priority areas identified by OEH, which are as follows:
        - "The highest priority in the Wilton GA is in the south- east section, where core koala habitat surrounds and almost fully encloses cleared land at the start of the primary corridor along Allen's Creek (Allen's corridor)."
        - "the length of the eastern side of the [Greater Macarthur] GA, to the east of Appin Road, directly adjacent to the Georges River corridor… Other areas include areas to the east of the Ousedale-Mallaty corridor to complete a corridor connection (on both ends) for a secondary corridor currently connected to a primary corridor at one end."
    - Where revegetation is located outside of areas highlighted as priority revegetation areas by OEH, the associated justification of the environmental benefits of the proposed revegetation is to be examined.

- Principle 4: Identify koala road kill hotspots requiring road kill mitigation fencing and/or underpasses to allow safe passage of koalas:
    - Assessing the locations of road kill hotspots which have been identified by OEH with regards to proposed locations of wildlife fencing and/or crossing structures. An assessment will be made as to whether the locations of the proposed fencing/crossing structures are likely to:
        - Reduce roadkill at roadkill hotspots
        - Result in changes in species movements across transport infrastructure through the wider locality
    - Assessing whether adequate provisions have been made for long-term maintenance and monitoring of fencing and/or crossing structures

- In the event of other and/or additional measures being proposed, available literature and/or expert advice will be assessed to consider the likely effectiveness of proposed measures in achieving desired outcomes.

It is considered that if the Plan addresses the principles as outlined it would result in the viability of the southern Sydney Koala population(s) would be maintained. With respect to Principle 3 and 4, revegetation and mitigation measures outside the Growth Areas could still benefit the southern Sydney Koala population(s), including inside the Growth Areas, and should be considered and discussed in the evaluation.

Question 3: How does the Plan consider the EPBC Act referral guidelines?

The evaluation will consider if and how the Plan has had regard for the objectives of the guidelines:

- Promote avoidance and mitigation of impacts on the koala
- Promote a clear, consistent and transparent approach for making decision on whether an action is likely to result in a significant impact on the koala
- Promote streamlined decision-making and approval processes
- Promote the recovery of the koala.

Additional considerations posed by the guidelines will also be evaluated:

- Potential impacts to habitat critical to the survival of the species
- Implementation of mitigation and management measures to protect the species.

It is considered the evaluation would adequately consider the EPBC Act referral guidelines.

Question 4: Has the Plan had regard for the Conservation Advice?

The koala Conservation Advice is a brief and broad document which is intended to provide generalised advice to both management/approval bodies and proponents with regards to conservation information and requirements for koalas in Queensland, New South Wales and the Australian Capital Territory.

The Advice acknowledges that the ecological characteristics and conservation requirements of Koala populations vary significantly across the range of localities covered by the Advice. Therefore, the Advice states that in many cases, local and regional research and Koala management plans may provide far more detail and may be more applicable at local and regional scales.

The evaluation will consider if and how the Plan has had regard for the Conservation Advice. This includes analysis of how the Plan relates to:

- Identified threats
- Research priorities
- Priority management actions.

It is considered the evaluation would adequately have regard for the Conservation Advice.

5.3 Summary

It is considered that with the data available that the evaluation method is appropriate for a landscape-scale assessment and would adequately assess the viability of the southern Koala population. It is agreed that due to poor data availability using PVA at this time may provide inadequate or false outputs and that it should not be used. The evaluation method's consideration of landscape issues such as connectivity and landscape-scale threats such as roads and disease means it is appropriate and the best possible approach, in light of the absence of suitable data for PVA.

The evaluation method addresses the terms of reference and has regard for conservation advice and EPBC Koala guidelines.

The peer review by Associate Professor Mathew Crowther and input from relevant government authorities such as the Commonwealth Department of Environment and Energy and NSW Office of Environment and Heritage have provided a robust audit mechanism.

5.4 Components that require improvement

The evaluation method is considered appropriate for a strategic assessment and components requiring improvement have not been identified. Although it is a complex method with many influencing and interactive factors, which will be difficult to interpret and synthesis, it is still considered more appropriate than a PVA and or a simpler method.

Use of a PVA in the future should be considered, but only if the current method is determined to be deficient or producing outputs that don't meet realities, and if sufficient data can be collected or becomes available. The effort required to collect data adequate for PVA over such a large area is significant, and will be extremely expensive, so should not be considered lightly.

6. Conservation priorities method

6.1 Overview of method

The Conservation Priorities Method aims to determine and prioritise conservation methods for the Cumberland Plain study area. To offset the impacts associated with development of the Growth Areas and transport corridors, it identifies areas suitable for conservation through establishment of Biodiversity Stewardship Sites or National Park Reserves. The method combines spatial data with an analysis of constraints and opportunities. Constraints with respect to establishment of offset sites include land where conservation measures are already required and urban/industrial zoned land. Opportunities include large areas of vegetation in good condition, and proximity to protected/important land such as national parks or riparian areas.

Offset requirements were determined by applying a ratio matrix that applies an offset ratio to all impacted entities based on their conservation status and condition. In accordance with the matrix, the offset ratio increases as conservation significance increases (i.e. from not listed through to critically endangered under the EPBC Act and/or BC Act) and as the condition of vegetation improves.

6.2 Legislative requirements

The project will comprise a strategic application, allowing greater flexibility in application of the offsetting requirements of the BC Act and EPBC Act. Nonetheless, the method aims to address the offsetting requirements of the BC Act and the offsetting principles stated in the OEH Draft Guidelines and EPBC Act Environmental Offsets Policy.

It is considered the method adequately addresses the above requirements and principles as it targets the vegetation and species that will be impacted by the development, aims to improve or maintain biodiversity values, emphasises important biodiversity areas such as national parks and aims to establish in-perpetuity protection for the offset areas.

6.3 Data sources and manipulation

The datasets used in the method are considered appropriate as they can be consistently applied across the study area and comprise the most up-to-date information regarding biodiversity values, development and land use.

The categorisation of constraints and opportunities is appropriate and successfully prioritises potential offset sites across the study area. The method favours privately owned land, which is likely to involve difficulties with landowner involvement and cooperation at this scale. However, the method prioritises offset sites, thereby providing alternative options if difficulties are encountered.

7. Conclusion

Niche were commissioned by DPE to undertake an independent peer review of the Western Sydney Strategic Assessment to meet the EPBC Terms of Reference. The review was based on a workshop held at DPE's Sydney office on 18th February 2019 where the authors of each method provided detailed presentations and an agenda for the workshop that summarised the details of each method of the assessment.

This peer review has summarised the methods for each component of the assessment and then provided comments on the adequacy of the data and method used, and whether there can be improvements. In general it is considered the datasets, methods for data collection and assumptions associated with the methods are appropriate for a strategic assessment and most components do not require improvement. However, in general, details associated with the input data and assumptions should be included to provide the reader a more complete understanding of the limitations of each method.

The methods used are generally conservative and unlikely to under-represent the presence or distribution of any threatened ecological community or species. In fact, the methods used in most methods are likely to over-predict distribution and it is important these approaches are not transposed to the offset component of the assessment as they may predict false presence in future offset lands. However, it is noted that all offset sites would be surveyed prior to establishment. Some species records are excluded from consideration based on patch size and this approach may exclude areas of potential habitat that could be utilised by some of these species.

Despite some potential issues with data error and an overly conservative approach, the interrogation of the data, coupled with independent review by suitably qualified ecologists, is considered appropriate for a strategic assessment and would achieve as much accuracy as possible without significantly more effort with respect to field verification.

Annex 1 – Curriculum Vitae

CV

Rhidian Harrington

BSc (Hons), MSc, PhD

Director and Ecologist

niche
Environment and Heritage

"My goal is to develop the best environmental consultancy in Australia: an organisation that staff are proud to be a part of and that clients partner with to achieve sustainable and efficient project outcomes."

- Founding director of Niche Environment and Heritage
- Over 25 years' experience as an ecologist and project manager
- Design, implementation and delivery of large complex ecological projects
- Extensive experience with road and mining projects, and offsetting
- Biodiversity Assessment Method (BAM) - Accredited Assessor under the NSW *Biodiversity Conservation Act 2016*
- Vice President, Environmental Institute of Australia and New Zealand (EIANZ)

Career overview

Rhidian is a professional ecologist and project manager with over 25 years' experience working across a diverse range of industry sectors and environments. Rhidian has been the senior scientist and project manager on many major projects, including environmental assessments, management plans and mitigation design, particularly for linear infrastructure and large mining developments.

Rhidian has experience in flora and fauna survey, federal and state offsetting schemes and project management for environmental approvals projects. Rhidian has conducted ecological work throughout Australia (NSW, VIC, QLD, SA and the NT) as well as overseas in southern Africa and Pakistan. He is experienced in the application of state and federal legislation which relates to the conservation of threatened species and communities, and related planning instruments. Rhidian has acted as an expert witness in the NSW Land and Environment Court. Rhidian is an Accredited BAM Assessor under the NSW BC Act.

Employment history

2009–present	Director and Ecologist, Niche Environment and Heritage
2003-2009	Manager/Senior Ecologist, Biosis
2002-2003	Project Officer, Black-eared Miner Recovery Team, La Trobe University
2002–2002	Scientific Writer, Institute for Land and Food Resources, Melbourne Uni
2000–2001	Zoologist/Project Manager, Melbourne Enterprises International Ltd
1998–2002	Research Assistant/Demonstrator, University of Melbourne
1995-1996	Research Assistant, Botswana National Parks
1997-1998	Lecturer/Demonstrator, University of the Witwatersrand, South Africa
1992-1992	Research Assistant, Australian Centre for Tropical and Freshwater Research (ACTFR), James Cook University

Skills

- Project management
- Ecology assessments for major projects
- Ecological survey and monitoring
- BioBanking and BAM assessments
- Offsetting strategies and BDAR's
- Stewardship Site Assessments
- Biodiversity offset brokerage
- Impact minimisation (mitigation)
- Expert witness and peer review
- Government agency consultation and advocacy
- Strategic planning and advice
- Regulatory compliance
- Quality assurance

Flagship projects

Key offsetting projects that Rhidian has project managed

Brimbin New Town; Biodiversity Certification Assessment, 2013-2014

Hunter Valley Operations (Rio Tinto); Upper Hunter Strategic Assessment, 2013-2015

Mobile: 0488 224 999 **Email**: rharrington@niche-eh.com

Wambo Coal Mine; Upper Hunter Strategic Assessment, 2013-2015
Boggabri Coal Mine; Independent audit of EBPC Act offsets, 2013
Transport for NSW; review of offsetting guide and calculator; 2015-2016
O'Donnelltown'; Biodiversity Stewardship site assessment; 2018
Edgeworth (NSW) residential development; offset strategy; 2016-2017
Austen Quarry Stage 2 Extension; BioBanking assessment and offset strategy; 2016-2017
'Piney Range'; BioBank site assessment; 2016-2017
Mt Thorley Warkworth Mine; biodiversity areas; bird assemblage monitoring; 2016
Warkworth Mine; offsets vegetation and habitat monitoring; 2014, 2015 and 2016
Chinese Theme Park; BioBanking assessment; 2014-2015
Oxley Hwy to Kempsey Pacific Hwy Upgrade; Biodiversity Offset Management Plan, 2014-15
Hunter Expressway; BioBanking assessment; 2013
West Wallsend residential development; SIS and offset strategy, 2012-2013
Caroona Coal Project; Fauna, aquatic ecology and offsetting assessment, 2013-2015
Hunter Valley Operations; Ecological assessment and offset strategy, 2012-2013
Warkworth Mine; Biodiversity offset strategy, 2013
Warkworth Mine; Local offsets vegetation and habitat monitoring program, 2014-2015
Warkworth Sands Woodland Restoration Plan, 2013
Vickery Coal Mine; SSD ecological assessment and offset strategy, 2011-2014
Tarrawonga Coal Mine; BioBanking Assessment, 2010-2011

Other offsetting projects Rhidian has been involved in

'Glenhaven'; BioBank site assessment; 2016
'Blackjack Mountain'; BioBank site assessment; 2014-2015
Tahmoor South Coal Mine; Ecological assessment and offset strategy, 2013-2014
Balranald Mineral Sands Project; Ecological assessment and offset strategy, 2013-2014
Marys Mount Quarry; Ecology assessment, Koala PoM and BioBanking assessment, 2013-14

Major road projects that Rhidian has project managed

Outer Suburban Arterial Roads Program; Technical Due Diligence Advisor – Ecology, 2017
Toowoomba Second Range Crossing; Technical Due Diligence Advisor – Ecology, 2014-2015
East West Link; Technical Due Diligence Advisor - Ecology, 2013-2014
Hunter Expressway; Project Ecologist, 2004-2009
Pacific Highway Upgrade: Tintenbar to Ewingsdale; Environmental Assessment, 2004-2009
Pacific Highway Upgrade: Woodburn to Ballina; Environmental Assessment, 2006-2008
Oxley Highway Upgrade: Species Impact Statement, 2004-2006
Pacific Highway Upgrade: Moorland to Herons Creek; Environmental Assessment, 2004-2006
Pacific Highway Upgrade: F3 to Raymond Terrace; Environmental Assessment, 2004-2006
Pacific Highway Upgrade: Ballina Bypass modification; Environmental Assessment, 2007-2008
Central Coast Highway Upgrade: Carlton to Matcham Road; EA, 2008-2009
Central Coast Highway Upgrade: Matcham Road to Ocean View Drive; EA, 2008-2009
Central Coast Highway Upgrade: Woy Woy Road Intersection at Kariong; EA, 2009
Princes Highway Upgrade: Tomerong Bypass; Environmental Assessment, 2011
Terrigal Drive Upgrade (two separate projects); Environmental Assessment, 2011
Picton Road Upgrade: Reverse Curves Stage 2; Environmental Assessment, 2012
Princess Highway Upgrade: Nowra Bypass; threatened species assessments, 2012
Pacific Highway Upgrade: Wyong Town Centre Study; Environmental Assessment, 2012
Shortland to Sandgate; Threatened species surveys and assessments, 2013
Federal Environment Department Linear Infrastructure Mitigation panel, 2007

CV

Evelyn Craigie

BSc (Zoology), MEM

Senior Ecologist

"I aim to find innovative solutions that maximise environmental benefits and progress sustainable development."

- Accredited BAM Assessor under the *Biodiversity Conservation Act 2016*
- 14 years' experience in the private and public sectors, including both State and local government
- Experienced in application of environmental and planning legislation and negotiating solutions to ecological issues
- Experience in flora and fauna field survey
- Member of Ecological Consultants Association of NSW

Career overview

Evelyn's career experience includes 10 years in ecological consulting and four years in the public sector. Evelyn's recent experience in development assessment at State and local government has given her a comprehensive working knowledge of environmental and planning legislation and valuable insight into the complexities of environmental planning, the development process and experience in stakeholder liaison.

Evelyn's experience in ecological consulting includes project management, planning and carrying out of field survey. Evelyn has prepared numerous high quality reports that are clearly written and comprehensible to all readers including clients, government agencies, site workers and the general public.

Employment history

2018 –present	Senior Ecologist, Niche Environment and Heritage.
2015 – 2018	Ecologist, Central Coast Council
2014 – 2016	Planning Officer, NSW Department of Planning and Environment
2011 – 2014	Senior Ecologist, Environmental Resources Management Pty Ltd
2004 – 2011	Ecologist, AECOM

Skills

- Comprehensive understanding of environment and planning legislation
- Flora and fauna survey
- Biobanking Assessment Methodology
- Stakeholder liaison and negotiation
- Project management
- Clear written communication

Flagship projects

Prepare Biobank Agreements on behalf of NSW Office of Environment and Heritage (OEH) (2018)

Evelyn has reviewed four applications to establish Biobank Sites and prepared the associated Biobank Agreements on behalf of OEH. This included a comprehensive review of all submitted documents to ensure compliance with the Biobanking Assessment Methodology, liaison with the applicant and OEH and preparation of the Biobank Agreement.

Reports in accordance with Biodiversity Assessment Method (2018)

Evelyn has undertaken survey and reporting in accordance with the Biodiversity Assessment Methodology (BAM) for Part 4 development applications, including development projects and stewardship site projects. Field survey included quadrats in accordance with the BAM and targeted threatened flora survey. Evelyn managed the process through to submission to local government and provided advice to the client with respect to meeting offset obligations.

Mobile: 0488 224 810 **Email**: ecraigie@niche-eh.com

Review of Biodiversity Reports on behalf of Bayside Council (2018)

Evelyn reviewed the biodiversity reports for a Planning Proposal on behalf of Bayside Council. Evelyn was able to draw on her previous State and Local government experience to ensure all biodiversity aspects of the proposal were adequately addressed.

Review of Flora and Fauna Assessments for Planning Proposals, Part 4 Development Applications and State Significant Development (2014 – 2018)

Evelyn assessed numerous ecological reports In her previous roles as a development assessment officer at the Department of Planning and Environment and Central Coast Council. Projects ranged from single dwellings to residential and industrial subdivisions and re-zonings. These roles provided Evelyn with a comprehensive working knowledge of planning and environmental legislation and experience in guiding projects through the complexities of the development application process.

Expert report – *Acacia bynoeana*

Expert report for *Acacia bynoeana* (Bynoe's Wattle), Dr Steven Douglas, February 2019

Expert Report For

Acacia bynoeana

(Bynoe's Wattle)

Strategic Assessment for the
Cumberland Plain Conservation Plan

Greater Macarthur, Greater Penrith to Eastern Creek,
Wilton, and Western Sydney Aerotropolis Growth Areas

Prepared for NSW Department of Planning & Environment, February 2019

1. Introduction

1.1 Purpose of the Expert Report

An Expert Report may be prepared under s.6.5 of the Biodiversity Assessment Method (BAM) in place of undertaking a threatened species survey of sufficient extent, intensity and duration as would otherwise be necessary to comply with the BAM. Use of an Expert Report may be beneficial where it is highly unlikely that a species may occur within a study area; where survey cannot meet BAM specifications; and/or the reliability of detecting the species is low. In respect of *Acacia bynoeana*, insufficient survey extent; constraints on the effectiveness of survey; and unreliability of detection due to aspects of the species' ecology are the primary reasons for preparing an Expert Report.

The purpose of this Report is to provide an assessment of the current status and conservation requirements of *Acacia bynoeana* within the four priority Growth Areas of Greater Macarthur (GMGA); Wilton (WGA); Greater Penrith to Eastern Creek (GPECGA); and Western Sydney Aerotropolis (WSAGA)to determine whether:

a) The species is unlikely to be present and would thus require no further assessment; or
b) The species is known or likely to be present, and the Expert Report must provide estimates of potential habitat within Growth Areas and development footprints as part of the biocertification process.

1.2 Project context

The NSW Government is identifying areas for future urban land use and associated infrastructure in western Sydney. The four priority Growth Areas are all located in the Cumberland Subregion under the Interim Biogeographic Regionalisation for Australia (IBRA) (SEWPaC, 2012).

As part of the planning for these areas, the Department of Planning and Environment (DPE) will prepare the Cumberland Plain Conservation Plan to identify land use outcomes. A strategic assessment of this Plan is underway, and this Expert Report will assist in determining the extent and quantum of impacts of the proposed urban growth on *Acacia bynoeana*.

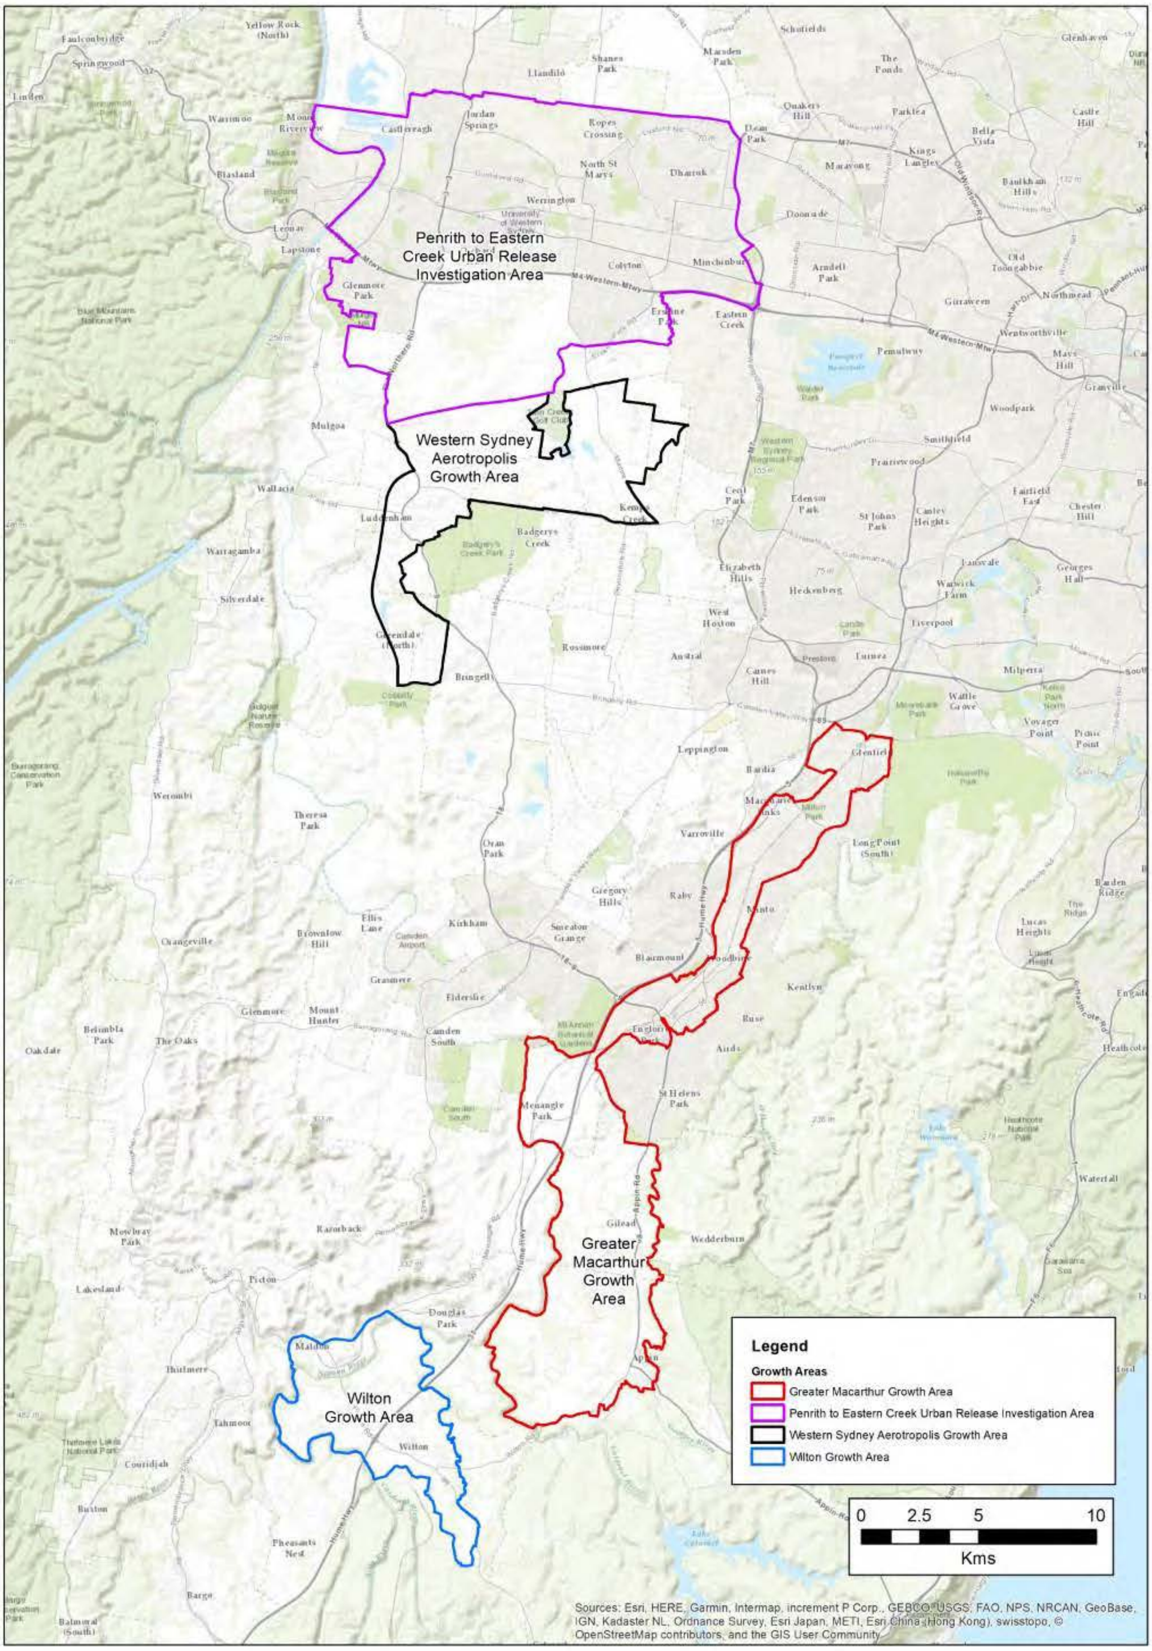
1.3 Study area



Map 1. Growth Areas subject to this Expert Report

Greater Penrith & Eastern Creek Growth Area (GPECGA)

A large portion of this Growth Area is already urbanised, with several areas of industrial land use. Significant rural and peri-urban areas remain in the central north, the centre, and the southwest. Large areas of remnant vegetation are present in the far north (former Australian Defence Industries site, now in part Wianamatta Regional Park), and the Orchard Hills Defence facility. Mining of alluvium for sand and soil continues in the far northwest of the area in the Penrith Lakes locality.

The area has been extensively cleared because of its relatively arable terrain, based mainly on shale and alluvium. Some of the remaining vegetation is associated with the much less arable to infertile Castlereagh Woodlands and its older, leached and mineralised alluvium and shale-derived soils. Strips of remnant vegetation are present along some of the larger watercourses such as Eastern and South Creeks. Significant parts of the study area are or were flood-prone, and this has influenced the retention of vegetation in some affected areas.

Western Sydney Aerotropolis Growth Area (WSAGA)

This Growth Area adjoins the Greater Penrith to Eastern Creek area, extending south to the locality of Greendale, west of Bringelly. It is currently largely rural, with villages at Luddenham and Kemps Creek. Most rural areas are pastoral, but there are significant areas of more intensive rural use, including poultry and egg production, a large dairy and associated fodder cropping, and some market gardens and enclosed fruit and vegetable production. Quarrying occurs at the localities of Badgerys Creek and Kemps Creek.

This Growth Area is extensively cleared but retains native vegetation in areas where rural uses were constrained by steeper terrain, flooding along streams, or unsuitable soils.

Greater Macarthur Growth Area (GMGA)

The GMGA occurs in southwestern Sydney on predominantly shale soils that have been heavily cleared for agriculture and urban or industrial use. The northernmost section has long-established urban and commercial / industrial land use, while the southern section is largely rural (pastoral, minor cropping), with some villages and primarily subsurface mining (e.g. coal and coal seam gas). It extends from urban Glenfield in the north, to the rural village of Appin in the south.

In the southernmost section, geological uplift and erosion have exposed infertile sandstone terrain along gullies and valleys. Much of that terrain remains naturally vegetated because it is unsuited to agriculture, however it occupies only a small percentage of the total area of this heavily-cleared region. Between the infertile sandstone valleys and the relatively arable shale plateau and hills is a geological and ecological transition zone. Whilst much of the vegetation of the shale terrain has been cleared, a greater area of vegetation remains on the transition zone, primarily in the south. Both the shale and transition zones support Critically Endangered ecological communities that are potential habitat for some threatened plant and animal species.

Wilton Growth Area (WGA)

The Wilton Growth Area is the most southerly of the four Western Sydney Growth Areas dealt with in this Report. It extends from the village of Douglas Park in the north, to the village of Wilton in the south. It is primarily rural (pastoral) area with some more intensive agriculture, significant but mostly underground mining (primarily coal), and some long-established villages. The Hume Motorway dissects this Growth Area.

The pattern of clearing and vegetation retention is broadly similar to that of Greater Macarthur, with the majority of remnant vegetation associated with infertile but biodiverse sandstone gullies and the Nepean River gorge, and with associated transition into the heavily cleared shale landscapes.

1.4 Justification for the use of an Expert Report

An Expert Report for *Acacia bynoeana* is required as part of the threatened biota assessment for the Cumberland Plain Conservation Plan because:

1) Survey effort for this species did not meet the recommendations in the OEH threatened species guidelines (OEH, 2016) for field traverses due to limitations on land access, particularly in the GMGA;
2) Survey quality was constrained by drought conditions. Whilst this species is perennial, under sufficiently severe drought and associated total grazing pressure (livestock, if relevant; native species; feral species), it can be suppressed such that it only remains apparent (but likely undetectable) as rootstock and as seed bank. Drought was a major limitation on survey effectiveness in this instance. A known location of the species was visited by fellow botanist, Robert Miller, but could not be detected, even though the habitat was still in place. This suggests that the surveys for this species will have under-detected it because of drought and associated increased grazing / browsing pressures;
3) Survey effectiveness was further constrained by parts of the study area having been long-unburnt. This can create an unnaturally dense shrub layer that limits access and that also creates conditions likely to suppress the species such that it may retreat to the seedbank until favourable conditions return (post-fire or equivalent disturbance).

Surveys associated with biocertification of the study areas and earlier projects in those areas have been insufficient to reliably determine the presence and extent of the species. An Expert Report is required to provide an assessment of the likely presence, location, and significance of occurrences of the species in those areas.

1.5 Credentials of expert

I have worked as an ecologist since the mid-1990s, primarily in the Greater Sydney region, but also in the ACT, Central Coast, southern NSW (coast, tablelands and slopes), throughout Victoria and into eastern South Australia. I have primarily been self-employed, with a mix of government, private, and corporate clients, and have also worked as a subconsultant to larger firms, including two university-based consultancies. I have also worked directly for the NSW NPWS, and more recently for OEH (Native Vegetation Information Science). A summary of my credentials as required under the BAM is provided below as Table 1. I was approved by OEH as a species expert for *Acacia bynoeana* under s.6.5 of the BAM in November 2018

Table 1. Credentials of Dr Steven Douglas as Expert in relation to *Acacia bynoeana*

BAM section	BAM requirement	Details
s.6.5.2.8 (g)	Name of expert	Dr Steven Douglas
s.6.5.2.3 (a)	Expert's qualifications	Bachelor of Science (Plant Ecology, Land Management, Resource & Environmental Management), Macquarie University, 1993. Master of Environmental Planning, Graduate School of Environment, Macquarie University, 1996. Doctor of Philosophy, Australian National University, 2008. Graduate Certificate of Information Literacy, ANU, 2006. BAM Accredited Ecologist, 2018.
s.6.5.2.3 (b)	History of experience in ecological research and survey method for the relevant entity	Review of BioNet and incorporated NSW Herbarium database records of *A. bynoeana* (DPE, 2018). Provision of expert witness evidence in relation to *Acacia bynoeana* (QUBE proposal, Moorebank; included assessment of adequacy of biobanking arrangements) L&EC 2017/81889 (2017-18). Discovery and documentation of new population of *Acacia bynoeana* in Penrose State Forest, including management advice to Forestry Corporation and monitoring (2015-on-going). Rediscovery and documentation of 'lost' 1960s 'Bundanoon' records of *Acacia bynoeana* in Morton National Park (2012-13). Acknowledged by OEH for contribution to the 2009 Draft Recovery Plan for *A. bynoeana*. Consultant to OEH in its review of the current, 2014 Draft Recovery Plan for *A. bynoeana*. On-going advice to OEH to maintain currency of this Plan. Preparation of species management profile for Hornsby and later Gosford LGA Threatened Biota Management Plans (1999 and 2001). Surveys, documentation and recommendations for threatened species including *Acacia bynoeana* as part of the Landcom ESD report (Total Environment Centre, 1999). Successfully nominated species for upgrade from Vulnerable to Endangered under Threatened Species Conservation Act 1995 (1998). Numerous historic surveys in northwest and western Sydney including Hills Shire, Hornsby Shire, Blue Mountains City, Hawkesbury and Penrith LGAs (1994-2000) as evidenced by BioNet and NSW Herbarium records.

s.6.5.2.3 (c)	Resumé detailing projects pertaining to the survey of the relevant entity	See Appendix 1. Relevant surveys and works listed above. Penrose SF population survey used OEH-compliant transects. Minor survey of potential habitat at locality of Kemps Creek for DPE Expert Report. Meandering transect used.
s. 6.5.2.3 (d)	Employer's name and period of employment (if relevant)	Self-employed ecological consultant, 1996 to present (continuous other than for periods of study). Employed by OEH as contracted staff from November 2015 to July 2018 (Wingecarribee Shire vegetation map, South Coast Regional vegetation map, Review of mapping issues for TECs).
s.6.5.2.3 (f)	Evidence that the person is a well-known authority on the relevant entity	Profiles prepared for this species in threatened biota management plans for Hornsby and Gosford Councils. Successful nomination to NSW Scientific Committee to upgrade species' conservation status. Consulted by DECCW on this and other threatened flora species of the region as part of a data review for the purposes of the Biobanking Tool (2006). Consulted by OEH in PAS2 and SOS reviews of this species. Current member of SOS project panel. Engaged by Forestry Corp to advise on management of this species in Penrose SF. Approved as a BAM species expert for *Acacia bynoeana* by OEH in November 2018.

2. Species information

2.1 Description

"Bynoe's Wattle is a semi-prostrate shrub to a metre high. The (adult) phyllodes ('leaves') are shiny, stiff and narrow, 1.5 - 5 cm long and 1 - 3 mm wide…" (OEH, 2017 online species profile). "Decumbent shrub to 0.3 (-0.5) m tall" (Cowan, 2001 in Flora of Australia on-line). "Decumbent shrub to 0.5 m high" (Kodela, 2012 in PlantNET on-line).

The species is best described as having a range of growth forms from prostrate to decumbent to erect, depending on habitat and disturbance history. The tallest plants occur in the lower Hunter / Lake Macquarie regions and can reach 1 metre high; the lowest-growing plants occur primarily on shallow and infertile soils derived from Hawkesbury, Narrabeen, or rarely, Nowra Sandstones and associated laterite, broadly south and west of Lake Macquarie and range from ground-hugging (<5 cm high) to ~20 cm high; and plants of 10 - 30 cm high occur on Paleogene-Neogene alluvium and associated laterite in the Castlereagh Woodlands (roughly in the centre of the species' distribution).

Driscoll (2006 in OEH, 2014) recognised what he considered to be a form of the species in Yengo National Park that was different to the many plants he'd seen in the north and north-east of the species' range. He stated that the Yengo plants have "a much shorter leaf length, sessile peduncles, and fewer flowers and anthers." I am cited in OEH (2014) as suggesting that Driscoll's comments about the Yengo plants are actually typical of the 'southern' populations (i.e. those south of the Lake Macquarie / Hunter area). Driscoll's work was largely in the far north of the species' range, and it is the northern occurrences that are atypical of the species as a whole, though there may be a cline of traits between the Central Coast and the Hunter district. The physical differences between the northernmost populations, and the more typical, much lower-growing plants that occur across most of the species' range is such that the recognition of two subtaxa has been suggested (Douglas, pers. obs. in OEH, 2014). Were a northern subspecies to be recognised, it would have a far smaller range than the typical form of the species, but it is apparently more abundant and potentially more fecund within that area of habitat than would be the typical form across the same sized area. Further research is required to clarify the taxonomic distinctions and any changes in conservation status that this might generate.

Acacia bynoeana in bud – handheld GPS unit for scale. Regenerating in slashed APZ, Penrose State Forest (© Forestry Corporation)

2.2 Ecology

"The single flower heads, on short hairy stems, appear anytime from September to March. Its seedpods are mature from September to January" (OEH, 2017).

Acacia species are generally self-incompatible, and the pollinators are likely to be small native bees and wasps (Bernhardt, 1987 cited in OEH, 2014).

Seed dispersal is most likely by ants seeking to collect the aril. Seeds are taken into the ant nest, and later discarded in a wide area around the nest (Whitney, 2002 and OEH, 2014). Seeds are likely to remain viable over many years in the absence of germination cues, with the species likely to develop a persistent, soil-stored seed bank, as is typical for most Acacias (NPWS, 2002, cited in OEH, 2014).

Driscoll (2006) states that the species is largely clonal and spreads vegetatively by underground stems. Consideration of stem thickness suggests that the plants are relatively long lived. The species is known to resprout following some forms of disturbance, including fire. It can survive in highly modified habitats such as slashed Asset Protection Zones, and road/trail verges.

Driscoll notes that most plants appear to be resprouts or other clonal growth, and that seedlings are rare. However, determining whether a plant is a seedling or a resprout can require some amount of excavation of the root and stem, which may be fatal. Most of Driscoll's assessments relate to populations in the northern part of the species' range, and they may not be representative of the species overall.

I have observed definitive seedlings of this species at Penrose (see below) on a disused fire trail. A BioNet record (Turner, 2005, Tadmore Rd, Cranebrook) also notes "one individual still with juvenile leaves at base, not seen on previous site visit so possibly recent recruit…". A search for the word 'juvenile' in BioNet records for this species within the Cumberland Subregion plus a 100 km buffer found only Turner's reference, though most records simply don't record details about the age of observed plants.

Plants are not always apparent and appear periodically, perhaps in response to local disturbance (Benson & McDougall 1996). The species is "cryptic, clonal and difficult to detect, particularly when not in flower" (OEH, 2014). It is described as "rather inconspicuus" by Fairley (2004).

Acacia bynoeana seedling showing juvenile (lobed) and adult (linear) leaves.

2.3 Distribution and abundance

A range of publications, including on-line resources, provide different distributions for this species, largely as a result of there being significant changes to its known range over time. Some describe it as occurring 'near Wollongong' but this is a result of database errors, as the only legitimate records in that region are not at all near the city and are a considerable distance inland to the north and west within the Woronora Plateau. Many outdated sources list the northern limit as Morriset (Lake Macquarie region), and the southern limit as the Mittagong area (Southern Highlands, Central Tablelands). Neither remain accurate, with the species now accepted to occur substantially further north and south of those areas, as well as further west.

Current knowledge is that *Acacia bynoeana* is found from the Hunter District (North Rothbury) in the north, to the Southern Tablelands (near Goulburn) and South Coast hinterland (Colymea / Parma Ck), and west to just beyond the Blue Mountains (Bogee in the Captertee Valley, and Lithgow areas).

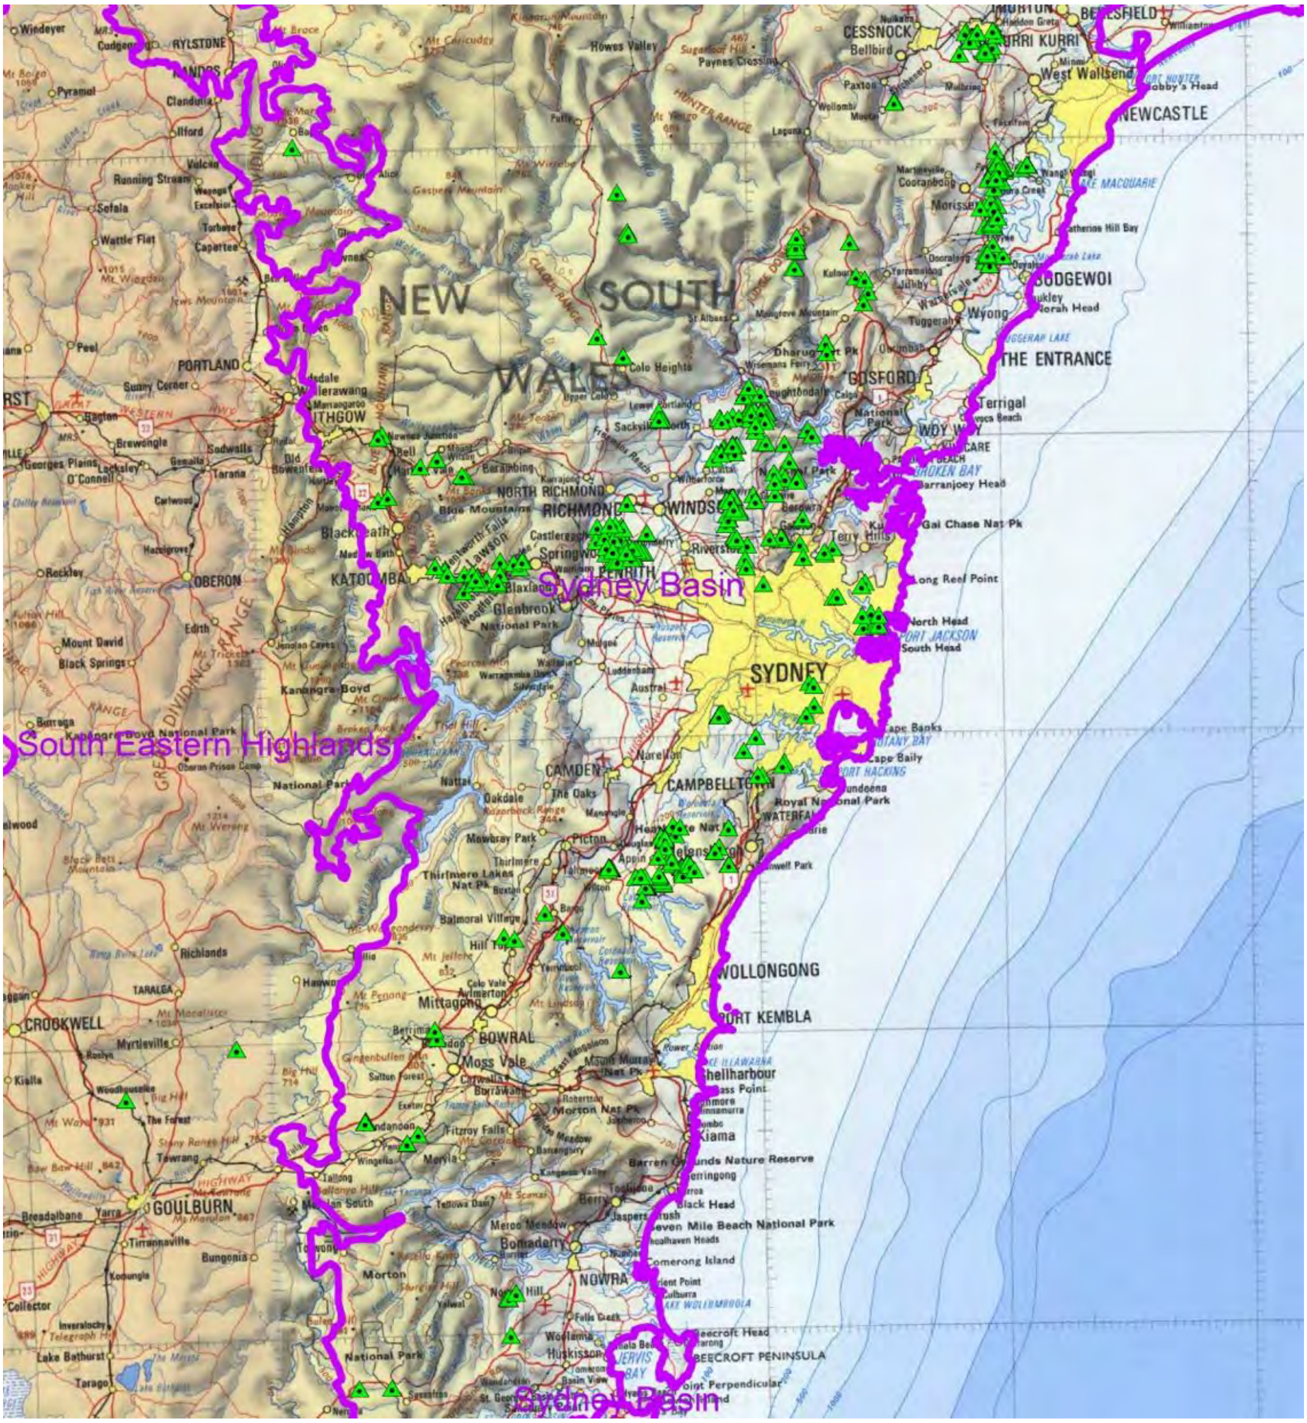
Based on cleaned BioNet data, this species is largely endemic to the Sydney Basin Bioregion, with the exception of three outliers: a record in Tarlo River National Park (part of an incomplete species list for that Park, with no co-ordinates available for this record, so potentially unreliable); a record north of Goulburn (in a vegetation sampling plot with accurate co-ordinates), both of which are within the South Eastern Highlands Bioregion; and another in the Capertee Valley (modern Herbarium specimen with sufficiently accurate co-ordinates), just within the South Western Slopes Bioregion[1].

Map 2 was generated from BioNet data and gives a generally accurate indication of the species' known range, but not the extent of potential habitat. Large areas of NPWS estate and Water NSW catchment lands have not been subject to the same level of survey effort as areas where pressure for land clearing is high or where activities such as underground mining have funded surveys in relation to surface works and subsidence concerns. The map shows an absence of records of the species between the urban areas of the Blue Mountains, and the Southern Highlands, despite there being extensive areas of potential habitat present. Similarly, there are very few records north from the Blue Mountains villages through Wollemi National Park, but again, the area contains significant areas of potential habitat.

As of 2006, the species was known from about 113 extant locations across 21 LGAs (Driscoll, 2006). The number of locations will have increased since that time, though known and unknown destruction of plants and perhaps populations is also likely in that time. The total *estimated* population size in 2006 was 1400 to potentially >6000, though counts were only made at 18 populations, and data indicates that 84 populations only support 1 plant. Two populations were known to support >400 individuals (another was known at that time but not to Driscoll), but 91% of all populations are estimated to support <100 individuals (Driscoll, 2006). Driscoll believes that most population data is very deficient, and that most sightings do not entail a sufficiently thorough census. I concur, as many records lack any population data. In one example provided by Driscoll and Bell, a population estimate of 9 changed to a count of >300 after systematic survey (with some allowance for clonality) (OEH, 2014). OEH has not published a more recent estimate of the number and size of populations, and the 2014 draft Recovery Plan had not proceeded to a final version at this time.

It is important to note that most population 'counts' are estimates because the species is partially clonal, so it is often not feasible to determine the number of actual individuals without genetic testing or potentially destructive sampling.

[1] The boundaries of Bioregions and subregions are often mapped very coarsely and can be misleading in some regards. In this instance, Steenbeeke (OEH / DPE, pers. comm.) states that the Capertee Valley primarily comprises Permo-Triassic deposits of the Sydney Geological Basin and should be included in the Sydney Basin Bioregion, not in the South Western Slopes Bioregion. He notes that the location of the *A. bynoeana* record in that area is on Permian Shoalhaven Group geology.



Map 2. Cleaned BioNet data (extracted 18/10/18)

The above map was generated from BioNet data and gives a generally accurate indication of the species' known range, but not the extent of potential habitat. Large areas of NPWS estate and Water NSW catchment lands have not been subject to the same level of survey effort as areas where pressure for land clearing is high or where activities such as mining have funded surveys. The map shows an absence of records of the species between the lower Blue Mountains and the Southern Highlands, despite there being extensive areas of potential habitat present. A recent record by Orme (not shown) from Joadja has begun to fill that gap. Similarly, there are very few records north from the Blue Mountains villages through to those north of Colo Heights and near St. Albans. Again, that area contains significant areas of potential habitat.

2.3.1 Reservation status

The NSW Scientific Committee (1999) states, "Most of the known sites (of *A. bynoeana*) are not reserved, although populations are known from several reserves including Marramarra National Park, Castlereagh Nature Reserve, Lake Macquarie SRA[2], Blue Mountains National Park". This information was updated by Driscoll (2006) who states that the species is known from 12 NPWS reserves (see Table 2). Five of these are State Conservation Areas that do not prohibit subsurface or surface mining, so do not provide the security that a National Park (NP) or Nature Reserve (NR) designation can.

At least one population (or part thereof) is reserved in a Biobanking offset site (Moorebank). However, that site was burnt in a very intense fire event in April 2017 during severe drought, and at this stage, the status of the *A. bynoeana* population there has not been documented. Part of the area had been burnt only 2-3 years prior to the arson event, which could result in extinction of this species in the affected area, depending on how fire affected the seedbank and how much, if any, successful recruitment occurs post-fire.

Steenbeeke (DPE, pers. comm.) suggests the species may be within the Westcliff Colliery 'managed offset'. Information about other reserved populations in Biobanking offset / stewardship sites was not available due to confidentiality constraints.

Table 2. Modified from Driscoll (2006) by DEE (2008) and for this report. *Best estimate.

Reserve	Records	Individuals*	Populations
Bargo SCA	1	2	1
Berowra Valley RP (now NP)	4	8	3
Blue Mountains NP	8	16	8
Castlereagh NR	4	8	1
Colymea SCA	1	2	1
Jilliby SCA	1	5	1
Ku-ring-gai Chase NP	4	8	4
Lake Macquarie SCA	1	1600	1
Maroota Ridge SCA	4	8	1
Marramarra NP	9	18	1
Wollemi NP	1	2	1
Yengo NP	10	94	1

[2] SRA = State Recreation Area. These were later replaced with the State Conservation Area designation, which has different planning and management parameters but is still a relatively low level of reservation.

Table 3. Additional NPWS reserves containing BioNet records of the species as of November 2018

Reserve	Records	Notes
Agnes Banks NR	1	No recent records despite intensive survey for associated species
Bargo River SCA	1	At edge of reserve
Dharawal NP	51	Detailed survey on and near firetrails and utility corridors. Number of populations much less than number of records
Dharawal SCA	2	One in reserve, one on roadside – may or may not be inside reserve
Morton NP	4	Two sets of two records, distant from each other
Parma Creek NR	1	Credible
Parr SCA	2	One site
Popran NP	1	Credible
Tarlo River NP	1	Dubious record in an incomplete species list for the reserve
Upper Nepean SCA	1	Credible
Werakata NP	3	One site, triplicated. Dubious, possible spatial error.
Wianamatta NR	7	One to three sites – some records with low spatial accuracy

In some instances, the number of records per reserve cited by Driscoll has since increased e.g. Colymea SCA (now 3 records not 1).

In its Final Determination to upgrade the species from Vulnerable to Endangered, the NSW Scientific Committee states, "Recent vegetation surveys in Royal National Park have not located the species. The species was also known from one site within Ku-ring-gai Chase National Park, but several subsequent searches of the site have failed to find any plants". BioNet data currently shows a duplicated, old record on the edge of Royal NP near Loftus, and 4 records in Ku-ring-gai NP. It is this record from Royal NP that has not been rediscovered. A review of cleaned BioNet data for the species in Ku-ring-gai Chase NP revealed 4 records: one by Auld in 1985 (the record referred to by the Scientific Committee); two by Foley in 1998, one of which is an apparent rediscovery of Auld's record, and the other at a nearby by separate site; and one by Foley in 2001 from a different population. Consequently, the statement in relation to the Ku-ring-gai Chase NP population by the Scientific Committee is now redundant. However, there are no records of the species at any of those sites since 2001, but this may be solely an artefact of no survey effort.

"Large populations are present in the Cessnock area of the Hunter Valley, but none of these are currently present in conservation reserves" (Bell & Driscoll, 2002). BioNet data indicates that these populations are near Ellalong and Kurri Kurri, and that one triplicated record may be within Werakata National Park, but they do not provide sufficient detail to verify this.

The species is also now known in considerable numbers (>100 apparent plants, but potentially far fewer individuals) within two sites in Penrose State Forest. Both are outside zones subject to plantation forestry, and the largest is wholly within a bushfire Asset Protection Zone. Whilst the APZ will be maintained to protect plantations, it is now managed with the conservation of *A. bynoeana* in mind, meaning that slashing is less frequent than has been the case; not as low to the ground (parts of the site are now bare due to historically intensive and low slashing); and timed to avoid flowering and seed production. Manual methods of vegetation suppression are also used between slashing events, and these target tree saplings and large shrubs. This practice likely favours *A. bynoeana* by reducing competition and shading through the maintenance of a derived low heathland in what would have been heathy to scrubby forest or woodland.

Additional populations may be reserved as a result of the pending declaration of several new Flora Reserves (deemed Koala Reserves, to be managed by NPWS) within State Forests. However, none were evident based on current BioNet data and Forestry Corporation tenure. Again, this may be a result of low or no survey effort. The species is likely to occur in at least two of the forthcoming Flora Reserves: Meryla and Jellore, both of which are in the Southern Highlands. It may also be present in the forthcoming Comleroy Flora Reserve northwest of Sydney.

The species is now known to occur in many more NPWS reserves than when it was gazetted as Endangered in 1999, or as reported in Driscoll's work of 2006, and by OEH (2014). However, the true size and viability of all such populations is largely unknown. There are also more records of the species, and some more information about apparent population sizes. However, the species remains inadequately conserved across much of its range, and most records either have no population data, or relate to a single plant.

2.4 Habitat

2.4.1 Geology and soil

Acacia bynoeana occurs primarily in heathland, scrub, woodlands and forests on Triassic and Permian primarily sandstone-derived soils (including but not limited to members of the Hawkesbury, Narrabeen & Shoalhaven Groups); the Wianamatta Shale / Hawkesbury Sandstone transition and often-associated Mittagong Formation; and on Paleogene-Neogene alluvium deposits of the Cumberland Plain and environs (*sensu* Martyn, 2018). Some occurrences are known from Quaternary and Cainozoic geologies (Driscoll, 2006), but these are a very small proportion across the species' range. The three geographically outlying records are apparently associated with older geologies that form the basement of the Sydney geological basin. Most occurrences are from sandstone plateaux, with the exception of those from parts of the Lake Macquarie and Hunter area, and those from the Castlereagh Forests and Woodlands of Western Sydney.

Associated Soil Landscapes include but are not limited to: Berkshire Park (Paleogene-Neogene alluvium); Faulconbridge, Bundeena, Gymea, Lambert, Somersby, Oxford Falls, Penrose, Penrose A, Soapy Flat, Nattai Tablelands (Hawkesbury Group); Lucas Heights, Hilltop (Mittagong Formation); Warragamba, Gorokan, Awaba (Narrabeen Group); Durran Durra (Ordovician Metasediments); Canobla Gap (Megalong Conglomerate and Berry Siltstone); Doyalson (Munmorah Conglomerate); Heddon Greta (Permian Branxton Formation). Other Soil Landscapes may be relevant towards the limits of the species' distribution but occur in areas without Soil Landscape maps or where the available data appears incorrect.

Altitude of known habitat ranges from 0-1000 m, though Driscoll (2006) believes that the species may be found at higher elevation subject to survey effort.

2.4.2. Associated vegetation communities and NSW TECs

The species "Seems to prefer open, sometimes slightly disturbed sites such as trail margins, edges of roadside spoil mounds and in recently burnt patches. Associated overstorey species include Red Bloodwood, Scribbly Gum, Parramatta Red Gum, Saw Banksia and Narrow-leaved Apple" (OEH, 2017). The listed overstorey species are only a subset of those that are relevant across the species' range, and are not representative, nor do they occur at all locations where the species is present.

OEH (2014) and the OEH Threatened Biodiversity Data Collection list the following Keith Vegetation Classes as being associated with *A. bynoeana*:

- Sydney Coastal Dry Sclerophyll Forests;
- Sydney Coastal Heaths;
- Sydney Hinterland Dry Sclerophyll Forests; and
- Sydney Sand Flats Dry Sclerophyll Forests.

The Threatened Biodiversity Data Collection indicates that *Acacia bynoeana* is potentially associated with 52 Plant Community Types (PCTs) across its range. Some of these are also associated with State and Commonwealth-listed Threatened Ecological Communities (TECs). Within the Growth Areas, relevant communities and NSW-listed TECs, excluding apparent errors, are shown in Table 4. The associated PCTs are treated by OEH as *potential* habitat, and the species may not actually occur in all of those communities.

Associations between a species and Vegetation Classes and PCTs in the Threatened Biodiversity Data Collection were determined by the species' Accountable Officer within OEH some years ago, and staff were required to take a relatively inclusive approach in accordance with the precautionary principle (Steenbeeke, pers. comm.). This may mean that for some species, Vegetation Classes and PCTs have been associated with them even though there is little or no empirical evidence to support that, but where the officer believed that these attributes credibly represent *potential* habitat. Given the limitations of vegetation mapping and that in most cases, survey effort for threatened species is incomplete across their range, such an approach is understandable.

It appears that in some cases, the associations with Vegetation Class and PCTs in the Threatened Biodiversity Data Collection may have been amended after the assignments described above, and that some more recent associations may be influenced by spatial errors in species' records and/or errors in or limitations of vegetation maps. The apparent association between *Acacia bynoeana* and PCT 1292 is apparent evidence of this, as this unit is a riparian scrub that is unsuitable habitat for this plant. Similarly, the association with PCT 849 is very likely unsound, as the species is not accepted to occur on Wianamatta Shale.

An assessment of the association between *A. bynoeana* and PCTs was undertaken to better understand the potential habitat for this species in terms of plant communities. The assessment is constrained by limitations of BioNet data and available vegetation maps. The assessment of the species' relationship with PCTs in and near the Cumberland Subregion used OEH vegetation maps that were publicly available at the time and did not use the updated vegetation maps produced within the Growth Areas. The information is used to generate 'species polygons' (maps of potential habitat) as required under the BAM. Whilst DPE required habitat associations to be graded i.e. strong to weak association with particular PCTs, only ungraded PCT association data was used to generate the 'species polygons'.

Some records of the species were seen to not be spatially associated with a PCT. This may be because:

- the record occurs in a site now cleared of native vegetation or too degraded to be captured by mapping;
- because the record is too spatially uncertain, so has been assigned generic co-ordinates, usually in a named town or suburb, and such settled areas often lack remnant native vegetation; and/or
- the record plots just outside an area of mapped vegetation because it is on a road verge, and even most GPS records are only accurate to 5m, meaning it could plot on the road, not on the vegetated verge.

To overcome this latter problem, those records were assigned a 10 m buffer so that they would associate with the nearest mapped vegetation polygon up to 10 m from the plotted location.

A further consideration is that survey effort for the species is not evenly distributed across the area subject to analysis. Some sites of potential habitat have had very little or no effort, often due to tenure constraints, yet others have had every apparent plant recorded (mostly in reserves or as part of ecological impact assessments). This creates very substantial biases in the data, which can create misleading weightings of association between the species and particular PCTs. Furthermore, most records do not include population data, such that a record might be for one plant or many. In short, this analysis is best used only for presence/absence i.e. whether the species has been recorded at a point that is mapped as a particular PCT, or not. Analysis beyond that is very constrained by deficiencies and biases in the datasets, especially in BioNet data.

The analysis of association with PCT in Table 4 below deals only with records in the Cumberland Subregion plus a 10 km buffer. Records that associate with a PCT when a 10 m buffer is used are included in the counts of sightings below and are not shown separately. Two analyses were undertaken: All records in the target area without regard to spatial Accuracy score; and only records in that area with Accuracy score of 100 m or better. The latter analysis is considered more reliable, but both sets of figures are provided. Sightings with Accuracy <=100 m are shown in square brackets **[ ]** and in bold text. Where available, the combined count of individuals associated with the records is provided in parentheses { }. Those counts relate only to records with Accuracy <=100 m. Where a record doesn't contain population data, it is assumed to relate to a single plant.

Only PCTs mapped in the Growth Areas are dealt with below. For PCTs outside the Growth Areas and within the 10 km buffer, only Coastal Sandstone Ridgetop Woodland (1777) is significantly associated with *Acacia bynoeana* (80 [71] {112} Very High).

Some PCTs can appear to have a greater or lesser association than is known or likely to be the case. This is evident for this species in that an uncritical review of the raw data would generate an association with this species and PCT 849, a form of Cumberland Plain Woodland that is not considered habitat for this species in any of the literature. The very few records that appear to be associated with that vegetation were more likely in Shale Gravel Transition Forest or Shale Sandstone Transition Forest, both of which can have a broad and indistinct ecotone with Cumberland Plain Woodland such that mapping of the boundary can be very difficult, even at quite a fine map scale.

Similarly, the raw data for PCT 1181 indicates a potentially Low to Moderate relevance as potential habitat, but this is likely to be influenced by spatial errors in the species' records and/or spatial and other limitations of the vegetation maps. At least some of the records associated with this sandstone-based PCT are more likely associated with PCT 1081, which may not have been accurately mapped. The association with 1181 is subsequently rated as Low probability/relevance as habitat.

Inclusion of PCTs 724, 725 and their derived shrubland state (808) as Very Low probability habitat in Table 4 would not ordinarily be supported by the methodology adopted here because there are no spatially credible records of the species from PCT 724 and only two from PCT 725. However, given the limitations of both survey data for the species (incomplete across its range, variable dependent on tenure/access, variable over time, variable in spatial accuracy, variable in quality, etc.) and of vegetation maps, inclusion of PCT 725 as potential habitat is in accordance with the precautionary principle and is made based on advice from Steenbeeke (DPE, pers. comm., relying on his field observations and his interpretation of habitat-related text associated with some records of the species). Steenbeeke also believes that 724 should be included as potential habitat, but I have not adopted that recommendation because there is insufficient evidence to support this, and I consider it unlikely to support the species, or at most, to be extremely low value habitat.

TABLE 4. Species records relative to mapped PCTs

PCT	PCT Name	Associated TECs (NSW BC Act)	% Cleared (VIS)	Sightings & Population	Relative association	Adjusted relative association#
724	Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain	Shale Gravel Transition Forest (E)	75	1 **[0]** {0}	Probably nil	Nil
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain	Cooks River/Castlereagh Ironbark Forest (E)	95	4 **[2]** {4}	Very Low	Very Low
808	Derived shrubland on Tertiary Gravels of the Cumberland Plain	Shale Gravel Transition Forest (E) Cooks River Castlereagh Ironbark Forest (E)	75-95 inferred from 724/725	Not mapped	Very Low (inferred)	Very Low
849	Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain	Cumberland Plain Woodland (CE)	93	7 **[2]** {2}	Very Low	Nil
883	Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain	Castlereagh Scribbly Gum Woodland (V) Castlereagh Swamp Woodland (E)	50	54 **[48]** {157}	High	High
1081	Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain	Not a TEC but some areas may be within Shale Sandstone Transition Forest (CE)	40	70 **[62]** {114}	Very High	Very high
1181	Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney	Not a TEC	20	17 **[10]** {71}	Low	Low
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain	Shale Sandstone Transition Forest (CE)	80	37 **[36]** {153}	High	Moderate

Description of PCTs associated with *Acacia bynoeana*

PCT 725

This community is not mapped in the WGA and GMGA, as the requisite geology is apparently not present. However, it may have been present to a minor extent in the far north of the GMGA because the presence of a very small area of 883 (below) indicates that there was at least one unmapped occurrence of Paleogene-Neogene alluvium.

This PCT is present to a very limited degree near the localities of Kemps and Badgerys Creeks in the WSAGA, and in the far central north of the GPECGA. It is restricted to Paleogene-Neogene alluvium/laterised shale, and this substrate is naturally rare and localised in those areas. Most occurrences in the GPECGA are within or near the currently gazetted and proposed portions of Wianamatta Regional Park, with only small patches occurring further east. It is part of the Cooks River/Castlereagh Ironbark Forest TEC.

PCT 883

This community is absent from the WGA, as the requisite geology is not present. It has been mapped only in the northern section of the GMGA as four small polygons in a section of infrequently-mown urban parkland adjoining a sporting facility. Whilst much of what little remnant vegetation remains, these polygons appear to be correctly ascribed to this community. However, aerial and ground-based photo interpretation indicates that much of the habitat within those polygons is likely to be too compromised to support this species, largely due to the nature of disturbance history and the severity of weed invasion (particularly African Love Grass). Engagement with Campbelltown Council as the land manager resulted in Council setting aside some areas from mowing. This increases the prospect for regeneration of *A. bynoeana*, but application of fire to stimulate regeneration is also likely to be necessary, especially in long-unburnt and long-unmown areas. The habitat value of the four polygons of 883 appears variable, but the ecology of *A. bynoeana* is such that it can persist in significantly compromised sites, such that these remnants are treated as potential habitat for the species.

PCT 883 has been mapped by OEH as two patches near the locality of Kemps Creek, only one of which is in the WSAGA, the other being just south of Elizabeth Drive. Fieldwork determined that the patch previously mapped within the WSAGA was incorrectly assigned and is better placed in one or two alternative PCTs (724/725). Based on the analysis shown in Table W, these two PCTs are very poorly associated with *A. bynoeana*, which may at least partially explain the absence of records of this species from this locality despite several surveys being undertaken there in association with recent land clearing applications.

OEH mapping shows four small patches of 883 in the central north of the GPECGA, three of which are within Wianamatta Regional Park. A few patches are mapped nearby at Llandilo on the northern border of the GPECGA. There could be additional very small patches within the GA that have not been correctly mapped due to the coarse resolution of soil and geology maps. The revision of OEH's map by Biosis has reduced this PCT's extent in the GPECGA to a single linear patch in the eastern portion of Wianamatta Regional Park. This PCT is extensive north from Cranebrook and is present within Castlereagh and Windsor Downs Nature Reserves. It is the most extensive community within what remains of the threatened Castlereagh Forests & Woodlands, partly because its soils are relatively infertile. It is a Vulnerable ecological community.

PCT 1081

This community is a form of 'shale sandstone transition forest' that was previously within the scope of the now circumscribed Shale Sandstone Transition Forest (SSTF) TEC. It has been independently assessed as a prospective threatened community, that whilst significantly reserved, is suffering on-going losses around Sydney, largely due to urban and peri-urban land use. It is a very significant habitat for *A. bynoeana* and several other threatened plant species.

This PCT is absent from GPECGA and WSAGA due to the lack of suitable geology. It is present as a very minor component of the northern GMGA (one site and three polygons) and as moderate component of the WGA. It is likely to have been naturally uncommon to rare in those areas and has probably not been heavily cleared there. It is not readily mapped with high reliability because of the broad ecotone with PCT 1395. Consequently, a precautionary approach is particularly necessary when dealing with areas mapped as PCT 1081, as some may be better classified as 1395 and therefore a Critically Endangered Ecological Community. It is also highly likely that 1081 is present but unmapped in areas that show 1395 immediately adjoining 1181, as the transition zone between the associated geologies is rarely as simple as most maps indicate.

PCT 1181

This community is mapped within the WGA and GMGA, but is generally outside the proposed areas of urbanisation, being associated with sandstone soils in gullies, valleys and steeper slopes. It is usually excluded from the proposed urban footprint because of its association with protected habitat along watercourses, and because of bushfire risk and steep, often rocky terrain. This PCT is not strongly associated with *A. bynoeana* habitat, and the association that is evident in the Bingara Gorge records may be an artefact of the vegetation mapping and of map scale. Most of those records are within vegetation mapped as 1395, with a small proportion close to or just over the boundary with 1181.

This PCT is not present in the GPECGA or the WSAGA due to the absence of associated geology.

PCT 1395

This community is the principal PCT of SSTF TEC and has a relatively moderately strong association with *A. bynoeana*. This community occurs on flat to gently sloping terrain, usually bordering cleared or highly modified rural land. This PCT is absent from the GPECGA and the WSAGA due to the lack of associated geology.

Even where proposed urbanisation does not involve clearing of SSTF, it can be increasingly threatened by urban encroachment in the form of bushfire hazard reduction works, recreational pressures, urban pollution e.g. nutrient-laden runoff, increased weed invasion from inappropriate landscaping/gardening, and increased predation of fauna by domestic pets.

2.4.3 Associated Commonwealth TECs

The Approved Conservation Advice for this species (DEE, 2013) contains significant errors that were brought to that agency's attention in 2016 but remain in its on-line publication as of November 2018. These include *incorrectly* associating *A. bynoeana* with the following nationally listed threatened ecological communities: Upland Basalt Eucalypt Forests of the Sydney Basin Bioregion, White Box-Yellow Box-Blakely's Red Gum Grassy Woodland and Derived Native Grassland, Western Sydney Dry Rainforest and Moist Woodland on Shale, and Blue Gum High Forest in the Sydney Basin.

The Advice correctly associates the species with Shale Sandstone Transition Forest (this is essentially the same entity as the NSW TEC of the same name), and to a minor degree, the species can be found near but not in Temperate Highland Peat Swamps on Sandstone. The latter does not occur in the Growth Areas. Other nationally listed threatened ecological communities are also relevant but remain absent from the now-outdated text provided by DEE (2013). These are Castlereagh Scribbly Gum and Agnes Banks Woodlands of the Sydney Basin Bioregion; and at least on the basis of statistics, Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest. These are composite entities that each combine at least two NSW TECs. The species is strongly associated with Castlereagh Scribbly Gum Woodland but less so with Agnes Banks Woodlands.

2.4.4 Habitat condition

Degraded and significantly modified areas of the above-described PCTs can still be habitat for this species due to its ability to persist as woody rootstock and in the soil seed bank. Such modified sites may have reduced or no canopy and/or midstorey, and/or reduced understorey and some weed invasion. It is known to occur in highly modified sites such as slashed bushfire Asset Protection Zones, and road and trail verges, and in former small-scale quarries. Some forms of disturbance, even relatively severe forms that would be considered clearing of vegetation, appear to be beneficial to this species, within limits. This situation is recognised for numerous threatened plant species in and beyond the Sydney Basin Bioregion. It is believed to be related to the fact that modern fire regimes are likely to be significantly different to those prior to 1788, and that some native animal species that had a role in seed dispersal and understorey modification are now extinct, locally or entirely.

The condition of potential habitat for this species is not, in itself, a reliable indicator of the species' presence, and accordingly, **all condition states are considered in determining suitable habitat** i.e. intact, thinned, scattered, derived shrubland and, to a lesser degree, derived grassland.

3. Description of the study area

3.1 Landscape context and land use history

All of the Growth Areas have been significantly cleared for earlier activities, primarily timber production associated with opening areas for agriculture and pastoralism, minor areas of surface resource mining, and to varying degrees, for urban and commercial/industrial use. They are proposed to accommodate phased increases in urban land use, primarily within existing cleared or highly modified lands. Increased urban use is planned as a response to population growth.

3.1.1. Greater Macarthur Growth Area (GMGA)

The GMGA extends from Glenfield in the north to Appin in the south. It is largely within the Campbelltown LGA with the southernmost section within the Wollondilly LGA. The northern half comprises an urban renewal corridor centred on the Sydney to Main Southern railway line. It encompasses the existing industrial and residential suburbs of Glenfield, Macquarie Fields, Minto, Leumeah and Campbelltown. The GMGA is associated with extensively cleared, gently undulating shale terrain typical of the Cumberland Plain, and contrasts the sandstone gorges of the Woronora Plateaus across the Georges River to the east. The northern portion of the GMGA is already substantially urbanised, with remnant vegetation largely restricted to creek-lines or small patches associated with designated open space. Vegetated creek-lines include Bunbury Curran Creek, Bow Bowing Creek, Leumeah Creek, Fishers Ghost Creek and Spring Creek.

The more extensive southern half of the GMGA, south of Rosemeadow, comprises proposed urban land releases at Menangle Park, Mount Gilead and Appin. Menangle Park and Mount Gilead are subject to separate planning processes, so are not within the scope of this biocertification. In the north-west, Mount Sugarloaf (213 m AHD) forms the southern end of a hilly ridge on the Luddenham Soil Landscape above the Menangle floodplain that extends north to Denham Court, then to Cecil Hills and Prospect Hill. Some native vegetation persists, although it is often invaded by African Olive. The floodplain is dissected by Menangle Creek and its tributaries, including Nepean Creek, Woodhouse Creek and Leafs Gully.

The southern GMGA is primarily semi-rural and agricultural land, with creek corridors and some larger patches of remnant vegetation located between the Nepean and Georges Rivers. Geologically, the area comprises gently undulating hills on Wianamatta Shale intergrading via a shale sandstone transitional zone (can include the Mittagong Formation) with steeper and infertile terrain on Hawkesbury Sandstone along the rivers. Transitional and sandstone geologies are sometimes exposed along the smaller creek lines.

3.1.2. Wilton Growth Area (WGA)

The WGA is a relatively smaller area that occurs to the south of the GMGA, extending from the vicinity of Douglas Park in the north, Maldon in the north-west, and beyond Wilton in the southeast. The boundaries closely follow the Nepean River in the north and west, a tributary Allens Creek in the east, and the Cordeaux River in the south. Away from the Nepean River and gullies, a higher, gently undulating zone has been largely cleared for agriculture. The Woronora Plateau forms the southern boundary and includes the northernmost section of the large Upper Nepean State Conservation Area, with unreserved but closed areas of the Water NSW Special Area (Sydney water supply catchment) extending to the east and southeast. The Hume Motorway dissects the WGA roughly north to south, and Picton Road traverses it roughly northwest to southeast.

The WGA includes both shale, shale sandstone transition and sandstone environments. Remnant vegetation occurs predominantly along the watercourses and on associated slopes. The flatter shale terrain has soils of the Blacktown Soil Landscape, which is derived from Ashfield Shale (a member of the Wianamatta Group), and typically supported the now Critically Endangered Cumberland Plain Woodlands. Much of this area is cleared or modified for agriculture and hobby farms. It comprises native/exotic grassland with smaller areas of Derived Native Grasslands in relatively better condition. Areas above the gullies feature soils of the Lucas Heights Soil Landscape derived from the Mittagong Formation (a transitional bed between the Wianamatta and Hawkesbury Groups). These support variable shale sandstone transition woodlands and forest, some of which are also Critically Endangered. In the steeper gullies, the Hawkesbury Soil Landscape dominates, and supports Hawkesbury Sandstone Gully Forest types with Ridgetop Woodlands on some of the upper slopes.

3.1.3. Greater Penrith to Eastern Creek Growth Area (GPECGA)

The GPECGA is a relatively large area that extends from Rooty Hill, Minchinbury and Hassell Grove in the east, across the Cumberland Plain to the Hawkesbury-Nepean River in the northwest, then south through Jamisontown, Glenmore Park, to the intersection between The Northern Road and the Warragamba Water Supply Pipelines in the far south-west.

The predominant geology is Wianamatta Shale on flat to gently undulating terrain that has been extensively cleared for agriculture, and later for housing and industrial use, with some remnant vegetation on current and former Defence holdings. The shale soils support(ed) Cumberland Plain Woodlands. Overlying the extensive shale deposits are small areas of weathered Paleogene-Neogene alluvium e.g. Shalvey and Willmot, that are much more common to the north. These support(ed) the Castlereagh Forests & Woodlands complex of vegetation types, which is strongly associated with several threatened plant species. More common are broadly linear deposits of Quaternary alluvium along watercourses such as South Creek and Eastern Creek, and on the flood terraces of the Hawkesbury-Nepean River. Other lithologies occur but are very rare and of very small extent.

Very little of the GPECGA is reserved in NPWS estate. Wianamatta Regional Park (which emphasises recreational uses) encloses small areas of former Defence land in the far north. Adjacent to the southwestern boundary is the small Mulgoa Nature Reserve (emphasises biodiversity values). Two Biobanking sites adjacent to the Nature Reserve have increased the area under conservation.

3.1.4. Western Sydney Aerotropolis Growth Area (WSAGA)

The WSAGA abuts the GPECGA's southernmost border near the locality of Sovereign (east of Mulgoa), then extends south past Greendale, northeast to the locality of Badgerys Creek, east to Kemps Creek, and northward to the vicinity of Mount Vernon, excluding Twin Creeks Golf Course and associated settlement.

The lithology and soils are broadly similar to that of the GPECGA, being effectively just an extension of that area to the south to incorporate the developing Badgerys Creek Airport and environs. The area is even more severely cleared of native vegetation, except along some streams and on rare occurrences of steeper terrain. It contains no NPWS reserves, with the nearest being the small Kemps Creek Nature Reserve, outside the Area to the southeast. Gulguer Nature Reserve and Bents Basin State Conservation Area occur to the southwest of Greendale.

3.2 Geology and remnant vegetation

All of the Growth Areas are within the Cumberland Subregion. The dominant lithology across all of the Growth Areas is Wianamatta Shale (Ashfield and Bringelly Shales), with much smaller areas of Paleogene-Neogene alluvium occurring largely outside these boundaries, and much larger areas of Quaternary alluvium associated with floodplains of the many watercourses.

The terrain varies from almost flat through to steeply hilly areas associated with minor volcanism and more often, in association with shale ranges. In the far south, the more elevated shale landscapes have been eroded down to the underlying Hawkesbury Sandstone in a series of gullies and gorges. A transition zone between the shale and the sandstone is discernible in some areas.

On the dominant shale geology, the associated Critically Endangered Cumberland Plain Woodlands are still present in all of the four Growth Areas but have been disproportionately cleared for rural and later urban and allied uses. Much of what remains of this ecological community occurs as paddock trees and areas of remnant native ground-layer vegetation in pastoral and other contexts, with the exception of some substantial, though fragmented and isolated remnants. Remnant vegetation in these relatively fertile and arable landscapes is often in poor condition. In the most heavily cleared areas, it can be restricted to strips along watercourses. Some forms are dominated by *Casuarina* species. Weeds are common and sometimes severe in the moister situations. Weeds often extend into higher and drier terrain, especially in the form of African Olive and African Love Grass, both of which can occur on a landscape scale.

Small areas of the biodiverse Castlereagh Forests & Woodlands persist in all but the Wilton Growth Area on often-laterised Paleogene-Neogene alluvium. These variable woodlands and open forests support a particularly high number of threatened plant species, and because their soils are less suitable for agriculture and grazing, are better conserved than the Cumberland Plain Woodlands. Nonetheless, they are all listed as threatened ecological communities.

In the two southern Growth Areas, vegetation of the shale sandstone transition zone is relatively common and tends to remain in less arable areas adjoining the largely cleared former Cumberland Plain Woodlands. It is often found fringing the largely uncleared sandstone-based terrain, and ranges from highly intact to significantly modified and degraded, largely due to grazing and weed invasion. The associated Shale Sandstone Transition Forest is recognised as Critically Endangered due to extensive clearing across its substantial range, and because of the severity of other threats. Very little is present in formal conservation areas.

In the two southern Growth Areas, diverse, sandstone-based vegetation persists in association with most of the many incised watercourses. This vegetation is broadly the same as what occurs in extensive conservation estate around urban Sydney, but some communities adjoining current or former Shale Sandstone Transition Forest are not well-conserved and are threatened by further clearing and degradation.

3.2.1 Plant Community Types

The following section lists the Plant Community Types mapped in each Growth Area with brief notes about their distribution in those Areas. The list is not restricted to PCTs associated with *A. bynoeana*.

3.2.1.1 Greater Macarthur Growth Area (GMGA)

The predominant ecological communities in the GMGA are or were Cumberland Plain Woodland (CPW), Shale Sandstone Transition Forest (SSTF) and River-flat Eucalypt Forest (RFEF), all of which are Threatened Ecological Communities. All have been extensively cleared and degraded, primarily by agriculture and weed invasion, but also by urban and allied uses. There are no NPWS reserves in this Growth Area. However, the very small Leacock, Edmondson and William Howe Regional Parks occur just outside the border and are managed primarily for recreation rather than conservation. Dharawal State Conservation Area and National Park border the southern portion of the Growth Area to the east.

A summary of the mapped ecological communities is found in Table 5. The maps are based on OEH products that have been updated by Biosis for DPE.

Table 5. Summary of all ecological communities within the Greater Macarthur Growth Area

PCT	PCT Name	Distribution & notes
830	Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain	Small patch at Menangle Sugarloaf on SE slopes.
835	Forest Red Gum – Rough- barked Apple grassy woodland on alluvial flats of the Cumberland Plain	Along creek lines in shale areas in northern and central parts of GMGA.
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	Small patches on shale soils throughout GMGA but mostly in northern and central parts.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	Very small patches on shale soils throughout GMGA, more common in southern parts on steeper terrain.
883	Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain	4 polygons, Macquarie Fields, most of which have long been historically mown (Milton Park Softball Complex). They are now subject to regeneration.
1081	Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain	One small occurrence mapped around the margins of bushland associated with Smiths Creek at Leumeah.
1105	River Oak open forest of major streams, Sydney Basin Bioregion and South East Corner Bioregion	Only mapped along the Nepean River north from Menangle Bridge.
1181	Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of west & south Sydney	Narrow zone along Nepean & Georges Rivers and tributary gullies and a small zone along Smiths Creek at Leumeah.
1292	Water Gum - Coachwood riparian scrub along sandstone streams, Sydney Basin Bioregion	Restricted to parts of the riparian zones of the more incised and larger watercourses. Very restricted extent in this Area.
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain	Relatively small remnants extend from Glenfield into the far south where it is extensive on transitional soils mostly south from Rosemeadow. Can intergrade with 849 and 1081.
1800	Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley	Only mapped to a very minor extent as highly linear remnants between Glenfield and Macquarie Fields (along the railway) and at Ingleburn (adjoining roads).

3.2.1.2 Wilton Growth Area (WGA)

The predominant ecological communities in the WGA are or were Cumberland Plain Woodland (CPW) and Shale Sandstone Transition Forest (SSTF) both of which are Threatened Ecological Communities. Sandstone-based communities occur in and surrounding the more incised watercourses. There are no NPWS reserves in this Growth Area, though Upper Nepean State Conservation Area occurs immediately to the south. There is a Biobanking site on the northern side of the river near Douglas Park (within the WGA), and three more such properties to the immediate north (including St Marys Towers) and those associated with coal mines (Steenbeeke, pers. comm.).

Table 6. Summary of all ecological communities within the Wilton Growth Area

PCT	PCT Name	Distribution & notes
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	On shale soils of higher, gently undulating terrain of northern and central areas. Small patches with scattered trees (farming properties) adjoining more extensive exotic and native grasslands.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	One patch in a derived grassland (treeless) condition in the west, and a much larger portion in the far north.
1081	Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain	Limited to a few patches in the north between 1395 on plateau edges and 1181 in sandstone gullies.
1181	Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of west & south Sydney	Common on slopes and plateau edges above and around incised sandstone-based watercourses that surround most of the Area.
1292	Water Gum – Coachwood riparian scrub along sandstone streams	Restricted to a very narrow riparian strip along the Nepean River.
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain	The most extensive community on shale sandstone transition soils between 849/850 and sandstone communities along gullies. Variable floristics.

3.2.1.3 Greater Penrith to Eastern Creek Growth Area (GPECGA)

The native vegetation of this Growth Area has been extensively cleared, with what remains classified as Threatened Ecological Communities. The majority of the Area formerly supported Cumberland Plain Woodlands, with a much smaller area supporting Shale Gravel Transition Forest and Castlereagh Forests & Woodlands. River-flat Eucalypt Forest was previously much more extensive along the Hawkesbury-Nepean River and adjoining primary floodplain, and it remains to varying degrees along many watercourses such as Eastern Creek, though frequently in poor condition, due largely to extensive weed invasion and a long interface with unsympathetic land uses. There is one NPWS reserve in this Growth Area: Wianamatta Regional Park, however it is already significantly fragmented and may be required to potentially accommodate a large transport corridor. The small Mulgoa Nature Reserve and associated Biobanking sites occur near the south-western border of this Growth Area. Yarramundi SCA occurs on the western boundary but across the Nepean River, and Wianamatta NR occurs near the NW corner.

Table 7. Summary of all ecological communities within the GPECGA

PCT	PCT Name	Distribution & notes
724	Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain	Scattered as small remnants and one larger remnant in the central portion, but with greater extent in the central north, mainly in the western ungazetted portion of Wianamatta Regional Park.
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain	A few very small remnants present south of the M4, with larger remnants within and near the gazetted and ungazetted portions of Wianamatta Regional Park.
781	Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion	Very limited extent, primarily in the far northwest, with some small remnants in the southwest, often associated with watercourses.
830	Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain	Present to a very minor extent on the southwestern edge adjoining Mulgoa Nature Reserve
835	Forest Red Gum – Rough- barked Apple grassy woodland on alluvial flats of the Cumberland Plain	Common along creek lines and associated floodplains through the south and central areas.
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	Common in and near Orchard Hills in the south, and former ADI lands in the central north, with some areas in the ungazetted portion of Wianamatta Regional Park. Other scattered remnants, particularly in the east.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	Very small patches in the south west, primarily in pastoral settings and on steeper terrain.
883	Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain	Restricted to one linear polygon in the eastern portion of Wianamatta Regional Park.
1105	River Oak open forest of major streams, Sydney Basin Bioregion and South East Corner Bioregion	Only mapped along the Hawkesbury-Nepean River, primarily near Penrith Lakes.
1800	Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley	Present as mostly-linear remnants along South Creek and Eastern Creek and tributaries, with some scattered occurrences, including along the M4.

3.2.1.4 Western Sydney Aerotropolis Growth Area (WSAGA)

The native vegetation of this Growth Area has been extensively cleared, with what remains classified as Threatened Ecological Communities. The majority of the Area formerly supported Cumberland Plain Woodlands, with a much smaller area supporting Castlereagh Forests & Woodlands near the localities of Kemps and Badgerys Creeks, and potentially in the vicinity of the water pipeline crossing of Luddenham Road. Riverflat Eucalypt Forest remains to varying degrees along most watercourses, though frequently in poor condition, due largely to extensive weed invasion and a long interface with unsympathetic land uses. Swamp Oak Forest occurs mainly along South Creek and some tributaries. There are currently no NPWS reserves in this Growth Area. The small Kemps Creek Nature Reserve occurs just outside the south-eastern corner and Gulguer Nature Reserve and Bents Basin State Conservation Area are near the south-western corner.

Table 8. Summary of all ecological communities within the WSAGA

PCT	PCT Name	Distribution & notes
724	Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain	Restricted to the Kemps and Badgerys Creek area as three patches of remnants.
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain	As above: two patches with smaller remnants nearby and on slightly higher ground than 724.
781	Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion	Very limited extent, primarily in the far northeast, with one remnant in the centre.
835	Forest Red Gum – Rough- barked Apple grassy woodland on alluvial flats of the Cumberland Plain	Common along creek lines and associated floodplains but very little remains, and most occurrences are linear.
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	The most common PCT in this Area, with remnants throughout on the dominant shale terrain.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	Only very small patches in the far south.
1800	Swamp Oak open forest on river-flats of the Cumberland Plain and Hunter valley	Present as mainly very linear remnants along most watercourses but largely absent from the southernmost portion.

4. Assessment of species' presence and suitable habitat

4.1 Existing records and surveys

The principal source of threatened flora records in NSW is the OEH BioNet database, which includes most records held by the NSW Herbarium (specimen-based), as well as sightings, including those associated with vegetation sampling for the purposes of mapping. Other databases, such as Atlas of Living Australia, largely mirror BioNet data within NSW, but are not used in this Report due to their having lower data quality control, and because they do not allow even a registered user to access data that may not have been generalised to obscure the exact location of a record. Very few flora records that are in ALA but not in BioNet are original – most are simply replicate records based on specimens held in other herbaria.

The preliminary assessment of threatened species records undertaken for the preparation of this Expert Report reiterated the merit of reviewing BioNet data and resolving a range of errors, rather than simply using data 'as held'. *Acacia bynoeana* records within BioNet were reviewed, and numerous corrections were made, though the majority of these relate to the assigned spatial accuracy scores and to clarifying or correcting location placements and descriptions. Not all records were able to be checked in that stage, and a second review for records in or near the Growth Areas was conducted to further improve data quality. The reviews eliminated a range of errors and allowed many records that were otherwise too spatially vague, to be refined such that they were suitable for habitat modelling and for general reference. Not all records were reviewed, and inaccuracies remain in the dataset, but records within the Cumberland Subregion are now far more accurate in terms of their identification of the species, their location, and their spatial accuracy score.

BioNet data should only be treated as indicative, not least because there has not been comprehensive survey of all of the Growth Areas or environs, and surveys have been variously constrained. The absence of records from an area does not necessarily mean the species is absent, as it may not have been surveyed there, or survey conditions and methods may have been inadequate.

Field survey undertaken by consultancy firms engaged by DPE (Biosis and Ecoplanning) did not add any records of this species. Fellow botanist, Robert Miller and I undertook very limited survey in the Kemps Creek locality. No new records of the species were generated.

4.1.1 Existing records by Growth Area

Acacia bynoeana records in Greater Macarthur Growth Area

There are no records of the species from the GMGA, but numerous records just outside its boundaries to the northeast (Moorebank), east (Wedderburn and Appin), and south (between Appin and Cataract).

Prior to the BioNet data cleansing process, a record of the species from 2006 plotted in Appin township, however that record was investigated and seen to have been collected from 'East of Appin'. It has since been moved to co-ordinates consistent with that location, east of the river, just outside the GMGA. There are over 50 records of the species in that wider area within 8km north, east and south of Appin.

Acacia bynoeana records in Wilton Growth Area

The species has been recorded in 2015 within the WGA (20 records in one population detected as part of survey for the Bingara Gorge urban development northeast of Wilton village). The nearest record outside the WGA is ~5km ESE and is part of a group of records south of Appin within the Water NSW water catchment area. Two records occur ~14 km SSW and SW of the Bingara Gorge population. One is within Upper Nepean SCA, the other plots west of Bargo on what is likely vacant Crown land.

Acacia bynoeana records in Greater Penrith to Eastern Creek Growth Area

There are no records of the species in the GPECGA, and the nearest occur between 1 and 2 km north of the northern GA boundary. Of these, the only records that are considered spatially reliable are those in the northern section of Wianamatta Nature Reserve near Cranebrook Road. Those to the east of the Nature Reserve (e.g. Rodd, 1967, RBG Collection, 'Llandilo' – plots in two arbitrary locations in rural areas (second record is Atlas duplicate); and Chamberlain & de Lacey, 1999 'Cherrywood in Llandilo') lack sufficient detail to determine where they were collected. The 'Cherrywood' reference likely relates to Cherrywood Oval or Cherrywood Bicentennial Park (apparently now Wianamatta NR), however the vegetation mapped by OEH near the oval or in much of the NR doesn't match that described by the Collectors. The 'Cherrywood' record has been moved to the edge of the NR, which is close to the Oval. A collection in the area by Hind in 1987 gives a road intersection reference that allows for adequate spatial accuracy. When reviewed, it plotted incorrectly but was able to be moved to match the location description, placing it ~2.6 km north of the GPECGA northern boundary.

If the species were present in the GPECGA, it would likely be found in remnant Castlereagh Forest & Woodland communities. These occur mainly north of the Growth Area through Llandilo, Londonderry to Windsor Downs, with some present just inside this Area at Ropes Crossing, Wilmot and Lethbridge Park (mostly within Wianamatta Regional Park).

Acacia bynoeana records in Western Sydney Aerotropolis Growth Area

There are no records of the species in the WSAGA, nor within several kilometres of its boundaries. This is unsurprising given the very limited area of historic and current potential habitat in this Area. Additionally, much of the potential habitat is apparently long-unburnt, which likely disfavours the detection of this species.

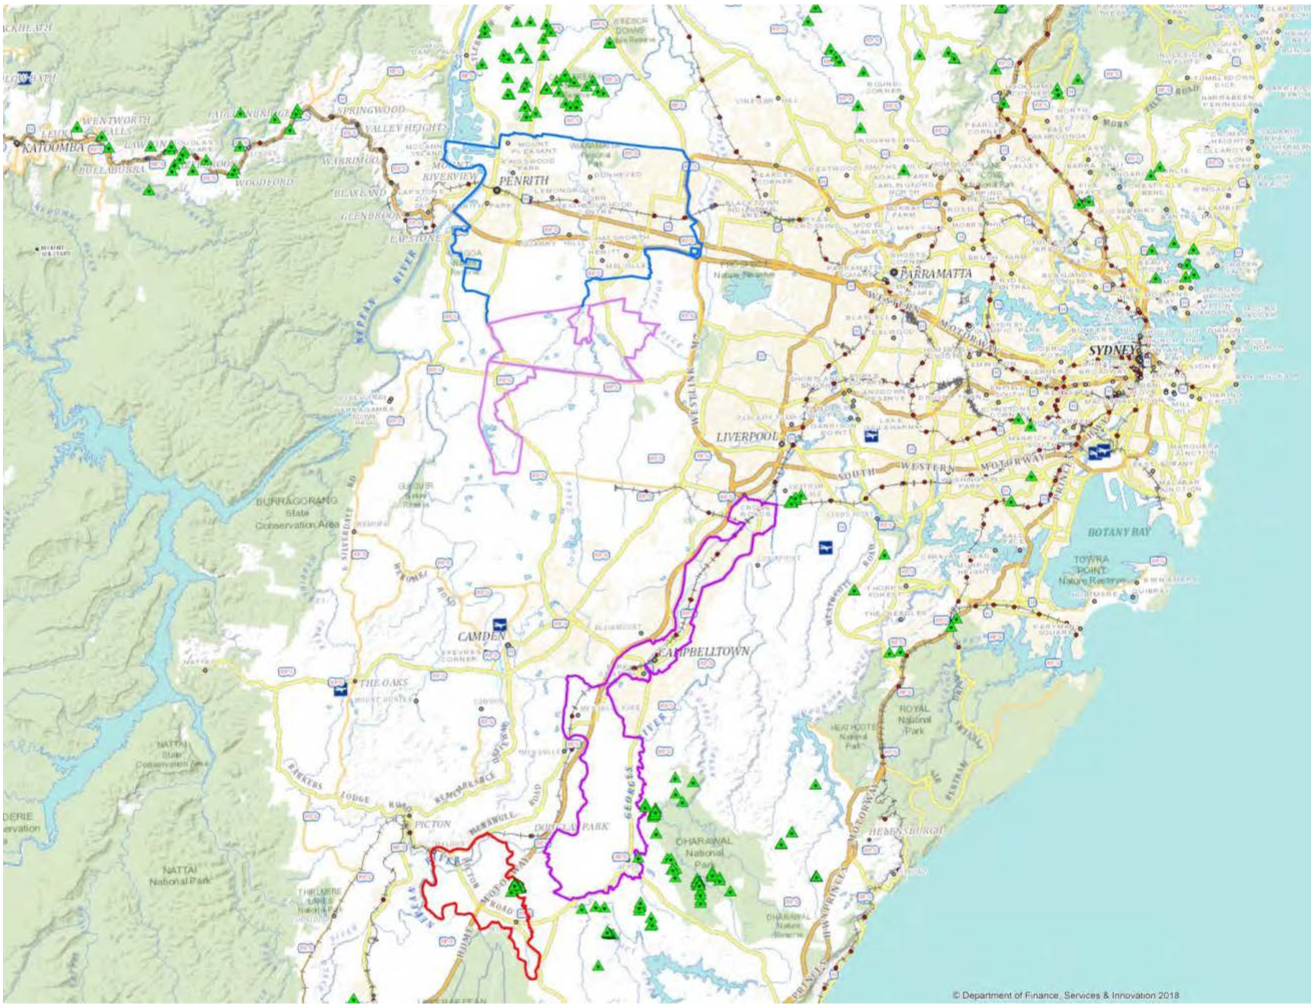
If the species is present in this Growth Area, it is likely to occur in remnant Castlereagh Forest & Woodland communities in the localities of Kemps Creek and Badgerys Creek. The only potential habitat in this Growth Area is ranked as having a Very Low association with *A. bynoeana*.

4.1.2 Prior surveys within each Growth Area

There is no central or local registry of surveys and survey effort for threatened biota, and a large proportion of survey reports are not made public or only made public when lodged with a planning consent authority. This makes it extremely difficult, if not impossible to compile a list of surveys, methods and findings across the study area.

The OEH Authorised Officer for *A. bynoeana* was contacted in this regard. He advised that he does not hold this information and he referred me to the manager of threatened biota matters in the Greater Sydney OEH office. No additional information was provided other than to note that a recent survey of State-owned land outside but near the GPECGA had contributed new threatened flora records to BioNet. No new records of *A. bynoeana* were apparent in that dataset.

I separately became aware of some earlier surveys of threatened flora that OEH had commissioned for areas of NPWS estate near the GPECGA. With approval from the NPWS, the lead ecologist who undertook those surveys provided information about his work, none of which entailed targeted searches for *A. bynoeana*, though incidental records were confirmed to have been lodged in BioNet.



Map 3. BioNet records (cleaned as of 26/11/18) relative to Growth Areas

NB each point may not designate a collection or observation at that location, as most very old records lacked any co-ordinates, or only supplied coarse co-ordinates, and may only have mentioned a town or locality. Such records will generally have a relatively poor Accuracy score (10-25 km) to indicate that the actual location of the species could be within a considerable distance of the designated point. Many such records are assigned the same indicative co-ordinates such that one point on a map may relate to several old records that were supplied with very little locational information.

4.2 Summary of survey work undertaken for the biocertification assessment

4.2.1 Vegetation mapping

Vegetation mapping of the Cumberland Subregion was completed in stages by OEH in 2013 and 2016. These two vegetation layers have been used as the base to compile an updated vegetation community layer for each of the Growth Areas. This updated work has been completed by Biosis under contract to DPE. The mapping update includes checking plant community types and confirming the accuracy of boundaries to account for clearing or regrowth that may have occurred since the original mapping was completed. Field verification of the mapping was undertaken by Biosis and Ecoplanning, both of whom undertook vegetation surveys where access was permitted.

Vegetation in the Growth Areas was mapped and assessed based on five vegetation condition classes:

- Intact;
- Non-offsettable Grassland;
- Offsettable Grassland;
- Scattered Trees;
- Thinned.

4.2.2 Field survey effort

The information in section 4.2.2 has been provided by DPE but has been edited here to only deal with threatened flora where feasible. Further details are provided separately by DPE:

An initial 726 letters were sent to landholders within the Wilton and Greater Macarthur Growth Areas in late 2017 with a second letter following in March 2018. To increase the response rate, Biosis commenced targeted door-knocking in May 2018. From this, just under 20% of landholders within these Growth Areas allowed access to their property. However, this included access to large parcels of land owned by major developers, which allowed a reasonable amount of access, particularly for the Wilton Growth Area.

Floristic plot data collected:

- Wilton (86 plots across 6 PCTs)
- Greater Macarthur (82 plots across 9 PCTs)

Approximately 150 of the plots required to meet BAM requirements were obtained by supplementing Biometric plots from various recent assessments. This involved locating the previous plots and collecting additional data on stem classes, number of large trees, and litter cover to meet BAM requirements. The ecologists had no trouble locating the original survey sites and found that the additional data was quick and easy to collect (approximately 30 minutes per site).

The remaining plots in Wilton and Greater Macarthur, and all of the plots in Western Sydney Aerotropolis and Greater Penrith to Eastern Creek consisted of new plots surveyed for this project. All plots were sampled according to the methods prescribed by the BAM Manual (OEH 2017). This includes collecting information on species cover and abundance from 20 x 20 m or equivalent configuration plots within each vegetation zone.

A total of 432 letters were sent to landholders across the Western Sydney Aerotropolis Growth Area between November 2017 and August 2018 with 84 landholders responding positively to provide access. A further seven properties were accessed after doorknocking resulting in a response rate of 21%.

A small number of targeted letters were sent to landholders in the Greater Penrith to Eastern Creek Growth Area from November 2017. However, most letters (more than 1500) were sent in August 2018, which included many urban and small acreage landholders. From this, 177 landholders provided access to their properties and an additional three landholders provided permission via doorknocking (12% response rate). Not all of these properties were surveyed as some did not support vegetation patches of interest. In addition, the Open Spaces Team at Penrith Council facilitated access to 64 lots owned by Council.

Floristic plot data collected:

- Western Sydney Aerotropolis (53 plots across 6 PCTs)
- Greater Penrith to Eastern Creek (26 plots across 7 PCTs)

Targeted survey for threatened species

Targeted survey for threatened plant species has been conducted on lands where access has been granted. Vegetation transects and random meanders for threatened flora was conducted by Ecoplanning and Biosis in accessible areas proposed for certification, with particular attention to areas of likely habitat. The survey has included effort through each PCT and vegetation zone and has extended into suitable habitat adjacent to the edge of the future urban area where potential indirect impacts to high quality habitat may occur (up to ~50m).

Likely habitat for most threatened flora species comprised areas of lower disturbance. This includes areas with a predominantly native understorey (with or without a canopy), the base of scattered trees in paddocks, paddocks with an apparent low grazing pressure, and known topographic/habitat preferences for certain flora.

Table 9. Survey effort for threatened plant species *and* fauna habitat by PCT

PCT No.	Area of PCT in Growth Area (ha)	Area of PCT in urban zone (ha)	Field survey area (ha)	Percent of PCT surveyed within Growth Area (%)	Percent of PCT surveyed relative to urban zone (%)
724	191.3	57.0	12.1	6.3%	21.2%
725	167.4	51.4	6.9	4.1%	13.4%
781	68.9	5.6	0.9	1.4%	16.8%
830	21.6	0.8	1.7	7.8%	206.5%
835	1175.8	287.3	30.5	2.6%	10.6%
849	3078.3	637.6	125.0	4.1%	19.6%
850	522.9	294.3	36.1	6.9%	12.3%
883	7.4	0.0	0.5	6.8%	
1081	74.2	0.0	0.2	0.3%	
1105	138.6	0.0	0.0	0.0%	
1181	780.7	0.2	39.6	5.1%	19794.4%
1292	39.8	0.0	0.3	0.7%	
1395	3326.6	486.9	483.4	14.5%	99.3%
1800	232.6	20.2	7.3	3.1%	36.2%
TOTAL	**9826.1**	**1841.3**	**744.5**	**7.6%**	**40.4%**

Field survey effort was not confined to the urban zone. Surveys occurred into nearby vegetation zoned for conservation. The urban zone has been revised over time and some areas where survey had already occurred were later removed. For these reasons, comparison of the survey area to the urban zone is indicative only. Survey effort has been calculated using a 20-metre buffer either side of GPS survey tracks. For the purposes of this analysis, the urban zone includes land zoned for future urban development plus transport corridors within the growth areas. It does not include any transport corridors outside the growth areas.

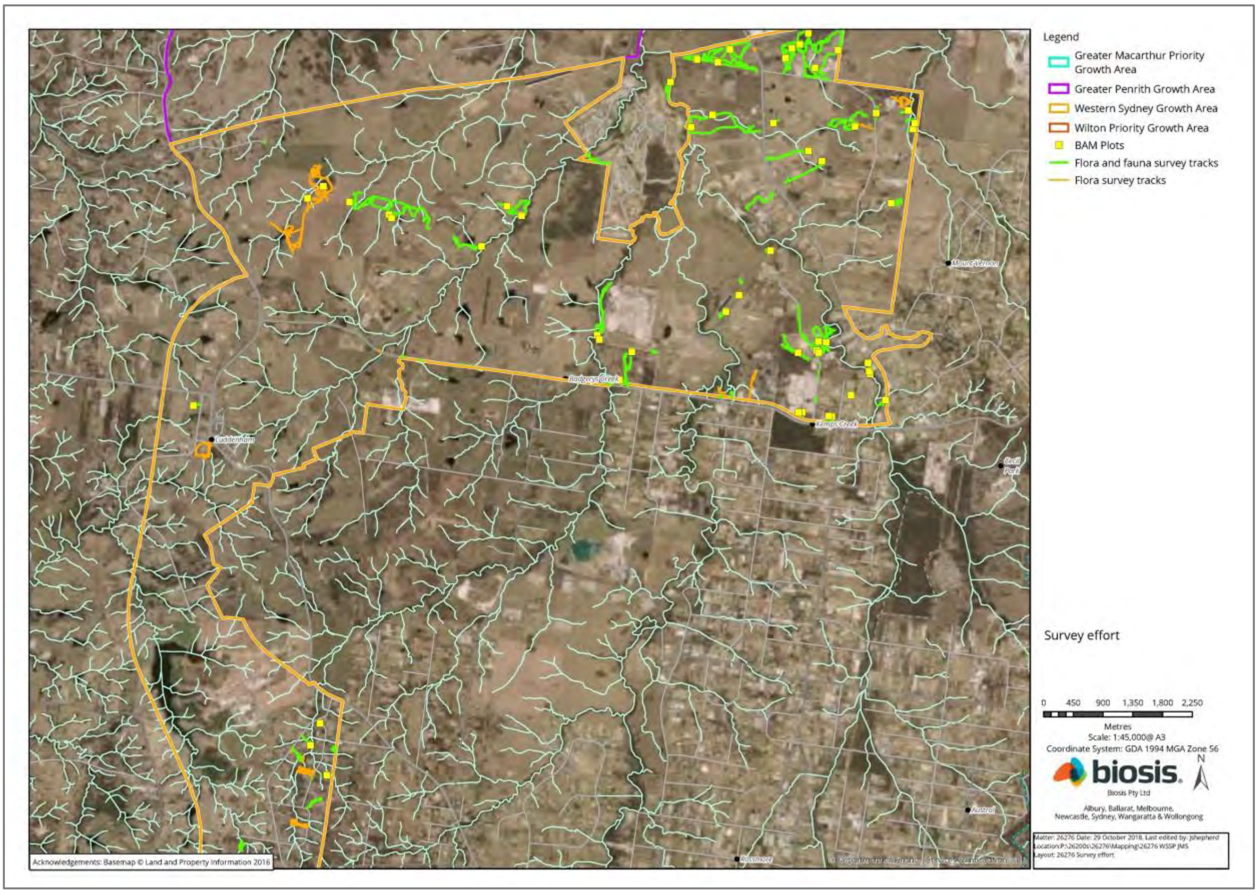
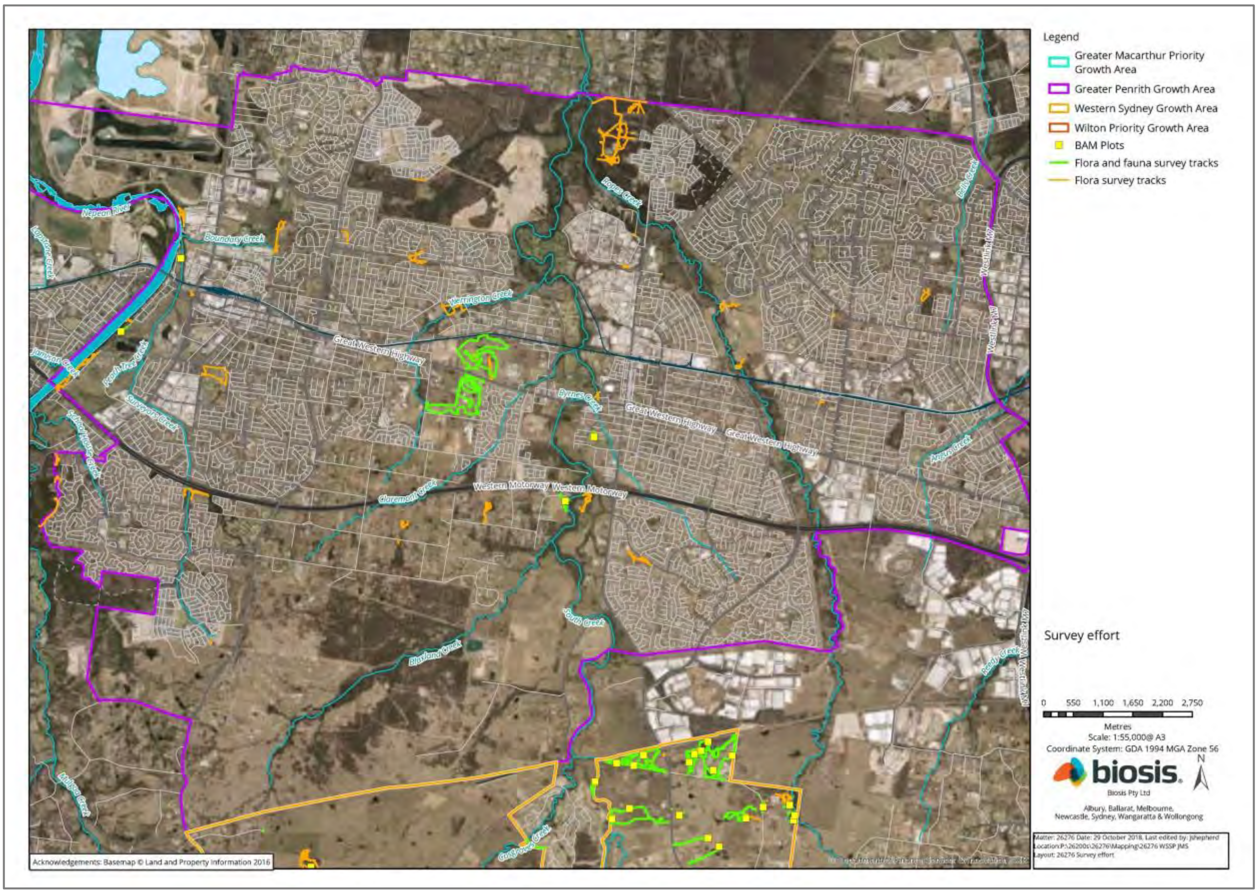


Map 6. WSAGA survey effort (Biosis and Ecoplanning)



Map 7. GPECGA survey effort (Biosis and Ecoplanning)

4.2.3 Survey constraints –timing / site conditions

As noted earlier, severe drought affected all of the study areas for some or all of the survey period. The Wilton and Greater Macarthur GAs were only surveyed during drought, whereas the Greater Penrith & Eastern Creek and the Aerotropolis GAs were surveyed both during intense drought and the subsequently slightly wetter conditions that followed in the Spring of 2018. Whilst wetter, drought remained present, and fellow Expert, Robert Miller, reported that vegetation was evidently drought-affected across all of the Growth Areas into November.

Drought, combined with increased intensity and extent of total grazing pressure, meant that affected surveys are likely to have under-recorded the target species compared to normal conditions. Whilst drought alone is unlikely to cause *A. bynoeana* to die back to rootstock or die and only remain as seedbank, when combined with increased herbivory due to drought, this is a far more likely outcome.

Irrespective of drought, surveys for this species are constrained by consideration of fire ecology, in that this species can be suppressed and even rendered apparently extinct at a site if the area has not been burnt for many years. Prolonged absence of fire is a constraint in some of the surveyed areas. Conversely, the species could be undetectable or not readily distinguished and identified in areas burnt recently. Areas burnt too often may also see the species suppressed or even eliminated. This is a factor in some of the survey sites closer to urban areas where a mix of hazard reduction burning and arson occur.

4.2.4 Survey constraint – surveys undertaken by generalists / non-experts

A. bynoeana is regarded as a cryptic species (OEH, 2014) and even when adult, it can occur as a very small plant with dull-coloured leaves such that it is easily missed, even by expert observers. It is more likely to be present but not recorded when surveyed by personnel not very familiar with the species and its ecology, particularly in terms of micro-habitat features.

Even when the prescribed OEH survey methods are used, a combination of site-based constraints, the species' sometime-cryptic nature, and a lack of familiarity with this species creates a situation where the species may be present but was not recorded. This is supported in part by the observations of Driscoll (cited in OEH, 2014) who noted that irrespective of issues arising from clonality, the population size and local extent of this species is often under-estimated by observers for a range of explicable reasons. I am aware of a repeatedly surveyed site involving effort by different consultancy firms over at least 10 years, yet none managed to record all occurrences of this species.

4.3 Surveys completed specifically for this Report

I was provided with the opportunity to undertake limited surveys in the Wilton and Greater Macarthur Growth Areas but elected not to on the basis that severe drought undermined the value of any survey in determining if the species was absent from any area. This decision was later validated by feedback from fellow botanist, Robert Miller, in relation to his not being able to detect *A. bynoeana* under those conditions at a site where he had previously recorded it, even though the habitat was intact.

I undertook surveys of potential habitat for *A. bynoeana*, *A. pubescens* and *Persoonia nutans* in the localities of Kemps Creek and Badgerys Creek in early November 2018. There were no records of the species in those areas, and only relatively small and sometimes significantly altered areas of very low probability potential habitat remain within the Growth Area, and not all were accessible for a range of reasons. Some other threatened plant species with which *A. bynoeana* is sometimes known to occur are present in this area.

I was accompanied by Robert Miller during my brief survey, and whilst we detected other threatened plant species, we did not detect any new records of *A. bynoeana*. We concluded that potential habitat is present on the surveyed site and on adjoining, more heavily vegetated land to the south. Both areas are now excluded from the proposed urban footprint / biocertified land.

The map below shows the transects associated with a brief survey within the WSAGA (northern line largely within a s.88b conservation area) and outside the WSAGA (short southern line).

Map 8. GPS track logs (purple lines)

4.4 Assessment of species' presence

4.4.1 Greater Macarthur Growth Area

The species is not known to be present in this Growth Area but is considered likely to occur in the southern portion. It is unlikely to occur within the majority of the proposed urban footprint because that area was never suitable habitat or has been too heavily modified.

The northern half of the GMGA is not likely to support the species based on the extent of land clearing and/or the absence of suitable habitat parameters such as plant communities and soil types. Were the species found in the highly urbanised northern GMGA, it is likely that unless on public land able to be managed for conservation, any such occurrence may not be viable in terms of size, area of habitat, threats including fragmentation / isolation of habitat, and ability to maintain ecological processes.

In contrast, the southern half of the GMGA contains significant areas of potential habitat as determined by the presence of associated PCTs. This habitat mainly occurs around the upper slopes and ridges associated with gullies and valleys of incised watercourses, and some other remnants that appear to have escaped clearing and grazing due to their relative infertility or other constraints. Some potential habitat is present within and on some edges of the biocertification area (urban footprint). However, potential habitat within the proposed urban footprint is likely to be of lower condition and less viable due to historic and current land uses.

4.2.2 Wilton Growth Area

The species is known to be present in this Growth Area, though only on a site outside the proposed urban footprint, within a separately approved urban release area. A significant area of similar habitat occurs largely outside but occasionally on the margins of or adjoining the proposed urban footprint. However, surveys of some nearby sites supporting apparently suitable habitat by the same personnel who found the documented population did not detect any further occurrences. This may be a result of the areas having different disturbance histories, particularly in terms of grazing and fire. This situation does not preclude the species being present in those sites, as it may be restricted to the seed bank or to rootstock.

The species is unlikely to occur within the majority of the proposed urban footprint as it was never suitable habitat or has been too heavily modified. Potential habitat within the proposed urban footprint is likely to be of lower condition and less viable due to historic and current land uses.

4.2.3 Greater Penrith to Eastern Creek Growth Area

The species is not known to be present in this Growth Area, but a relatively small area of potential habitat is present within the proposed urban footprint, including within Wianamatta Regional Park, which appears to be proposed for further clearing and fragmentation to accommodate a large transport corridor. Areas of potential habitat are limited to the far central north of the Growth Area. On the Cumberland Plain, this species primarily occurs north of the GPECGA in the Castlereagh / Londonderry area.

4.2.4 Western Sydney Aerotropolis Growth Area

The species is not known to be present in this Growth Area, and most mappable areas of potential habitat are outside the proposed urban footprint. There is very little direct conflict between proposed urbanisation and potential habitat for the species in this area. The extent of potential habitat is limited to a few patches of remnant vegetation between the localities of Kemps Creek and Badgerys Creek. There are no nearby records. Most of the WSAGA was always unsuitable habitat for this species based on geology, soil and plant community associations.

4.5 Assessment of suitable habitat for *Acacia bynoeana*

4.5.1 Description and relative significance of potential habitat

As per the findings presented earlier in Table 4, combined with expert knowledge, the following vegetation communities are regarded as potential habitat for *A. bynoeana* where they occur across any of the Growth Areas. However, not all parts of these communities are likely to support the species. Wetter and sometimes more thickly vegetated areas associated with drainage lines are unlikely habitat, as this species prefers drier, more open conditions. This limitation is addressed later through the specification of riparian exclusion buffers.

Table 9. PCTs known or likely to be habitat for *A. bynoeana*

PCT	PCT Name	Relative significance
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain	**Very Low**
883	Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain	High
1081	Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain	Very High
1181	Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney	Low
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion	Moderate

The following sections describe the relative habitat value and local occurrences of each PCT mapped in each Growth Area.

<u>Greater Macarthur Growth Area</u>

The vegetation mapping provided for use in the project indicates that there is **1614.1 ha** of potential habitat for this species in this Growth Area based only on the extent of relevant PCTs. However, significant portions of some components are of lesser habitat significance due to persistent disturbance, particularly intensive pastoralism (sewing of introduced pasture species, addition of fertiliser, commercial stocking rates), and are less likely to retain this species in any form. However, *Acacia* seeds can remain viable for ~100 years, so even in highly modified sites with persistent suppressive factors such as grazing, the species could regenerate from seed were those factors to cease or be adequately reduced in intensity and duration.

Table 10. Potential habitat in the GMGA

PCT	Distribution	Relative habitat value of local occurrences
883	Four very small polygons at Macquarie Fields	Very low at this site due to historical land use. The species may regenerate if issues of mowing, absence of fire, and intense weed invasion are remedied. Any resultant population would be isolated from core habitat and surrounded by unsympathetic land uses.
1081	Restricted to one remnant surrounding an incised watercourse in urban bushland.	Moderate to high but this community is of relatively limited extent in this GA
1181	Common only on the edges of and within sandstone gullies and gorges but very limited extent; from Gilead south, mainly on GA boundaries, with a small outlier at Leumeah	Low potentially extending to Moderate depending on sandstone influence – high sandstone and no shale influence is of lower habitat value. Not suitable habitat close to watercourses.
1395	Common in the far south from around Menangle Park through Gilead to Appin area; between cleared shale landscapes and the upper margins of sandstone gullies	Moderate to high depending on shale content – high shale content is of lower habitat value. Unlikely habitat when near watercourses

Wilton Growth Area

1380.8 ha of potential habitat is identified in the WGA, with several recent records within one population mapped as part of the Bingara Gorge housing project. Similar habitat extends along the upper slopes of many remnant vegetation areas associated with larger watercourses.

Table 11. Potential habitat in the WGA

PCT	Distribution	Relative habitat value of local occurrences
1081	Uncommon and restricted to three substantial patches above sandstone gorges, mainly on or near edges of WGA.	Moderate to high but this community is of relatively limited extent in this GA
1181	Common within sandstone gullies and gorges, mainly on or near WGA boundaries.	Low to moderate depending on sandstone influence – high sandstone and no shale influence is of lower habitat value. Not suitable habitat close to watercourses.
1395	Common in the far south from around Menangle Park through Gilead to Appin area; between cleared shale landscapes and the upper margins of sandstone gullies	Moderate to high depending on shale content – high shale content is of lower habitat value. Unlikely habitat when near watercourses

Greater Penrith to Eastern Creek Growth Area

There was always very limited scope for the species to occur in this Area, and much less so as a result of historic and on-going land clearing. However, **132.9 ha** of potential habitat is identified

Table 12. Potential habitat in the GPECGA

PCT	Distribution	Relative habitat value of local occurrences
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain	This PCT occurs primarily in the far central north and is mostly within reserve. Very Low ranking but may be present depending on the disturbance history of the habitat.
883	Only in far north, and of very minor extent	High – strong association with this PCT but no records from this area at present, though proximate records are present to the north and northwest.

Western Sydney Aerotropolis Growth Area

Only a relatively small area of habitat existed in this Area, and even less remains due to historic and on-going land clearing. What little remains is known or likely to be associated with other threatened plant species. There are currently no records of *A. bynoeana* in this area. **39.8 h**a of potential habitat is identified.

Table 13. Potential habitat in the WSAGA

PCT	Distribution	Relative habitat value of local occurrences
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain	Very Low ranking but may be present depending on the disturbance history of the habitat. Restricted to Kemps Ck and Badgerys Ck localities as relatively small remnants – apparently long-unburnt.

4.5.2 Species habitat polygons

Species habitat polygons generated by this report relate to the extent of potential habitat and the area and percentage that is proposed to be cleared for urbanisation or transport corridors (Maps 9-11). These habitat polygons and associated calculations were generated to inform biodiversity offset requirements. The data presented in this section does not deal with species habitat outside proposed urban and allied zones as those areas are treated as conservation zones or are excluded from urban and associated transport zones for a range of reasons.

The species habitat polygons include all relevant condition classes of relevant PCTs as identified in this Report. In this case, all condition classes are included.

As part of the formulation of the species habitat polygons, graded riparian exclusion buffers were used in recognition that *A. bynoeana* does not occur in riparian vegetation. Buffers are relatively large for this species as it does not occur in riverflat/creekflat situations. The buffer distances increase with the mapped Strahler stream order as shown in Table 14. The accuracy of the buffers is limited by available data, including the mapped location of streams. The buffer is applied either side of the mapped stream centreline. Note that these riparian buffer distances are a different concept and serve a different purpose to those applied by DPE for the purposes of protecting streamside vegetation and watercourses in its planning within the Growth Areas.

Table 14. Buffer distance applied to stream orders

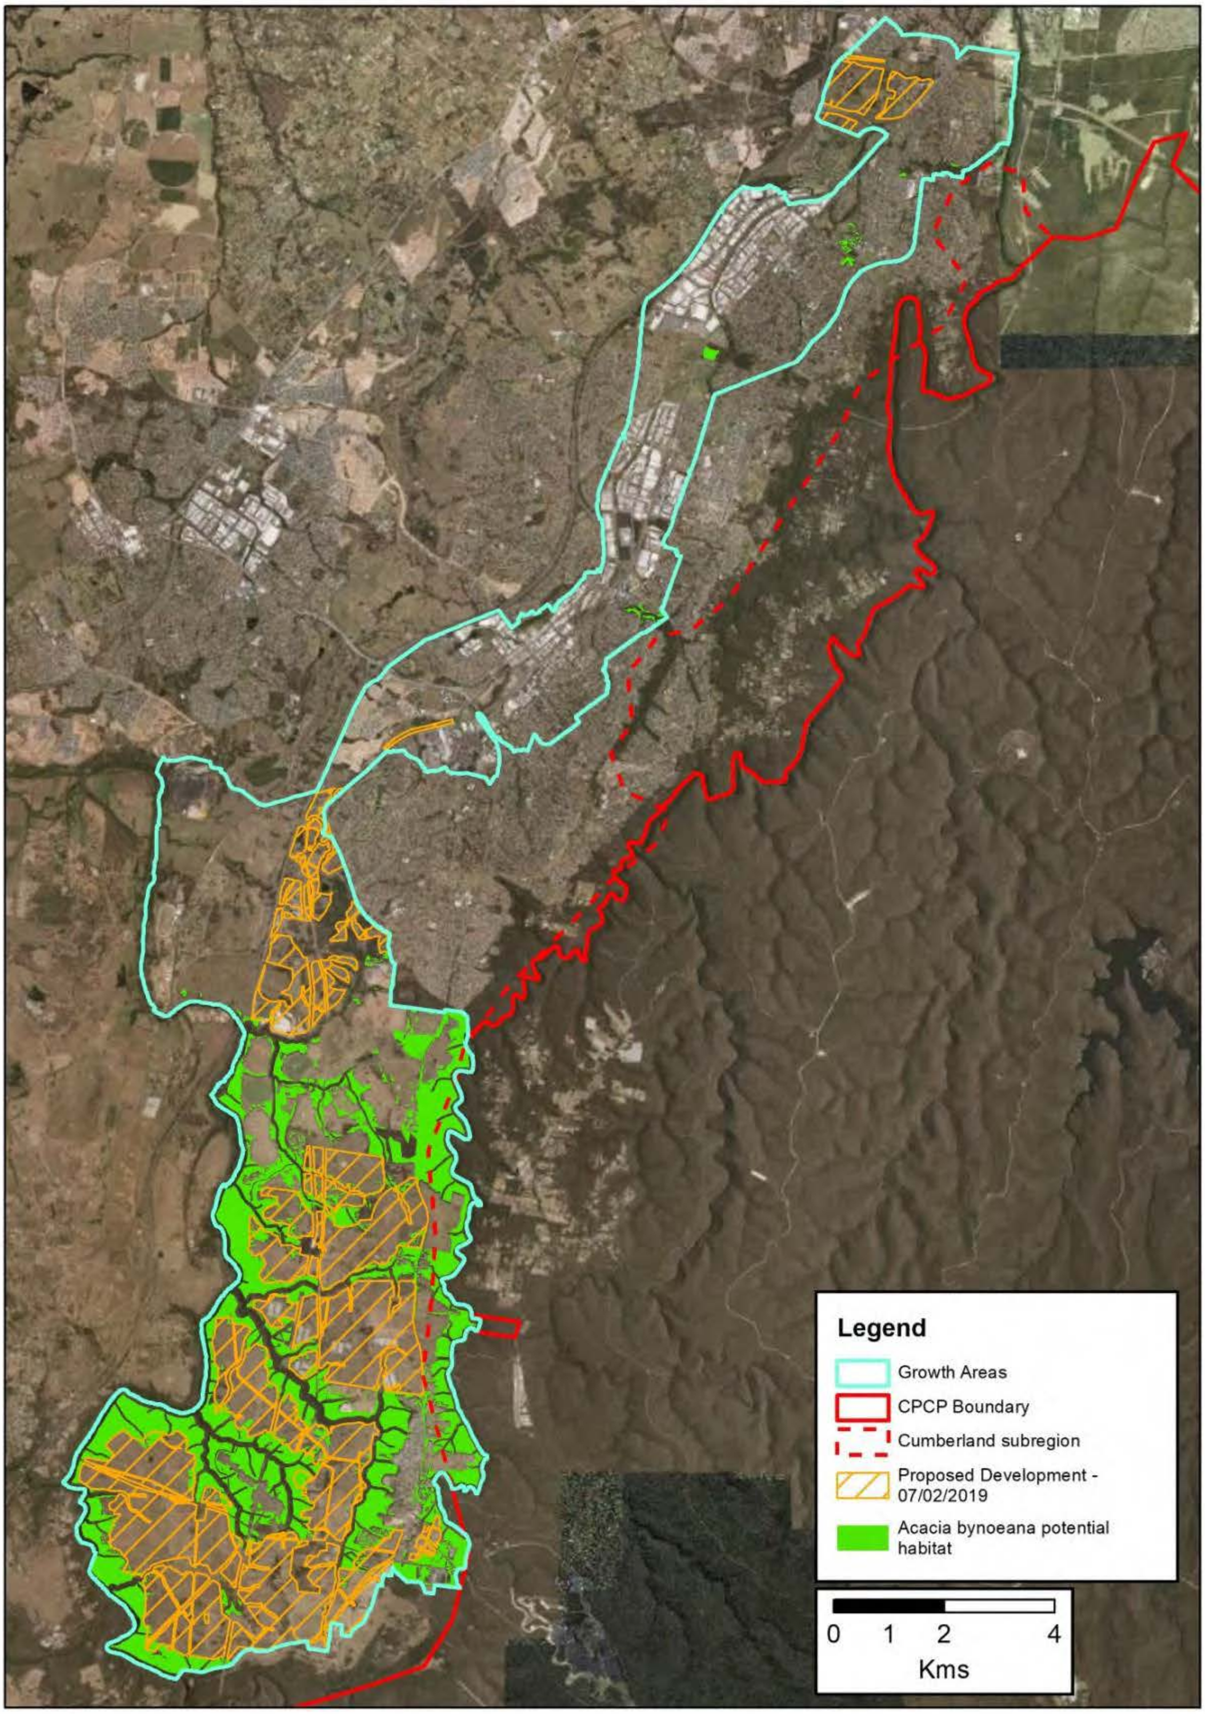
Stream order	Buffer distance (m)
1	20
2	30
3	40
4	60
5	70
6	80
7	90

Table 15. Potential habitat and proposed removal of potential habitat by Growth Area

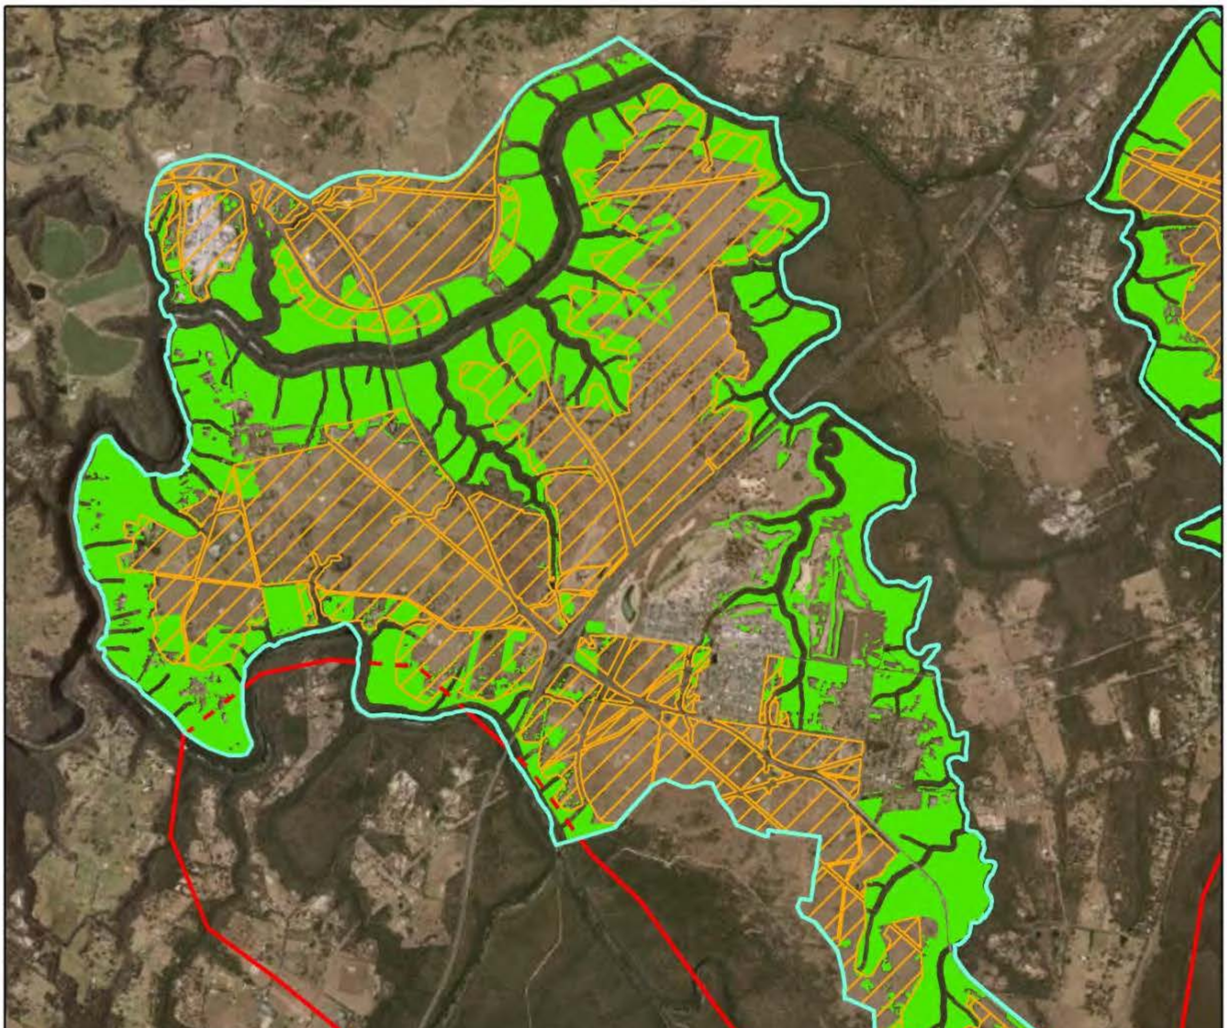
Growth Area	Area of potential habitat (ha)	Area of potential habitat removal (ha)	% area of potential habitat removal by GA
Greater Penrith to Eastern Creek	132.9	3.8	2.9
Western Sydney Aerotropolis	39.8	11.8	29.6
Greater Macarthur	1614.1	126.5	7.8
Wilton	1380.8	300.8	21.8
Transport corridors **(all GAs)**	-	20.7	0.7
TOTAL	**3167.6**	**463.7**	**14.6**

These figures are based on precautionarily modelled *potential* habitat, and do not necessarily equate with *actual* habitat, nor do they provide any information of potential population sizes or population viability. It is unlikely that a large percentage of the potential habitat identified in this Report would actually support *A. bynoeana* because this species is naturally rare and patchily distributed, even though it can sometimes be locally abundant in favourable conditions.

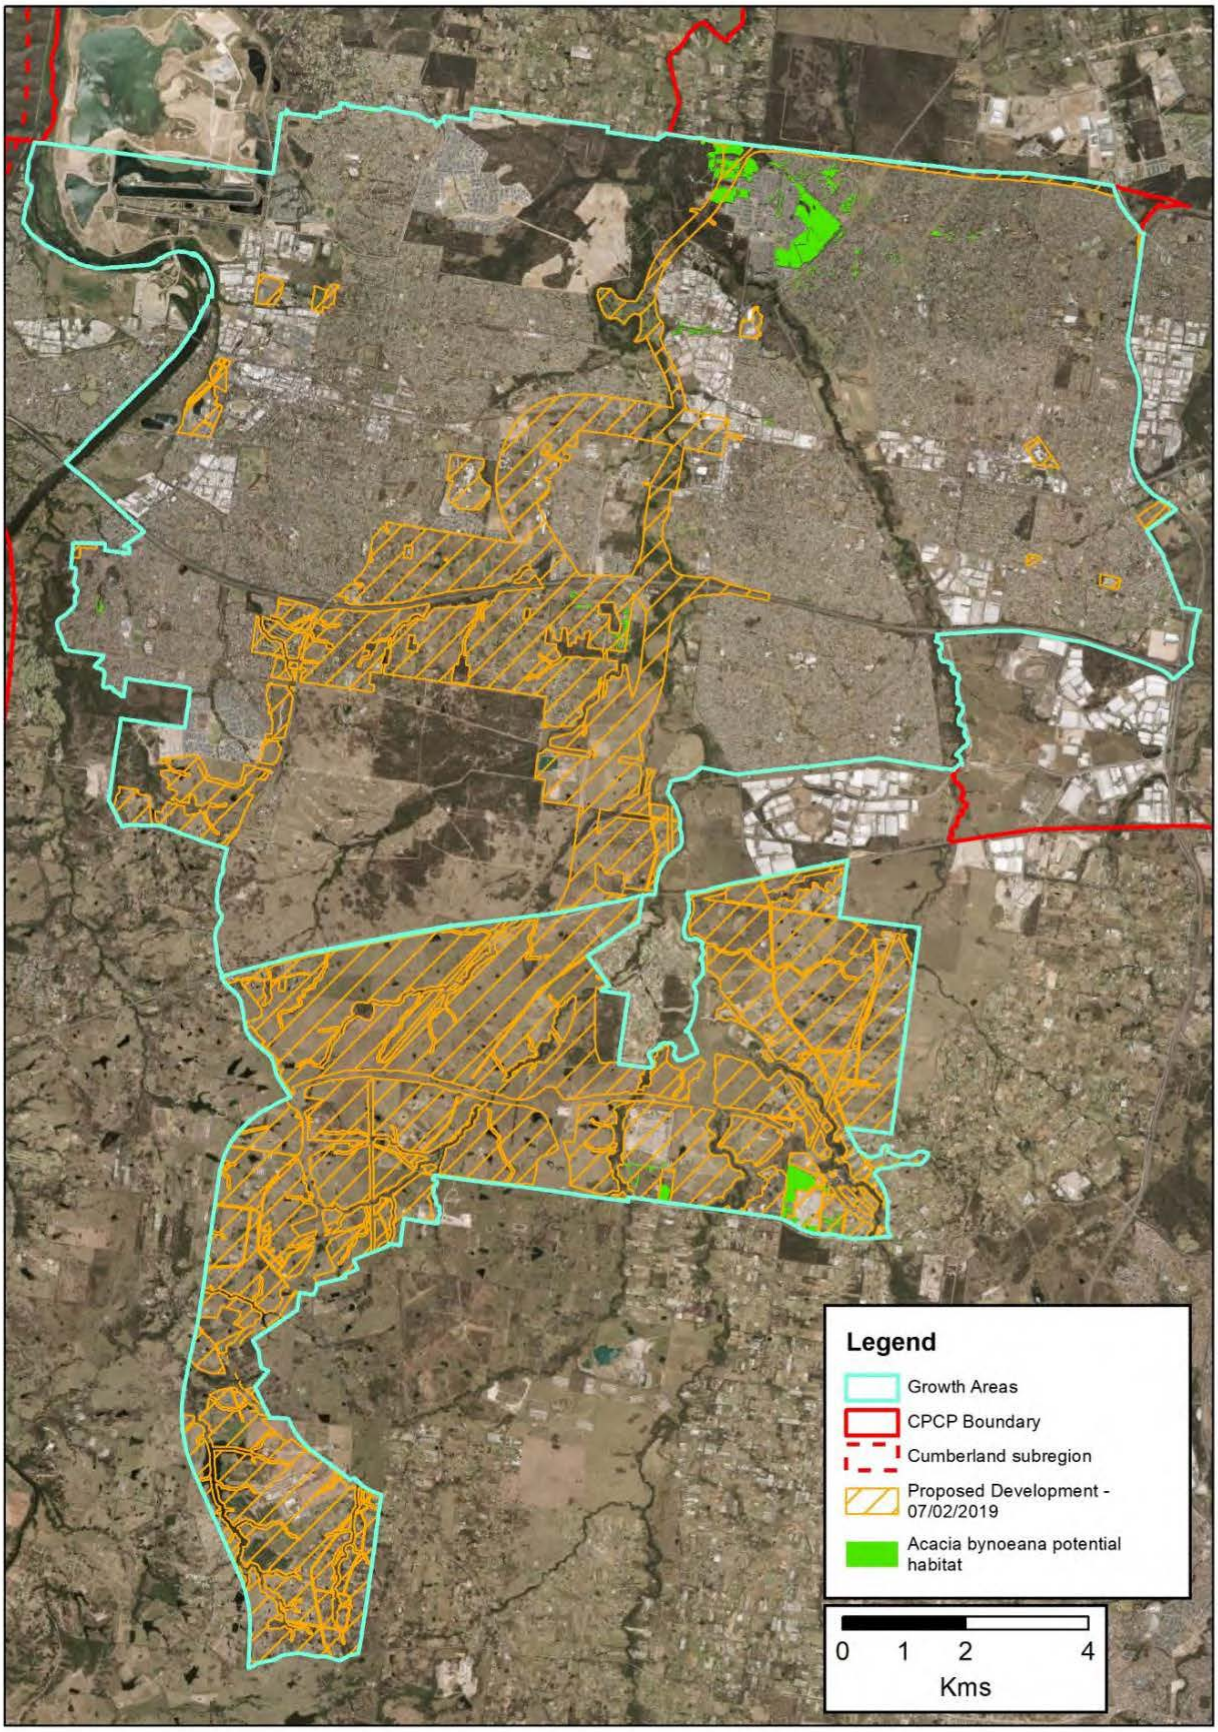
Map 9 Greater Macarthur - Potential habitat and proposed urban/transport habitat removal



Map 10 Wilton - Potential habitat and proposed urban/transport habitat removal



Map 11 Greater Penrith & Eastern Creek plus Western Sydney Aerotropolis
– potential habitat and proposed urban/transport habitat removal



5. Summary and conclusion

Within the four Growth Areas, *Acacia bynoeana* is currently only known from the Wilton GA. However, potential habitat for this species exists in all four Growth Areas, based on the species' known association with specified Plant Community Types, with other threatened plant species, and with abiotic factors. In the southern Growth Areas, it is most likely to occur in habitat associated with the shale sandstone transition, the Mittagong Formation, and upper Hawkesbury Group on plateaux margins and upper slopes. In the northern Growth Areas, it is likely to occur only in relatively small remnants of a particular subset of Paleogene-Neogene alluvium associated with the Castlereagh Forests & Woodlands.

Based on current information, the proposed urban footprint and associated transport corridors of all four Growth Areas would destroy 463.7 hectares of potential habitat for *A. bynoeana*. This equates to 14.6% of the area of potential habitat identified in those Growth Areas. Not all of the area proposed for removal is of equal value as potential habitat, and different PCTs and condition classes have different probabilities of supporting *A. bynoeana*. The actual extent of conflict between habitat for the species and proposed clearing for urbanisation is likely to be much smaller as the species is naturally rare and patchily distributed.

In the Greater Penrith to Eastern Creek Growth Area, the greatest direct conflict between proposed urbanisation and potential habitat for this species is a proposed transport corridor through the western (apparently ungazetted) portion of Wianamatta Regional Park. Most of this Growth Area is and always was unsuitable habitat for this species for geological reasons, and only relatively small areas remain in the central far north in and near the Regional Park.

In the Greater Macarthur, Western Sydney Aerotropolis, and Wilton Growth Areas, the majority of potential habitat for this species is outside the proposed urban footprint. However, because this species is relatively tolerant of some quite intense types of disturbance, and that it can persist for many decades in the soil seedbank, as well as surviving for some time as rootstock, it may occur in habitat that might otherwise be disregarded and even not mapped as native vegetation. It is likely that highly modified sites that might support the species in some form are of relatively low significance for it in the context of the much larger areas of more intact potential habitat that are excluded from proposed urbanisation. It is also feasible that disturbance associated with urbanisation, particularly the creation of bushfire Asset Protection Zones between bushland conservation areas and housing, could advantage this species, especially where the habitat has not burnt for many years. Thinning of the shrub layer by fire or mechanical means could favour the species, as may soil disturbance associated with fire trail construction. More frequent, moderate intensity burning of bushland that represents known or likely habitat for this species, may, within limits, also advantage it compared to low frequency and/or very cool burning.

The positioning of the bushland/urban interface and associated infrastructure such as APZs should have regard to this species' habitat and ecology, and appropriate buffers and other strategies are required to prevent direct and indirect harm to this species as a result of the urbanisation of adjoining lands. For example, potential habitat should not be compromised by the placement of housing nearby as this might prevent that habitat being managed for conservation, especially in terms of bushfire risk management. DPE has informed me that APZs would be accommodated within the proposed urban footprint, not in the adjoining non-biocertified bushland.

The absence of records from areas of potential habitat does not mean it could not be present because:

- not all areas have been surveyed historically or recently;
- all surveys have a range of limitations, and recent efforts were particularly constrained by drought;
- not all discoveries of threatened species are disclosed;
- large areas of potential habitat are highly likely to have fire regimes that do not favour this species, meaning it may currently occur in very low numbers or as seedbank, yet could appear in substantial numbers after an appropriate fire or equivalent disturbance; and
- this species can persist in cryptic forms such that even thorough coverage of a site cannot rule out its presence if otherwise suitable habitat is present.

These factors have been considered in the preparation of the species habitat polygons that will inform DPE in relation to biodiversity offset obligations.

6. Information used in the assessment

6.1 DPE or OEH resources

- BioNet data (internal access provided under license for use in this Expert Report and associated dataset cleaning for the purposes of species habitat modelling to meet EPBC Act requirements)
- Atlas of Living Australia on-line (partial use to check for records not in BioNet)
- EMU data (NSW Herbarium specimen database, provided by OEH)
- OEH on-line threatened species profile
- OEH Threatened Species Data Collection on-line
- OEH BioNet Vegetation Classification Database (previously known as VIS)
- EPBC Act Listing/Conservation Advice
- OEH PCT (vegetation) maps for Sydney Metropolitan and Cumberland Plain
- Field data from Biosis and Ecoplanning consultancies engaged by DPE
- GIS layers and maps provided by DPE and its contractors

7. Acknowledgements

I acknowledge the contributions of DPE staff, particularly Dayle Green, Greg Steenbeeke and Christian Marando (GIS), and DPE contractor Darren James (GIS) in the preparation and refinement of this document and associated maps. My contractor, Rhys Grogan, also assisted with GIS output in the form of drafts of the 'species polygons'.

Consultant botanist, Robert Miller assisted with fieldwork at Kemps Creek, and provided information about field observations associated with searches for his target species and with opportunistic sitings of my target species.

OEH staff assisted with some aspects of data availability and with the processing of many amendments to BioNet records.

8. Statement of professional independence

Whilst I was engaged and funded by DPE to prepare this Expert Report, and draft reports and maps were reviewed by DPE staff, I was not coerced by DPE to amend my work in any manner that I did not otherwise agree with. I believe that I had appropriate professional independence in the preparation of this document and associated maps.

I also declare that I do not have any personal or commercial conflict of interest in the preparation of this Report. I do not own real estate or businesses with property in the Growth Areas, nor do I have other active clients with real estate or associated commercial interests in the Growth Areas.

9. Appendix 1. Author's *Curriculum Vitae*

Dr Steven Douglas (BSc., MEnv. Plan., PhD.)

I have over twenty years of experience as an ecologist and environmental planner, primarily in New South Wales, with some experience in the ACT, Victoria and South Australia. I have worked for all levels of government, for environmentalist non-government organisations (NGOs), and for a large number of private clients ranging from individuals to multinational firms, directly and as a subcontractor. I have often worked as a sole consultant but have also collaborated with other specialists and have sometimes been part of large teams involved in large-scale, even interstate projects.

I specialise in the detection, management and conservation of rare and threatened flora species and communities, and in associated ecological impact assessment and mitigation.

I have qualifications and experience in a range of general and specific ecological, social, organisational and 'sustainability' fields.

I have served on environment-related ministerial committees and have held other ministerial appointments in NSW, including those dealing with bushfire management.

I have published in journals dealing with plant conservation, environmental law and policy, social science, and ecological ethics. Aspects of my work have been published by government, prominent NGOs, and in the popular press and other media.

This CV only contains content directly related to my botanical expertise.

Employment summary

1996 to present:

Self-employed, trading as *Ecological Surveys & Planning* (www.ecologicalsurveys.net)

Through this enterprise, I have undertaken a large number of consultancies for public and private sector clients including environmental impact assessment and mitigation; threatened biota research, profiling and management; vegetation mapping; preparing management plans for conservation estate; providing environmental planning and catchment management advice; advising on bushfire risk management; acting as an expert witness in Land & Environment Court proceedings; and developing organisational sustainability policies and practices.

July 2017 to July 2018:

Senior Ecologist, NSW Office of Environment & Heritage (NVIS, Science Division)

My work on the project below led to OEH retaining my services to research and document problems with the description, interpretation and mapping of Threatened Ecological Communities (TECs) statewide. This project provides advice to OEH, the NSW Threatened Species Scientific Committee, and through those agencies, to the Commonwealth Threatened Species Scientific Committee. It identifies technical issues with the description of TECs and their mapping, as well as wider problems of how TECs are defined. It draws on a major project undertaken by OEH for the NSW EPA and Forestry Corporation, in which TECs of the east coast and ranges were assessed and mapped for regulatory purposes on forestry estate. However, my work includes many more TECs and recent information emerging from Save Our Species project panels.

November 2015 to July 2017:

Team Leader, NSW Office of Environment & Heritage (NVIS, Science Division)

This project in Wingecarribee Shire is the first in which OEH's vegetation mapping team has worked at a very fine scale for a single local government area. The project entails auto-segmentation of digital aerial photography; supervising contract vegetation sampling; conducting strategic sampling; modelling of most vegetation communities; describing new communities; and extensive remote and on-ground map validation. I was hired partly because of my extensive familiarity with much of the vegetation of this geodiverse and biodiverse region. The role included supervision of two staff; liaison with consultants; and substantial networking with OEH and Wingecarribee Council staff. An update of vegetation classification will occur from mid 2019 onwards, and I have drafted a peer-reviewed journal article about the project that will be submitted for publication.

1995/6:

Project consultant, then Project Manager, Urban Bushland Biodiversity Survey (NPWS)

The Urban Bushland Biodiversity Survey was undertaken by the NPWS to compile comprehensive data on indigenous flora and fauna in twelve local government areas in Western Sydney. Contracted initially as a consultant to design and scope the project, I was later employed as Project Manager. Responsibilities involved an extensive literature review, preparation of a project plan and a background paper for the Survey and the overall management of the project including up to twelve staff and several consultants. The major focus was on coordinating research work, fauna and flora field surveys, and a community liaison and media campaign. Extensive flora survey work and scientific data analysis was undertaken. I provided a tour of important vegetation sites for the South Creek Catchment Management Committee. I also wrote media releases and conducted various media events including a live-to-air interview on ABC Radio National, and filming of a story in the field for the Totally Wild program.

1994:

Catchment Environment Officer (*Hawkesbury City Council*).

The project was funded by a grant from the former Hawkesbury-Nepean Catchment Management Trust and had the objective of identifying land uses on riverside properties to assess their potential to generate water pollution. The information on land use and riparian vegetation was primarily gained from aerial photo interpretation, limited land-based inspections and several water-based inspections, and was recorded in a GIS. Work site inspections, pollution control on agricultural lands, community meetings, site visits with landowners, and facilitating the formation of a Landcare group in the Sackville area.

1993/4:

Technical Officer (*Hawkesbury-Nepean Catchment Management Trust*).

Work included assisting with the preparation of a vegetation management strategy for the Trust and the outline of a revegetation strategy for South Creek. Other responsibilities involved providing scientific advice for development assessments, the preparation of hard copy and computer-based catchment maps, and advising on the implementation of revegetation projects in the catchment.

Ministerial appointments

- Appointed a member of the **National Parks & Wildlife Service Regional Advisory Committee** (South Coast) (2010-mid 2018). I opted not to reapply for this role after serving two terms. The restructure of the NPWS meant that the Committee would operate from Wollongong to the Victoria border and inland to the Tablelands. This was logistically fraught, and the role of RACs was evidently being diminished, with larger areas to manage but less meetings held.
- Appointed a member of the **NSW Sustainability Network** (2001), part of the Sustainability Advisory Council reporting to the Minister for Planning. I did not take up this position due to my relocating to Victoria.
- Nature Conservation Council representative on the former NSW **Native Vegetation Advisory Council** (1999-2001) reporting to the Minister for Land & Water Conservation under the Native Vegetation Conservation Act. I served as a member of the Regional Vegetation Planning Subcommittee, which amongst other matters, reviewed draft Regional Vegetation Management Plans and Codes of Practice for activities such as native forestry and timber plantations. I was particularly involved in reviewing and recommending amendments to the Code of Practice for plantation forestry. I resigned due to my relocating to Victoria.
- Nature Conservation Council representative on the former **Southern Catchment Management Board** (June 2000 - March 2001). I resigned due to relocating to Victoria. I expressed my dissatisfaction with the design of the catchment boards and recommended to the Minister that they be replaced with the Catchment Management Authority model used in Victoria. The Boards were later replaced with such Authorities.
- Nature Conservation Council representative on Baulkham Hills and Hornsby-Ku-ring-gai **District Bushfire Management Committees** (1995-2001).
- Australian Conservation Foundation representative on the former **Environmental Works Community Audit Committee** reporting to the Minister for Environment in relation to the Special Environment Levy imposed by the then Water Board (1993-5). I completed my term when the Committee concluded its business and dissolved upon acceptance of its final report by the Minister.

Tertiary qualifications & titles

Adjunct Research Fellow

School of Philosophical, Historical & International Studies, Monash University, 2014-16

Doctor of Philosophy

Fenner School of Environment & Society, The Australian National University, 2004-7

The research was undertaken in the transdisciplinary Human Ecology Program and covered fields such as ecological philosophy, ecotheology, environmental policy-making, policy evaluation, organisational change, and critical systemic analysis. My thesis was passed unanimously and unamended by one Australian and two USA-based professors. I was awarded a $10,000 Publication Fellowship by the Fenner School and have since published aspects of my research.

Master of Environmental Planning

Macquarie University Grad. Sch. Env., 1994-96

This course included environmental law and politics, community involvement in planning, environmental education, development approval processes, urban planning, EIA, environmental science/fieldwork and heritage management. The dissertation component involved a pioneering report on the significant flora of the Greater Cattai Region (Cattai subcatchment) in north-western Sydney and led to my being offered employment with the NSW NPWS to design and manage a biodiversity survey of western Sydney.

Bachelor of Science

Macquarie University, 1990-93

My degree majors are Resource and Environmental Management, Land Management, and Plant Biology/Ecology.

Graduate Certificate of Research Information Literacy

The Australian National University, 2004-7

This course included advanced word processing, citation management, literature gathering (including on-line literary databases and other Internet sources), on-line publishing, presentation software, and thesis production.

Professional memberships

- Founding member of the Ecological Consultants Association of New South Wales (did not renew due to my relocating to Victoria and later to the ACT).
- Member of the NSW Environmental Defenders Office (EDO) Scientific Advisory Service (continuing).

Threatened biota experience

The following threatened plant species and populations and threatened ecological communities (TECs) have been engaged with in the various forms and processes listed below. The list is not complete, and some processes are on-going. I also successfully nominated three Key Threatening Processes under the TSC Act: Bushrock Removal; Clearing of Native Vegetation; Competition from European Honey Bee.

Species / population	Work conducted
Acacia bynoeana	Fieldwork, research, successful nomination, monitoring, advice to authorities, expert witness, rediscovered lost population, documented new population near range limit, PAS2 review, SOS review panel, review and amendment of BioNet dataset. Recognised by OEH as a species expert (Nov 2018).
A. gordonii	Fieldwork, successful nomination, advice to NPWS, PAS2 review, SOS research and monitoring program (fire ecology, BMtns NP), review and amendment of BioNet dataset.
A. prominens	Successful nomination of Endangered Population
A. pubescens	Fieldwork, contribution to Recovery Plan, confirmed disjunct southern populations, nominated population, PAS2 review, review and amendment of BioNet dataset. Recognised by OEH as a species expert (Nov 2018).
Ancistrachne maidenii	Fieldwork, research, successful nomination, advice to NPWS, CAM review
Asterolasia elegans	Fieldwork, species profile, advice to Council and NPWS
Baloskion longipes	Research linked to *Carex klaphakei*, review of BioNet records, advice to OEH
Boronia deanei	Research, SOS review, CAM review, advice to OEH
Bossiaea oligosperma	SOS fieldwork, review of records (NW population), report to OEH, establishment of monitoring plots in Yerranderie SCA
Callistemon linearifolius	Fieldwork, research, successful nomination, advice to RMS and NPWS, PAS2 review
Callistemon megalongensis	Co-described new species, successful nominations (listing then upgrade), fieldwork, advice to Council and OEH, PAS2 review, SOS monitoring program (OEH, BMCC, on-going)
Callistemon purpurascens	Described new species, fieldwork, successful nominations, advice to Council and OEH, SOS monitoring project (2018 on-going)
Calotis glandulosa	Fieldwork (new and extended populations, Kosci NP), CAM review
Calotis pubescens	Fieldwork (new population, Kosci NP), CAM review
Carex klaphakei	SOS research project and recommendation for monitoring; resolved errors in BioNet records

Species / population	Work conducted
Commersonia prostrata	PAS2 / PKF research, fieldwork, advice to NPWS and OEH, documentation and monitoring of new and known populations for Forestry Corp, designed recovery actions for populations in Wingello and Penrose SFs
Cullen parvum	Fieldwork, located new NE population, report to NPWS
Dampiera fusca	Research, fieldwork, successful nominations, monitoring program for ACT Parks & Conservation, advice to NPWS and OEH, CAM review
Darwinia biflora	Fieldwork, research, contributor to Recovery Plan, PAS2 review, review and amendment of BioNet dataset.
Darwinia glaucophylla	Fieldwork, research, successful nomination, advice to NPWS, PAS2 review
Darwinia fascicularis ssp. *oligantha*	Fieldwork, research, successful nomination of population
Darwinia peduncularis	Research, successful nomination, CAM review
Dillwynia tenuifolia	Fieldwork, research, successful population nominations, advice to OEH
Epacris purpurascens var. *purpurascens*	Fieldwork, research, nomination, new SW range limit (Nattai NP), advice to NPWS/OEH
Eucalyptus aggregata	Research, successful nomination of species and population, fieldwork (Wingecarribee Shire) and advice to Council and OEH, CAM reviews
E. aquatica	Fieldwork, advice to Council and Forestry Corporation
E. sp. *Cattai*	Successfully argued for recognition of this entity as a new species, successful nomination, fieldwork, PAS2 review, advice to OEH, SOS project panel
E. kartzoffiana	Fieldwork, research, expert witness
E. macarthurii	Fieldwork, research, successful nominations, advice to Council and OEH
E. parvula	Fieldwork (Wadbilliga NP), CAM review
E. pulverulenta	Fieldwork (Bredbo Hills), CAM review
Galium australe	PAS2 research, recommended taxonomic review of most records in NSW based on Herbarium assessment, advice to OEH, CAM review
Grevillea juniperina ssp. *juniperina*	Fieldwork, research, advice to OEH (Colebee NR offset site)
Grevillea molyneuxii	Fieldwork, advice to OEH for CAM review
Grevillea parviflora ssp. *parviflora*	Fieldwork, research, expert witness, review and amendment of BioNet dataset.
Grevillea parviflora ssp. *supplicans*	Fieldwork, research, nomination, advice to NPWS
Grevillea raybrownii	Fieldwork, research, nomination and advice to NSWSC – listing pending
Gyrostemon thesioides	Successful nomination
Helichrysum calvertianum	Fieldwork, research, nomination, advice to NSWSC – listing pending
Hibbertia fumana	Research, minor fieldwork, expert witness
*H. incana (*syn. *superans)*	Successful nomination of population then species
H. praemorsa	ROTAP, researched, fieldwork (informal)
H. puberula ssp. *furcatula*	Fieldwork (incidental) documenting new occurrence, advice to OEH/NPWS
H. puberula ssp. *puberula*	Research, minor fieldwork with R. Miller, expert witness
Homoranthus binghiensis	CAM review (recommended changing to CE)
Keraudrenia corrolata var. *denticulata*	Successful nomination of population
Lasiopetalum joyceae	Fieldwork, research, successful nomination, species profiling for Council and NPWS, PAS2 review

Species / population	Work conducted
Leptospermum deanei	Fieldwork, research into hybridization with *L. trinervium*, advice to RBG, Council, OEH
Leucopogon fletcheri ssp. *fletcheri*	Fieldwork, research, successful nomination, advice to OEH and NPWS
Melaleuca deanei	Research, fieldwork, successful nominations, advice to NPWS/OEH and species profile for Council, review and amendment of BioNet dataset. Recognised by OEH as a species expert under BC Act (Nov 2018).
Olearia cordata	Fieldwork and report to NPWS, PAS2 review
Persoonia acerosa	Fieldwork, PAS2 review, SOS monitoring plots, advice to Council and OEH
Persoonia bargoensis	Fieldwork, research, successful nomination, PAS2 review, CAM review, review and amendment of BioNet dataset.
Persoonia hirsuta	Fieldwork, research, nominations of species and population, PAS2 review, review and amendment of BioNet dataset.
Persoonia glaucescens	Fieldwork, nomination, report to NPWS, PAS 2 review, CAM review, review and amendment of BioNet dataset.
Persoonia marginata	Fieldwork and report to OEH, CAM review
Persoonia mollis ssp. *revoluta*	Fieldwork, research, advice to OEH and Forestry Corp., nomination as Vulnerable - listing pending
Persoonia nutans	Fieldwork, nomination, advice to OEH, review and amendment of BioNet dataset. Recognised by OEH as a species expert under BC Act (Nov 2018).
Phyllota humifusa	PAS2 fieldwork and research; advice to NPWS, OEH, Council, Forestry Corp (monitoring plots, reduced APZ width), review of BioNet dataset.
Pimelea curviflora var. *curviflora*	Fieldwork, research, successful nomination, advice to OEH
Pomaderris brunnea	Incidental fieldwork and documentation of new populations and range extension; review and amendment of BioNet dataset.
P. cotoneaster	Fieldwork, research, advice to Council, NPWS, OEH, liaise with ANBG seed collectors, CAM review
P. sericea	PAS2 research (review of records and habitat), recommended consideration of Presumed Extinct or at least CE
Pultenaea elusa	PAS2 research (review of records and habitat), recommended Presumed Extinct
P. glabra	SOS fieldwork and monitoring plots. Review of Mts Wilson/Irvine records resulted in these being reallocated to an undescribed species given the interim name, *P. monticola*.
P. parviflora	SOS fieldwork and report to OEH (Colebee NR offset site); review and amendment of BioNet dataset.
P. pedunculata	Fieldwork, research, expert witness, CAM review
Solanum armourense	PAS2 fieldwork, research, report, advice to OEH, CAM review
S. celatum	Fieldwork, research, new populations (new range limit and habitat), advice to OEH, CAM review
Tetratheca glandulosa	Fieldwork, PAS2 review, advice to OEH and Cwlth DEE re conservation status
Triplarina nowraensis	SOS fieldwork, review of BioNet records, advice to OEH/NPWS, establishment of monitoring plots
Zieria involucrata	Fieldwork, input to Recovery Plan, CAM review
Zieria murphyi	Liaise with ANBG, fieldwork, advice to OEH

Threatened Ecological Communities (TECs)

My work for OEH in reviewing all NSW and EPBC Act TECs in the State has given me at least some familiarity with most of these entities and builds on already-strong knowledge of some. I have also been an expert witness in cases involving some of these communities – some entailing basic reviews and advice, and others involving in-depth considerations. All of the EPBC Act parallel listings are not included here unless I was involved in a particular nomination:

Ecological community	Nature of engagement
Blue Gum High Forest	Successful nomination, expert witness
Blue Mountains Basalt Cap Forest	SOS panel
Blue Mountains Shale Cap Forest	Successful nomination, SOS panel
Blue Mountains Swamps	Fieldwork, mapping, advice to BMtns Council, modelling
Castlereagh Scribbly Gum Woodland	Successful nomination, advice to DEE re Cwlth listing, expert witness
Cooks River / Castlereagh Ironbark Forest	Advice to DEE for EPBC Act listing
Cumberland Plain Woodland	Correction of OEH mapping, fieldwork, assessments, advice to Councils and NPWS
Eastern Suburbs Banksia Scrub	Major review for DEE Recovery Plan update, advice to OEH
Elderslie Banksia Scrub Forest	Major review for DEE Recovery Plan, SOS panel
Illawarra Lowlands Grassy Woodland	DEE review panel for EPBC Act listing
Lowland Grassy Woodland & Forest of SE Corner Bioregion	Successful nomination
Maroota Sands Swamp Forest	Successful nomination, SOS panel
Melaleuca armillaris Tall Shrubland	fieldwork, mapping, advice to OEH
Montane Peatlands & Swamps	Fieldwork, modelling and mapping, advice to OEH
Mount Gibraltar Forest	Detailed review for modelling and mapping, and advice about revised listing, advice to DEE re Upland Basalt Eucalypt Forest inclusion of NSW TECs
O'Hares Creek Shale Forest	Research and review for modelling and mapping
Pittwater & Wagstaffe Spotted Gum Forest	Successful nomination
Riverflat Eucalypts Forest on Coastal Floodplains	Successful nomination (component), research, modelling and mapping (limited extent)
Robertson Basalt Tall Open-forest	Modelling and mapping, advice to NSW SC
Robertson Rainforest	Modelling and mapping
Shale/Gravel Transition Forest	Mapping, TEC review
Shale/Sandstone Transition Forest	First to describe this concept c. 1996 based on Masters research. Formally published as a concept in NPWS (1997, UBBS). Successful nomination, research, major review and advice to DEE for EPBC Act listing, modelling and mapping
Southern Highlands Shale (Forest &) Woodland	Major contributor to DEE listing, drafting of Listing and Conservation Advices, advice to OEH about revision of NSW listing, modelling and mapping. Contracted to prepare listing for upgrade to CE.
Subtropical & Temperate Coastal Saltmarsh (EPBC Act)	Funded to prepare successful nomination
Sun Valley Cabbage Gum Forest	Successful nomination, mapping, advice to Council, SOS project panel

Ecological community	Nature of engagement
Swamp Sclerophyll Forest on Coastal Floodplains	Allied major research project cited in the Final Determination, TEC review (gap analysis)
Sydney Turpentine Ironbark Forest	Successful nomination, mapping, advice to Councils and to OEH/SC about revision
Tablelands Basalt Forest	Research, expert witness, advice to OEH about revision, modelling and mapping
Tablelands Snow Gum…Grassy Woodland	Fieldwork documenting new occurrences, modelling and mapping, advice to OEH
Upland Basalt Eucalypt Forest (EPBC Act)	Major contributor to DEE listing of this composite community that includes several NSW TECs. Draft Listing and Conservation Advices
Western Sydney Dry Rainforest and Moist Shale Woodland	SOS panel, TEC review

Consultancy projects

Short descriptions of the many larger projects that I have been involved in are available at http://ecologicalsurveys.net/?page_id=10, and a list of smaller projects is at http://ecologicalsurveys.net/?page_id=14

Voluntary and other works

- Assist **International Union for the Conservation of Nature (IUCN)** with a review of the conservation status of *Proteaceae* in eastern Australia (Melbourne, 2019).
- Assist **NSW Environmental Defenders Office** with a review of NPWS monitoring proposals to assess the effects of permitting horse riding in declared Wilderness areas (Kosciusko National Park) (2014).
- Assist **NSW Environmental Defenders Office** in the preparation of its submission to the NSW Government's review of the Noxious Weeds Act 1993 (in 2011)
- Assist **NSW Environmental Defenders Office** in the preparation of its submission to the NSW Government's review of the Threatened Species Conservation Act 1995 (in 2010)
- Assist discoverers (**Blue Mountains Bushcare**) of a previously undescribed *Epacris* species (*E. apungens* Coleby & Brown) in south Leura to prepare an article for the journal, *Telopea*, describing this species and its ecology
- Assist **NPWS** with a search for the ultra-endemic and rare rainforest plant, *Thismia clavarioides*, in Morton National Park (2010)
- Expert panel member assisting **Hawkesbury-Nepean CMA** with its Draft Climate Change Vulnerability Assessment for selected threatened ecological communities of the NSW Southern Highlands (2010)
- Assist PhD student, David Field (**University of Wollongong and CSIRO**) with information about the ecology, distribution, and conservation status of *Eucalyptus aggregata* (Black Gum) (2007)
- Fieldwork assisting with group preparation of vascular plant species lists in numerous NPWS and ACT Parks reserves in the Southern Tablelands area. **Australian Native Plants Society** (2003-2007)
- Searches for *Euphrasia scabra* (critically endangered) in Packers Swamp and Nunnock Swamp. Discovered new population (3rd in NSW) in unnamed swamp, SE Forests National Park. **Friends of Grasslands** (2004)
- Assistant part-time editor of "*Danthonia*" (now *Australasian Plant Conservation*), the journal of the **Australian Network for Plant Conservation** Inc., Canberra (2002-2003)
- Assist PhD student, David Clunas (**University of Wollongong**) with review of his research in the ecology of the nationally Rare, *Pultenaea villifera* var. *villifera* (2002)
- Provide technical assistance to four final year undergraduate Environmental Science students (**Australian Catholic University**) working in Marramarra National Park, (c. 2000)
- Discovery of and subsequent surveys for *Persoonia hirsuta* ssp. nov. 'Yengo NP'. **NPWS/RBG**
- Vascular flora and fauna (microchiropteran bats) surveys within Pilliga Nature Reserve. **NPWS** Coonabarabran
- Supervisor for undergraduate dissertation, "Environmental rehabilitation of Peats Crater and Peats Bight in Muogamarra Nature Reserve" (D. Maestri), **Southern Cross University** (1997)
- Co-supervisor for undergraduate dissertation "Riparian Vegetation of upper Cattai Creek" (D. Buckle). **Southern Cross University** (1997)
- Preliminary flora assessment for proposed subdivision and development; Red Gum Avenue, Pennant Hills. The bushland area was subsequently added to Berowra Valley Regional Park. **Friends of Berowra Valley Bushland**

- **NSW National Parks Association** (NPA) Biodiversity Audit, proposed Bargo River National Park. Team Leader, Vegetation - threatened flora
- Guided interpretive walk of Fred Caterson Reserve. **Cattai Catchment Management Committee**
- **NSW NPA** audit of Greater Sydney proposed conservation reserves and additions - assistant and author of NW Sydney reserve proposals
- **NSW NPA** Biodiversity Audit of the proposed Dyarrabin Nature Reserve (~2000 ha) - Project Co-ordinator
- **NSW NPA** Proposal for the creation of Dyarrabin Nature Reserve; revised submission and report of the second NPA Biodiversity Audit
- Preliminary flora study of Crown lands (Functional Area 1), Cattai Ridge Road, Halcrows Road, Hillside/Glenorie; submission to Director NPWS and to Baulkham Hills Council. **NSW NPA**
- Flora survey of Morans Rock Crown lands for proposed addition to Wollemi National Park. **NSW NPA**
- Proposed Welcome Reef Dam (Shoalhaven River north of Braidwood) - assist with flora and fauna surveys. **NSW NPA**. Much of the area is now within Nadgigomar Nature Reserve
- Flora survey of surplus Department of Education lands at Ellerman Park, Round Corner. The local community proposed that the area become a reserve to protect a critically endangered plant community present on the site. **Friends of Ellerman Park**
- Flora survey of Crown lands at South Maroota for proposed Crescent Reach Nature Reserve (later declared as the Maroota Ridge State Conservation Area), **NSW NPA**
- Calangara Nature Reserve Proposal in Kenthurst. Survey and report to **NSW NPA**
- Preliminary Survey of bushland in Holland Reserve, Glenhaven
- Survey of Crown Reserve (now part Scheyville NP), Pitt Town; report to **NSW NPA**

Expert report – *Acacia pubescens*

Expert report for *Acacia pubescens* (Downy Wattle), Dr Steven Douglas, February 2019

ECOLOGICAL SURVEYS & PLANNING

Expert Report For

Acacia pubescens

(Downy Wattle)

Strategic Assessment for the Cumberland Plain Conservation Plan

Greater Macarthur, Greater Penrith to Eastern Creek,
Wilton, and Western Sydney Aerotropolis Growth Areas

Prepared for NSW Department of Planning & Environment, February 2019

Table of Contents

1. Introduction

1.1 Purpose of the Expert Report

An Expert Report may be prepared under s.6.5 of the Biodiversity Assessment Method (BAM) in place of undertaking a threatened species survey of sufficient extent, intensity and duration as would otherwise be necessary to comply with the BAM. Use of an Expert Report may be beneficial where it is highly unlikely that a species may occur within a study area; where survey cannot meet BAM specifications; and/or the reliability of detecting the species is low. In respect of *Acacia pubescens*, insufficient survey extent; constraints on the effectiveness of survey; and unreliability of detection due to aspects of the species' ecology are the primary reasons for preparing an Expert Report.

The purpose of this Report is to provide an assessment of the current status and conservation requirements of *Acacia pubescens* within the four priority growth areas of Greater Macarthur (GMGA); Wilton (WGA); Penrith to Eastern Creek (PECGA); and Western Sydney Aerotropolis (WSAGA)to determine whether:

a) The species is unlikely to be present and would thus require no further assessment; or
b) The species is known or likely to be present, and the Expert Report must provide estimates of potential habitat within growth areas and development footprints as part of the biocertification process.

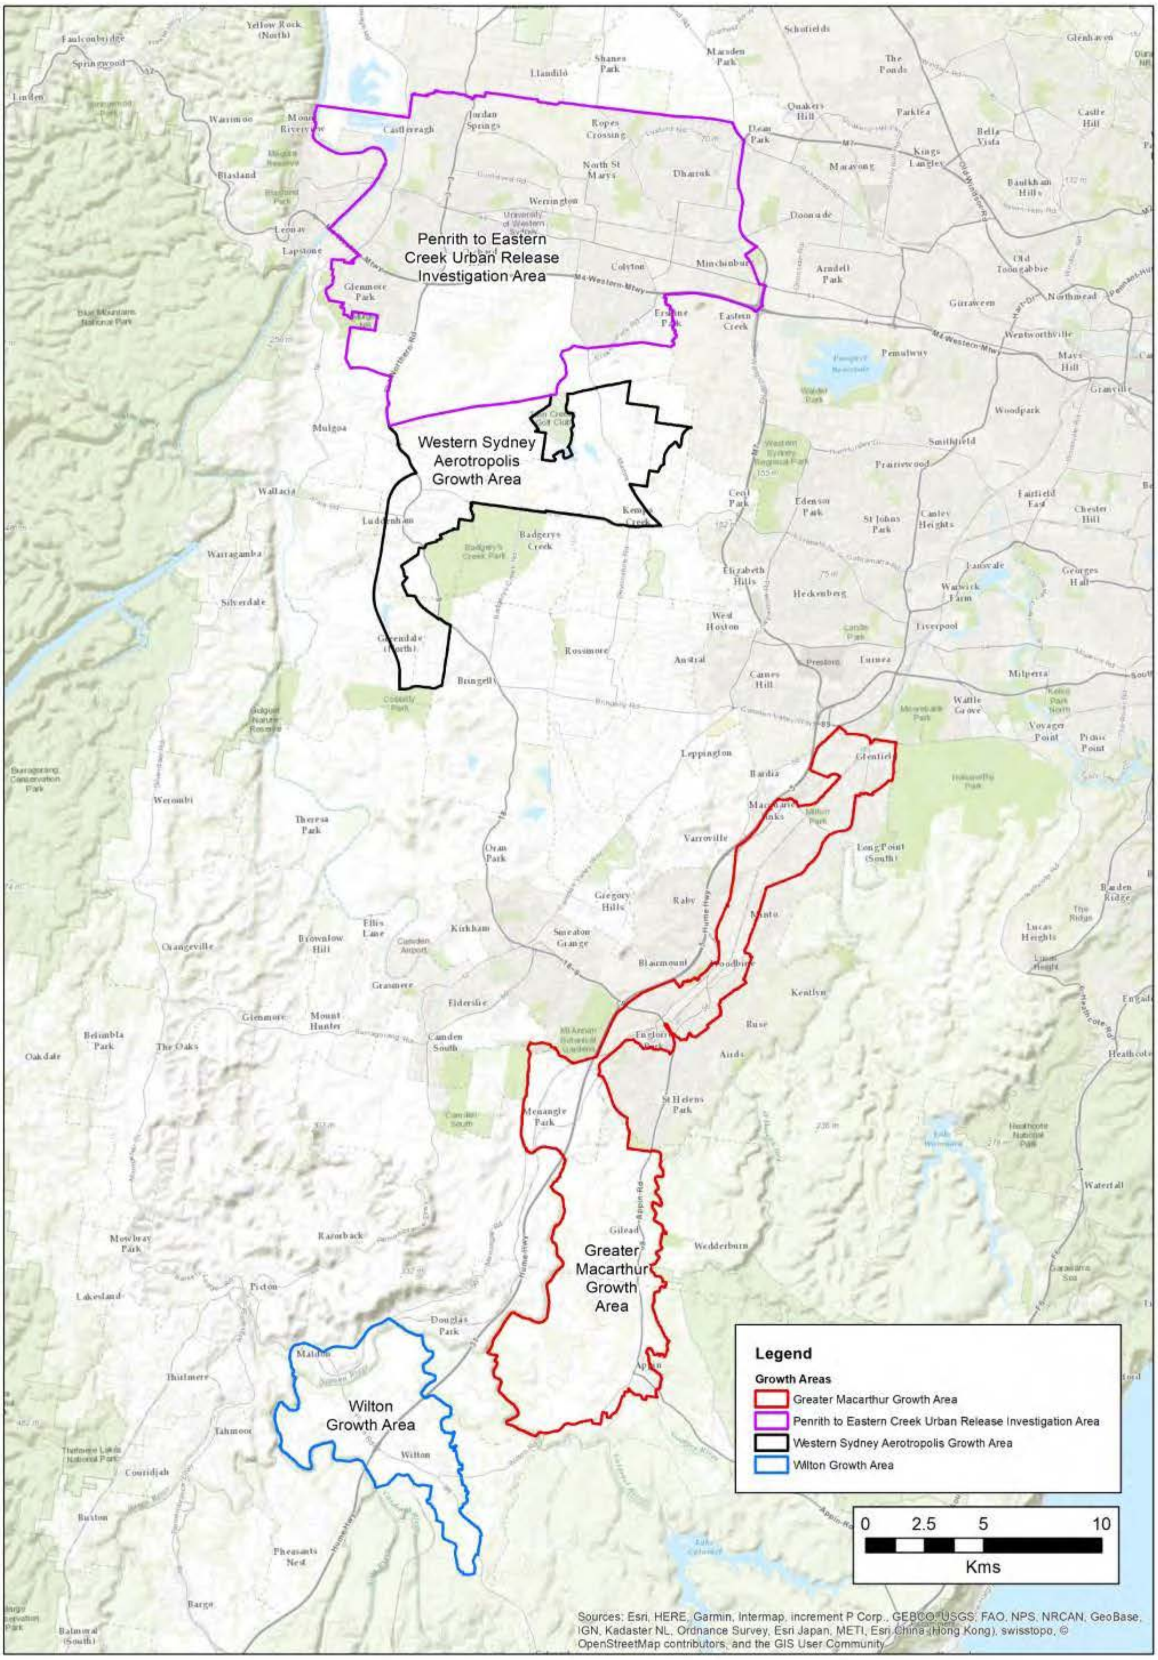
1.2 Project context

The NSW Government is identifying areas for future urban land use and associated infrastructure in western Sydney. The four priority growth areas are all located in the Cumberland Subregion under the Interim Biogeographic Regionalisation for Australia (IBRA) (SEWPaC, 2012).

As part of the planning for these areas, the Department of Planning and Environment (DPE) will prepare the Cumberland Plain Conservation Plan to identify land use outcomes. A strategic assessment of this Plan is underway, and this Expert Report will assist in determining the extent and quantum of impacts of the proposed urban growth on *Acacia pubescens*.

Acacia pubescens, Aylmerton © S. Douglas

1.3 Study area



Map 1. Growth Areas subject to this Expert Report

Greater Penrith & Eastern Creek Growth Area (GPECGA)

A large portion of this Growth Area is already urbanised, with several areas of industrial land use. Significant rural and peri-urban areas remain in the central north, the centre, and the southwest. Large areas of remnant vegetation are present in the far north (former Australian Defence Industries site, now in part Wianamatta Regional Park), and the Orchard Hills Defence facility. Mining of alluvium for sand and soil continues in the far northwest of the area in the Penrith Lakes locality.

The area has been extensively cleared because of its relatively arable terrain, based mainly on shale and alluvium. Some of the remaining vegetation is associated with the much less arable to infertile Castlereagh Woodlands and its older, leached and mineralised alluvium and shale-derived soils. Strips of remnant vegetation are present along some of the larger watercourses such as Eastern and South Creeks. Significant parts of the study area are or were flood-prone, and this has influenced the retention of vegetation in some affected areas.

Western Sydney Aerotropolis Growth Area (WSAGA)

This Growth Area adjoins the Greater Penrith to Eastern Creek area, extending south to the locality of Greendale, west of Bringelly. It is currently largely rural, with villages at Luddenham and Kemps Creek. Most rural areas are pastoral, but there are significant areas of more intensive rural use, including poultry and egg production, a large dairy and associated fodder cropping, and some market gardens and enclosed fruit and vegetable production. Quarrying occurs at the localities of Badgerys Creek and Kemps Creek.

This Growth Area is extensively cleared but retains native vegetation in areas where rural uses were constrained by steeper terrain, flooding along streams, or unsuitable soils.

Greater Macarthur Growth Area (GMGA)

The GMGA occurs in southwestern Sydney on predominantly shale soils that have been heavily cleared for agriculture and urban or industrial use. The northernmost section has long-established urban and commercial / industrial land use, while the southern section is largely rural (pastoral, minor cropping), with some villages and primarily subsurface mining (e.g. coal and coal seam gas). It extends from urban Glenfield in the north, to the rural village of Appin in the south.

In the southernmost section, geological uplift and erosion have exposed infertile sandstone terrain along gullies and valleys. Much of that terrain remains naturally vegetated because it is unsuited to agriculture, however it occupies only a small percentage of the total area of this heavily-cleared region. Between the infertile sandstone valleys and the relatively arable shale plateau and hills is a geological and ecological transition zone. Whilst much of the vegetation of the shale terrain has been cleared, a greater area of vegetation remains on the transition zone, primarily in the south. Both the shale and transition zones support Critically Endangered ecological communities that are potential habitat for some threatened plant and animal species.

Wilton Growth Area (WGA)

The Wilton Growth Area is the most southerly of the four Western Sydney Growth Areas dealt with in this Report. It extends from the village of Douglas Park in the north, to the village of Wilton in the south. It is primarily rural (pastoral) area with some more intensive agriculture, significant but mostly underground mining (primarily coal), and some long-established villages. The Hume Motorway dissects this Growth Area.

The pattern of clearing and vegetation retention is broadly similar to that of Greater Macarthur, with the majority of remnant vegetation associated with infertile but biodiverse sandstone gullies and the Nepean River gorge, and with associated transition into the heavily cleared shale landscapes.

1.4 Justification for the use of an Expert Report

An Expert Report for *Acacia pubescens* is required as part of the threatened biota assessment for the Cumberland Plain Conservation Plan because:

1) Survey effort for this species did not meet the recommendations in the OEH threatened species guidelines (OEH, 2016) for field traverses due to limitations on land access, particularly in the GMGA;
2) Survey quality was constrained by drought conditions. Whilst this species is perennial, under sufficiently severe drought and associated total grazing pressure (livestock, if relevant; native species; feral species), it can be suppressed such that it only remains apparent (but likely undetectable) as rootstock and as seed bank. Drought was a major limitation on survey effectiveness in this instance. A known location of the threatened species, *Acacia bynoeana* was visited by fellow botanist, Robert Miller, but could not be detected, even though the habitat was still in place. This is believed to be a result of drought;
3) Survey effectiveness was further constrained by parts of the study area having been long-unburnt. This can create an unnaturally dense shrub layer that limits access.

Surveys associated with biocertification of the study areas and earlier projects in those areas have been insufficient to reliably determine the presence and extent of the species. An Expert Report is required to provide an assessment of the likely presence, location, and significance of occurrences of the species in those areas.

1.5 Credentials of expert

I have worked as an ecologist since the mid-1990s, primarily in the Greater Sydney region, but also in the ACT, Central Coast, southern NSW (coast, tablelands and slopes), throughout Victoria and eastern South Australia. I have primarily been self-employed with a mix of government, private, and corporate clients, and have also worked as a subconsultant to larger firms, including two university-based consultancies. I have also worked directly for the NSW NPWS, and more recently for OEH (Native Vegetation Information Science). A summary of my credentials as required under the BAM is provided below as Table 1. I was approved by OEH as a species expert for *Acacia pubescens* under s.6.5 of the BAM in November 2018.

Table 1. Credentials of Dr Steven Douglas as Expert in relation to *Acacia pubescens*

BAM section	BAM requirement	Details
s.6.5.2.8 (g)	Name of expert	Dr Steven Douglas
s.6.5.2.3 (a)	Expert's qualifications	Bachelor of Science (Plant Ecology, Land Management, Resource & Environmental Management), Macquarie University, 1993. Master of Environmental Planning, Graduate School of Environment, Macquarie University, 1996. Doctor of Philosophy, Australian National University, 2008. Graduate Certificate of Information Literacy, ANU, 2006. BAM Accredited Ecologist, 2018.
s.6.5.2.3 (b)	History of experience in ecological research and survey method for the relevant entity	Review of BioNet and incorporated NSW Herbarium database records of *A. pubescens* (DPE, 2018). Included reclassification of suspect outlying records, known plantings, hybrids, and significant refinement of data about the outlying Mountain Lagoon population (a single collection site, not several). Provision of expert witness evidence in relation to *Acacia pubescens* (QUBE proposal, Moorebank; included assessment of adequacy of biobanking arrangements) L&EC 2017/81889 (2017-18). Rediscovery, documentation and validation of disjunct Southern Highlands record of *Acacia pubescens* (2016-17). Advice to OEH and Wingecarribee Shire Council. Successfully nominated Wingecarribee Shire population of *A. pubescens* as Endangered under *Threatened Species Conservation Act* – later omitted due to changes caused by Biodiversity Conservation Act. Rediscovery and validation of disjunct southernmost population (South Nowra) (2016-17). Acknowledged by NPWS for contributions to and review of the Recovery Plan for *A. pubescens* (2003). Consulted by OEH in relation to illegal clearing of a known population, and appropriate remedial actions (2017). Consulted by NPWS in relation to proposed horse riding in known and likely habitat for this species (2018). Numerous historic surveys in northwest and western Sydney including Hills Shire, Hawkesbury Shire, Fairfield City, and Penrith LGAs (1994-2000) as evidenced by BioNet and NSW Herbarium records.
s.6.5.2.3 (c)	Resumé detailing projects pertaining to the survey of the relevant entity	See Appendix 1. Relevant surveys and works listed above. Minor incidental survey of potential habitat at locality of Kemps Creek for DPE Expert Report. Meandering transect used.
s. 6.5.2.3 (d)	Employer's name and period of employment (if relevant)	Self-employed ecological consultant, 1996 to present (continuous other than for periods of study). Employed by OEH as contracted staff from November 2015 to July 2018 (Wingecarribee Shire vegetation map, South Coast Regional vegetation map, Review of mapping issues for TECs).

s.6.5.2.3 (f)	Evidence that the person is a well-known authority on the relevant entity	Consulted by OEH in PAS2 reviews of this species. Engaged by DPE to review and refine/correct BioNet data for this species. Consulted by DECCW on this and other threatened flora species of the region as part of a data review for the purposes of the BioBanking Tool (2006). Requested by OEH to nominate as a contributor to forthcoming CAM / BAM Calculator review of this (and numerous other threatened flora) (2018/19). Approved as a BAM species expert for *Acacia pubescens* by OEH in November 2018.

2. Species information

2.1 Description

Acacia pubescens is "A spreading (to slightly weeping) shrub, 1 - 5 m high with brilliant yellow flowers, bipinnate leaves (divided twice pinnately) and conspicuously hairy branchlets" (OEH, 2017; Kodela, 2016; NPWS, 2003a; Benson & McDougall, 1996).

It "May be confused with *A. cardiophylla*, which has cordate pinnules. Hybridises with *A. baileyana*, *A. cardiophylla* and other species" (Kodela, 2016) including the nationally rare *A. jonesii* (NPWS, 2003a). All such hybrids are unnatural occurrences as the other species have been introduced into *A. pubescens'* range. This is a threat to the species' genetic integrity (NPWS, 2003a, b), though the extent of such occurrences are unknown. Natural hybrids with *A. irrorata*, *A. mearnsii* and other local species are feasible where they co-occur.

2.2 Ecology

A. pubescens "Flowers from August to October. Pollination of *Acacia* flowers is usually by insects and birds. The pods mature in October to December." (OEH, 2017). *Acacia* species are generally self-incompatible, and the pollinators are likely to be small native bees and wasps (Bernhardt, 1987).

Seed dispersal is most likely by ants seeking to collect the aril. Seeds are taken into the ant nest, and later discarded in a wide area around the nest (Whitney, 2002). Seeds are likely to remain viable over many years in the absence of germination cues, with the species likely to develop a persistent, soil-stored seed bank, as is typical for most *Acacias* (NPWS, 2003a, b).

A. pubescens can occur as copses or thickets due to its suckering habit, especially in areas where there has been disturbance such as slashing, attempted / earlier clearing or 'underscrubbing', roadworks, excavations or fire. Many remnant occurrences are linear and restricted to roadsides and fence lines.

"Recruitment is more commonly from vegetative reproduction than from seedlings. The percentage of pod production and seed fall for this species appears to be low. *Acacia* species generally have high seed dormancy... It is thought that the species needs a minimum fire free period of 5 - 7 years to allow an adequate seedbank to develop. Longevity is unknown, but clonal species [such as *A. pubescens*] have been known to survive for many decades" (OEH, 2017). Preliminary generic work by Moore *et al*. (1999) has shown that in most cases, the often-dense patches in which the species can occur, often with hundreds of stems, are one individual (NPWS, 2003). One clonal individual was seen to cover 1.2 ha (Moore *et al*., 1999).

Experiments that involved providing *A. pubescens* seed to captive emus provided preliminary evidence that seeds that survived digestion germinated earlier than those not ingested, but the experiment was truncated and did not produce a result in relation to germination frequency differences (P. Ridgeway, pers. comm., 2018).

Acacia pubescens © S. Douglas

2.3 Distribution and abundance

NPWS (2003a) describes the species as being restricted to clayey soils in the Sydney region, with most occurrences on the Cumberland Plain. Kodela (2016) lists the species' distribution as "Bilpin to Georges River and in the Oakdale area (Central Coast botanical division); southern limit outlier populations at Aylmerton (Central Tablelands) and Nowra area (South Coast); dubiously recorded at Woodford where it is possibly cultivated." OEH (2017) states the species' distribution is "Concentrated around the Bankstown-Fairfield-Rookwood area and the Pitt Town area, with outliers occurring at Barden Ridge, Oakdale and Mountain Lagoon."

As the species has been in cultivation for some decades, care is required to ensure that database records are not plantings or associated naturalisations. Three records of the species (all are apparent replicates) at Woodford in the Blue Mountains are regarded by NPWS (2003a) as plantings. They occur in a former garden, not in bushland, and on geology not known to support the species. These were recoded as 'planted' during the BioNet data cleansing project that forms part of the DPE biocertification assessment.

A publicly available BioNet map of the species' distribution will generally be accurate at a coarse scale, but can include records that are unsound e.g. misidentified, data entry error, incorrectly located, and in this case, potentially planted. "Some organisations have planted *A. pubescens* on land under their control… Bankstown Council planted *A. pubescens* in at least five reserves (Mirambeena Reserve, Salt Pan Creek Reserve, Deepwater Park, Roberts Park and at The Crest of Bankstown). It is also believed that the RTA planted some plants along the M5 Motorway, which were taken from plants lost during its construction... There are also *ex situ* plantings of the species in Mount Annan Botanic Garden, the Australian National Botanic Gardens and the Burrendong Arboretum. The species is sold in some commercial and Council nurseries…" (NPWS, 2003a). Known plantings may be appear in general BioNet search results but should be clearly coded as such and will be shown with the annotation 'cv' (cultivated) in Herbarium records.

Two north-eastern outlying records of the species in the Central Coast region were also assessed. The northernmost has been corrected as it was apparently a data entry error. The other, east of Gosford is regarded as a planting or naturalisation from a planting (the identification is supported by a vouchered specimen, but the habitat is considered illegitimate – Narrabeen Sandstone in or at least near wet sclerophyll forest). NPWS (2003a) sensibly dismisses a reference to the species at the junction of Yalwal and Ettrema Creeks in Morton National Park as a likely misidentification of *A. irrorata*. That record no longer appears in BioNet.

The northern-western limit of the species at Mountain Lagoon (referred to by some as Bilpin) remains the same as described in NPWS (2003a, b). However, a review of BioNet data, particularly that from the Royal Botanic Gardens Sydney Database, revealed that there were numerous records spread across that area and beyond, yet there is only one actual location where the species occurs at that locality. Explanations for the spread of those records, most of them in unsuitable habitat for the species, include generalisation of records due to the use of coarse resolution co-ordinates, plus what appear to be data entry errors when co-ordinates were entered into one of the databases. A record from nearby 'Bilpin' is likely to also be from Mountain Lagoon, and a record from Scheyville that plotted incorrectly south of Bilpin has been corrected. The Mountain Lagoon population was confirmed by me in early December 2018.

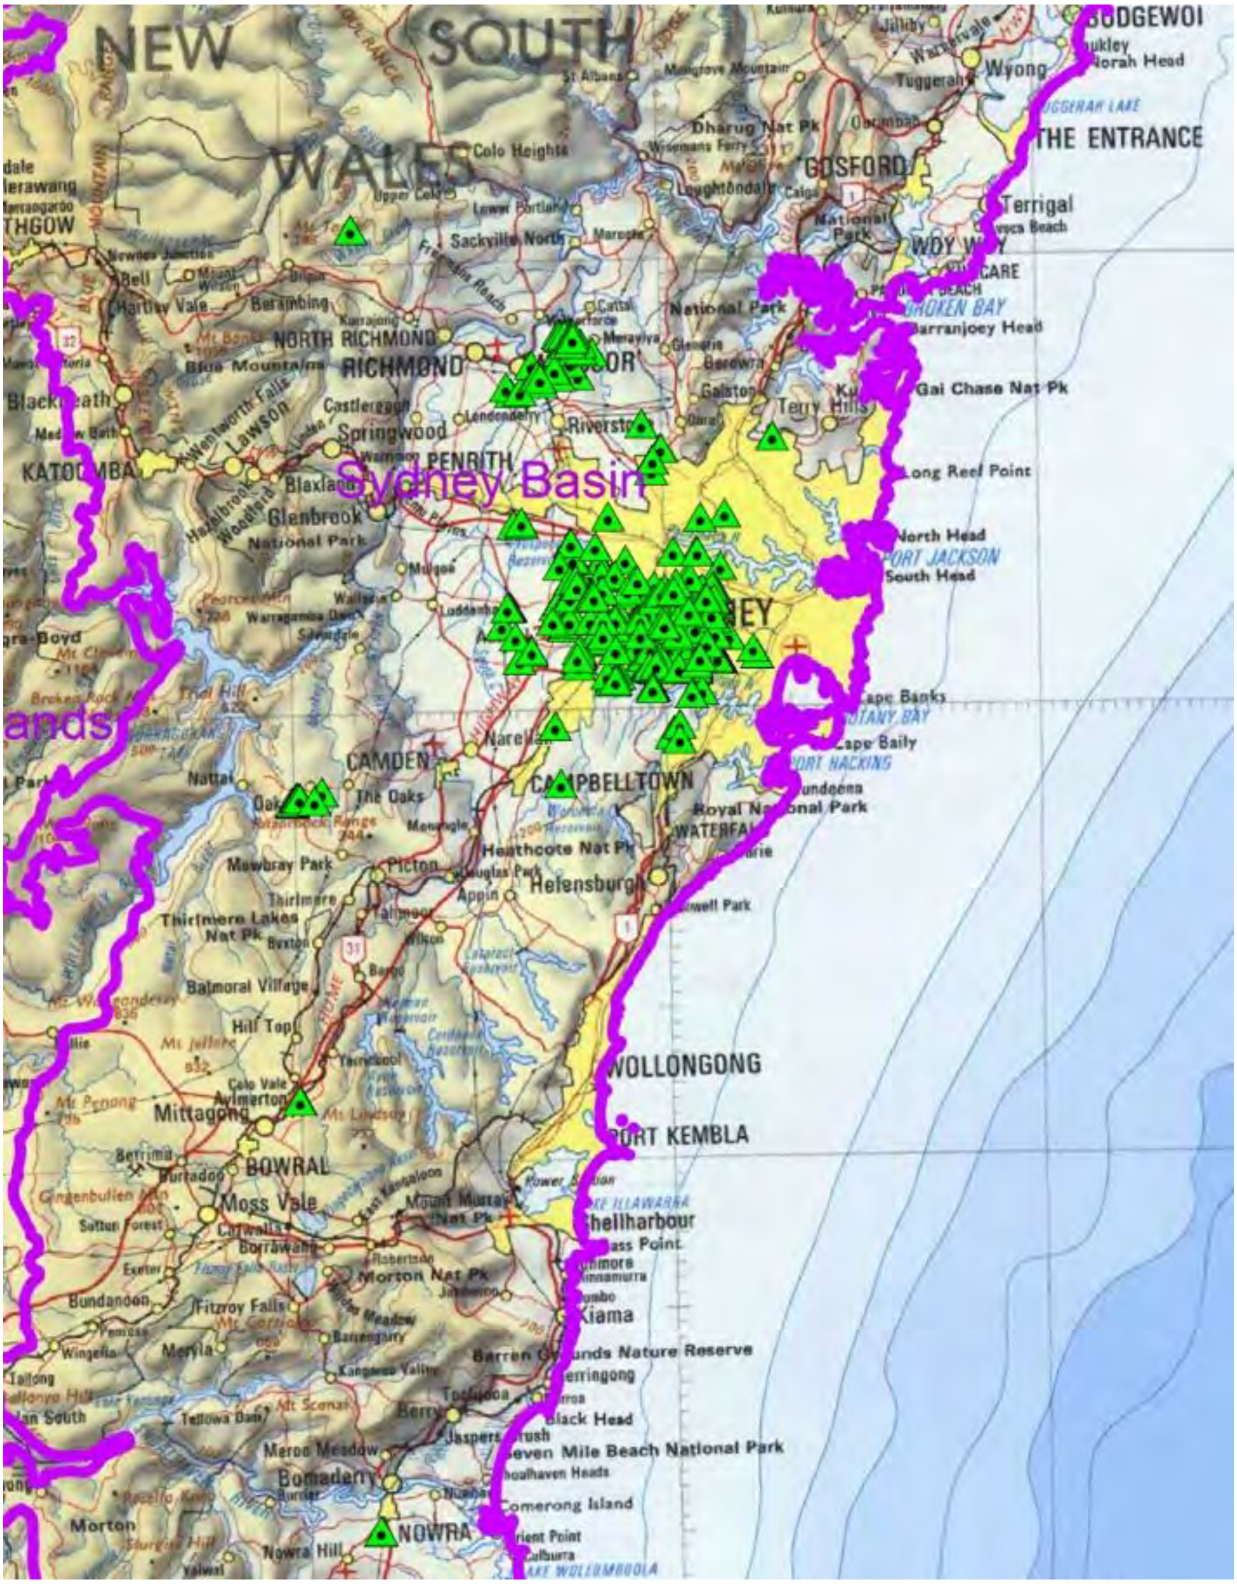
The south-western limit of the species is still the Macarthur district (The Oaks) in the form of several records within one scattered population. The easternmost record is at Bardwell Creek (1999). It was rediscovered, and its location was more accurately recorded in 2012. A '1770' collection from 'Port Jackson' plots on South Head but will likely be from much further inland, probably close to the Parramatta River where other collections have been made. South Head is not a legitimate eastern limit for the species and is inappropriate habitat. That record has since been moved to the nearest known population as part of the data cleansing process. A new north-eastern extant limit was documented in 2009 from North Turramurra and is accepted to be valid.

The now quite dated Recovery Plan for this species (NPWS, 2003a) reports, "*Acacia pubescens* has been recorded from 195 sites and is currently known from 151 of these. Although the species is known from a large number of sites, a high percentage of these (51%) consist of populations of fewer than 20 ramets (or 'clones'). Most of these populations are subject to numerous threats."

The range of Downy Wattle prior to European settlement is likely to have been similar to the current extent, however considerable losses from within this range have occurred. This is particularly evident within the Sydney region. It is likely that many more populations or subpopulations have been destroyed by the clearing of habitat, prior to their discovery. "Habitat loss is a major issue in Western Sydney. Over 90% of the original distribution of vegetation in the region has been cleared (NPWS, 1997). Eleven of the sites recorded on the Atlas for NSW Wildlife (as of 1998) no longer contain *A. pubescens*. Most of these sites have been lost to residential development. Many old records indicate that the species occurred in locations that have now been developed, such as Georges Hall, Belmore, Cabramatta, Chester Hill and Warwick Farm" (NPWS, 2003a). It is likely that approval has been granted by authorities to the destruction of some of the known populations since 2003, though previously undocumented populations are also likely to have been found, primarily towards the edges of its range where pressure for habitat removal and thus survey effort is likely to have been historically lesser.

Some translocation projects are known to have occurred. In the absence of an updated Recovery Plan or component information, it is not known how many populations are extant, and what the estimated total population size is. It is important to note that because the species is clonal, most population 'counts' are estimates because it is often very difficult to determine the number of individuals without genetic testing or potentially destructive sampling. NPWS (2003a) uses a separation distance of 300 m to arbitrarily define individuals.

Most of the Plant Community Types (PCTs) that are significantly associated with this species in the Growth Areas are Threatened Ecological Communities ranging from Critically Endangered to Vulnerable, with some having different status under NSW and Federal law. Some of the other PCTs that are known habitat for this species are also threatened by historic and on-going clearing and degradation, and by inadequate reservation.



Map 2. Cleaned BioNet data (extracted 26/11/18)

NB, each point may not designate a collection or observation at that location, as most very old records lacked any co-ordinates, or only supplied coarse co-ordinates, and may only have mentioned a town or locality. Such records will generally have a relatively poor Accuracy score (10-25 km) to indicate that the actual location of the species could be within a considerable distance of the designated point. Many such records are assigned the same indicative co-ordinates such that one point on a map may relate to several old records that were supplied with very little locational information.

2.3.1 Reservation status

NPWS (2003a, b) state that "Only five of the 151 known sites (of the species) occur within conservation reserves (Scheyville National Park and Windsor Downs Nature Reserve)." As of 2018, there are currently only two records of the species in Windsor Downs Nature Reserve, and both are on the northern edge of the reserve, adjoining an established urban area. There are many more records from Scheyville National Park and on an adjoining Crown road reserve. Since 2003, Prospect Nature Reserve has been declared and incorporates three records of the *A. pubescens*. The species is also now known from Western Sydney Regional Park (4 records in the reserve, several just outside).

NPWS (2003a) note that some NSW Herbarium specimen records of the outlying population at Mountain Lagoon say that they were obtained in Wollemi National Park, but NPWS could only locate the species at one site on land then owned by the Department of Land and Water Conservation (DLWC) i.e. not in the National Park. Part of the problem in this instance is that historically, there have been numerous records of the species incorrectly plotted around the Mountain Lagoon locality and beyond. When reviewed as part of the BioNet data cleansing project funded by DPE, the large number of records from this locality were interpreted to have all been collected at the one readily detected roadside site – the one verified by NPWS in 2003 as part of the Recovery Plan. All BioNet records of the species (and NSW Herbarium records) have since been moved to that location which was checked by me and confirmed to be in what is now NPWS estate. The former DLWC portion appears to have been added to the National Park since 2003. Searches for this species at the locality of Mountain Lagoon on and near trails in NPWS estate resulted in no new occurrences being detected (Goosen, N. and Monahan, D. [NPWS] pers. comm. 2018).

A. pubescens also occurs in numerous Council reserves, though some of these are known to entail outright plantings (NPWS, 2003a) or augmentation plantings. BioNet data suggests that the greatest number of apparent plants on public land occur within Council reserves, though this may be at least in part a result of increased survey effort in those areas. NPWS (2003) also notes that a population at Rookwood Cemetery and another at Liverpool Showground are subject to protective management.

The species is present in a Biobanking offset site on former Defence Department land at Moorebank, and may be present in other such areas, but this information was not provided by OEH. Information about other reserved populations in Biobanking offset / stewardship sites was requested from the Biodiversity Conservation Trust that now administers such areas. DPE has since advised that it has been provided with that information but is unable to provide it to me due to confidentiality constraints.

2.4 Habitat

2.4.1 Geology and soil

Acacia pubescens occurs on Paleogene-Neogene and Quaternary alluviums; on Wianamatta Shale; at the interface between it and Hawkesbury Sandstone (including the Mittagong Formation); and in one atypical instance, on a clayey variant of Permian Nowra Sandstone. Occurrences associated with the Wianamatta Shale / Hawkesbury Sandstone interface tend to represent the limits of the species' distribution where the once-more extensive shale soils are eroding. The majority of occurrences are associated with Paleogene-Neogene alluvium (including Londonderry Clay, Rickabys Creek Gravels) and its interface with Wianamatta Shale. Associated soils can be gravelly, often with ironstone i.e. laterite (*sensu* Martyn, 2018). Soil Landscapes include but are not limited to Berkshire Park; Blacktown, Luddenham, Glenorie; Faulconbridge; Lucas Heights; South Creek, Birrong, Richmond; and Nowra.

"The topography of the habitat of the species is flat to gently undulating: a characteristic of the Cumberland Plain region. The sites of *A. pubescens* range in altitude from 0 to 650 metres a.s.l." (NPWS, 1998 cited in NPWS, 2003a). This information remains broadly correct. It appears that in 1998, NPWS already regarded the Southern Highlands outlier as legitimate (the specimen was collected by a NPWS staff member), as it is the only population to occur anywhere near as high as 650 m elevation (the altitude is ~550 m).

2.4.2 Associated vegetation communities and NSW TECs

The species "occurs in open woodland and forest, in a variety of plant communities including Cooks River/Castlereagh Ironbark Forest, Shale/Gravel Transition Forest and Cumberland Plain Woodland" (OEH, 2017). All of these are Threatened Ecological Communities (TECs). According to the OEH Threatened Species Database, NPWS (2003a), and analysis undertaken for this Report, additional TECs that should be mentioned in the OEH profile include Shale/Sandstone Transition Forest, and Castlereagh Scribbly Gum Woodland. The strong correlation between this species and TECs is an indication of how threatened its habitat is. The species is also known from plant communities that are not currently TECs, but those associations are relatively weak. These are discussed later in this Report.

"Stands of *A. pubescens* have been recorded in open, disturbed areas, surrounded by exotic species. Although these areas are clearly not the natural habitat of *A. pubescens*, the species may survive in these situations for many years, due to its suckering nature and ability to tolerate some levels of disturbance. These areas are important as they provide information as to the original extent of the species and they may contain examples of genetic variability that have been lost elsewhere" (NPWS, 2003a). In a particularly acute example of the species' resilience, in 1999, the species was found surviving in tiny pockets of remnant habitat within a formal carpark at Fairfield Showground. Many such small and/or significantly modified habitats are not mapped as native vegetation.

The OEH Threatened Biodiversity Data Collection (July 2018) listed the following Keith vegetation classes as being associated with *A. pubescens*:

- Coastal Valley Grassy Woodlands;
- Cumberland Dry Sclerophyll Forests;
- Northern Hinterland Wet Sclerophyll Forests;
- Sydney Coastal Dry Sclerophyll Forests;
- Sydney Hinterland Dry Sclerophyll Forests;
- Sydney Sand Flats Dry Sclerophyll Forests; and
- 'Highly disturbed areas with no or limited native vegetation'.

Associations between a species and Vegetation Classes and Plant Community Types (PCTs) in the Threatened Species Data Collection were determined by the species' Accountable Officer within OEH some years ago, and staff were required to take a relatively inclusive approach in accordance with the precautionary principle (Steenbeeke, pers. comm.). This may mean that for some species, Vegetation Classes and PCTs have been associated with them even though there is little or no empirical evidence to support that, but where the officer believed that these attributes credibly represent *potential* habitat. Given the limitations of vegetation mapping and that in most cases, survey effort for threatened species is incomplete across their range, such an approach is understandable.

It appears that in some cases, the associations with Vegetation Class and PCTs in the Threatened Biodiversity Data Collection may have been amended after the assignments described above, and that some more recent associations may be influenced by spatial errors in species' records and/or errors in or limitations of vegetation maps. In this case, the link to Northern Hinterland WSF is unsound and most likely produced by an invalid northern outlying record of the species. OEH was advised of this and related issues in mid-July 2018. Some such errors have since been rectified through the BioNet data cleansing process undertaken as part of DPE's assessment of the effects of biocertification on threatened species.

An assessment of the association between *A. pubescens* and PCTs was undertaken to better understand the potential habitat for this species in terms of plant communities. The assessment is constrained by limitations of BioNet data and available vegetation maps. The assessment of the species' relationship with PCTs in and near the Cumberland Subregion used OEH vegetation maps that were publicly available at the time and did not use the updated vegetation maps produced within the Growth Areas by the biocertification process. The information is used to generate 'species polygons' (maps of potential habitat) as required under the BAM. Whilst DPE required habitat associations to be graded i.e. strong to weak association with particular PCTs, only ungraded PCT association data was used to generate the species polygons.

Some records of the species were seen to not be spatially associated with a PCT. This may be because:

- the record occurs in a site now cleared of native vegetation or too degraded to be captured by mapping;
- because the record is too spatially uncertain, so has been assigned generic co-ordinates, usually in a named town or suburb, and such settled areas often lack remnant native vegetation; and/or
- the record plots just outside an area of mapped vegetation because it is on a road verge, and even most GPS records are only accurate to 5m, meaning it could plot on the road, not on the vegetated verge.

To overcome this latter problem, those records were assigned a 10 m buffer so that they would associate with the nearest mapped vegetation polygon up to 10 m from the plotted location.

A further consideration is that survey effort for the species is not evenly distributed across the area subject to analysis. Some sites of potential habitat have had very little or no effort, often due to tenure constraints, yet others have had every apparent plant recorded (mostly in reserves or as part of ecological impact assessments). This creates very substantial biases in the data, which can create misleading weightings of association between the species and particular PCTs.

Most records do not include population data, meaning that a record might relate to one apparent plant or to many: a situation significantly compounded by the clonal nature of this species such that many apparent plants may be one individual. Furthermore, not all occurrences have been subject to intensive surveys that record all apparent individuals. This can cause a bias in the apparent strength of association between a PCT and the species. In short, this analysis is best used only for presence/absence i.e. whether the species has been recorded at a point that is mapped as a particular PCT, or not. Analysis beyond that is very constrained by deficiencies and biases in the datasets, especially in BioNet data.

The analysis of association with PCT in Table 2 deals only with records in the Cumberland Subregion plus a 10 km buffer. Records that associate with a PCT when a 10 m buffer is used are included in the counts of sightings below and are not shown separately. Two analyses were undertaken: All records in the target area without regard to spatial Accuracy score; and only records in that area with Accuracy score of 100 m or better. The latter analysis is considered more reliable, but both sets of figures are provided. Sightings with Accuracy <=100 m are shown in square brackets **[ ]** and in bold text. Where available, the combined count of individuals associated with the records is provided in parentheses { }. Those counts relate only to records with Accuracy <=100 m. Where a record doesn't contain population data, it is assumed to relate to a single plant.

Only PCTs mapped in the Growth Areas are dealt with in Table 2. This can mask associations between the species and PCTs that occur elsewhere. Because of the concentration of occurrences on the Cumberland Plain, this effect is largely limited to outlying and atypical populations beyond the Cumberland Subregion.

In the raw data, some PCTs can appear to have a greater or lesser association than is actually the case. PCTs 850 and 1181 have been excluded from Table 2 and are not regarded as potential habitat for the species on the basis of there being too few records mapped in those PCTs, and on known habitat parameters. The very few records that the raw data showed to be associated with those PCTs are likely a result of spatial errors in the records or spatial or other limitations of the vegetation maps. Additionally, there are 68 records of the species in Mangrove Forest, 4 in Coastal Lagoons, and 2 in Saltmarsh, yet the species does not occur in any of those communities. Consequently, all such occurrences are excluded from the analysis in Table 2, though some regard has been given to the PCTs in which those records most likely occur, and this has been used in the weightings afford to PCTs in the column 'Adjusted relative association'.

TABLE 2 – BioNet records of *A. pubescens* and counts of individuals relative to mapped PCTs

PCT	PCT Name	Associated TECs (NSW BC Act)	% Cleared (VIS)	Sightings & Population	Relative association	Adjusted relative association#
724	Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain	Shale Gravel Transition Forest (E)	75	1887 **[1780]** {10278}	Very High	Very High
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain	Cooks River/Castlereagh Ironbark Forest (E)	95	2240 **[2405]** {2930}	Very High	Very High
808	Derived shrubland on Tertiary Gravels of the Cumberland Plain	Shale Gravel Transition Forest (E) Cooks River/Castlereagh Ironbark Forest (E)	75-95 inferred from 724/725	Not mapped	Very High (inferred)	Very High (inferred)
835	Forest Red Gum – Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain	River-flat Eucalypt Forest of Coastal Floodplains (E)	93	93 **[78]** {77}	Low	Low
849	Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain	Cumberland Plain Woodland (CE)	93	579 **[521]** {10262}	High	Moderate
883	Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain	Castlereagh Scribbly Gum Woodland (V) Castlereagh Swamp Woodland (E)	50	33 **[33]** {2955}	Very Low	Very Low
1081	Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain	Not a TEC but some areas may be within Shale Sandstone Transition Forest (CE)	40	164 **[164]** {285}	Moderate	Low
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain	Shale Sandstone Transition Forest (CE)	80	5 **[3]** {155}	Very Low	Very Low

2.4.2 Associated Commonwealth TECs

The Commonwealth Department of Environment & Energy (DEE) Species Profile and Threats Database for *Acacia pubescens* (DEE, 2003) shows that an Approved Conservation Advice for this species was released in 2016 (TSSC, 2016). However, like the species' SPRAT webpage, this only reiterates content from the Recovery Plan and other NSW Government sources. The now quite dated (2003) Recovery Plan is relied upon to list the associated TECs, but only NSW-listed TECs are mentioned – not Commonwealth TECs. For this species, the NSW TECs with which the species is accepted to be associated are largely equivalent to or components of Commonwealth TECs. An exception is River-flat Eucalypt Forest of Coastal Floodplains, which does not have a Commonwealth equivalent.

2.4.3 Habitat condition

Degraded and significantly modified areas of the PCTs that are known or likely habitat for *A. pubescens* can still support it due to its ability to persist in the soil seed bank and as root suckers. Modified sites may have reduced or no canopy and/or midstorey, and/or reduced understorey and some weed invasion. Some may be dominated by shrubs in areas of regrowth after earlier clearing or 'under-scrubbing'.

This species is known to occur in highly modified sites such as slashed bushfire Asset Protection Zones, and road / trail and railway verges and corridors, and in former small-scale quarries or spoil dumps (NPWS, 2003a, 2003b; Kodela, 2016; Douglas, pers. obs.). Some forms of disturbance, even relatively severe forms that would be considered clearing of vegetation, appear to be beneficial to this species, within limits. This situation is recognised for numerous threatened plant species in and beyond the Sydney Basin Bioregion. It may be related to the fact that modern fire regimes are likely to be significantly different to those prior to 1788, and that some native animal species that had a role in seed dispersal and understorey modification are now extinct or regionally extinct.

The condition of potential habitat for this species is not a reliable indicator of the species' presence, and accordingly, **all vegetation condition states are considered in determining potential habitat,** i.e. intact, thinned, scattered, derived shrubland, and derived grassland. However, sites with long and intensive grazing history will be unlikely to retain the species.

3. Description of the study area

3.1 Landscape context and land use history

All of the Growth Areas have been significantly cleared for earlier activities, primarily timber production associated with opening areas for agriculture and pastoralism, minor areas of surface resource mining, and to varying degrees, for urban and commercial/industrial use. They are proposed to accommodate phased increases in urban land use, primarily within existing cleared or highly modified lands. Increased urban use is planned as a response to population growth.

3.1.1. Greater Macarthur Growth Area (GMGA)

The GMGA extends from Glenfield in the north to Appin in the south. It is largely within the Campbelltown LGA with the southernmost section within the Wollondilly LGA. The northern half comprises an urban renewal corridor centred on the Sydney to Southern Highlands railway line. It encompasses the existing industrial and residential suburbs of Glenfield, Macquarie Fields, Minto, Leumeah and Campbelltown. The GMGA is associated with extensively cleared, gently undulating shale terrain typical of the Cumberland Plain, and contrasts the sandstone gorges of the Woronora Plateau across the Georges River to the east. The northern portion of the GMGA is already substantially urbanised, with remnant vegetation largely restricted to creek-lines or small patches associated with designated open space. Vegetated creek-lines include Bunbury Curran Creek, Bow Bowing Creek, Leumeah Creek, Fishers Ghost Creek and Spring Creek.

The more extensive southern half of the GMGA, south of Rosemeadow, comprises proposed urban land releases at Menangle Park, Mount Gilead and Appin. Menangle Park and Mount Gilead are subject to separate planning processes, so are not within the scope of this biocertification. In the north-west, Mount Sugarloaf (213 m AHD) forms the southern end of a hilly ridge on the Luddenham Soil Landscape above the Menangle floodplain that extends north to Denham Court, then to Cecil Hills and Prospect Hill. Some native vegetation persists, although it is often invaded by African Olive. The floodplain is dissected by Menangle Creek and its tributaries, including Nepean Creek, Woodhouse Creek and Leafs Gully.

The southern GMGA is primarily semi-rural and agricultural land, with creek corridors and some larger patches of remnant vegetation located between the Nepean and Georges Rivers. Geologically, the area comprises gently undulating hills on Wianamatta Shale intergrading via a shale sandstone transitional zone (can include the Mittagong Formation) with steeper and infertile terrain on Hawkesbury Sandstone along the rivers. Transitional and sandstone geologies are sometimes exposed along the smaller creek lines.

3.1.2. Wilton Growth Area (WGA)

The WGA is a relatively smaller area that occurs to the south of the GMGA, extending from the vicinity of Douglas Park in the north, Maldon in the north-west, and beyond Wilton in the southeast. The boundaries closely follow the Nepean River in the north and west, a tributary Allens Creek in the east, and the Cordeaux River in the south. Away from the Nepean River and gullies, a higher, gently undulating zone has been largely cleared for agriculture. The Woronora Plateau forms the southern boundary and includes the northernmost section of the large Upper Nepean State Conservation Area, with unreserved but closed areas of the Water NSW Special Area (Sydney water supply catchment) extending to the east and southeast. The Hume Motorway dissects the WGA roughly north to south, and Picton Road traverses it roughly northwest to southeast.

The WGA includes both shale, shale sandstone transition and sandstone environments. Remnant vegetation occurs predominantly along the watercourses and on associated slopes. The flatter shale terrain has soils of the Blacktown Soil Landscape, which is derived from Ashfield Shale (a member of the Wianamatta Group), and typically supported the now Critically Endangered Cumberland Plain Woodlands. Much of this area is cleared or modified for agriculture and hobby farms. It comprises native/exotic grassland with smaller areas of Derived Native Grasslands in relatively better condition. Areas above the gullies feature soils of the Lucas Heights Soil Landscape derived from the Mittagong Formation (a transitional bed between the Wianamatta and Hawkesbury Groups). These support variable shale sandstone transition woodlands and forest, some of which are also Critically Endangered. In the steeper gullies, the Hawkesbury Soil Landscape dominates, and supports Hawkesbury Sandstone Gully Forest types with Ridgetop Woodlands on some of the upper slopes.

3.1.3. Greater Penrith to Eastern Creek Growth Area (GPECGA)

The GPECGA is a relatively large area that extends from Rooty Hill, Minchinbury and Hassell Grove in the east, across the Cumberland Plain to the Hawkesbury-Nepean River in the northwest, then south through Jamisontown, Glenmore Park, to the intersection between The Northern Road and the Warragamba Water Supply Pipelines in the far south-west.

The predominant geology is Wianamatta Shale on flat to gently undulating terrain that has been extensively cleared for agriculture, and later for housing and industrial use, with some remnant vegetation on current and former Defence holdings. The shale soils support(ed) Cumberland Plain Woodlands. Overlying the extensive shale deposits are small areas of weathered Paleogene-Neogene alluvium e.g. Shalvey and Willmot, that are much more common to the north. These support(ed) the Castlereagh Forests & Woodlands complex of vegetation types, which is strongly associated with several threatened plant species. More common are broadly linear deposits of Quaternary alluvium along watercourses such as South Creek and Eastern Creek, and on the flood terraces of the Hawkesbury-Nepean River. Other lithologies occur but are very rare and of very small extent.

Very little of the GPECGA is reserved in NPWS estate. Wianamatta Regional Park (which emphasises recreational uses) encloses small areas of former Defence land in the far north. Adjacent to the southwestern boundary is the small Mulgoa Nature Reserve (emphasises biodiversity values). Two Biobanking sites adjacent to the Nature Reserve have increased the area under conservation.

3.1.4. Western Sydney Aerotropolis Growth Area (WSAGA)

The WSAGA abuts the GPECGA's southernmost border near the locality of Sovereign (east of Mulgoa), then extends south past Greendale, northeast to the locality of Badgerys Creek, east to Kemps Creek, and northward to the vicinity of Mount Vernon, excluding Twin Creeks Golf Course and associated settlement.

The lithology and soils are broadly similar to that of the GPECGA, being effectively just an extension of that area to the south to incorporate the developing Badgerys Creek Airport and environs. The area is even more severely cleared of native vegetation, except along some streams and on rare occurrences of steeper terrain. It contains no NPWS reserves, with the nearest being the small Kemps Creek Nature Reserve, outside the Area to the southeast. Gulguer Nature Reserve and Bents Basin State Conservation Area occur to the southwest of Greendale.

3.2 Geology and remnant vegetation

All of the Growth Areas are within the Cumberland Subregion. The dominant lithology across all of the Growth Areas is Wianamatta Shale (Ashfield and Bringelly Shales), with much smaller areas of Paleogene-Neogene alluvium occurring largely outside these boundaries, and much larger areas of Quaternary alluvium associated with floodplains of the many watercourses (*sensu* Martyn, 2018).

The terrain varies from almost flat through to steeply hilly areas associated with minor volcanism and more often, in association with shale ranges. In the far south, the more elevated shale landscapes have been eroded down to the underlying Hawkesbury Sandstone in a series of gullies and gorges. A transition zone between the shale and the sandstone is discernible in some areas.

On the dominant shale geology, the associated Critically Endangered Cumberland Plain Woodlands are still present in all of the four Growth Areas but have been disproportionately cleared for rural and later urban and allied uses. Much of what remains of this ecological community occurs as paddock trees and areas of remnant native ground-layer vegetation in pastoral and other contexts, with the exception of some substantial, though fragmented and isolated remnants. Remnant vegetation in these relatively fertile and arable landscapes is often in poor condition. In the most heavily cleared areas, it can be restricted to strips along watercourses. Some forms are dominated by *Casuarina* species. Weeds are common and sometimes severe in the moister situations. Weeds often extend into higher and drier terrain, especially in the form of African Olive and African Love Grass, both of which can occur on a landscape scale.

Small areas of the biodiverse Castlereagh Forests & Woodlands persist in all but the Wilton Growth Area on often-laterised Paleogene-Neogene alluvium. These variable woodlands and open forests support a particularly high number of threatened plant species, and because their soils are less suitable for agriculture and grazing, are better conserved than the Cumberland Plain Woodlands. Nonetheless, they are all listed as threatened ecological communities.

In the two southern Growth Areas, vegetation of the shale sandstone transition zone is relatively common and tends to remain in less arable areas adjoining the largely cleared former Cumberland Plain Woodlands. It is often found fringing the largely uncleared sandstone-based terrain, and ranges from highly intact to significantly modified and degraded, largely due to grazing and weed invasion. The associated Shale Sandstone Transition Forest is recognised as Critically Endangered due to extensive clearing across its substantial range, and because of the severity of other threats. Very little is present in formal conservation areas.

In the two southern Growth Areas, diverse, sandstone-based vegetation persists in association with most of the many incised watercourses. This vegetation is broadly the same as what occurs in extensive conservation estate around urban Sydney, but some communities adjoining current or former Shale Sandstone Transition Forest are not well-conserved and are threatened by further clearing and degradation.

3.2.1 Plant Community Types

The following section lists the Plant Community Types mapped in each Growth Area with brief notes about their distribution in those Areas. The list is not restricted to PCTs associated with *A. pubescens*.

3.2.1.1 Greater Macarthur Growth Area (GMGA)

The predominant ecological communities in the GMGA are or were Cumberland Plain Woodland (CPW), Shale Sandstone Transition Forest (SSTF) and River-flat Eucalypt Forest (RFEF), all of which are Threatened Ecological Communities. All have been extensively cleared and degraded, primarily by agriculture and weed invasion, but also by urban and allied uses. There are no NPWS reserves in this Growth Area. However, the very small Leacock, Edmondson and William Howe Regional Parks occur just outside the border and are managed primarily for recreation rather than conservation. Dharawal State Conservation Area and National Park border the southern portion of the Growth Area to the east. A summary of the mapped ecological communities is found in Table 3. The maps used here are based on OEH products that have been updated by Biosis for DPE.

Table 3. Summary of all ecological communities within the Greater Macarthur Growth Area

PCT	PCT Name	Distribution & notes
830	Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain	Small patch at Menangle Sugarloaf on SE slopes.
835	Forest Red Gum – Rough- barked Apple grassy woodland on alluvial flats of the Cumberland Plain	Along creek lines in shale areas in northern and central parts of GMGA.
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	Small patches on shale soils throughout GMGA but mostly in northern and central parts.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	Very small patches on shale soils throughout GMGA, more common in southern parts on steeper terrain.
883	Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain	4 polygons, Macquarie Fields, most of which have long been historically mown (Milton Park Softball Complex). They are now subject to regeneration.
1081	Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain	One small occurrence mapped around the margins of bushland associated with Smiths Creek at Leumeah.
1105	River Oak open forest of major streams, Sydney Basin Bioregion and South East Corner Bioregion	Only mapped along the Nepean River north from Menangle Bridge.
1181	Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of west & south Sydney	Narrow zone along Nepean & Georges Rivers and tributary gullies and a small zone along Smiths Creek at Leumeah.
1292	Water Gum - Coachwood riparian scrub along sandstone streams, Sydney Basin Bioregion	Restricted to parts of the riparian zones of the more incised and larger watercourses. Very restricted extent in this Area.
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain	Relatively small remnants extend south from Glenfield; extensive on transitional soils mostly south from Rosemeadow. Can intergrade with 849 and 1081.
1800	Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley	Only mapped to a very minor extent as highly linear remnants between Glenfield and Macquarie Fields (along the railway) and at Ingleburn (adjoining roads).

3.2.1.2 Wilton Growth Area (WGA)

The predominant ecological communities in the WGA are or were Cumberland Plain Woodland (CPW) and Shale Sandstone Transition Forest (SSTF) both of which are Threatened Ecological Communities. Sandstone-based communities occur in and surrounding the more incised watercourses. There are no NPWS reserves in this Growth Area, though Upper Nepean State Conservation Area occurs immediately to the south. There is a Biobanking site on the northern side of the river near Douglas Park (within the WGA), and three more such properties to the immediate north (including St Marys Towers) and those associated with coal mines (Steenbeeke, pers. comm.).

Table 4. Summary of all ecological communities within the Wilton Growth Area

PCT	PCT Name	Distribution & notes
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	On shale soils of higher, gently undulating terrain of northern and central areas. Small patches with scattered trees (farming properties) adjoining more extensive exotic and native grasslands.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	One patch in a derived grassland (treeless) condition in the west, and a much larger portion in the far north.
1081	Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain	Limited to a few patches in the north between 1395 on plateau edges and 1181 in sandstone gullies.
1181	Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of west & south Sydney	Common on slopes and plateau edges above and around incised sandstone-based watercourses that surround most of the Area.
1292	Water Gum – Coachwood riparian scrub along sandstone streams	Restricted to a very narrow riparian strip along the Nepean River.
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain	The most extensive community on shale sandstone transition soils between 849/850 and sandstone communities along gullies. Variable floristics.

3.2.1.3 Greater Penrith to Eastern Creek Growth Area (GPECGA)

The native vegetation of this Growth Area has been extensively cleared, with what remains classified as Threatened Ecological Communities. The majority of the Area formerly supported Cumberland Plain Woodlands, with a much smaller area supporting Shale Gravel Transition Forest and Castlereagh Forests & Woodlands. River-flat Eucalypt Forest was previously much more extensive along the Hawkesbury-Nepean River and adjoining primary floodplain, and it remains to varying degrees along many watercourses such as Eastern Creek, though frequently in poor condition, due largely to extensive weed invasion and a long interface with unsympathetic land uses. There is one NPWS reserve in this Growth Area: Wianamatta Regional Park, however it is already significantly fragmented and may be required to potentially accommodate a large transport corridor. The small Mulgoa Nature Reserve and associated Biobanking sites occur near the south-western border of this Growth Area. Yarramundi SCA occurs on the western boundary but across the Nepean River, and Wianamatta NR occurs near the NW corner.

Table 5. Summary of all ecological communities within the GPECGA

PCT	PCT Name	Distribution & notes
724	Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain	Scattered as small remnants and one larger remnant in the central portion, but with greater extent in the central north, mainly in the western ungazetted portion of Wianamatta Regional Park.
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain	A few very small remnants present south of the M4, with larger remnants within and near the gazetted and ungazetted portions of Wianamatta Regional Park.
781	Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion	Very limited extent, primarily in the far northwest, with some small remnants in the southwest, often associated with watercourses.
830	Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain	Present to a very minor extent on the southwestern edge adjoining Mulgoa Nature Reserve
835	Forest Red Gum – Rough- barked Apple grassy woodland on alluvial flats of the Cumberland Plain	Common along creek lines and associated floodplains through the south and central areas.
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	Common in and near Orchard Hills in the south, and former ADI lands in the central north, with some areas in the ungazetted portion of Wianamatta Regional Park. Other scattered remnants, particularly in the east.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	Very small patches in the south west, primarily in pastoral settings and on steeper terrain.
883	Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain	Restricted to one linear polygon in the eastern portion of Wianamatta Regional Park.
1105	River Oak open forest of major streams, Sydney Basin Bioregion and South East Corner Bioregion	Only mapped along the Hawkesbury-Nepean River, primarily near Penrith Lakes.
1800	Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley	Present as mostly-linear remnants along South Creek and Eastern Creek and tributaries, with some scattered occurrences, including along the M4.

3.2.1.4 Western Sydney Aerotropolis Growth Area (WSAGA)

The native vegetation of this Growth Area has been extensively cleared, with what remains classified as Threatened Ecological Communities. The majority of the Area formerly supported Cumberland Plain Woodlands, with a much smaller area supporting Castlereagh Forests & Woodlands near the localities of Kemps and Badgerys Creeks, and potentially in the vicinity of the water pipeline crossing of Luddenham Road. Riverflat Eucalypt Forest remains to varying degrees along most watercourses, though frequently in poor condition, due largely to extensive weed invasion and a long interface with unsympathetic land uses. Swamp Oak Forest occurs mainly along South Creek and some tributaries. There are currently no NPWS reserves in this Growth Area. The small Kemps Creek Nature Reserve occurs just outside the south-eastern corner and Gulguer Nature Reserve and Bents Basin State Conservation Area are near the south-western corner.

Table 6. Summary of all ecological communities within the WSAGA

PCT	PCT Name	Distribution & notes
724	Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain	Restricted to the Kemps and Badgerys Creek area as three patches of remnants.
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain	As above: two patches with smaller remnants nearby and on slightly higher ground than 724.
781	Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion	Very limited extent, primarily in the far northeast, with one remnant in the centre.
835	Forest Red Gum – Rough- barked Apple grassy woodland on alluvial flats of the Cumberland Plain	Common along creek lines and associated floodplains but very little remains, and most occurrences are linear.
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	The most common PCT in this Area, with remnants throughout on the dominant shale terrain.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	Only very small patches in the far south.
1800	Swamp Oak open forest on river-flats of the Cumberland Plain and Hunter valley	Present as mainly very linear remnants along most watercourses but largely absent from the southernmost portion.

4. Assessment of species' presence and suitable habitat

4.1 Existing records and surveys

The principal source of threatened flora records in NSW is the OEH BioNet database, which includes most records held by the NSW Herbarium (specimen-based), as well as sightings, including those associated with vegetation sampling for the purposes of mapping. Other databases, such as Atlas of Living Australia, largely mirror BioNet data within NSW, but are not used in this Report due to their having lower data quality control, and because they do not allow even a registered user to access data that may not have been generalised to obscure the exact location of a record. Very few flora records that are in ALA but not in BioNet are original – most are simply replicate records based on specimens held in other herbaria.

The preliminary assessment of threatened species records undertaken for the preparation of this Expert Report reiterated the merit of reviewing BioNet data and resolving a range of errors, rather than simply using data 'as held'. *Acacia pubescens* records within BioNet were reviewed, and numerous corrections were made, though the majority of these relate to the assigned spatial accuracy scores and to clarifying or correcting location placements and descriptions. Not all records were able to be checked in that stage, and a second review for records in or near the Growth Areas was conducted to further improve data quality. The reviews eliminated a range of errors and allowed many records that were otherwise too spatially vague, to be refined such that they were suitable for habitat modelling and for general reference. Not all records were reviewed, and inaccuracies remain in the dataset, but records are now far more accurate in terms of their identification of the species, their location, and their spatial accuracy score.

BioNet data should only be treated as indicative, not least because there has not been comprehensive survey of all of the Growth Areas or environs, and surveys have been variously constrained. The absence of records from an area does not necessarily mean the species is absent, as it may not have been surveyed there, or survey conditions and methods may have been inadequate.

Field survey undertaken by consultancy firms engaged by DPE (Biosis and Ecoplanning) did not add any records of this species. Fellow botanists engaged by DPE to prepare Expert Reports also reported that no new records of this species were found by them.

4.1.1 Existing records by Growth Area

Acacia pubescens records in Greater Macarthur Growth Area

There is one duplicated record (NSW Herbarium and Wildlife Atlas) in this Growth Area. It is a 1960 collection that only gives the location as 'Minto'. This record was reviewed and given a 5000 m spatial accuracy to reflect the potential spatial variability within this suburb. There are no modern or spatially accurate records from this Growth Area, but there are several just beyond the northeast corner within current and former Defence Department land at Moorebank / Holsworthy. Part of this population is now within a Biobank reserve. There are also several records from an industrial area in Prestons, just north of the northern end of the Growth Area. There is one record near the central eastern boundary of the Growth Area at Kentlyn.

Acacia pubescens records in Wilton Growth Area

The species has been never been recorded within or near the WGA. The nearest records are approximately 14, 19 and 24 km from the WGA boundary to the northwest, northeast, and southeast. There is no apparent reason that the species could not occur here, as there are PCTs that the species is known to occur in. However, outside its core range on the Cumberland Plain, the species appears to be very sparsely distributed, with substantial distances between what are now quite disjunct remnant populations. This Growth Area may be naturally devoid of this species, or it could be present in unsurveyed habitat or in seedbank.

Acacia pubescens records in Greater Penrith to Eastern Creek Growth Area

There are seven records of the species in the southeast of this Growth Area. Some are duplicates or capture separate apparent plants at a scale finer than the resolution of GPS units used to record the sightings. All occur in the vicinity of the M4, Roper Road and Eastern Creek. There is only one location on the M4 in a small, thin section of remnant vegetation that has likely been subject to some supplemental planting. The other locations are associated with a very thin strip of apparently remnant vegetation bordering a large industrial site east of Eastern Creek off Sargents Road, Minchinbury. Some of the plants may be within Daraga Badu Reserve, but most of that land lacks tree cover, appears highly modified / degraded, and seems to be primarily associated with high voltage electricity easements and a floodway.

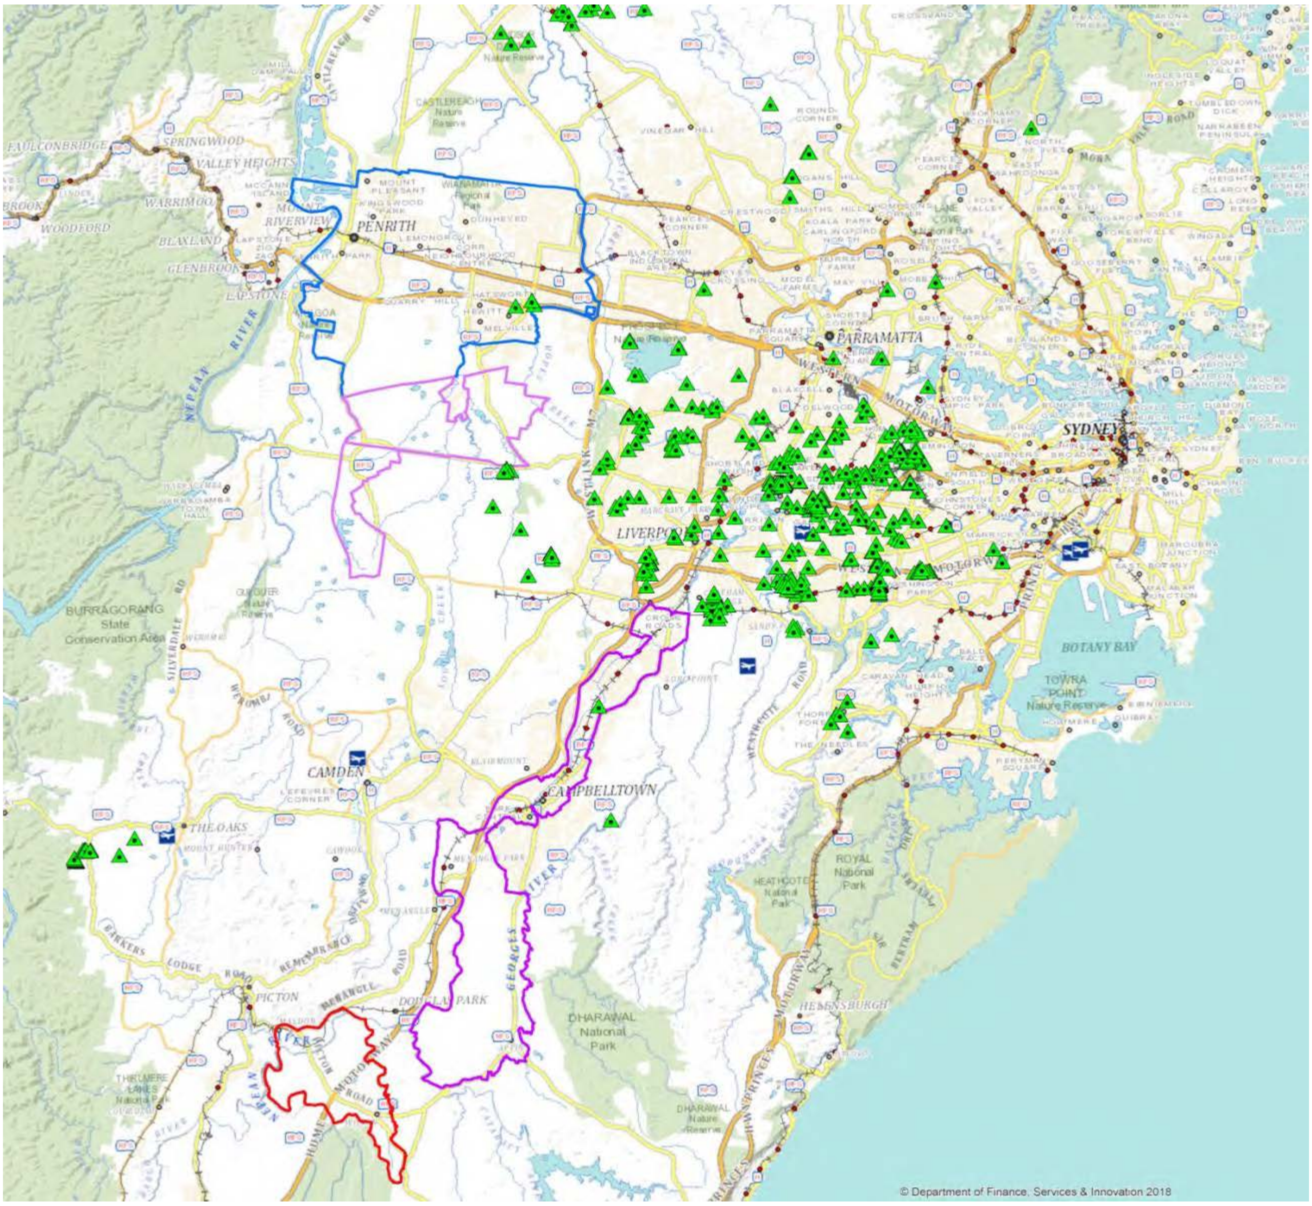
Acacia pubescens records in Western Sydney Aerotropolis Growth Area

The species is not currently known from this Growth Area but there are a small number of credible records immediately south of the Area's southeastern corner near Elizabeth Drive and Cross Street. All are associated with an isolated remnant of Paleogene-Neogene alluvium. Equivalent habitats occur north of Elizabeth Drive within the Growth Area but have been excluded from biocertification.

4.1.2 Prior surveys within each Growth Area

There is no central or local registry of surveys and survey effort for threatened biota, and a large proportion of survey reports are not made public or only made public when lodged with a planning consent authority. This makes it extremely difficult, if not impossible to compile a list of surveys, methods and findings across the study area.

The OEH Authorised Officer for *A. pubescens* was contacted in this regard. He advised that he does not hold a record of this information, so I contacted the manager of threatened biota matters in the Greater Sydney OEH office for further assistance. She committed to providing the relevant information by consulting key staff. I was included in the associated emails. No additional information about this species was provided.



Map 3. BioNet records (cleaned as of 26/11/18) relative to the Growth Areas

NB each point may not designate a collection or observation at that location, as most very old records lacked any co-ordinates or only supply coarse co-ordinates, and they may only have mentioned a town or locality. Such records will generally have a relatively poor Accuracy score (10-25 km) to indicate that the actual location of the species could be within a considerable distance of the designated point. Many such records are assigned the same indicative co-ordinates such that one point on a map may relate to several old records that were supplied with very little locational information.

A BioNet map of the species' distribution gives a generally accurate indication of its known range, but not the extent of potential habitat. Large areas of private or corporate tenure have not been subject to the same level of survey effort as more accessible areas. An absence of records of the species where potential habitat remains should not be taken to indicate that the species does not occur there.

4.1.2 Prior surveys within each Growth Area

There is no central or local registry of surveys and survey effort for threatened biota, and a large proportion of survey reports are not made public or only made public when lodged with a planning consent authority. This makes it extremely difficult, if not impossible to compile a list of surveys, methods and findings across the study area.

The OEH Authorised Officer for *A. pubescens* was contacted in this regard. He advised that he does not hold a record of this information, so I contacted the manager of threatened biota matters in the Greater Sydney OEH office for further assistance. She committed to providing the relevant information by consulting key staff. I was included in the associated emails. No additional information about this species was provided.

4.2 Summary of survey work undertaken for the biocertification assessment

4.2.1 Vegetation mapping

Vegetation mapping of the Cumberland Subregion was completed in stages by OEH in 2013 and 2016. These two vegetation layers have been used as the base to compile an updated vegetation community layer for each of the Growth Areas. This updated work has been completed by Biosis under contract to DPE. The mapping update includes checking plant community types and confirming the accuracy of boundaries to account for clearing or regrowth that may have occurred since the original mapping was completed. Field verification of the mapping was undertaken by Biosis and Ecoplanning, both of whom undertook vegetation surveys where access was permitted.

Vegetation in the Growth Areas was mapped and assessed based on five vegetation condition classes:

- Intact;
- Non-offsettable Grassland;
- Offsettable Grassland;
- Scattered Trees;
- Thinned.

4.2.2 Field survey effort

The information in section 4.2.2 has been provided by DPE but has been edited here to only deal with threatened flora where feasible. Further details are provided separately by DPE:

An initial 726 letters were sent to landholders within the Wilton and Greater Macarthur Growth Areas in late 2017 with a second letter following in March 2018. To increase the response rate, Biosis commenced targeted door-knocking in May 2018. From this, just under 20% of landholders within these Growth Areas allowed access to their property. However, this included access to large parcels of land owned by major developers, which allowed a reasonable amount of access, particularly for the Wilton Growth Area.

Floristic plot data collected:

- Wilton (86 plots across 6 PCTs)
- Greater Macarthur (82 plots across 9 PCTs)

Approximately 150 of the plots required to meet BAM requirements were obtained by supplementing Biometric plots from various recent assessments. This involved locating the previous plots and collecting additional data on stem classes, number of large trees, and litter cover to meet BAM requirements. The ecologists had no trouble locating the original survey sites and found that the additional data was quick and easy to collect (approximately 30 minutes per site). The remaining plots in Wilton and Greater Macarthur, and all of the plots in Western Sydney Aerotropolis and Greater Penrith to Eastern Creek consisted of new plots surveyed for this project. All plots were sampled according to the methods prescribed by the BAM Manual (OEH 2017). This includes collecting information on species cover and abundance from 20 x 20 m or equivalent configuration plots within each vegetation zone.

A total of 432 letters were sent to landholders across the Western Sydney Aerotropolis Growth Area between November 2017 and August 2018 with 84 landholders responding positively to provide access. A further seven properties were accessed after doorknocking resulting in a response rate of 21%.

A small number of targeted letters were sent to landholders in the Greater Penrith to Eastern Creek Growth Area from November 2017. However, most letters (more than 1500) were sent in August 2018, which included many urban and small acreage landholders. From this, 177 landholders provided access to their properties and an additional three landholders provided permission via doorknocking (12% response rate). Not all of these properties were surveyed as some did not support vegetation patches of interest. In addition, the Open Spaces Team at Penrith Council facilitated access to 64 lots owned by Council.

Floristic plot data collected:

- Western Sydney Aerotropolis (53 plots across 6 PCTs)
- Greater Penrith to Eastern Creek (26 plots across 7 PCTs)

Targeted survey for threatened species

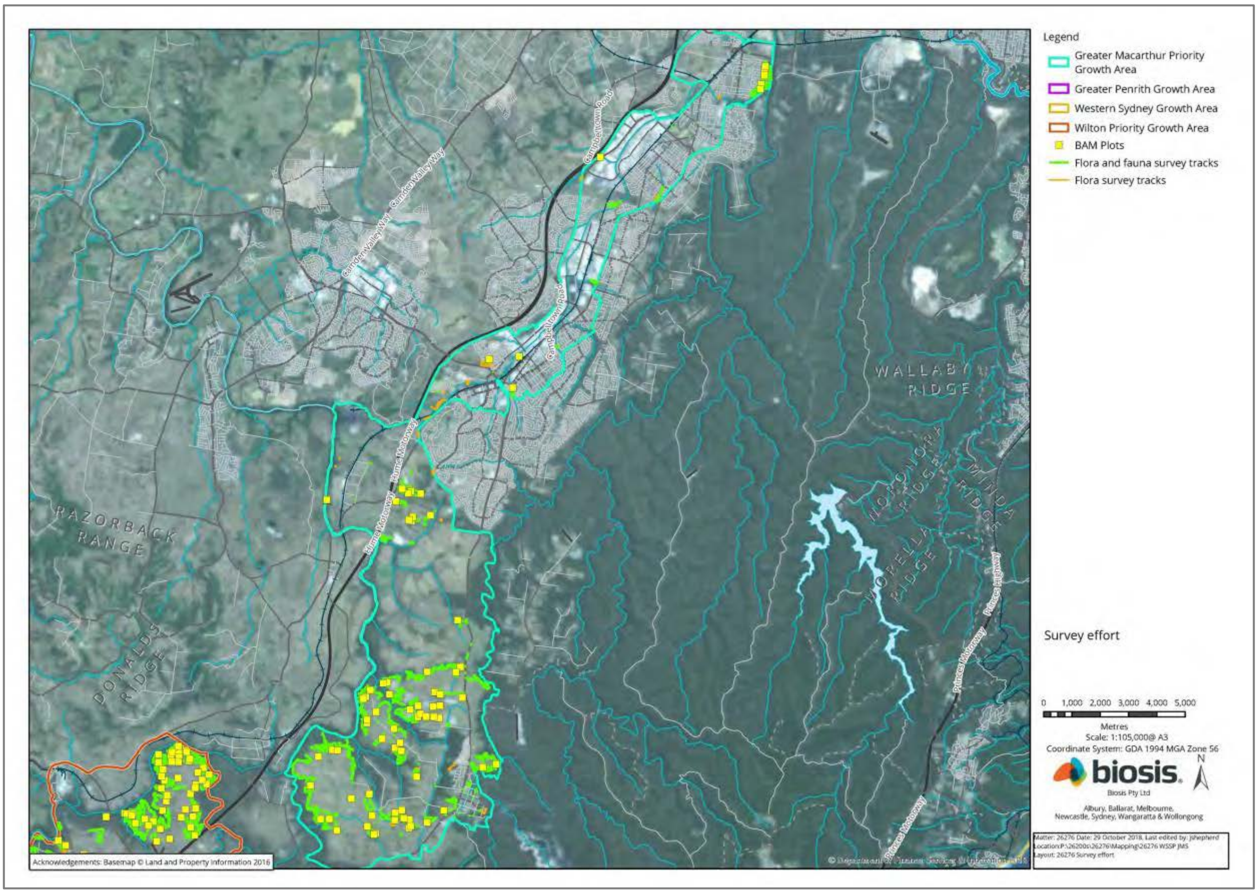
Targeted survey for threatened plant species has been conducted on lands where access has been granted. Vegetation transects and random meanders for threatened flora was conducted by Ecoplanning and Biosis in accessible areas proposed for certification, with particular attention to areas of likely habitat. The survey has included effort through each PCT and vegetation zone and has extended into suitable habitat adjacent to the edge of the future urban area where potential indirect impacts to high quality habitat may occur (up to ~50m).

Likely habitat for most threatened flora species comprised areas of lower disturbance. This includes areas with a predominantly native understorey (with or without a canopy), the base of scattered trees in paddocks, paddocks with an apparent low grazing pressure, and known topographic/habitat preferences for certain flora.

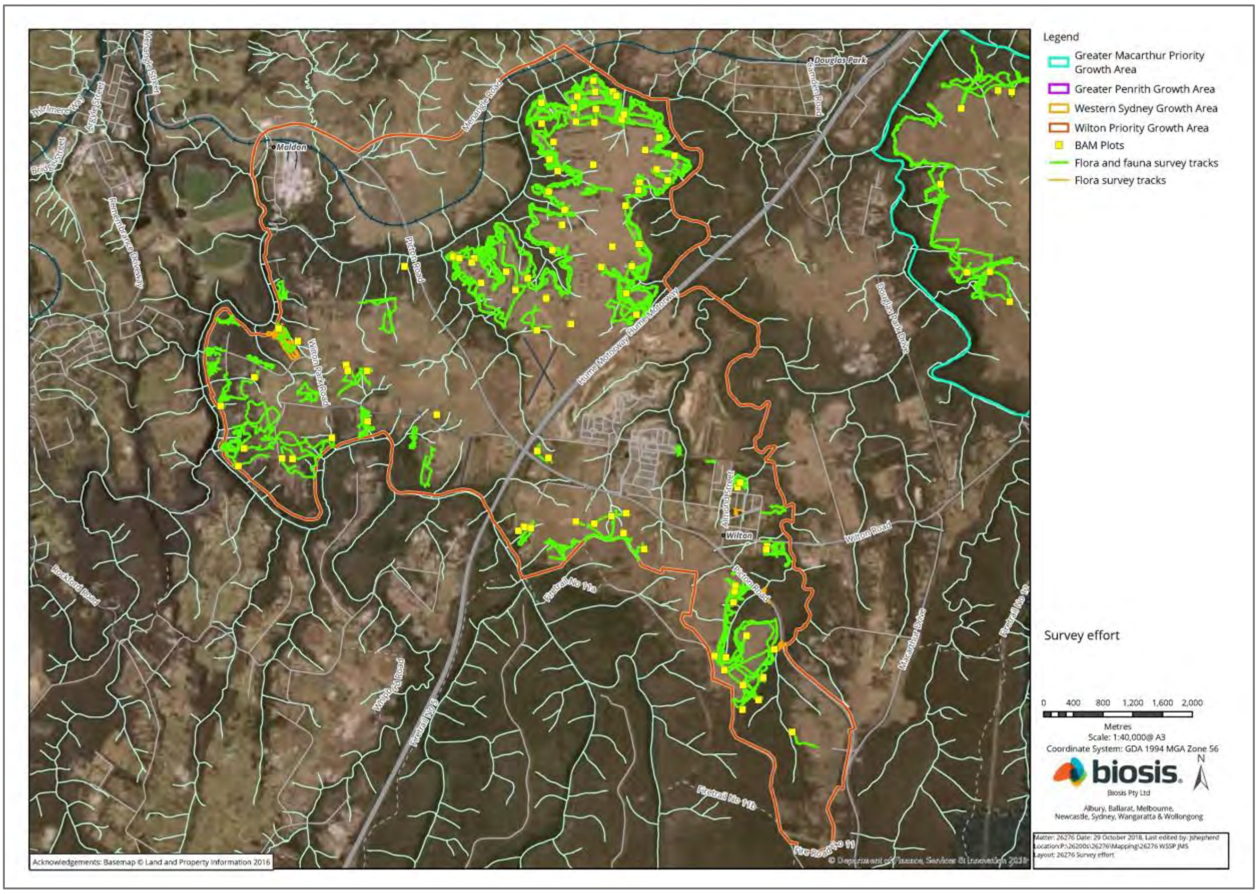
Table 7. Survey effort for threatened plant species *and* fauna habitat by PCT

PCT No.	Area of PCT in Growth Area (ha)	Area of PCT in urban zone (ha)	Field survey area (ha)	Percent of PCT surveyed within Growth Area (%)	Percent of PCT surveyed relative to urban zone (%)
724	191.3	57.0	12.1	6.3%	21.2%
725	167.4	51.4	6.9	4.1%	13.4%
781	68.9	5.6	0.9	1.4%	16.8%
830	21.6	0.8	1.7	7.8%	206.5%
835	1175.8	287.3	30.5	2.6%	10.6%
849	3078.3	637.6	125.0	4.1%	19.6%
850	522.9	294.3	36.1	6.9%	12.3%
883	7.4	0.0	0.5	6.8%	
1081	74.2	0.0	0.2	0.3%	
1105	138.6	0.0	0.0	0.0%	
1181	780.7	0.2	39.6	5.1%	19794.4%
1292	39.8	0.0	0.3	0.7%	
1395	3326.6	486.9	483.4	14.5%	99.3%
1800	232.6	20.2	7.3	3.1%	36.2%
TOTAL	**9826.1**	**1841.3**	**744.5**	**7.6%**	**40.4%**

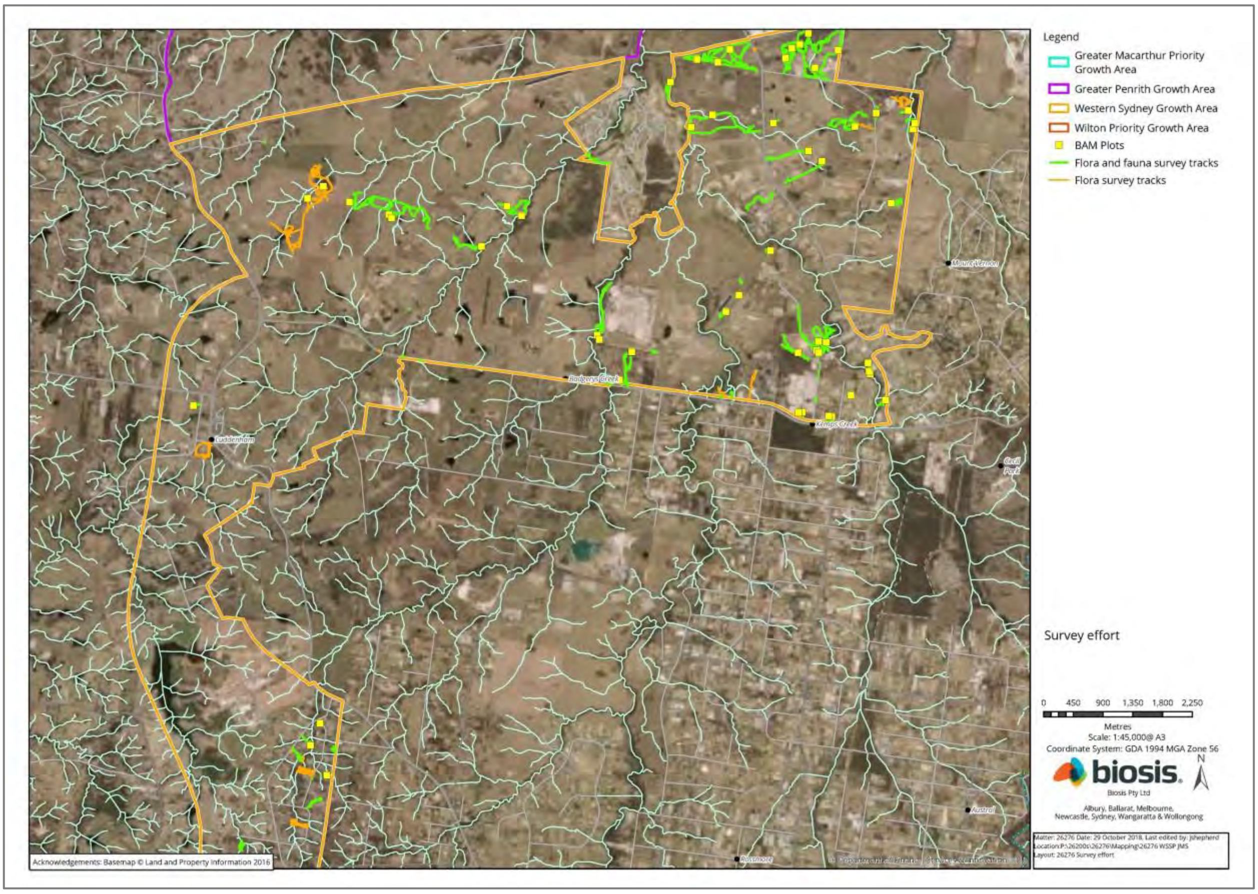
Field survey effort was not confined to the urban zone. Surveys occurred into nearby vegetation zoned for conservation. The urban zone has been revised over time and some areas where survey had already occurred were later removed. For these reasons, comparison of the survey area to the urban zone is indicative only. Survey effort has been calculated using a 20-metre buffer either side of GPS survey tracks. For the purposes of this analysis, the urban zone includes land zoned for future urban development plus transport corridors within the growth areas. It does not include any transport corridors outside the growth areas.



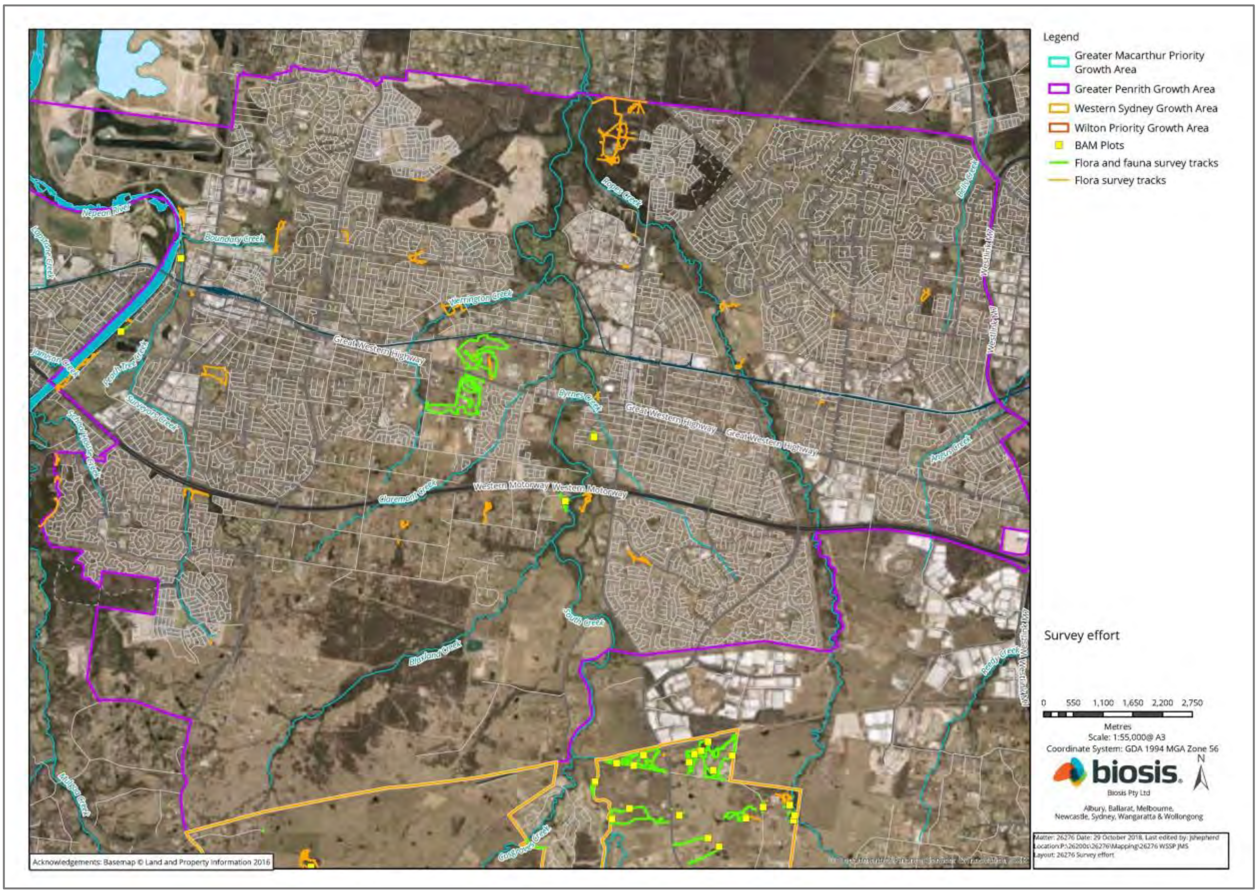
Map 4. GMGA survey effort (Biosis & Ecoplanning)



Map 5. WGA survey effort (Biosis and Ecoplanning)



Map 6. WSAGA ('Western Sydney') survey effort (Biosis and Ecoplanning)



Map 7. GPECGA survey effort (Biosis and Ecoplanning)

4.2.3 Survey constraints –timing / site conditions

As noted earlier, severe drought affected all of the study areas for some or all of the survey period. The Wilton and Greater Macarthur GAs were only surveyed during drought, whereas the Greater Penrith & Eastern Creek and the Aerotropolis GAs were surveyed both during intense drought and the subsequently slightly wetter conditions that followed in the Spring of 2018. Whilst wetter, drought remained present, and fellow botanist, Robert Miller, reported that vegetation was evidently drought-affected across all of the Growth Areas into November.

Drought, combined with increased intensity and extent of total grazing pressure, meant that affected surveys are likely to have under-recorded the target species compared to normal conditions. Whilst drought alone is unlikely to cause *A. pubescens* to die back to rootstock or die and only remain as seedbank, when combined with increased herbivory due to drought, this is a far more likely outcome.

4.2.4 Survey constraint – surveys undertaken by generalists / non-experts

Even when the prescribed OEH survey methods are used, a combination of site-based constraints, a species' ecology and a lack of familiarity with the species creates a situation where it is likely that it can be present in plant form, but not recorded, or present only as seedbank.

Acacia pubescens, like *P. nutans* and *A. bynoeana* is one of several threatened plant species that should not be treated as absent simply because it was not observed in plant form. If suitable habitat occurs, the species should be considered present unless there are clear reasons to rule otherwise. That approach is taken in this Report in relation to the designation of 'species polygons' (i.e. maps of where the plant is known or likely to occur).

4.3 Surveys completed for this Report

I undertook a very brief survey of potential habitat for *P. nutans, A. bynoeana* and *A. pubescens* in the locality of Kemps Creek in mid-November 2018. Robert Miller was also present to survey for his target species. He examined some sites that I did not. He is very familiar with these species and did not report any new sightings of *A. pubescens*.

The main remnant habitat in this locality is just to the south of the WSAGA but was checked by Miller for reference purposes. That remnant was seen to be largely unmanaged and degrading due to several threats, and it is feasible that the species is now restricted to seed bank at that location, though it could be present on disturbance margins that were not traversed.

Relatively little potential habitat remains for this species in the WSAGA, and whilst little of this was available to be surveyed by me or by consultants engaged by DPE, all such habitat has been excluded from the proposed urban footprint. The map below shows the transects associated with a brief survey within the WSAGA (northern line largely within a s.88b conservation area) and outside the WSAGA (short southern line).

Map 8. GPS track logs (purple lines)

I did not survey for any of my target species in the GPECGA because most of the potential habitat is either reserved, or proposed for reservation by OEH, and because of logistical constraints (time, property access). DPE offered access to a large area of remnant bushland in this Growth Area, but it was already excluded from the proposed urban footprint, so I did not take up that offer.

I did not survey the WGA, as the species is not known from or likely to occur there. Logical constraints were also a consideration.

I did not survey the GMGA due to a mix of logistical constraints and knowledge that most areas of potential habitat had already been excluded from the proposed urban footprint.

4.4 Assessment of species' presence

4.4.1 Greater Macarthur Growth Area

There are no modern or spatially accurate records of this species in this Growth Area, but suitable habitat is present. The extent of earlier habitat removal in the two thirds of the Growth Area has greatly limited where the species might remain amongst the now urban and industrial areas. Most of the potential habitat is present in the southern third of the Growth Area in what is largely rural land. Much of that area is fragmented by clearing of the higher and more arable shale-based vegetation, primarily leaving the shale/sandstone transitional vegetation and the sandstone vegetation associated with gullies.

4.2.2 Wilton Growth Area

The species is not known from this Growth Area but could be present in most of the remaining native vegetation, with the exception of the sandstone-based terrain around the gullies and larger watercourses. Most of the potential remnant habitat occurs around the edges of the Growth Area, primarily associated with the shale/sandstone transition. Much of that environment is or has been grazed but remains potentially viable habitat.

4.2.3 Greater Penrith to Eastern Creek Growth Area

The species is present in this Growth Area, and most of the native vegetation that remains in this heavily cleared Area is potential habitat for this species. The largest areas of potential habitat are within the former Australian Defence Industries land in the far north, some of which is within or proposed to become part of Wianamatta Regional Park; and the Orchard Hills Defence site in the southwest.

4.2.4 Western Sydney Aerotropolis Growth Area

Extensive clearing has meant that relatively little native vegetation remains in this Growth Area, however, the species could be present in most of the associated remnants. The most likely potential habitat is limited to a few patches of remnant vegetation in the localities of Kemps Creek and Badgerys Creek. Other areas occur throughout the Growth Area.

4.5 Assessment of suitable habitat for *Acacia pubescens*

4.5.1 Description and relative significance of potential habitat

As per the findings presented earlier in Table 2, combined with expert knowledge, the following PCTs are regarded as potential habitat for *A. pubescens*. Not all of these PCTS are present in all of the Growth Areas, and not all occurrences or parts of these communities are likely to support the species in plant or seedbank forms. Wetter and sometimes more thickly vegetated areas associated with drainage lines are less likely habitat. Riparian buffer exclusions will be used as a component of the 'species polygons' discussed later. All vegetation condition classes are included:

Table 10. PCTs known or likely to be habitat for *A. pubescens*

PCT	PCT Name	Relative significance
724	Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain	Very High
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain	Very High
835	Forest Red Gum – Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain	Low
849	Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain	Moderate
883	Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain	Very Low
1081	Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain	Low
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain	Very Low

The following sections describe the relative habitat value and local occurrences of each PCT mapped in each Growth Area.

Greater Macarthur Growth Area

The vegetation mapping provided for use in the project indicates that there is **2364.2 ha** of potential habitat for this species in this Growth Area based only on the extent of relevant PCTs.

Table 11. Potential habitat in the GMGA

PCT	Distribution	Relative habitat value
835	Scattered remnants in the northern two-thirds.	Low on the basis of PCT association.
849	Scattered remnant throughout.	Moderate on the basis of PCT association
883	Four very small polygons at Macquarie Fields	Low on the basis of PCT association but also because of a long history of mowing and weed invasion.
1081	A small remnant at Leumeah (Smiths Creek) is the only occurrence in this Growth Area.	Low on the basis of PCT association and being restricted to a single urban remnant that is likely to be significantly compromised.
1395	Common in the far south from around Menangle Park through Gilead to Appin area; between cleared shale landscapes and sandstone gullies	Moderate to high depending on shale content – high shale content is of lower habitat value. Unlikely habitat when near watercourses

Wilton Growth Area

The vegetation mapping provided for use in the project indicates that there is **1742.7 ha** of potential habitat for this species in this Growth Area based only on the extent of relevant PCTs.

Table 12. Potential habitat in the WGA

PCT	Distribution	Relative habitat value
849	A few medium to large remnants, mainly in the northern half, and some are in 'derived grassland' condition.	Moderate on the basis of PCT association. Likely reduced value in derived grassland remnants.
1081	Uncommon and restricted to three patches above sandstone gorges, mainly on or near northern edges.	Low on the basis of PCT association but habitat quality appears good.
1395	Common around and near margins between cleared shale landscapes and sandstone gullies.	Very Low based on PCT association over the four Growth Areas, but probably Moderate in this Growth Area. Unlikely habitat when near watercourses.

Greater Penrith to Eastern Creek Growth Area

The vegetation mapping provided for use in the project indicates that there is **2640.4 ha** of potential habitat for this species in this Growth Area based only on the extent of relevant PCTs.

Table 13. Potential habitat in the PECGA

PCT	Distribution	Relative habitat value
724	Uncommon, mostly in the central north, but also the centre, with smaller remnants further east. Very little combined extent.	Very high based on PCT association
725	Largely restricted to a few relatively large remnants in the central north, primarily in Wianamatta Regional Park (east) and nearby. Smaller remnants to the east in largely urban areas.	Very high based on PCT association
835	Relatively common along drainage lines, so most remnants are linear.	Low on the basis of PCT association. Many remnants are likely to be significantly degraded by weeds, though this species can survive in such situations.
849	The most extensive PCT in this Growth Area but largest remnants are Orchard Hills (SW) and former ADI lands (central north).	Moderate on the basis of PCT association. Not so likely to be found in the north due to prior survey efforts over some years.
883	Only one polygon in eastern Wianamatta Regional Park (in Biosis map)	Very low on the basis of PCT association plus the very small area involved.

<u>Western Sydney Aerotropolis Growth Area</u>

The vegetation mapping provided for use in the project indicates that there is **721.4 ha** of potential habitat for this species in this Growth Area based only on the extent of relevant PCTs.

Table 14. Potential habitat in the WSAGA

PCT	Distribution	Relative habitat value
724	Uncommon, restricted to localities of Kemps Ck and Badgerys Ck. Very little combined extent.	Very high based on PCT association plus proximate records.
725	Uncommon, restricted to localities of Kemps Ck and Badgerys Ck. Very little combined extent.	Very high based on PCT association plus proximate records.
835	Relatively common along drainage lines, so most remnants are linear.	Low on the basis of PCT association. Many remnants are likely to be significantly degraded by weeds, though this species can survive in such situations.
849	The most extensive PCT in this Growth Area but many remnants are grazed.	Moderate on the basis of PCT association and proximate records, though these are associated with other PCTs

4.5.2 Species habitat polygons

Species habitat polygons generated by this report relate to the extent of potential habitat that is proposed to be cleared for urbanisation or transport corridors (Maps 9-11). These habitat polygons and associated calculations were generated to inform biodiversity offset requirements. The data presented in this section does not deal with species habitat outside proposed urban and allied zones as those areas are treated as conservation zones or are excluded from urban and associated transport zones for a range of reasons.

The habitat polygons include all relevant condition classes of relevant PCTs as identified in this Report. In this case, all condition classes are included.

As part of the formulation of the species habitat polygons, graded riparian exclusion buffers were used in recognition that *A. pubescens* does not occur in riparian vegetation. Buffers are relatively small for this species as *A. pubescens* can occur in riverflat/creekflat situations. The buffer distances increase with the mapped Strahler stream order as shown in Table 15. The accuracy of the buffers is limited by available data, including the mapped location of streams. The buffer is applied either side of the mapped stream centreline. Note that these riparian buffer distances are a different concept and serve a different purpose to those applied by DPE for the purposes of protecting streamside vegetation and watercourses in its planning within the Growth Areas.

Table 15. Stream exclusion buffers

Stream order	Buffer distance (m)
1	5
2	10
3	15
4	20
5	25
6	30
7	40

As *A. pubescens* can occur in quite modified sites, all condition classes are included for the relevant PCTs identified as potential habitat.

Furthermore, as this species can occur in sites that are so modified that they would not be mapped as native vegetation, this report may under-estimate the extent of potential habitat. This should be considered an inherent methodological constraint. The only alternative to the PCT-based approach taken here would seem to be mapping all areas with suitable soil/geology as potential habitat, and not excluding what would otherwise be viewed as ‘cleared’ land. I do not consider that practical in this context. I consider that land not mapped as native vegetation is less likely to support this species, and that if the species were present there, such populations may be less viable because of the extent of habitat modification. I suggest that if feasible within the scope of biocertification, there remain a provision that if a threatened plant species is detected in any surveys or works, OEH be advised and assessments undertaken by that agency with a view to conserving or translocating the material if feasible.

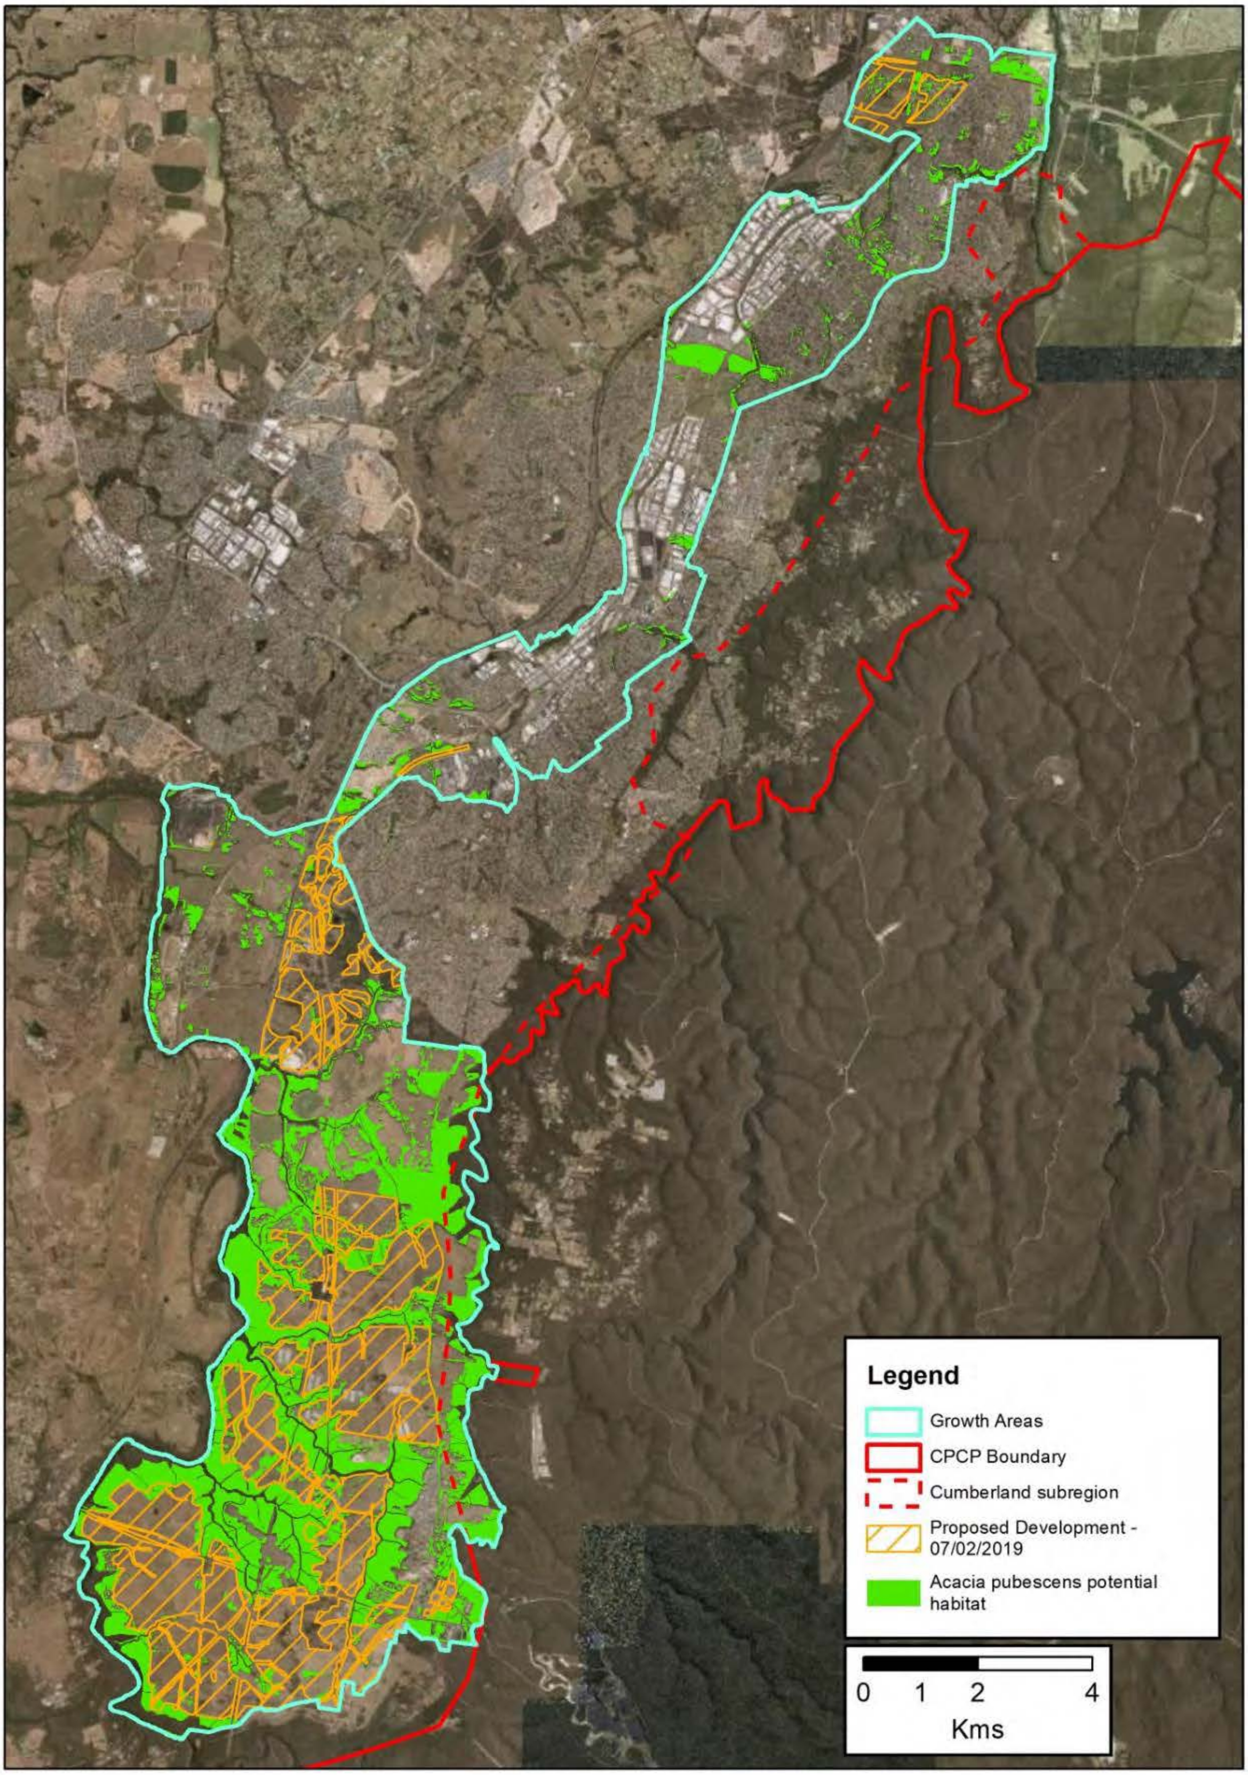
Species polygons in the form of GIS shape files were provided to the Biodiversity and Sustainability Branch of DPE in November 2018. Analysis of the area of potential habitat that is subject to development/removal in each of the four growth areas is shown in Table 16. A summary of the potential habitat that may be removed as a percentage of total potential habitat present in the growth areas is presented in Table 16.

These figures are based on precautionarily modelled *potential* habitat, and do not necessarily equate with *actual* habitat, nor do they provide any information of potential population sizes or population viability. It is unlikely that a large percentage of the potential habitat identified in this Report would actually support *A. pubescens* because this species is naturally rare and patchily distributed, even though it can be locally abundant in favourable conditions.

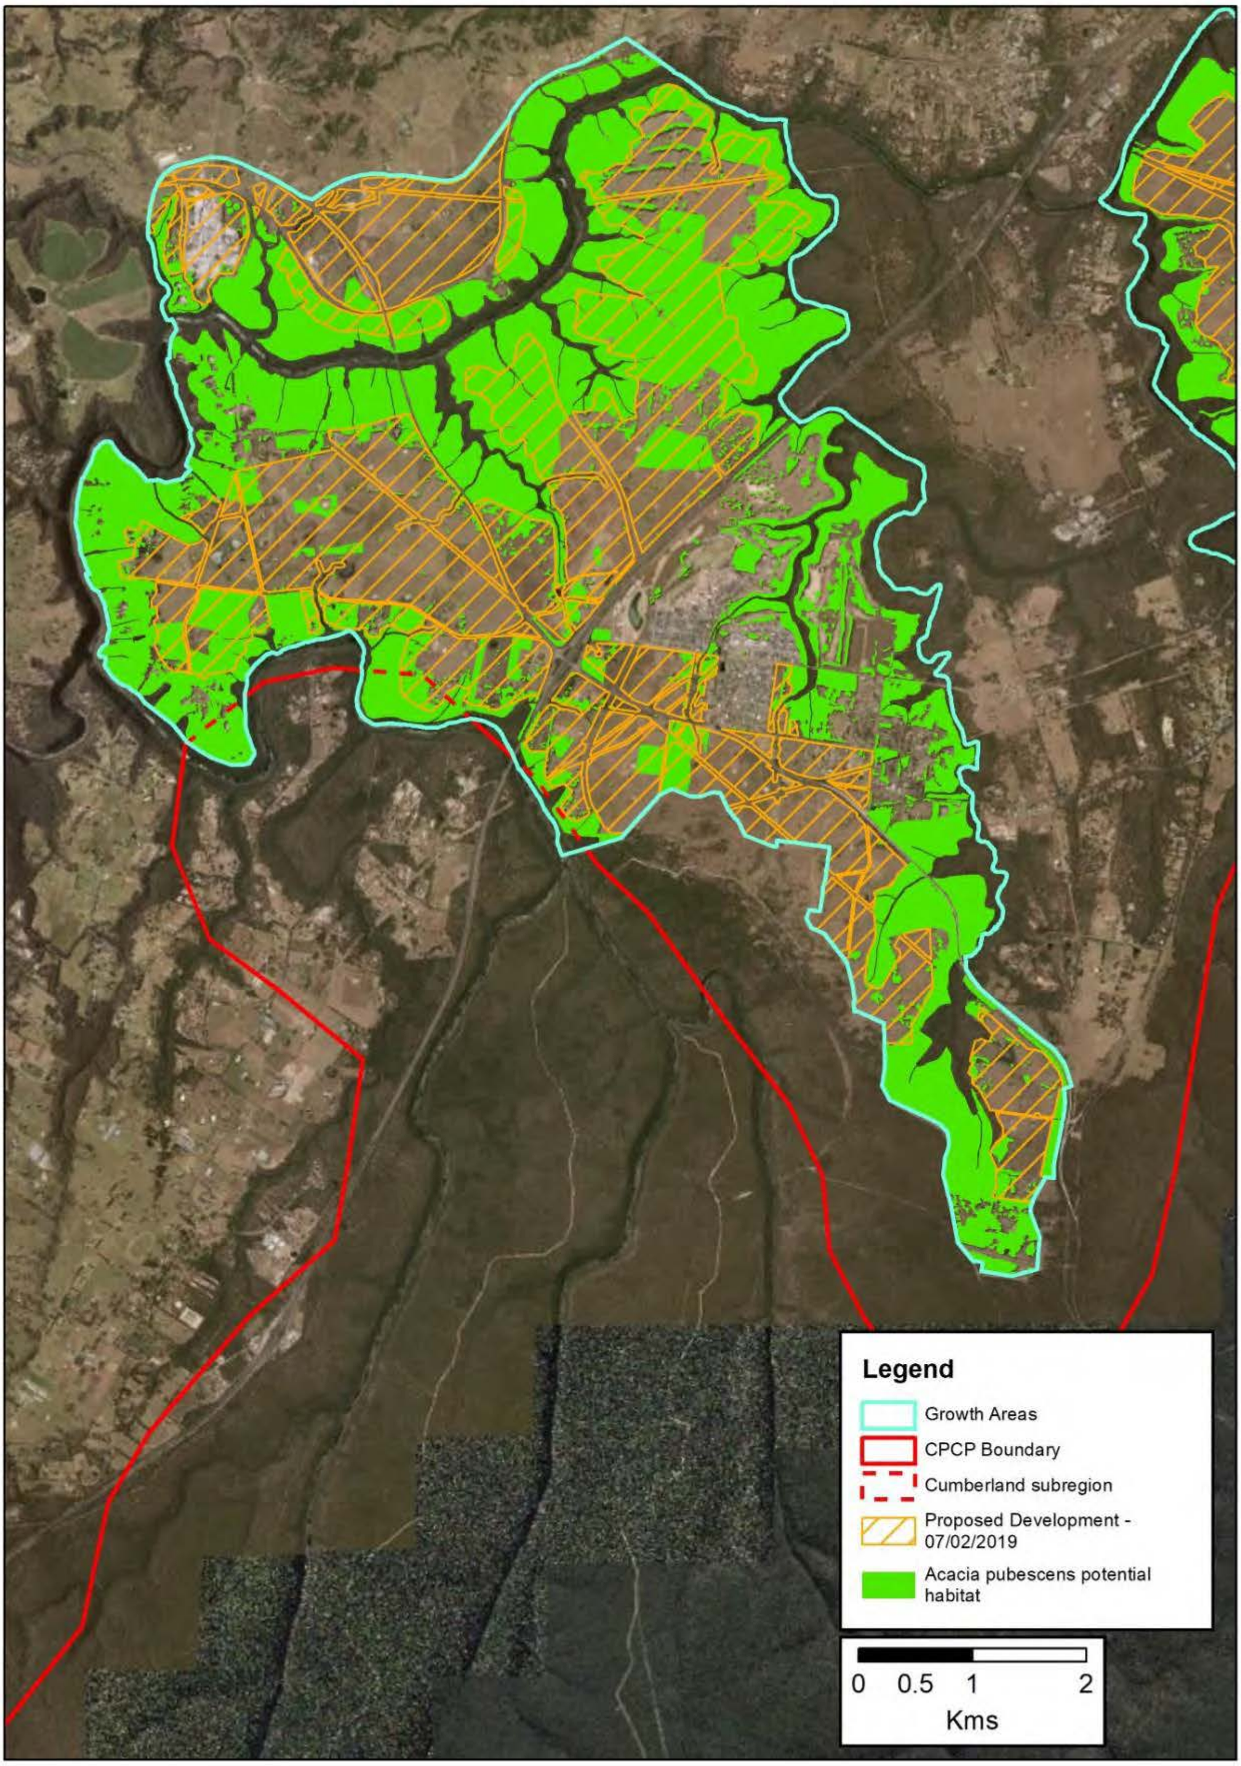
Table 16. Potential habitat and proposed removal of potential habitat by Growth Area

Growth Area	**Area of potential habitat (ha)**	**Area of potential habitat removal (ha)**	**% area of potential habitat removal by GA**
Greater Penrith to Eastern Creek	2640.4	105.6	4.0
Western Sydney Aerotropolis	721.4	325.4	45.1
Greater Macarthur	2364.2	251.4	10.6
Wilton	1742.7	543.5	31.2
Transport corridors **(all GAs)**	-	277.7	3.7
TOTAL	**7468.8**	**1503.6**	**20.1**

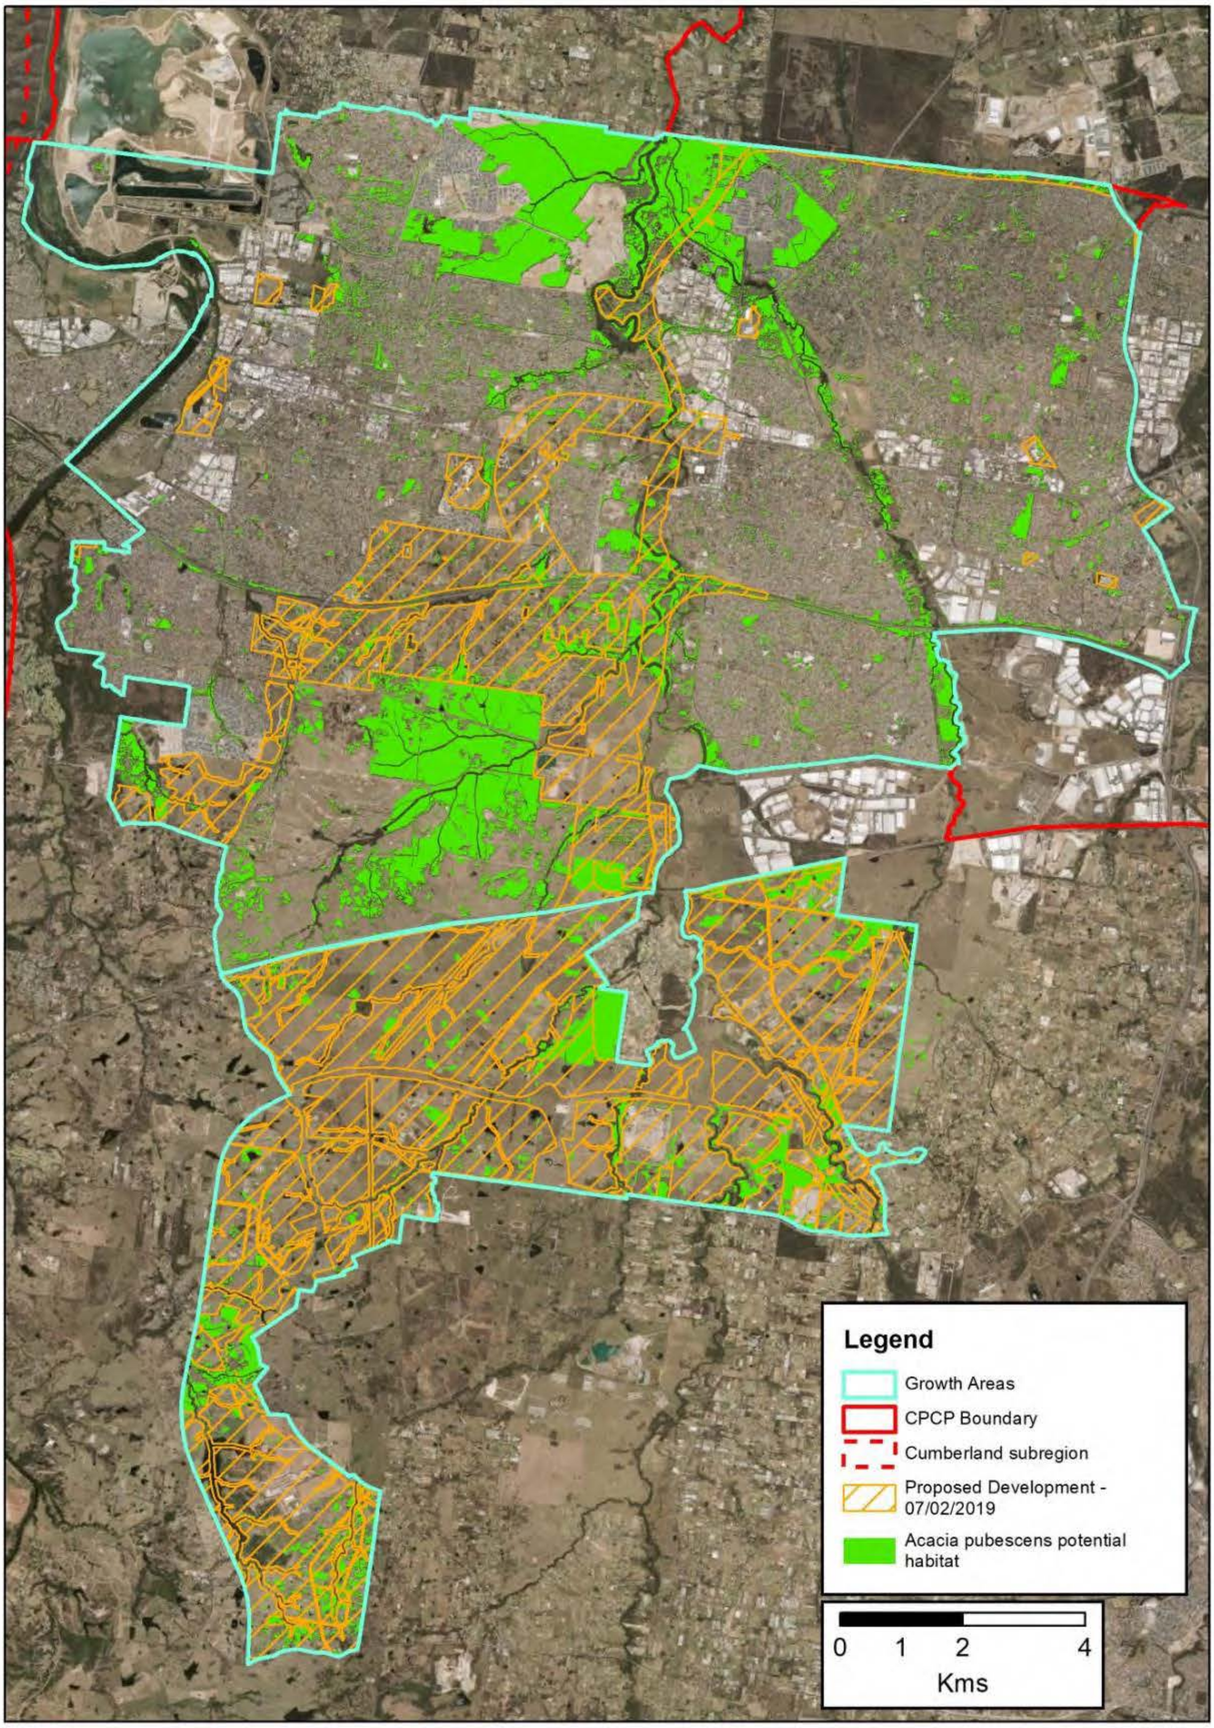
Map 9 Greater Macarthur - Potential habitat and proposed urban/transport habitat removal



Map 10 Wilton - Potential habitat and proposed urban/transport habitat removal



Map 11 Greater Penrith & Eastern Creek plus Western Sydney Aerotropolis
– potential habitat and proposed urban/transport habitat removal



5. Summary and conclusion

Within the four Growth Areas, *Acacia pubescens* is historically known from a single record in the Greater Macarthur Growth Area and from seven modern records (some apparent replicates) in a small area of the Greater Penrith to Eastern Creek Growth Area. Proximate records occur near all of the Growth Areas other than Wilton. Potential habitat exists across all of the Growth Areas and has been identified, ranked and mapped to generate 'species polygons' that inform calculations of biodiversity offsets and the design of the proposed urban footprint.

Based on current information, the proposed urban footprint and associated transport corridors of all four Growth Areas would destroy 1503.6 hectares of potential habitat for *A. pubescens*. This equates to 20.1% of the area of potential habitat identified in those Growth Areas. Not all of the area proposed for removal is of equal value as potential habitat, and different PCTs and condition classes have different probabilities of supporting *A. pubescens*. The actual extent of conflict between habitat for the species and proposed clearing for urbanisation is likely to be much smaller as the species is naturally rare and patchily distributed, even though it can be locally common where conditions are favourable.

As this species is relatively tolerant of significant disturbance and can persist as long-lived seedbank or as root suckers, it can occur in highly modified sites that may not be mapped as native vegetation, so are not captured by the PCT-based modelling of potential habitat used in this Report. It is likely that highly modified sites that might support the species in some form are of relatively low significance for it in the context of the much larger areas of more intact potential habitat that are excluded from urbanisation and associated clearing. It is also feasible that disturbance associated with urbanisation, particularly the creation of bushfire Asset Protection Zones between bushland conservation areas and housing, could advantage this species, especially where the habitat has not burnt for many years. More frequent, moderate intensity burning of bushland that represents known or likely habitat for this species, may, within limits, also advantage it compared to low frequency and/or very cool burning.

The positioning of the bushland/urban interface and associated infrastructure such as APZs should have regard to this species' habitat and ecology, and appropriate buffers and other strategies are required to prevent direct and indirect harm to this species as a result of the urbanisation of adjoining lands. For example, potential habitat should not be compromised by the placement of housing nearby as might prevent that habitat being managed for conservation, especially in terms of bushfire risk management. DPE has informed me that APZs would be accommodated within the proposed urban footprint, not in the non-biocertified bushland areas that may adjoin it.

The absence of records of this species from areas of potential habitat does not mean it could not be present. This is because:

- not all areas have been surveyed historically or recently;
- all surveys have a range of limitations, and recent efforts were likely constrained by drought;
- not all discoveries of threatened species are disclosed; and
- large areas of potential habitat are highly likely to have fire regimes that do not favour this species, meaning it may currently occur in very low numbers, in dense and inaccessible habitat, or as seedbank, yet could appear in substantial numbers after an appropriate fire or equivalent disturbance.

These factors have been considered in the preparation of the species habitat polygons that will inform DPE in relation to biodiversity offset obligations.

6. Information used in the assessment

6.1 DP&E or OEH resources

- BioNet data (internal access provided under license for use in this Expert Report and associated dataset cleaning for the purposes of species habitat modelling to meet EPBC Act requirements)
- Atlas of Living Australia on-line (partial use to check for records not in BioNet)
- EMU data (NSW Herbarium specimen database, provided by OEH)
- OEH on-line threatened species profile
- OEH Threatened Species Data Collection on-line
- OEH BioNet Vegetation Classification Database (previously known as VIS)
- EPBC Act Listing/Conservation Advice
- OEH PCT (vegetation) maps for Sydney Metropolitan and Cumberland Plain
- Field data from Biosis and Ecoplanning consultancies engaged by DPE
- GIS layers and maps provided by DPE and its contractors

7. Acknowledgements

I acknowledge the contributions of DPE staff, particularly Dayle Green, Greg Steenbeeke and Christian Marando (GIS), and DPE contractor Darren James (GIS) in the preparation and refinement of this document and associated maps. My contractor, Rhys Grogan, also assisted with GIS output in the form of drafts of the 'species polygons'.

Consultant botanist, Robert Miller assisted with fieldwork at Kemps Creek, and provided information about field observations associated with searches for his target species and with opportunistic sitings of my target species.

OEH staff assisted with some aspects of data availability and with the processing of many amendments to BioNet records.

8. Statement of professional independence

Whilst I was engaged and funded by DPE to prepare this Expert Report, and draft reports and maps were reviewed by DPE staff, I was not coerced by DPE to amend my work in any manner that I did not otherwise agree with. I believe that I had appropriate professional independence in the preparation of this document and associated maps.

I also declare that I do not have any personal or commercial conflict of interest in the preparation of this Report. I do not own real estate or businesses with property in the Growth Areas, nor do I have other active clients with real estate or associated commercial interests in the Growth Areas.

9. Appendix 1. Author's *Curriculum Vitae*

Dr Steven Douglas (BSc., MEnv. Plan., PhD.)

I have over twenty years of experience as an ecologist and environmental planner, primarily in New South Wales, with some experience in the ACT, Victoria and South Australia. I have worked for all levels of government, for environmentalist non-government organisations (NGOs), and for a large number of private clients ranging from individuals to multinational firms, directly and as a subcontractor. I have often worked as a sole consultant but have also collaborated with other specialists and have sometimes been part of large teams involved in large-scale, even interstate projects.

I specialise in the detection, management and conservation of rare and threatened flora species and communities, and in associated ecological impact assessment and mitigation.

I have qualifications and experience in a range of general and specific ecological, social, organisational and 'sustainability' fields.

I have served on environment-related ministerial committees and have held other ministerial appointments in NSW, including those dealing with bushfire management.

I have published in journals dealing with plant conservation, environmental law and policy, social science, and ecological ethics. Aspects of my work have been published by government, prominent NGOs, and in the popular press and other media.

This CV only contains content directly related to my botanical expertise.

Employment summary

1996 to present:

Self-employed, trading as *Ecological Surveys & Planning* (www.ecologicalsurveys.net)

Through this enterprise, I have undertaken a large number of consultancies for public and private sector clients including environmental impact assessment and mitigation; threatened biota research, profiling and management; vegetation mapping; preparing management plans for conservation estate; providing environmental planning and catchment management advice; advising on bushfire risk management; acting as an expert witness in Land & Environment Court proceedings; and developing organisational sustainability policies and practices.

July 2017 to July 2018:

Senior Ecologist, NSW Office of Environment & Heritage (NVIS, Science Division)

My work on the project below led to OEH retaining my services to research and document problems with the description, interpretation and mapping of Threatened Ecological Communities (TECs) statewide. This project provides advice to OEH, the NSW Threatened Species Scientific Committee, and through those agencies, to the Commonwealth Threatened Species Scientific Committee. It identifies technical issues with the description of TECs and their mapping, as well as wider problems of how TECs are defined. It draws on a major project undertaken by OEH for the NSW EPA and Forestry Corporation, in which TECs of the east coast and ranges were assessed and mapped for regulatory purposes on forestry estate. However, my work includes many more TECs and recent information emerging from Save Our Species project panels.

November 2015 to July 2017:

Team Leader, NSW Office of Environment & Heritage (NVIS, Science Division)

This project in Wingecarribee Shire is the first in which OEH's vegetation mapping team has worked at a very fine scale for a single local government area. The project entails auto-segmentation of digital aerial photography; supervising contract vegetation sampling; conducting strategic sampling; modelling of most vegetation communities; describing new communities; and extensive remote and on-ground map validation. I was hired partly because of my extensive familiarity with much of the vegetation of this geodiverse and biodiverse region. The role included supervision of two staff; liaison with consultants; and substantial networking with OEH and Wingecarribee Council staff. An update of vegetation classification will occur from mid 2019 onwards, and I have drafted a peer-reviewed journal article about the project that will be submitted for publication.

1995/6:

Project consultant, then Project Manager, Urban Bushland Biodiversity Survey (NPWS)

The Urban Bushland Biodiversity Survey was undertaken by the NPWS to compile comprehensive data on indigenous flora and fauna in twelve local government areas in Western Sydney. Contracted initially as a consultant to design and scope the project, I was later employed as Project Manager. Responsibilities involved an extensive literature review, preparation of a project plan and a background paper for the Survey and the overall management of the project including up to twelve staff and several consultants. The major focus was on coordinating research work, fauna and flora field surveys, and a community liaison and media campaign. Extensive flora survey work and scientific data analysis was undertaken. I provided a tour of important vegetation sites for the South Creek Catchment Management Committee. I also wrote media releases and conducted various media events including a live-to-air interview on ABC Radio National, and filming of a story in the field for the Totally Wild program.

1994:

Catchment Environment Officer (*Hawkesbury City Council*).

The project was funded by a grant from the former Hawkesbury-Nepean Catchment Management Trust and had the objective of identifying land uses on riverside properties to assess their potential to generate water pollution. The information on land use and riparian vegetation was primarily gained from aerial photo interpretation, limited land-based inspections and several water-based inspections, and was recorded in a GIS. Work site inspections, pollution control on agricultural lands, community meetings, site visits with landowners, and facilitating the formation of a Landcare group in the Sackville area.

1993/4:

Technical Officer (*Hawkesbury-Nepean Catchment Management Trust*).

Work included assisting with the preparation of a vegetation management strategy for the Trust and the outline of a revegetation strategy for South Creek. Other responsibilities involved providing scientific advice for development assessments, the preparation of hard copy and computer-based catchment maps, and advising on the implementation of revegetation projects in the catchment.

Ministerial appointments

- Appointed a member of the **National Parks & Wildlife Service Regional Advisory Committee** (South Coast) (2010-mid 2018). I opted not to reapply for this role after serving two terms. The restructure of the NPWS meant that the Committee would operate from Wollongong to the Victoria border and inland to the Tablelands. This was logistically fraught, and the role of RACs was evidently being diminished, with larger areas to manage but less meetings held.
- Appointed a member of the **NSW Sustainability Network** (2001), part of the Sustainability Advisory Council reporting to the Minister for Planning. I did not take up this position due to my relocating to Victoria.
- Nature Conservation Council representative on the former NSW **Native Vegetation Advisory Council** (1999-2001) reporting to the Minister for Land & Water Conservation under the Native Vegetation Conservation Act. I served as a member of the Regional Vegetation Planning Subcommittee, which amongst other matters, reviewed draft Regional Vegetation Management Plans and Codes of Practice for activities such as native forestry and timber plantations. I was particularly involved in reviewing and recommending amendments to the Code of Practice for plantation forestry. I resigned due to my relocating to Victoria.
- Nature Conservation Council representative on the former **Southern Catchment Management Board** (June 2000 - March 2001). I resigned due to relocating to Victoria. I expressed my dissatisfaction with the design of the catchment boards and recommended to the Minister that they be replaced with the Catchment Management Authority model used in Victoria. The Boards were later replaced with such Authorities.
- Nature Conservation Council representative on Baulkham Hills and Hornsby-Ku-ring-gai **District Bushfire Management Committees** (1995-2001).
- Australian Conservation Foundation representative on the former **Environmental Works Community Audit Committee** reporting to the Minister for Environment in relation to the Special Environment Levy imposed by the then Water Board (1993-5). I completed my term when the Committee concluded its business and dissolved upon acceptance of its final report by the Minister.

Tertiary qualifications & titles

Adjunct Research Fellow

School of Philosophical, Historical & International Studies, Monash University, 2014-16

Doctor of Philosophy

Fenner School of Environment & Society, The Australian National University, 2004-7

The research was undertaken in the transdisciplinary Human Ecology Program and covered fields such as ecological philosophy, ecotheology, environmental policy-making, policy evaluation, organisational change, and critical systemic analysis. My thesis was passed unanimously and unamended by one Australian and two USA-based professors. I was awarded a $10,000 Publication Fellowship by the Fenner School and have since published aspects of my research.

Master of Environmental Planning

Macquarie University Grad. Sch. Env., 1994-96

This course included environmental law and politics, community involvement in planning, environmental education, development approval processes, urban planning, EIA, environmental science/fieldwork and heritage management. The dissertation component involved a pioneering report on the significant flora of the Greater Cattai Region (Cattai subcatchment) in north-western Sydney and led to my being offered employment with the NSW NPWS to design and manage a biodiversity survey of western Sydney.

Bachelor of Science

Macquarie University, 1990-93

My degree majors are Resource and Environmental Management, Land Management, and Plant Biology/Ecology.

Graduate Certificate of Research Information Literacy

The Australian National University, 2004-7

This course included advanced word processing, citation management, literature gathering (including on-line literary databases and other Internet sources), on-line publishing, presentation software, and thesis production.

Professional memberships

- Founding member of the Ecological Consultants Association of New South Wales (did not renew due to my relocating to Victoria and later to the ACT).
- Member of the NSW Environmental Defenders Office (EDO) Scientific Advisory Service (continuing).

Threatened biota experience

The following threatened plant species and populations and threatened ecological communities (TECs) have been engaged with in the various forms and processes listed below. The list is not complete, and some processes are on-going. I also successfully nominated three Key Threatening Processes under the TSC Act: Bushrock Removal; Clearing of Native Vegetation; Competition from European Honey Bee.

Species / population	Work conducted
Acacia bynoeana	Fieldwork, research, successful nomination, monitoring, advice to authorities, expert witness, rediscovered lost population, documented new population near range limit, PAS2 review, SOS review panel, review and amendment of BioNet dataset. Recognised by OEH as a species expert under BC Act (Nov 2018).
A. gordonii	Fieldwork, successful nomination, advice to NPWS, PAS2 review, SOS research and monitoring program (fire ecology, BMtns NP), review and amendment of BioNet dataset.
A. prominens	Successful nomination of Endangered Population
A. pubescens	Fieldwork, contribution to Recovery Plan, confirmed disjunct southern populations, nominated population, PAS2 review, review and amendment of BioNet dataset. Nominated by DPE and recognised by OEH as a species expert under BC Act (Nov 2018).
Ancistrachne maidenii	Fieldwork, research, successful nomination, advice to NPWS, CAM review
Asterolasia elegans	Fieldwork, species profile, advice to Council and NPWS
Baloskion longipes	Research linked to *Carex klaphakei*, review of BioNet records, advice to OEH
Boronia deanei	Research, SOS review, CAM review, advice to OEH
Bossiaea oligosperma	SOS fieldwork, review of records (NW population), report to OEH, establishment of monitoring plots in Yerranderie SCA
Callistemon linearifolius	Fieldwork, research, successful nomination, advice to RMS and NPWS, PAS2 review
Callistemon megalongensis	Co-described new species, successful nominations (listing then upgrade), fieldwork, advice to Council and OEH, PAS2 review, SOS monitoring program (OEH, BMCC, on-going)
Callistemon purpurascens	Described new species, fieldwork, successful nominations, advice to Council and OEH, SOS monitoring project (2018 on-going)
Calotis glandulosa	Fieldwork (new and extended populations, Kosci NP), CAM review
Calotis pubescens	Fieldwork (new population, Kosci NP), CAM review

Species / population	Work conducted
Carex klaphakei	SOS research project and recommendation for monitoring; resolved errors in BioNet records
Commersonia prostrata	PAS2 / PKF research, fieldwork, advice to NPWS and OEH, documentation and monitoring of new and known populations for Forestry Corp, designed recovery actions for populations in Wingello and Penrose SFs
Cullen parvum	Fieldwork, located new NE population, report to NPWS
Dampiera fusca	Research, fieldwork, successful nominations, monitoring program for ACT Parks & Conservation, advice to NPWS and OEH, CAM review
Darwinia biflora	Fieldwork, research, contributor to Recovery Plan, PAS2 review, review and amendment of BioNet dataset.
Darwinia glaucophylla	Fieldwork, research, successful nomination, advice to NPWS, PAS2 review
Darwinia fascicularis ssp. *oligantha*	Fieldwork, research, successful nomination of population
Darwinia peduncularis	Research, successful nomination, CAM review
Dillwynia tenuifolia	Fieldwork, research, successful population nominations, advice to OEH
Epacris purpurascens var. *purpurascens*	Fieldwork, research, nomination, new SW range limit (Nattai NP), advice to NPWS/OEH
Eucalyptus aggregata	Research, successful nomination of species and population, fieldwork (Wingecarribee Shire) and advice to Council and OEH, CAM reviews
E. aquatica	Fieldwork, advice to Council and Forestry Corporation
E. sp. *Cattai*	Successfully argued for recognition of this entity as a new species, successful nomination, fieldwork, PAS2 review, advice to OEH, SOS project panel
E. kartzoffiana	Fieldwork, research, expert witness
E. macarthurii	Fieldwork, research, successful nominations, advice to Council and OEH
E. parvula	Fieldwork (Wadbilliga NP), CAM review
E. pulverulenta	Fieldwork (Bredbo Hills), CAM review
Galium australe	PAS2 research, recommended taxonomic review of most records in NSW based on Herbarium assessment, advice to OEH, CAM review
Grevillea juniperina ssp. *juniperina*	Fieldwork, research, advice to OEH (Colebee NR offset site)
Grevillea molyneuxii	Fieldwork, advice to OEH for CAM review
Grevillea parviflora ssp. *parviflora*	Fieldwork, research, expert witness, review and amendment of BioNet dataset.
Grevillea parviflora ssp. *supplicans*	Fieldwork, research, nomination, advice to NPWS
Grevillea raybrownii	Fieldwork, research, nomination and advice to NSWSC – listing pending
Gyrostemon thesioides	Successful nomination

Species / population	Work conducted
Helichrysum calvertianum	Fieldwork, research, nomination, advice to NSWSC – listing pending
Hibbertia fumana	Research, minor fieldwork, expert witness
*H. incana (*syn. *superans)*	Successful nomination of population then species
H. praemorsa	ROTAP, researched, fieldwork (informal)
H. puberula ssp. *furcatula*	Fieldwork (incidental) documenting new occurrence, advice to OEH/NPWS
H. puberula ssp. *puberula*	Research, minor fieldwork with R. Miller, expert witness
Homoranthus binghiensis	CAM review (recommended changing to CE)
Keraudrenia corrolata var. *denticulata*	Successful nomination of population
Lasiopetalum joyceae	Fieldwork, research, successful nomination, species profiling for Council and NPWS, PAS2 review
Leptospermum deanei	Fieldwork, research into hybridization with *L. trinervium*, advice to RBG, Council, OEH
Leucopogon fletcheri ssp. *fletcheri*	Fieldwork, research, successful nomination, advice to OEH and NPWS
Melaleuca deanei	Research, fieldwork, successful nominations, advice to NPWS/OEH and species profile for Council, review and amendment of BioNet dataset. Nominated by DPE and recognised by OEH as a species expert under BC Act (Nov 2018).
Olearia cordata	Fieldwork and report to NPWS, PAS2 review
Persoonia acerosa	Fieldwork, PAS2 review, SOS monitoring plots, advice to Council and OEH
Persoonia bargoensis	Fieldwork, research, successful nomination, PAS2 review, CAM review, review and amendment of BioNet dataset.
Persoonia hirsuta	Fieldwork, research, nominations of species and population, PAS2 review, review and amendment of BioNet dataset.
Persoonia glaucescens	Fieldwork, nomination, report to NPWS, PAS 2 review, CAM review, review and amendment of BioNet dataset.
Persoonia marginata	Fieldwork and report to OEH, CAM review
Persoonia mollis ssp. *revoluta*	Fieldwork, research, advice to OEH and Forestry Corp., nomination as Vulnerable - listing pending
Persoonia nutans	Fieldwork, nomination, advice to OEH, review and amendment of BioNet dataset. Nominated by DPE and recognised by OEH as a species expert under BC Act (Nov 2018).
Phyllota humifusa	PAS2 fieldwork and research; advice to NPWS, OEH, Council, Forestry Corp (monitoring plots, reduced APZ width), review of BioNet dataset.
Pimelea curviflora var. *curviflora*	Fieldwork, research, successful nomination, advice to OEH

Species / population	Work conducted
Pomaderris brunnea	Incidental fieldwork and documentation of new populations and range extension; review and amendment of BioNet dataset.
P. cotoneaster	Fieldwork, research, advice to Council, NPWS, OEH, liaise with ANBG seed collectors, CAM review
P. sericea	PAS2 research (review of records and habitat), recommended consideration of Presumed Extinct or at least CE
Pultenaea elusa	PAS2 research (review of records and habitat), recommended Presumed Extinct
P. glabra	SOS fieldwork and monitoring plots. Review of Mts Wilson/Irvine records resulted in these being reallocated to an undescribed species given the interim name, *P. monticola*.
P. parviflora	SOS fieldwork and report to OEH (Colebee NR offset site); review and amendment of BioNet dataset.
P. pedunculata	Fieldwork, research, expert witness, CAM review
Solanum armourense	PAS2 fieldwork, research, report, advice to OEH, CAM review
S. celatum	Fieldwork, research, new populations (new range limit and habitat), advice to OEH, CAM review
Tetratheca glandulosa	Fieldwork, PAS2 review, advice to OEH and Cwlth DEE re conservation status
Triplarina nowraensis	SOS fieldwork, review of BioNet records, advice to OEH/NPWS, establishment of monitoring plots
Zieria involucrata	Fieldwork, input to Recovery Plan, CAM review
Zieria murphyi	Liaise with ANBG, fieldwork, advice to OEH

Threatened Ecological Communities (TECs)

My work for OEH in reviewing all NSW and EPBC Act TECs in the State has given me at least some familiarity with most of these entities and builds on already-strong knowledge of some. I have also been an expert witness in cases involving some of these communities – some entailing basic reviews and advice, and others involving in-depth considerations. All of the EPBC Act parallel listings are not included here unless I was involved in a particular nomination:

Ecological community	Nature of engagement
Blue Gum High Forest	Successful nomination, expert witness
Blue Mountains Basalt Cap Forest	SOS panel
Blue Mountains Shale Cap Forest	Successful nomination, SOS panel
Blue Mountains Swamps	Fieldwork, mapping, advice to BMtns Council, modelling
Castlereagh Scribbly Gum Woodland	Successful nomination, advice to DEE re Cwlth listing, expert witness
Cooks River / Castlereagh Ironbark Forest	Advice to DEE for EPBC Act listing
Cumberland Plain Woodland	Correction of OEH mapping, fieldwork, assessments, advice to Councils and NPWS
Eastern Suburbs Banksia Scrub	Major review for DEE Recovery Plan update, advice to OEH
Elderslie Banksia Scrub Forest	Major review for DEE Recovery Plan, SOS panel
Illawarra Lowlands Grassy Woodland	DEE review panel for EPBC Act listing
Lowland Grassy Woodland & Forest of SE Corner Bioregion	Successful nomination
Maroota Sands Swamp Forest	Successful nomination, SOS panel
Melaleuca armillaris Tall Shrubland	fieldwork, mapping, advice to OEH
Montane Peatlands & Swamps	Fieldwork, modelling and mapping, advice to OEH
Mount Gibraltar Forest	Detailed review for modelling and mapping, and advice about revised listing, advice to DEE re Upland Basalt Eucalypt Forest inclusion of NSW TECs
O'Hares Creek Shale Forest	Research and review for modelling and mapping
Pittwater & Wagstaffe Spotted Gum Forest	Successful nomination
Riverflat Eucalypts Forest on Coastal Floodplains	Successful nomination (component), research, modelling and mapping (limited extent)
Robertson Basalt Tall Open-forest	Modelling and mapping, advice to NSW SC

Ecological community	Nature of engagement
Robertson Rainforest	Modelling and mapping
Shale/Gravel Transition Forest	Mapping, TEC review
Shale/Sandstone Transition Forest	First to describe this concept c. 1996 based on Masters research. Formally published as a concept in NPWS (1997, UBBS). Successful nomination, research, major review and advice to DEE for EPBC Act listing, modelling and mapping
Southern Highlands Shale (Forest &) Woodland	Major contributor to DEE listing, drafting of Listing and Conservation Advices, advice to OEH about revision of NSW listing, modelling and mapping. Contracted to prepare listing for upgrade to CE.
Subtropical & Temperate Coastal Saltmarsh (EPBC Act)	Funded to prepare successful nomination
Sun Valley Cabbage Gum Forest	Successful nomination, mapping, advice to Council, SOS project panel
Swamp Sclerophyll Forest on Coastal Floodplains	Allied major research project cited in the Final Determination, TEC review (gap analysis)
Sydney Turpentine Ironbark Forest	Successful nomination, mapping, advice to Councils and to OEH/SC about revision
Tablelands Basalt Forest	Research, expert witness, advice to OEH about revision, modelling and mapping
Tablelands Snow Gum…Grassy Woodland	Fieldwork documenting new occurrences, modelling and mapping, advice to OEH
Upland Basalt Eucalypt Forest (EPBC Act)	Major contributor to DEE listing of this composite community that includes several NSW TECs. Draft Listing and Conservation Advices
Western Sydney Dry Rainforest and Moist Shale Woodland	SOS panel, TEC review

- **NSW NPA** Biodiversity Audit of the proposed Dyarrabin Nature Reserve (~2000 ha) - Project Co-ordinator
- **NSW NPA** Proposal for the creation of Dyarrabin Nature Reserve; revised submission and report of the second NPA Biodiversity Audit
- Preliminary flora study of Crown lands (Functional Area 1), Cattai Ridge Road, Halcrows Road, Hillside/Glenorie; submission to Director NPWS and to Baulkham Hills Council. **NSW NPA**
- Flora survey of Morans Rock Crown lands for proposed addition to Wollemi National Park. **NSW NPA**

- Proposed Welcome Reef Dam (Shoalhaven River north of Braidwood) - assist with flora and fauna surveys. **NSW NPA**. Much of the area is now within Nadgigomar Nature Reserve
- Flora survey of surplus Department of Education lands at Ellerman Park, Round Corner. The local community proposed that the area become a reserve to protect a critically endangered plant community present on the site. **Friends of Ellerman Park**
- Flora survey of Crown lands at South Maroota for proposed Crescent Reach Nature Reserve (later declared as the Maroota Ridge State Conservation Area), **NSW NPA**
- Calangara Nature Reserve Proposal in Kenthurst. Survey and report to **NSW NPA**
- Preliminary Survey of bushland in Holland Reserve, Glenhaven
- Survey of Crown Reserve (now part Scheyville NP), Pitt Town; report to **NSW NPA**

Expert report – Cumberland Plain Land Snail

Expert report on the Cumberland Plain Land Snail, *Meridolum corneovirens* (Pfeiffer, 1851) in the Penrith, Western Sydney Aerotropolis, Greater Macarthur and Wilton Growth Areas, Stephanie A. Clark, December 2018

Strategic assessment for Cumberland Plain Conservation Plan

Expert report on the Cumberland Plain Land Snail, *Meridolum corneovirens* (Pfeiffer, 1851) in the Penrith, Western Sydney Aerotropolis, Greater Macarthur and Wilton Growth Areas.

Prepared for the New South Wales Department of Planning & Environment

Stephanie A. Clark

Contents

1. Introduction

1.1 Project context

The Department of Planning and Environment is currently preparing a strategic assessment to identify development impacts and conservation outcomes within four new urban growth areas on the Cumberland Plain in Western Sydney. Expert reports may be used as part of the threatened species assessment as outlined in the Biodiversity Assessment Method (BAM).

The BAM requires surveys for all 'Species Credit Species' (SCS) identified as likely to occur in the study area unless an expert report is prepared, or the species is assumed to be present. The Department of Planning and Environment engaged Biosis and Ecoplanning to undertake surveys for candidate SCS within the growth areas in accordance with the BAM and Office of Environment and Heritage (OEH) threatened species survey guidelines. Surveys were undertaken over the period November 2017 to November 2018.

1.2 Purpose of the expert report

Large areas of suitable habitat were unable to be surveyed due to land access issues and the snail is an uncommon species that can easily be misidentified. For these reasons an expert report on *Meridolum corneovirens* was required to supplement the data collected as part of the survey effort.

The purpose of this report is to provide an assessment of the current status and potential presence of *Meridolum corneovirens* within four defined Growth Areas of Western Sydney and to determine whether:

a) The species is unlikely to be present and thus requires no further assessment; or
b) The species is known or likely to be present, and if so the report must provide estimates of potential habitat within the Growth Areas and the proposed urban development zones.

1.3 The study area

The strategic assessment covers four growth areas in Western Sydney:

- Greater Penrith to Eastern Creek Urban Investigation Area
- Western Sydney Aerotropolis Growth Area
- Greater Macarthur Growth Area
- Wilton Growth Area

The Greater Penrith to Eastern Creek and Western Sydney Aerotropolis Growth Areas are located in the western part of the Sydney Metropolitan Area between Llandilo in the north and Bringelly in the south and Emu Heights in the west and Eastern Creek in the east. The Greater Macarthur and Wilton Growth Areas are located in the south western part of the Sydney Metropolitan Area, between Casula in the north and Wilton in the south and Tahmoor in the west and Holsworthy in the east (see Figure 1).

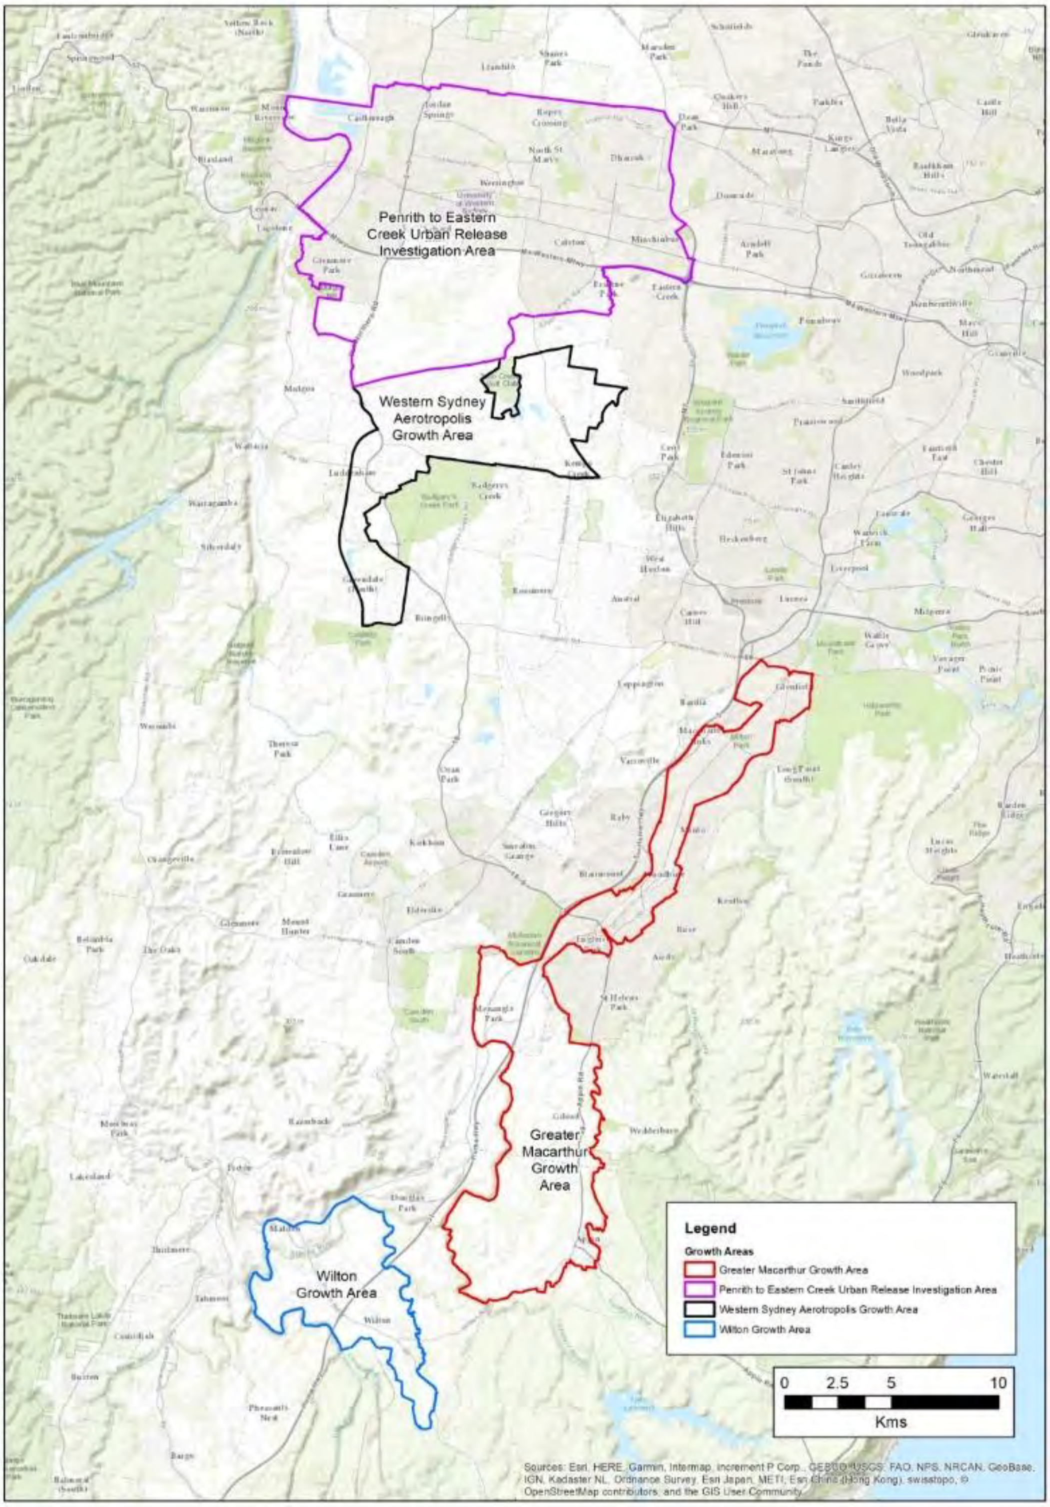

Figure 1. Showing the location of the four growth areas.

1.4 Reasons for use of an expert report

An expert report for *Meridolum corneovirens* is required as part of the threatened species assessment for the Cumberland Plain Conservation Plan for the following reasons:

1. Large areas of habitat were not able to be surveyed. Not all land holders allowed ecologists to enter their property and conduct BAM surveys or targeted fauna surveys. This restricted the opportunity to visit all potential areas of habitat within the proposed development footprint, especially within the Greater Macarthur Growth Area. The initial surveys focussed on flora species and did not specifically target *Meridolum corneovirens.*
2. Section 4.4 of the NSW Guide to Surveying Threatened Plants (OEH 2016) provides for the consideration of 'site survey and an expert report' where areas are large. This species has been searched for during the survey but is very cryptic. Preparation of an expert report will supplement the field surveys to identify the area of occupancy and likely density of individuals.
3. The species' relatively small size, its cryptic habitat, its ability to remain dormant in unfavourable environmental conditions and it can be easily overlooked/missed by non-specialists.

1.5 Credentials of expert

Dr Stephanie Clark is an invertebrate taxonomist with more than 30 years of experience in the identification and taxonomy of molluscs (and in particular gastropods). She currently consults worldwide on invertebrate identification through her business Invertebrate Identification Australasia.

Dr Clark was the first expert to be approved by OEH as an Expert under section 6.5.2.4 of the Biodiversity Assessment Method on the 15 May 2018 (valid for the next six years). A resume is included in the Appendix.

2 Species information

2.1 Species description

The shell is globose to subglobose in shape (Figure 2), up to about 24mm in height and 29mm in width. Spire moderately elevated. Aperture roundly ovate, up to about 14mm in height and 19mm in width. Total number of whorls 4.8–5.7. Last teleoconch whorl rounded, or with slight angulation; up to about 21mm in height. Shell sculpture consists of coarse growth lines and weak pustules. Teleoconch periostracal sculpture of weak zigzag ridges. Protoconch sculpture weakly pustulose. Shell uniform brown to tan or olive green, darker coloured individuals not uncommon. Red umbilical patch typically absent, occasionally faintly present. Red subsutural band very thin. Inner lip white (rarely pale pink), strongly reflected, largely occluding umbilical depression in adults, lip thin and not reflected in juveniles. Outer lip moderately deflected below midline of last whorl. Umbilicus closed to slightly open in adults, open in juveniles (modified from Clark, 2009).

The colour of the body of the snail is grey and the mantle is pale yellow (typical) to yellow.

Figure 2. Specimen of *Meridolum corneovirens* from Mulgoa.

2.2 Life cycle

Little is known of the biology, fecundity and longevity for the species. It is a hermaphrodite and capable of selfing, it lays clutches of about 20-25 small, round, white eggs in moist, dark places (Clark, 2009, Ridgeway *et al*., 2014), such as at the base of grass clumps and under logs (Figure 3). The snails probably live between 2-5 years but can certainly estivate in the soil or under logs etc for several months, especially when conditions are dry, such as those prevailing in Sydney in 2018. They feed predominately on fungi, but have been observed eating fresh dead individuals of *M*. *corneovirens* and other carrion, paper, plant detritus and old shells (Clark, personal observations; Ridgeway *et al*., 2014).

The snails are generally active at night or on moist, warm overcast days.

A  B. 

Figure 3. A. *Meridolum corneovirens* laying eggs in a grass clump at Mount Druitt. B. Three egg clutches of *Meridolum corneovirens* that were found under a log at Kemps Creek.

2.3 Distribution and abundance

Meridolum corneovirens is endemic to the Cumberland subregion in the western portion of Sydney, from Pitt Town in the north to Tahmoor in the south and from Georges Hall in the east to Mowbray Park in the west (Clark, 2005; 2009, NSW OEH Cumberland Plain Land Snail – profile). The total number of individuals of *M*. *corneovirens* across its range is unknown, nor the densities that the species can occur. The species can be relatively common when suitable habitat is present. However, most known populations are found on relatively small, isolated patches of habitat that are often surrounded by some combination of industrial, agricultural or urban development.

2.4 Habitat requirements

Meridolum corneovirens is wholly restricted to western Sydney and is primarily associated with the critically endangered Cumberland Plain Woodland ecological community. However, it has also been found in the following listed ecological communities: Moist Shale Woodland, Shale Gravel Transition Forest, Shale Sandstone Transition Forest, Cooks River/Castlereagh Ironbark Forest, Castlereagh Scribbly Gum Woodland, Castlereagh Swamp Woodlands and the margins of River-flat Eucalypt Forest. It can be found in leaf litter, grass tussocks, under logs and non-natural debris such as cardboard and old furniture etc. Where conditions permit it will bury into loose soil up to 10 cm such as under logs and around the bases of trees (Clark, 2009; Ridgeway et al., .2014).

3 Description of the study area

3.1 Land use history

From the early 1800s there has been extensive clearing of the native vegetation for agricultural, industrial and urban development, which has resulted in a significant reduction in the extent of the native vegetation, leading to increased fragmentation and isolation of the remaining remnants. This increased fragmentation has led to a loss of biodiversity and to the spread of invasive and non-indigenous species.

The extensive clearing, fragmentation and degradation of the remaining vegetation remnants has led to a reduction in the distribution, extent and abundance of *M. corneovirens* that existed prior to European settlement.

3.2 Landscape context

The majority of the study area consists of gentle undulating hills and valleys and is bounded by the sandstone cliff lined valleys of the Nepean River on the western, southern and south western boundaries and the Georges River on the south eastern boundary and the Cecil Hills Ridge and the Castlereagh sand deposits along the northern and eastern boundaries.

3.3 Native vegetation communities

Meridolum corneovirens inhabits a range of vegetation types across the study area, although most typically it is found in the Cumberland Plain Woodlands.

Meridolum corneovirens has been recorded from the following plant communities which are found within one or more of the four growth areas:
724 – Broad-leaved Ironbark – Grey Box – *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain;
725 –Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion;

830 - Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain;
835 - Forest Red Gum – Rough Barked Apple grassy woodland on alluvial flats of the Cumberland Plain;
849 - Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain;
850 - Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain;
1395 - Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain;

Meridolum corneovirens will potentially be found in any remaining intact or relatively intact remnants / patches of suitable habitat, especially if there is a well-developed leaf litter layer, plenty of woody debris on the ground and few exotic/invasive species. It can also be found at the boundaries of plant communities that do provide suitable habitat and those that typically do not such as where Cumberland Plain Woodland adjoins Swamp Oak Floodplain Forest in the western parts of the Cumberland Subregion.

4 Assessment of species presence and habitat

4.1 Existing records and surveys

Meridolum corneovirens has previously been recorded from a number of locations across the Greater Penrith to Eastern Creek, Western Sydney Aerotropolis and Greater Macarthur Growth Areas but not to date in the Wilton Growth Area (Clark, 2009, Bionet, 2018, Clark, personal observations from 1998-2002) (Figures 4-6).

To the best of the author's knowledge there have been no region-wide surveys for *M. corneovirens* across the four growth areas or the entire range of the species since 1999 when the author was asked by NPWS to survey 130 sites across the greater Sydney area. During this survey the species was detected at 61 sites, of which 14 fall within the growth areas defined here (10 in Penrith, 4 in Greater Macarthur).

The majority of the previous records are from targeted surveys for development sites by the author and other consultants, general collecting by the author (89 sites), colleagues and other random observations by the general public, local and state government personnel.

4.2 Surveys completed for the biocertification

Targeted fauna surveys were completed by Biosis during the period November, 2017 to November, 2018. Surveys on foot covered a total area of 100 hectares across the four growth areas calculated by applying a 20m buffer either side of GPS survey tracks. This represents around 5% of the future development footprint (where surveys were concentrated) and around 1% of the total vegetated habitat within the growth areas (GIS analysis supplied by DPE, November 2018).

Meridolum corneovirens was found at three locations by Biosis staff. Two of these locations were previously known to the author, being south of Goldsmith Ave and Wianamatta Regional Park (formerly known as the ADI site). However, the conditions since the beginning of the biocertification process have been extremely dry and warm with well below normal rainfall. Although Ecoplanning and Biosis have conducted extensive surveys across the study area, the statistics above confirm that the vast majority of these surveys were botanical in nature and not targeted toward fauna species such as *M*. *corneovirens*.

The targeted fauna surveys that have been conducted by Ecoplanning and Biosis have been hampered by issues such as limited access to properties, extremely dry conditions, concentrating limited staff resources towards surveying for the larger threatened vertebrate species and a lack of specialised knowledge about *M*. *corneovirens*, resulting in low detection rates. In addition, there is a very similar looking, closely related species, *M*. *sheai* Clark, 2009, which can be found in the shale-sandstone transition forest and sandstone forest community types within the Greater Macarthur and Wilton Growth Areas.

4.3 Surveys completed for this assessment

The extended dry period, cold night time temperatures and access issues since 6 June, 2018 has made detecting *M*. *corneovirens* relatively difficult. Nonetheless, between 6-30 June and 30 October to 15 November, 2018, the author detected evidence for *M*. *corneovirens* at 23 locations (8 in the Greater Penrith to Eastern Creek Growth Area; 2 in the Western Sydney Aerotropolis Growth Area and 13 in the Greater Macarthur Growth Area) (Figures 4-6).

Attempts were made to verify a number of BioNet records from around Gordon Lewis Oval, Appin and along the southern side of the Nepean River, west of Elladale Creek, Appin but because of the extremely dry and cool conditions no evidence for the species was found. The author was unable to access the Macquarie Road Reserve, Ingleburn, due to the area being fenced off. Campbelltown City Council was contacted and were happy to provide access but unfortunately this was not possible on the day and it was decided to organise a site visit at a future to be determined date.

The vast majority of the individuals of *M*. *corneovirens* encountered were empty shells and fragments, while less than 20 living specimens, all juveniles and subadults were observed at 10 sites (four in the Greater Penrith to Eastern Creek and six in the Greater Macarthur Growth Areas). The largest number of living individuals observed at a site was 10 (juveniles and subadults) at Goldsmith Ave (within the Greater Macarthur Growth Area), after heavy rain earlier in the day. At the other nine locations only one or two living snails were observed and all were buried in the leaf litter or under logs and woody debris.

Within the Wilton Growth Area relatively little of the potential habitat was accessible and the only occasion that *Meridolum* was found was at the Shingle Hill property off Picton Rd on 20 June, where two very long dead specimens of what appear to be *M*. *sheai* were found. The day before staff from Biosis had recorded the presence of a number of individuals of *M*. *corneovirens* from the more open areas of the property between a farm dam and Picton Rd, but on later examination of some voucher specimens these were identified as *Cornu aspersum*, the Common Garden Snail.

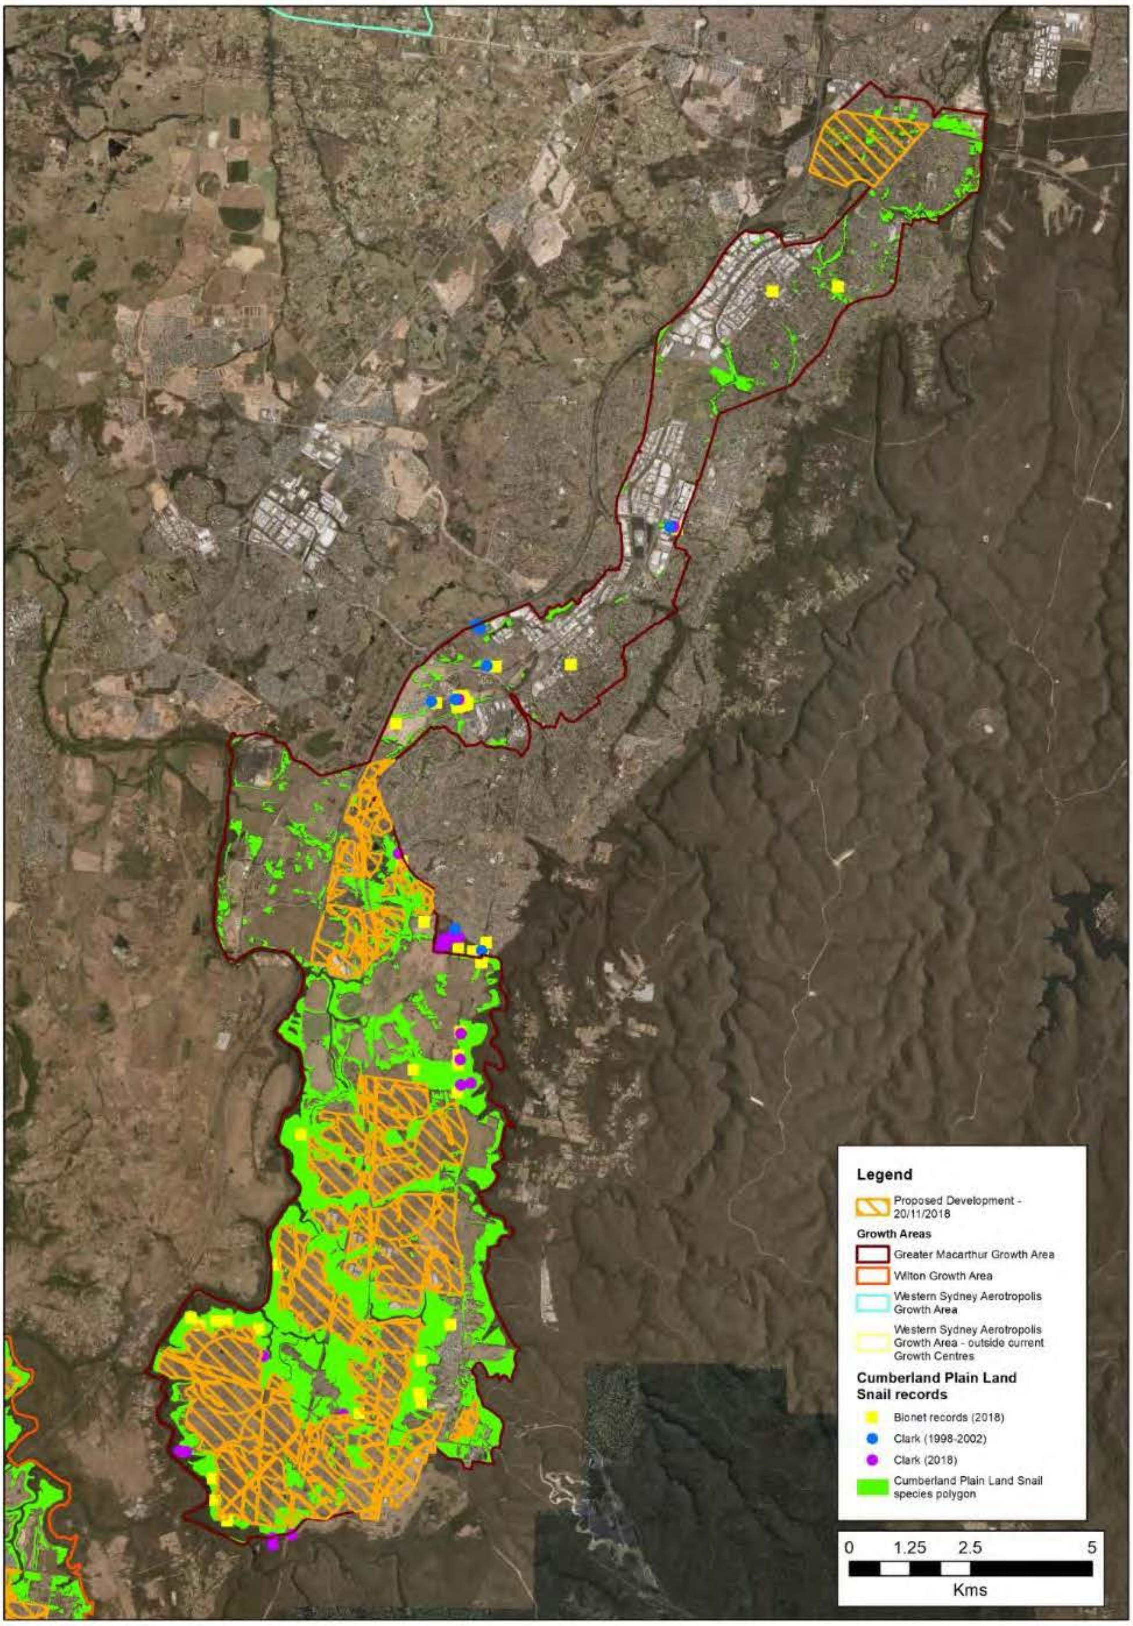

Figure 4. Map of the Greater Macarthur Growth Area showing the records of *Meridolum corneovirens* and the species polygons are in green. The yellow squares are the BioNet records (2018), the purple dots are records found during the current survey and the blue dots are records found by the author between 1998 and 2002.

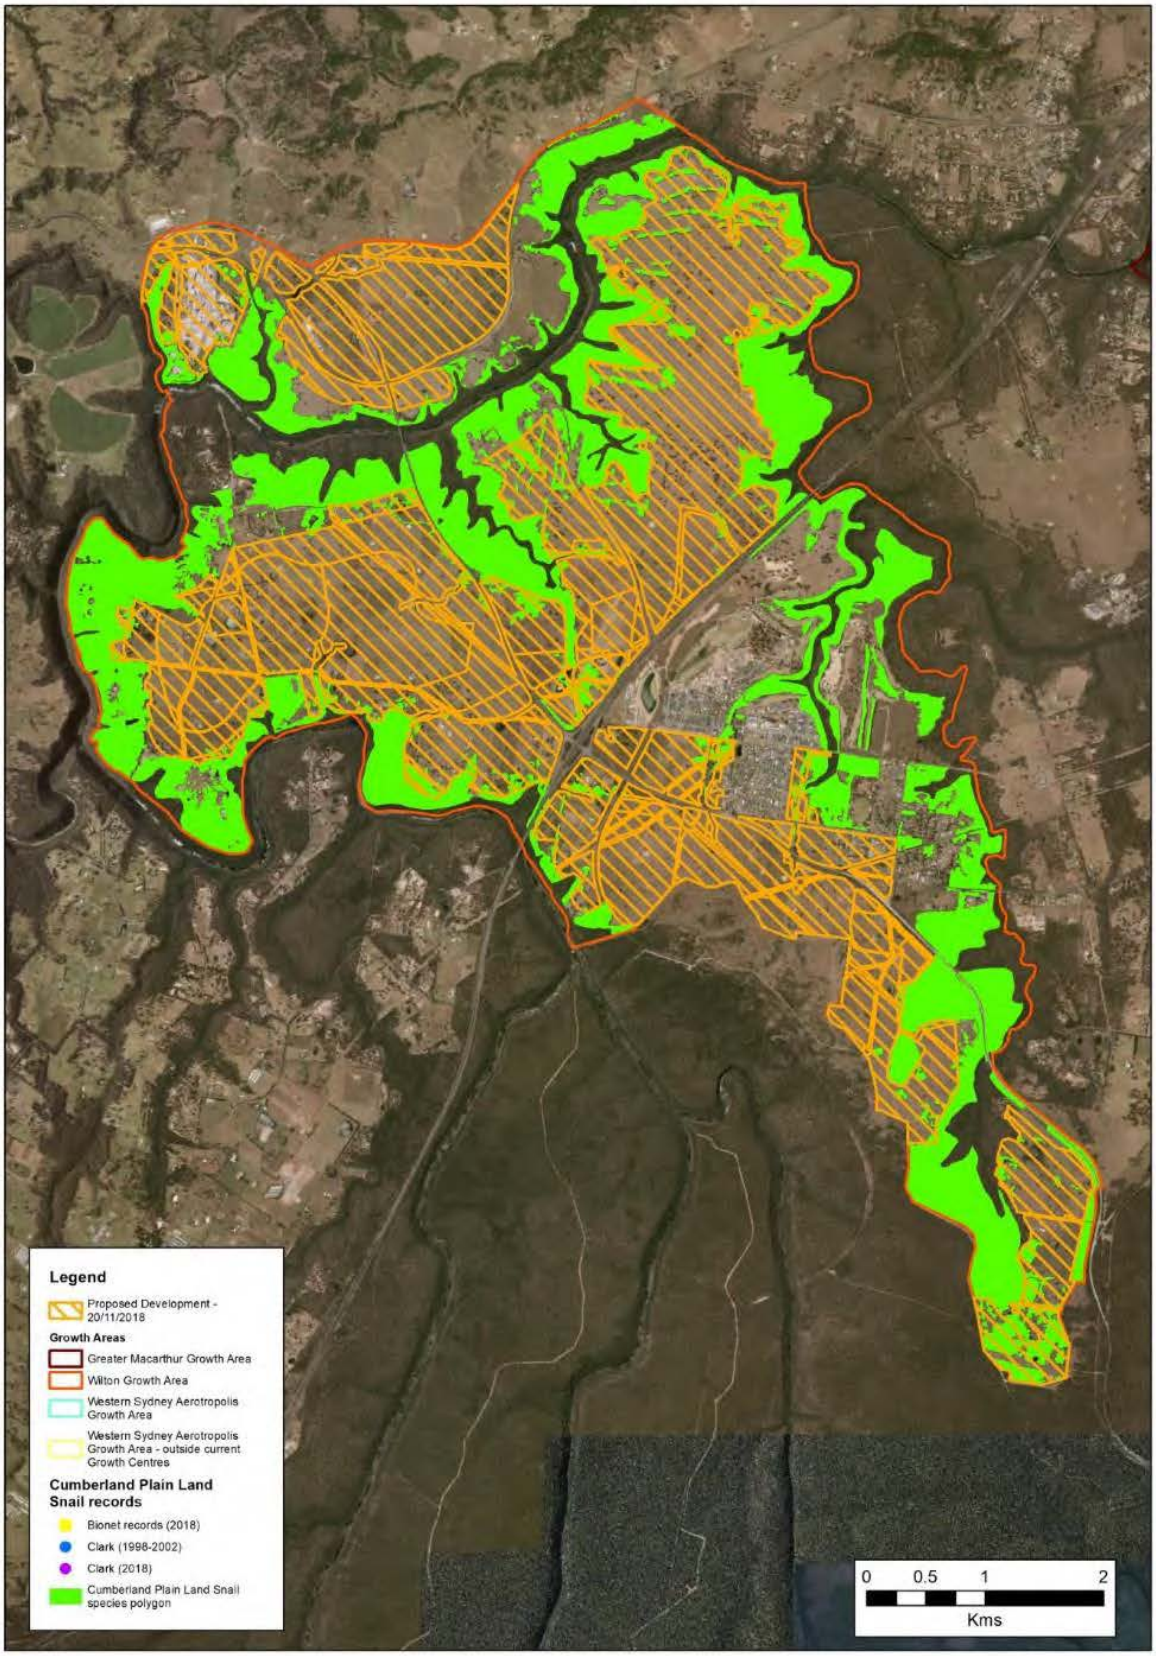

Figure 5. Map of the Wilton Growth Area showing the species polygons in green. Currently no records for *M*. *corneovirens* have been found in the area. However, the closely related species *M*. *sheai* has been recorded within and just outside of the growth area in 2017-2018.

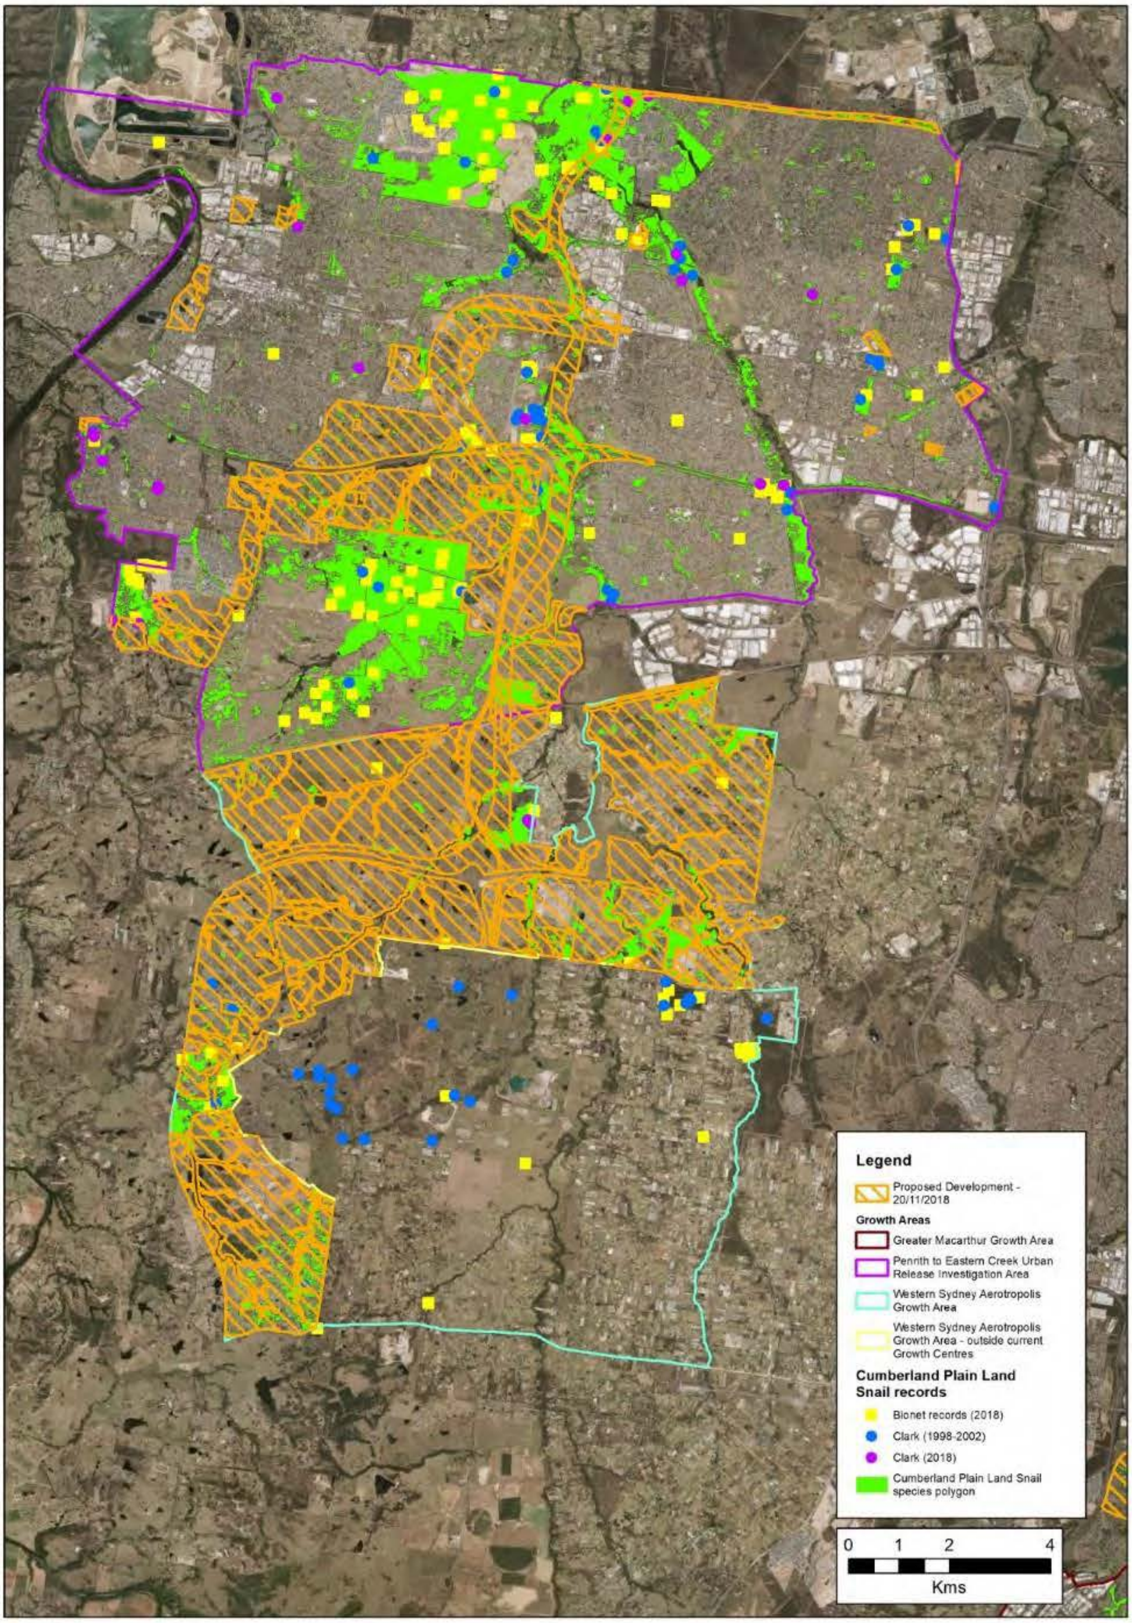

Figure 6. Map of the Penrith and Western Sydney Aerotropolis Growth Areas showing the species polygons in green. The yellow squares are the BioNet records (2018), the purple dots are records found during the current survey and the blue dots are records found by the author between 1998 and 2002.

4.4 Assessment of species presence

Likelihood of species presence

There are 13 records of *M. corneovirens* that fall within the future development footprint of the Greater Penrith to Eastern Creek Growth Area, mostly in the transportation corridors. There are six records that fall within the future development footprint of the Western Sydney Aerotropolis. While, no records were found within the future development footprint for the Greater Macarthur and Wilton Growth Areas (Figures 4-6).

However, there is potential for *M. corneovirens* to be found in areas of suitable habitat within the biocertification areas that have yet to be surveyed, or that have been surveyed but conditions were not conducive to detecting the species at the time of the survey, especially if there is plenty of leaf litter and woody debris.

Justification for determining presence

The species polygons (Figures 4-6) are based on a combination of the vegetation communities where the species has been found during the current survey and previous surveys, and the assumption that where suitable habitat is present within the growth areas that the species is likely to be present but due to a variety reasons (such as access issues and extremely dry conditions) the species has not been detected.

4.5 Assessment of suitable habitat

Suitable habitat within the growth areas

Suitable habitat was presumed to include all the PCT's mentioned above that had been mapped as either intact or thinned that occurred across the four growth areas.

Species polygons

Figures 4-6 show the species polygons for *M. corneovirens* across the four growth areas.

Estimate of area of habitat

Across the four growth areas there is a total of 6953.3 hectares of potential habitat for *M. corneovirens* (Table 1), with a total of 987.0 hectares found within the future development footprint, of which:

- 2421.3 hectares occur within the Greater Macarthur Growth Area of which 215.5 hectares occur within the future development footprint
- 2788.3 hectares occur in the Greater Penrith to Eastern Creek Growth Area of which 351.0 hectares occur within the future development footprint
- 592.9 hectares occur within the Western Sydney Aerotropolis and of which 259.0 hectares occur within the future development footprint
- 1150.8 hectares occur within the Wilton Growth Area of which 161.6 hectares occur within the future development footprint.

The total area in hectares of each of the different PCTs listed above in which *M. corneovirens* can potentially be found across each of the growth areas are listed in Table 1. The Greater Penrith to Eastern Creek Growth Area contains the largest area of suitable habitat as well as the highest number of records for *M. corneovirens*.

PCT	GMGA	GPECGA	WSA	WGA	Totals
724 intact		69.2	3.3		72.5
724 thinned		65.7	49.5		115.2
725 intact		87.4	19.8		107.2
725 thinned		33.9	16.4		50.3
830 intact	2.2	2.8			5.0
830 thinned	16.4				16.4
835 intact	56.4	321.4	13.4		391.2
835 thinned	121.3	496.6	111.2		729.1
849 intact	94.9	430.7	29.3	4.2	559.1
849 thinned	176.5	1225.5	344.2	70.3	1816.5
850 intact	86.8	0.2			87.0
850 thinned	133.8	52.9	5.8		192.5
1395 intact	1296.2			543.2	1839.4
1395 thinned	436.8	2.0		533.1	971.9
Totals	2421.3	2788.3	592.9	1150.8	6953.3

Table 1. Lists the area of each of the different PCTs (in hectares) that provide known or suitable habitat for *M. corneovirens* across the four growth areas. GMGA - Greater Macarthur Growth Area; GPECGA - Greater Penrith to Eastern Creek; WSA - Western Sydney Aerotropolis; WGA – Wilton Growth Area.

5 Information used in this assessment

The information used to make the above assessment is drawn from the literature (Clark, 2005, 2009; Cumberland Plain Land Snail – profile) and the authors' personal observations and knowledge of the species built up over the past 30 years. The author also prepared the original Cumberland Plain Large Land Snail as it was then called, threatened species information and environmental impact assessment guidelines information sheets in 1999.

Additional records were obtained by searching the BioNet and ALA (Australian Living Atlas) databases. Biosis and Ecoplanning provided records that they found during the surveys they carried out for the current project.

Vegetation mapping for the growth areas was provided by DPE.

GIS analysis of the PCT's and preparation of the species polygons following the authors' requirements were provided by Darren James (DAJ Environmental).

EDUCATION

Ph.D., 2005. University of Western Sydney, New South Wales, Australia. Taxonomy and conservation.
M.Sc., 1998. Macquarie University, New South Wales, Australia. Taxonomy and genetics.
B.App.Sc., 1990. University of Technology, Sydney, New South Wales, Australia. Major biochemistry.

PROFESSIONAL EXPERIENCE

Current and/or completed:

1997 - present. Consultant work (Invertebrate Identification Australasia - Owner) for various Australian and United States councils, government agencies (State, Commonwealth and Federal), environmental consultancies, mining companies and developers on short and medium term projects dealing mostly with molluscs and insects (particularly endangered species assessments).

Oct 2017 - Completed Biodiversity Assessment Method (BAM) course.

Aug 2017 – Sept 2017. Conduct one day snail identification workshops for the Department of Agriculture & Water Resources, biosecurity biomonitoring sections in Sydney, Melbourne and Perth.

Sept 2016 - Mar 2017. Identified almost 4000 lots of North American land and freshwater molluscs for the Field Museum of Natural History, Chicago, IL.

July 2016 – Dec 2016. Formally describe the US federally endangered freshwater snail, the Banbury Lanx for the Boise Office of the US Fish and Wildlife Service.

Feb 2015 – Mar 2016. Preparing a list of all the names, synonyms and combinations applied to the non-marine molluscs of North America, for the Field Museum of Natural History, Chicago, IL.

Oct 2014 – Feb 2016. Prepare a status report for the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) on the Shortface Lanx (*Fisherola nuttallii*) in Canada.

Jan 2013. Conducted a one day workshop on the identification of the endangered Cumberland Land Snail (*Meridolum corneovirens*) for the Ecological Consultants Association of NSW, Mount Annan, NSW, Australia.

June 2011 – present. Contracted with Deixis Consultants to write a Field Guide to the freshwater Molluscs of the Pit-Sacramento Rivers, California by the Cantara Trustee Council Grant Program.

Ponder, W.F. and Clark, S.A. Australian Biological Resources Study - Interactive CD-Rom guide and key to the freshwater Mollusca of Australia. Jan 1999 - Dec 2001. $90,000.

PROFESSIONAL SOCIETIES

American Malacological Society;
Conchological Society of Great Britain and Ireland;
Malacological Society of London;
Malacological Society of Australasia;
Member of the IUCN SSC Mollusc Specialist Group;
The Ecological Consultants Association of New South Wales.

RESEARCH INTERESTS

Systematics, population and conservation genetics of invertebrates particularly terrestrial and freshwater molluscs.

EXPERIENCE

I have over 30 years' experience in the collection, identification and taxonomy of marine, estuarine, freshwater and terrestrial molluscs in 28 countries and 41 US states. I have over 12 years' experience using allozyme electrophoresis to study speciation and population genetics particularly of molluscs but also some work with reptiles and spiders and at least 5 years' experience analysing DNA data. I have about 6 years' experience preparing material for and using a scanning electron microscope and have dissected individuals from several hundred populations of freshwater and terrestrial molluscs.

LEGAL EXPERIENCE

I have served as an expert witness for the Land and Environment Court of New South Wales on six occasions since 1997 and have provided expert testimony for several other cases.

PROFESSIONAL ACTIVITIES

Research Associate at the Field Museum of Natural History, Chicago, Illinois, June, 2010 to present.

Vice President of the Chicago Shell Club, Chicago, Illinois, May, 2010 to May, 2016.

Courtesy Postdoctoral Researcher, Division of Malacology at the Florida Museum of Natural History, Gainesville, Florida, September, 2009 to 2016.

Invited participant at the IUCN Red List workshop assessing the Red List status of the world's freshwater molluscs, organised jointly by the Zoological Society of London, the Encyclopedia of Life (EOL), International Union for Conservation of Nature (IUCN), and the IUCN SSC Mollusc Specialist Group. Held in London, United Kingdom, February, 2010.

Served on the Status Review Panel for the federally endangered Idaho Springsnail (*Pyrgulopsis robusta*), in Boise, Idaho, for the United States Fish and Wildlife Service, Western Region, October, 2005.

TELEVISION

Short interview about my PhD project on the endangered endemic Sydney land snail *Meridolum corneovirens*, aired on 'Totally Wild' (a children's educational program on wildlife and the environment), Australia wide, 7 May 2002.

Short interview regarding the endangered endemic Sydney land snail *Meridolum corneovirens* and how the Olympic Coordinating Authority (OCA) has helped in its conservation, aired on 'A Current Affairs' (a prime time news and current affairs program) Australia wide on the 15 September, 1998.

RADIO

Short interview with Brian Bury, 4BC, Brisbane, about Australian native snail diversity aired Nov. 2002.

NEWSPAPER/INTERNET

Several interviews about molluscs, endangered species and rediscovering a species previously thought to be extinct, with national, local and internet media outlets, both in Australia and the United States since 2002.

Cumberland Plain Conservation Plan

Expert report for *Dillwynia tenuifolia*

---

1. Introduction

1.2 Purpose of the expert report

The Department of Planning and Environment is currently preparing a strategic assessment to identify development impacts and conservation outcomes within new urban growth areas on the Cumberland (Interim Biogeographic Regionalisation for Australia [IBRA] subregion) in Western Sydney. Expert reports may be used as part of the threatened species assessment as outlined in the Biodiversity Assessment Method (BAM).

This document outlines the need for an expert report for the threatened plant species *Dillwynia tenuifolia* and the suitability of the expert who is proposed to prepare the report. The expert report is intended to supplement the data collected as part of the current survey effort.

1.3 Project context

The NSW Government is identifying areas for future urban development and associated infrastructure in Western Sydney. These future urban areas cover four priority growth areas: Wilton, Greater Macarthur (Campbelltown and Appin), Western Sydney Airport, and Greater Penrith to Eastern Creek. These new growth areas are all located within the Cumberland Plain Interim Biogeographic Regionalisation for Australia (IBRA) sub-region.

As part of the planning for the priority growth areas, the Department of Planning and Environment (DPE) will prepare the Cumberland Plain Conservation Plan to identify development and conservation outcomes for the growth areas.

1.4 The study area

The study area is the Cumberland, Western Sydney, focusing on the urban growth areas: Wilton, Greater Macarthur, Western Sydney Aerotropolis and Penrith to Eastern Creek (Figure 1).

Greater Penrith & Eastern Creek Growth Area (GPECGA)

A large portion of this Growth Area is already urbanised, with several areas of industrial land use. Significant rural and peri-urban areas remain in the central north, the centre, and the southwest. Large areas of remnant vegetation are present in the far north (former Australian Defence Industries site, now in part Wianamatta Regional Park), and the Orchard Hills Defence facility. Mining of alluvium for sand and soil continues in the far northwest of the area in the Penrith Lakes locality.

Western Sydney Aerotropolis Growth Area (WSAGA)

This Growth Area adjoins the Greater Penrith & Eastern Creek area, extending south to the locality of Greendale, west of Bringelly. It is currently largely rural, with villages at Luddenham and Kemps Creek. Most rural areas are pastoral, but there are significant areas of more intensive rural use, including poultry and egg production, a large cattle feedlot and associated fodder cropping, and some market gardens and enclosed fruit and vegetable production. Quarrying occurs at the localities of Badgerys Creek and Kemps Creek.

Greater Macarthur Growth Area (GMGA)

The GMGA occurs in southwestern Sydney on predominantly shale soils that have been heavily cleared for agriculture and urban or industrial use. The northernmost section has long-established urban and commercial / industrial land use, while the southern section is largely rural (pastoral, minor cropping), with some villages and primarily subsurface mining (e.g. coal and coal seam gas). It extends from urban Glenfield in the north, to the rural village of Appin in the south.

Wilton Growth Area (WGA)

The Wilton Growth Area is the most southerly of the four Western Sydney Growth Areas dealt with in this Report. It extends from the village of Douglas Park in the north, to the village of Wilton in the south. It is primarily rural (pastoral) area with some more intensive agriculture, significant but mostly underground mining (primarily coal), and some long-established villages. The Hume Highway dissects this Growth Area.

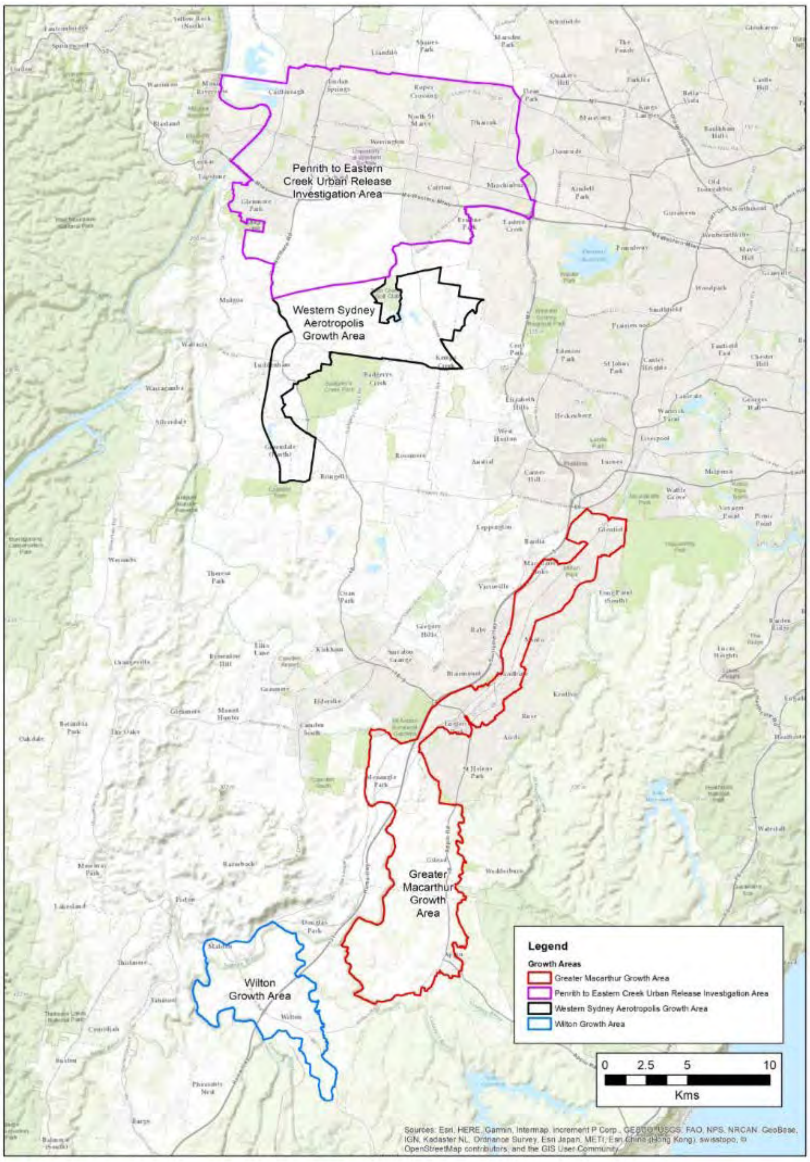

Figure 1: Map of the urban growth areas in Western Sydney

1.5 Reasons for use of an expert report

An expert report for *D. tenuifolia* is required as part of the threatened species assessment for the Cumberland Plain Conservation Plan for the following reasons:

1. Areas of habitat were not able to be surveyed. Not all land holders allowed the ecologists to enter their property and conduct BAM surveys. This restricted the opportunity to visit all potential areas of habitat within the proposed development footprint.
2. Section 4.4 of the NSW Guide to Surveying Threatened Plants (OEH 2016) provides for the consideration of 'site survey and an expert report' where areas are large. Based on site surveys and Bionet data, the species is unlikely to occur within the Wilton or Greater Macarthur growth areas. However due to the cryptic nature of this species outside the peak flowering season an expert in the species is required to determine whether suitable habitat exists.

1.6 Credentials of expert

Dr Paul Rymer is a senior lecturer at the Hawkesbury Institute for the Environment, Western Sydney University. He teaches and researches plant biology with a focus on conservation biology. Paul has contributed to the understanding of the biology and management of several threatened species, including *D. tenuifolia* and *Persoonia bargoensis* that were the focus of his postgraduate research. He has published his work in peer reviewed scientific journals, and provided reports to land managers.

2 Species information

2.1 Species description

"*Dillwynia tenuifolia* is a low spreading pea-flower shrub to a metre high. Its leaves are small and narrow (linear-terete, soft, 4-12mm long, with the tip often bent downwards). The wide orange-yellow and red pea-flowers are usually single, at or near the tips of the branches. Seed pods are brownish, egg-shaped, 4-5mm long with reticulate seeds. Both the singular orange flowers and the stem hairs distinguish it from the similar and more common yellow-flowered *Dillwynia glaberrima* and *D. floribunda*."
https://www.environment.nsw.gov.au/threatenedspeciesapp/profile.aspx?id=10226

2.2 Life cycle

Dillwynia tenuifolia is a fire sensitive (Auld 1996), perennial, woody, leguminous shrub (Harden 1991). Flowering occurs sporadically throughout much of the year, with a peak in flower production from August to October. Flowers are hermaphroditic and protandrous, and are commonly found individually on lateral branchlets. Seeds mature in December when they are released into the soil. Seed are physically dormant with a hard seed coat, requiring cracking (via physical disturbance or the heat of fire) to allow water to enter and germination to proceed. Seed can remain viable in the soil for several decades (Auld 1996), such that large soil stored seed banks can accumulate in healthy populations and regeneration may occur even when the standing population has expired some time before.

2.3 Distribution and abundance

Dillwynia tenuifolia is an endemic species that forms large populations within a restricted geographic range and specific habitat [predominately the Castlereagh Ironbark Forest (9e); (Benson 1992)]. It is limited to New South Wales, with the core distribution on the Cumberland , west of Sydney, and disjunct populations in the Lower Blue Mountains and Lower Hunter Region (records in the National Herbarium of NSW).

The core distribution is in the Cumberland from Windsor and Penrith east to Dean Park near Colebee. Other populations in western Sydney are recorded from Voyager Point and Kemps Creek in the Liverpool LGA, Luddenham in the Penrith LGA and South Maroota in the Baulkham Hills Shire. Disjunct localities outside the Cumberland include the Bulga Mountains at Yengo in the north, and Kurrajong Heights and Woodford in the Lower Blue Mountains.
https://www.environment.nsw.gov.au/threatenedspeciesapp/profile.aspx?id=10226

2.4 Habitat requirements

Dillwynia tenuifolia is predominately found in the Castlereagh Ironbark Forest (9e); (Benson 1992) on shale-transition soils.

"In western Sydney, may be locally abundant particularly within scrubby/dry heath areas within Castlereagh Ironbark Forest and Shale Gravel Transition Forest on tertiary alluvium or laterised clays. May also be common in transitional areas where these communities adjoin Castlereagh Scribbly Gum Woodland."
https://www.environment.nsw.gov.au/threatenedspeciesapp/profile.aspx?id=10226

3 Description of the study area

3.1 Land use history

The Cumberland, Western Sydney, has a long history of land clearing for agricultural, industrial and urban development. Less than 7% of the native vegetation remains, much of which is distributed in small isolated remnant patches.

3.2 Landscape context

The study area for this report comprises the growth areas of Greater Macarthur (Campbelltown and Appin) and Wilton (see Figure 1). It is located within the Cumberland subregion on Triassic Wianamatta Group Shales and transitional shale/sandstone areas in south-eastern parts of the Cumberland, Western Sydney. The eastern and southern margins are within the Sydney Cataract subregion defined by the Triassic Hawkesbury Sandstone plateau. The study area is within the Hawkesbury-Nepean and Georges River catchments.

Greater Macarthur Growth Area

The Greater Macarthur PGA extends from Glenfield in the north to Appin in the south. The northern zone is already well developed with remnant vegetation largely restricted to creek-lines or small patches associated with open space reserves. Southern parts of the area, south of Rosemeadow, comprise primarily agricultural lands with larger patches of remnant vegetation associated with the Nepean and Georges Rivers, and associated tributaries.

Wilton Growth Area

The Wilton PGA occurs to the south of the Greater Macarthur Growth Area extending from Douglas Park in the north to south of Wilton. The boundaries closely follow the Nepean River in the north and west, and a tributary Allens Creek in the east. Away from the river and creeks the higher areas are largely cleared for agriculture and hobby farms. Remnant vegetation occurs predominantly along the watercourses and on associated slopes. The Woronora sandstone plateau (within the Upper Nepean State Conservation Area) forms the southern boundary. The Hume Highway dissects the growth area.

Greater Penrith to Eastern Creek Growth Area (GPECGA)

The GPECGA is a relatively large area that extends from Rooty Hill, Minchinbury and Hassell Grove in the east, across the Cumberland to the Hawkesbury-Nepean River in the northwest, then south through Jamisontown, Glenmore Park, to the intersection between The Northern Road and the Warragamba Water Supply Pipelines in the far south-west. The predominant geology is Wianamatta Shale on flat to gently undulating terrain that has been extensively cleared for agriculture, and later for housing and industrial use, with some remnant vegetation on current and former Defence holdings. The shale soils support(ed) Cumberland Plain Woodlands. Overlying the extensive shale deposits are small areas of weathered Tertiary alluvium e.g. Shalvey and Willmot, that are much more common to the north. These support(ed) the Castlereagh Woodlands complex of vegetation types, which is strongly associated with several threatened plant species. More common are broadly linear deposits of Quaternary alluvium along watercourses such as South Creek and Eastern Creek, and on the flood terraces of the Hawkesbury-Nepean River. Other lithologies occur but are very rare and of very small extent.

Western Sydney Aerotropolis Growth Area (WSAGA)

The WSAGA abuts the GPECGA's southernmost border near the locality of Sovereign (east of Mulgoa), then extends south past Greendale, northeast to the locality of Badgerys Creek, east to Kemps Creek, and northward to the vicinity of Mount Vernon, excluding Twin Creeks Golf Course and associated settlement. The lithology and soils are broadly similar to that of the GPECGA, being effectively just an extension of that area to the south to incorporate the developing Badgerys Creek Airport and environs. The area is even more severely cleared of native vegetation, except along some streams and on rare occurrences of steeper terrain. It contains no NPWS reserves, with the nearest being the small Kemps Creek Nature Reserve, outside the Area to the southeast. Gulguer Nature Reserve and Bents Basin State Conservation Area occur to the southwest of Greendale

3.3 Native vegetation communities

There are 14 different vegetation communities (PCTs) found in the urban growth areas. The PCTs are associated with different soils and topology, as well as history of land use and disturbance. The four growth areas differ in the composition of PCTs (Table 1).

Table 1. Area of PCTs by Growth Area (highlighting the PCTs D. tenuifolia is associated)

PCT	PCT name *	Greater Macarthur	Greater Penrith to Eastern Creek	Western Sydney Aerotropolis	Wilton	TOTAL (ha)
724	Broad-leaved Ironbark – Grey Box – Melaleuca decora grassy open forest on clay/gravel		138.3	52.9		191.3
725	Cooks River Castlereagh Ironbark Forest		127.5	39.9		167.4
781	Freshwater wetland		65.4	3.5		68.9
830	Forest Red Gum – Grey Box shrubby woodland on shale	18.8	2.8			21.5
835	Forest Red Gum – Rough-barked Apple grassy woodland	186.6	826.3	162.9		1175.8
849	Grey Box – Forest Gum grassy woodland on alluvial flats	444.5	1794.0	550.1	289.8	3078.3
850	Grey Box – Forest Gum grassy woodland on shale (southern)	269.9	80.8	7.7	164.5	522.9
883	Hard-leaved Scribbly Gum – Parramatta Red Gum healthy woodland	0.9	6.5			7.4
1081	Red Bloodwood – Grey Gum woodland	7.5			66.7	74.2
1105	Rive oak open forest of major streams	44.4	94.2			138.6

1800	Swamp Oak	4.1	118.4	110.1		232.6
TOTAL (ha)		3288.3	3256.2	927.1	2354.5	9826.1

* of the Cumberland, Sydney Basin Bioregion

Each vegetation polygon was assigned to one of four vegetation condition categories by DPE based on LiDAR and nearmap remote sensing data, along with field validation:

1. Intact - Visual inspection of the Nearmap imagery showed significant patches of continuous canopy and the CHM (Canopy Height Model) showed vegetation returns for both the upper and mid storeys.

2. Thinned – Visual inspection of the Nearmap shows patches of continuous canopy but less dense and the CHM presented only canopy and ground returns.

3. Scattered trees – Visual inspection of Nearmap imagery and LiDAR canopy polygons showed one or a few likely native trees surrounded by cleared land.

4. Grassland – Treeless areas which were visually assessed to be potential native grassland and were not in areas of improved pasture or cropland.

4 Assessment of species presence and habitat

4.1 Existing records and surveys

BioNet records for *D. tenuifolia* generally support the description of the distribution in 2.3. There are a number of outlier points that may be mis-identifications if not significant expansion of geographic range.

Notably, *D. tenuifolia* is absent from the Wilton and Greater Macarthur growth areas. There is however an outlier record immediately to the southeast of Wilton and there is similar vegetation to that in which the species is found in the core distribution.

Western Sydney Aerotropolis growth area, includes a significant population of *D. tenuifolia*. There is a cluster of records in Kemps Creek, which is the most southerly population of the species. The Kemps Creek population is listed as a Threatened population.

There are clusters of records in the Greater Penrith to Eastern Creek urban growth area around St Marys. A large number of records from Marsden Park, Shanes Park, Llandillo, Cranebrook on the northern edge of the GPECGA. Further to the north there are large populations from Richmond to Windsor.

4.2 Surveys completed for the biocertification

Surveys completed by Biosis and Ecoplanning on behalf of DPE were provided (Figure 2).

They include 11 records of *D. tenuifolia* in Kemps Creek (-33.86978667, 150.7902583, ALT 70.5 m). All of which are within the Western Sydney Aerotropolis growth area.

Figure 2: Map of D. tenuifolia records provided by BIOSIS aaround Kemps Creek in WSAGA

An additional two records of *D. tenuifolia* were provided from Dr Peter Weston at the Royal Botanic Gardens Sydney, who observed the species while undertaking field surveys for other expert reports.

GJ3 - Castlereagh Nature Reserve, Northern Rd, Londonderry, 33°40'44.9"S, 150°44'37.3"E, 52 m, Tertiary alluvium, brown, gravelly clay-loam, 0°, dry sclerophyll forest, sparse shrubby understory. This record is north of the GPECGA.

GJ7 - Bill Anderson Reserve, Kemps Creek site 2, 33°52'53.2"S, 150°47'19.0"E, 66 m, Bringelly Shale, red-brown sandy loam, <5°N, disturbed dry sclerophyll woodland, moderately dense shrubby understory.
This record is immediately south of the Western Sydney Aerotropolis growth area.

4.3 Surveys completed for this assessment

My own records of occurrence and knowledge of habitat preference of *D. tenuifolia*, combined with those provided through DPE via email and in the spatial portal were used to plan field work and target sites for assessment. I plotted the target sites on Google Earth for use in the field via my smartphone (Figure 3).

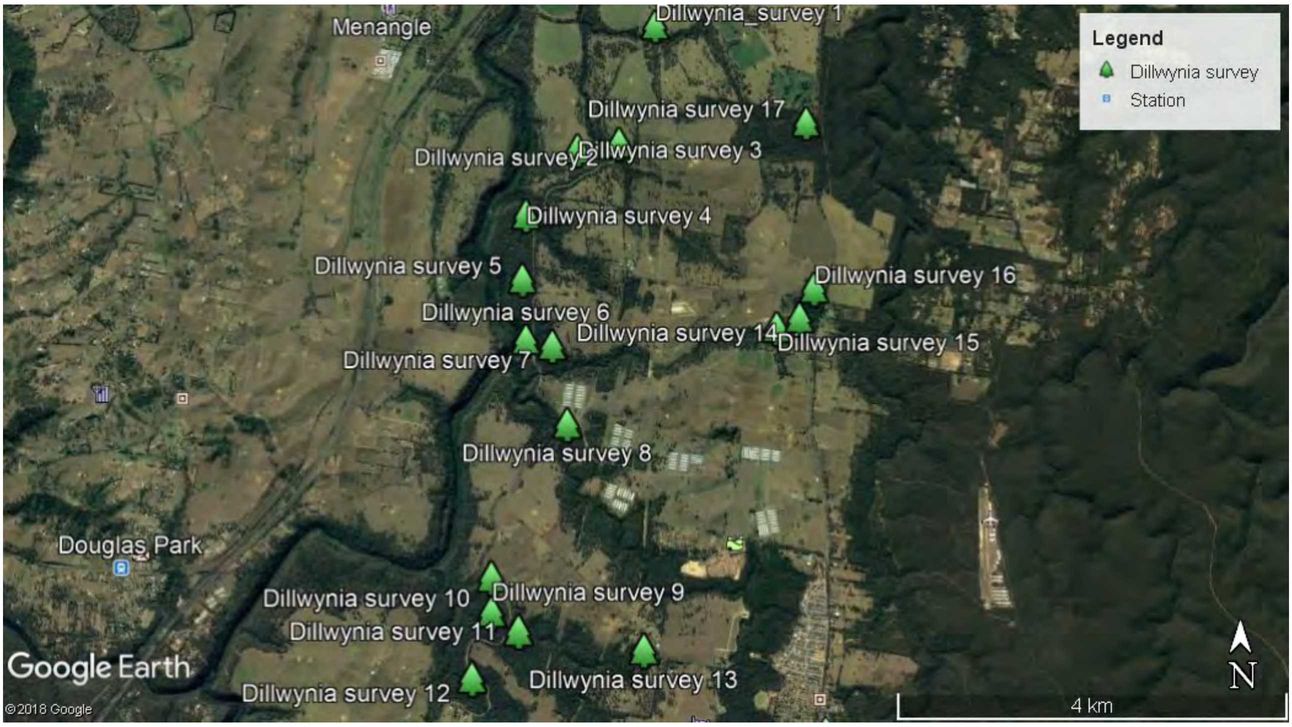

Figure 3: Map of planned survey sites in the Greater Macarthur Growth Area.

The target site was located on the ground via google map navigation tool. In many cases access to the site was prevented by locked gates, or private property owners not providing permission. Additional sites were sought on the ground in adjacent areas, and others based on alternative records of occurrence from the Atlas of Living Australia.

A full list of sites where ground surveys have been conducted are in the appendix.

Ground surveys were conducted on foot with a visual search of the suitable habitat. The search effort at each site varied by the survey area and typically ranged from 15-60min. Some sites were much larger and represented a series of occurrence records that were traversed on foot (c. 2 hour). A random walk was used to cover as much ground as possible searching for the target species. The search included living and dead plants, along with examination of the leaf litter / upper soil profile for plant fruits and seeds.

A photo was taken of the site along with a screenshot of the map to confirm the survey was conducted. When a target plant or other significant plant was located a photo was taken with a map screenshot for the location details.

4.4 Assessment of species presence

Likelihood of species presence

Species Distribution Models (SDM) have been conducted to estimate the suitable habitat for D. tenuifolia in the Cumberland bioregion. The SDM used records of occurrences from field surveys along with spatially valid records from the Atlas of Living Australia (ALA; www.ala.org.au) combined with temperature, rainfall and soil GIS layers to conduct a MaxENT model predicting habitat suitability at 1km grid scale. Mean annual temperature was the most important variable in the SDM followed by precipitation seasonality, annual precipitation, and temperature seasonality (Table 2). While soil layers contributed a lower percentage to the overall SDM they were important in refining the local patterns within the Cumberland.

Table 2: The relative importance of the variables in the MaxENT species distribution model.

Variable	Percent contribution	Permutation importance
Temperature - annual mean (Bio01) (el874)	31.5	63.1
Precipitation - seasonality (Bio15) (el882)	20.2	12.6
Precipitation - annual (Bio12) (el893)	19.3	1.7
Temperature - seasonality (Bio04) (el892)	17.4	3.3
Drainage - average (el670)	5.1	10.2
Clay % (el814)	3.5	0.7
Phosphorus - plant-available pre-European (el811)	2.4	5.9
Moisture - average (el669)	0.5	1.9
Carbon - organic (el665)	0.2	0
Nitrogen - plant-available pre-European (el831)	0	0.6

The SDM for *D. tenuifolia* provided an accurate prediction of the habitat suitability within the Cumberland (Figure 4). The predicted habitat suitability was tested with 25% of the observation records, demonstrating the SDM accuracy at >95%. Furthermore, the main populations within the Cumberland are all within areas of high habitat suitability. Some of the areas predicted as suitable for *D. tenuifolia* do not have any valid occurrence records (notably Penrith), while other areas native vegetation has been converted into industrial or urban developments. The species persistent soil seedbank and ability to persist in small degraded sites (e.g. roadside verges) would support the integrity of the SDM habitat suitability for low quality vegetation classes (Figure 4).

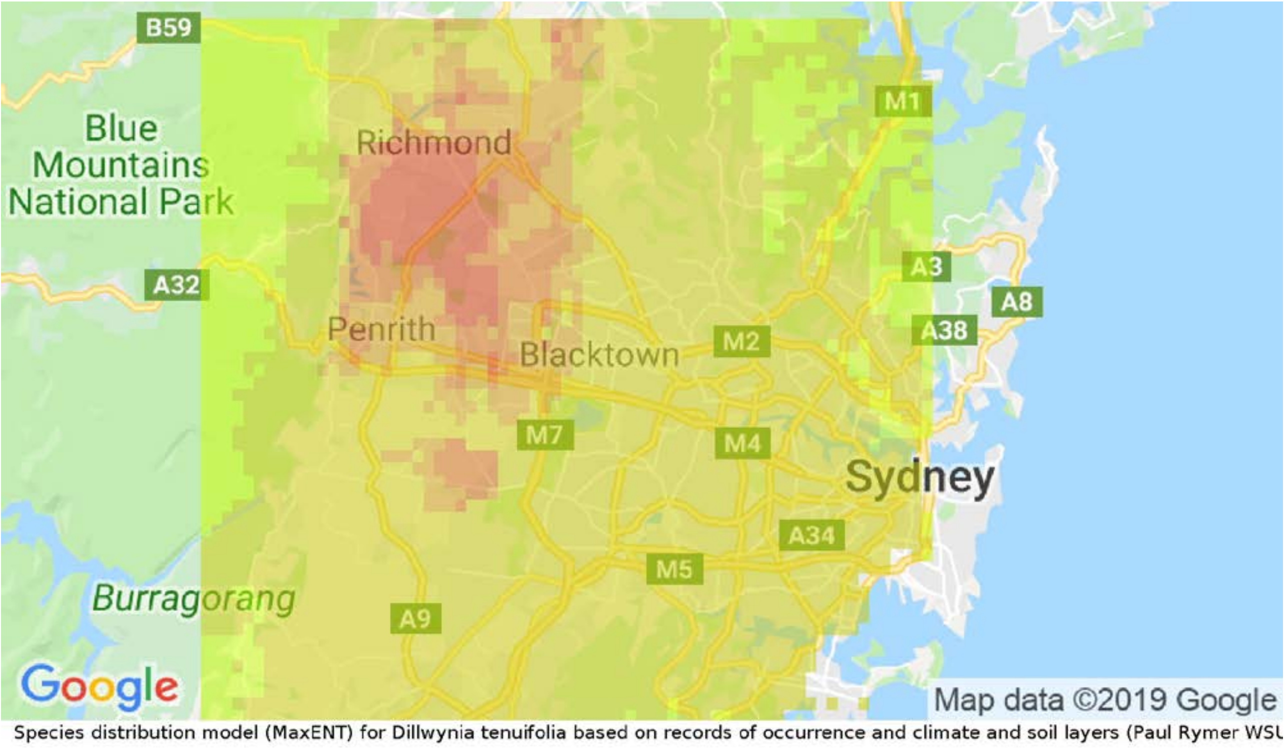

Figure 4: Dillwynia tenuifolia habitat suitability in the Cumberland predicted based on the MaxENT species distribution model. Grid cells with darker red colours are more suitable (max 85%), orange intermediate (~30%), and yellow/green is the lowest suitability (min 5%).

URBAN GROWTH AREAS

Dillwynia tenuifolia is not likely to occur in the Wilton or Greater Macarthur growth areas. The field surveys targeting areas with previous records, and in potential habitat, did not find any *D. tenuifolia* plants in this area. The SDM confirmed there is low habitat suitability in Wilton or Greater Macarthur growth areas.

Western Sydney Aerotropolis Growth Area

The most southerly known population of *D. tenuifolia* is found in Kemps Creek partly within the Western Sydney Aerotropolis Growth Area.

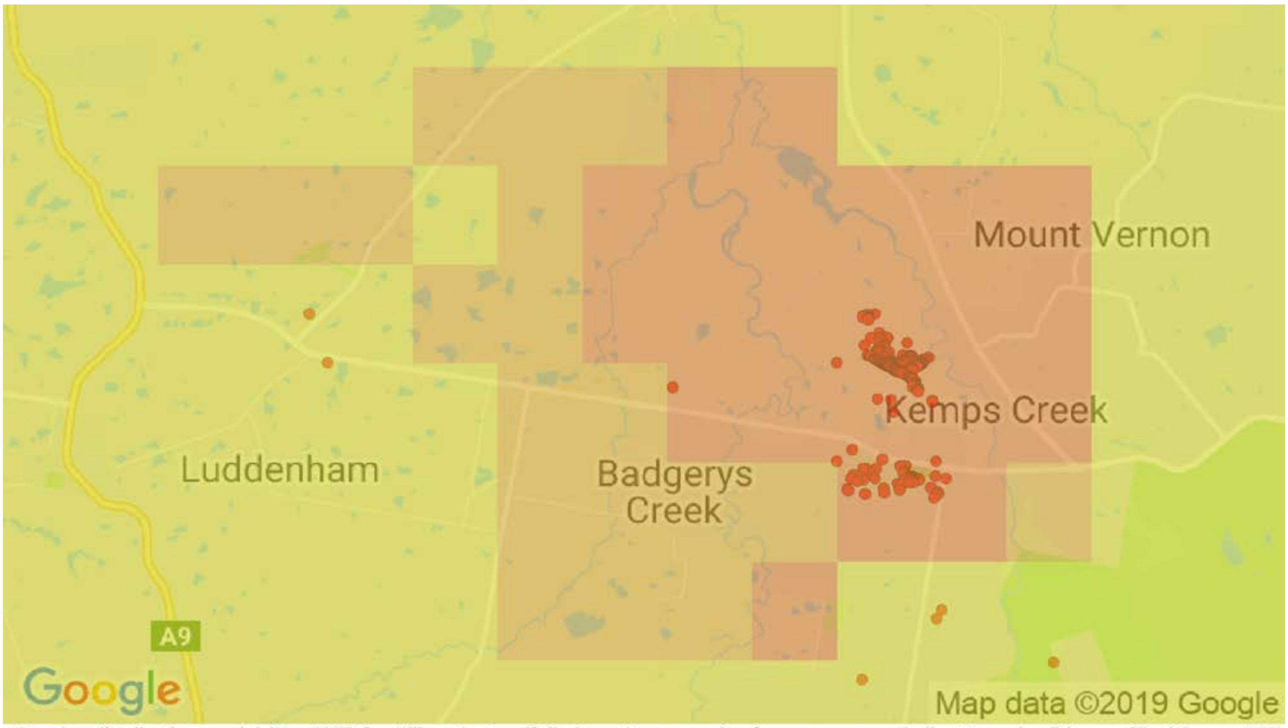
An 'Endangered Population' has been declared under the NSW Biodiversity Conservation Act 2016 for the area bounded by Western Road, Elizabeth Drive, Devonshire Road and Cross Street, Kemps Creek in the Liverpool Local Government Area. It is managed under the OEH Saving Our Species program. Which is immediately to the south of the Western Sydney Aerotropolis Growth Area. Major threats include weeds, inappropriate fire regimes, illegal dumping and development of adjacent sites (https://www.environment.nsw.gov.au/threatenedSpeciesApp/profile.aspx?id=10225).

Field surveys confirmed a large population of *D. tenuifolia* in the Kemps Creek area (see observation records in the appendix). There is a patch south of Elizabeth Drive, Kemps Creek, in a large remnant block of native vegetation between Western Road and Cross Street. The Kemps

Creek population of *D. tenuifolia* continues north of Elizabeth Drive (inside the Western Sydney Aerotropolis Growth Area) along Clifton Avenue where there is second patch in remnant native vegetation on either side of Clifton Avenue (lot 90 (west) and lot 316 (east)).

Historic and contemporary development in this area has impacted on the extent of occupation and the population size of *D. tenuifolia*. Long periods between fire in the remnant vegetation may have reduced the standing population of plants, however it is likely there is a viable soil stored seedbank from which plants could re-establish following fire or soil disturbance.

The SDM confirms the Kemps Creek area as having high habitat suitability (Figure 5). This corresponds to the Castlereagh Ironbark Forest and shale-transition soils, along with the large clusters of recent and historic sightings in the area.



Species distribution model (MaxENT) for Dillwynia tenuifolia based on records of occurrence and climate and soil layers (Paul Rymer WSU

Figure 5: Dillwynia tenuifolia habitat suitability focusing on the Kemps Creek population. Grid cell colour indicates suitability: darker red (max 85%), orange (~30%), yellow/green (min 5%). Red points are the records of occurrence for D. tenuifolia.

The Western Sydney Aerotropolis Growth Area draft plan (https://www.planning.nsw.gov.au/Plans-for-your-area/Priority-Growth-Areas-and-Precincts/Western-Sydney-Aerotropolis/Map) has zoned the Kemps Creek population in predominantly 'Flexible Employment' and marginally 'Non Urban Land'. The route of the proposed M12 motorway would go over the northern Clifton Avenue patch, representing more than half of the Kemps Creek population. While this is outside of the area specified as the Kemps Creek Endangered Population, the northern patch of the Kemps Creek population (Figure 5) is likely to be part of the same genetic population, which is genetically isolated from the core distribution (Rymer etal. 2002). Development in the surrounding area has been listed as a threat to the viability of the Kemps Creek Endangered Population. Negative impacts include a reduction in the effective population size with loss of plants in the adjacent area, increased nutrient and weed loads, inappropriate fire regimes and altered hydrology.

GPECGA has a large number of records of occurrence and some well-established populations of *D. tenuifolia*. Field surveys have validated the occurrence of plants in Minchinbury, St Marys, Ropes Crossing and Shanes Park. The SDM highlights these areas as high habitat suitability for *D. tenuifolia* (Figure 6). There is also substantial populations of *D. tenuifolia* to the north of Penrith to Eastern Creek, notably the Shanes Park population on the northern edge. As with other areas in the Cumberland historic and contemporary development has impacted on the extent of occupation and the population size of *D. tenuifolia*, however improved land management and ecological restoration could re-establish viable populations. On the other hand, urban development can have negative impacts on adjacent remnant vegetation and plant populations through increased nutrient and weed loads, inappropriate fire regimes and altered hydrology.

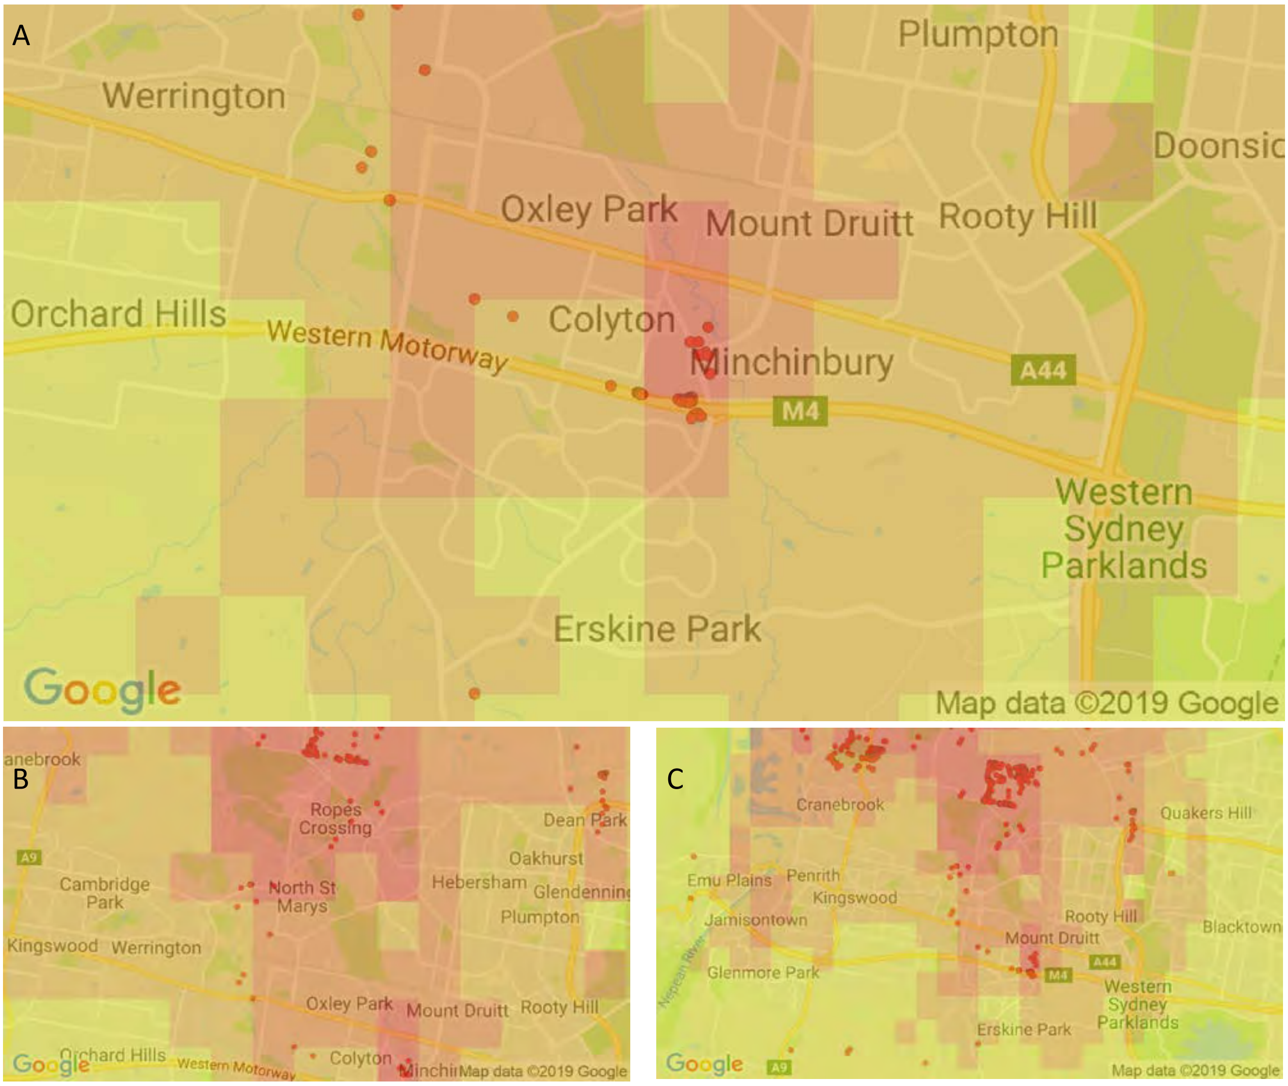


Figure 6: *Dillwynia tenuifolia* habitat suitability focusing on (A) Minchinbury, (B) Penrith and Eastern Creek area, and (C) surrounding area. Grid cell colour indicates suitability: darker red (max 85%), orange (~30%), yellow/green (min 5%). Red points are the records of occurrence for *D. tenuifolia.*

Justification for determining presence

Based on the field surveys, collated records of occurrence, and species distribution models I have assessed the likelihood of species occurrence on the proposed growth areas. Several of the records available in BioNet are incorrect in the species identification, or location information. Priority of records:

1. Current survey documented species being present
2. Records from trusted surveys with taxonomic expertise
3. Records in BioNet from multiple years and collectors
4. Other records were questioned for integrity

4.5 Assessment of suitable habitat

Suitable habitat within the growth areas

Dillwynia tenuifolia is associated with the “Castlereagh Ironbark Forest and Shale Gravel Transition Forest on tertiary alluvium or laterised clays” classified in PCTs 724, 725, 849, and 883.

Populations of *D. tenuifolia* can develop large soil stored seedbanks, which can persist as viable seed for several decades. As such populations can remain viable in intact and degraded vegetation (scattered, thinned) in interconnected large and small patches, including roadside plants (Figure 7).

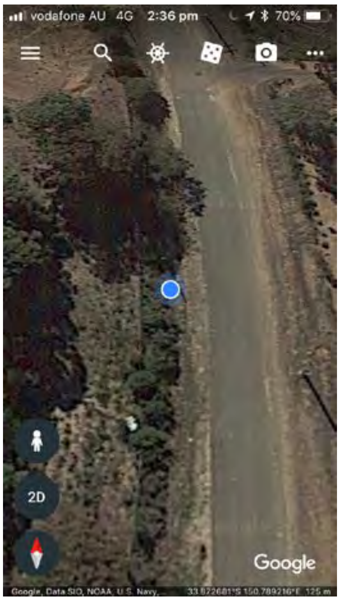

Figure 7: Roadside population of D. tenuifolia recorded along Clifton Avenue, Kemps Creek.

Species polygons

A map of species polygons for the Western Sydney Aerotropolis and Penrith to Eastern Creek growth areas was produced by Darren James (dajenvironmental) based on the area of occurrence (2km grids) overlayed with the PCTs (listed above) (Figure 8).

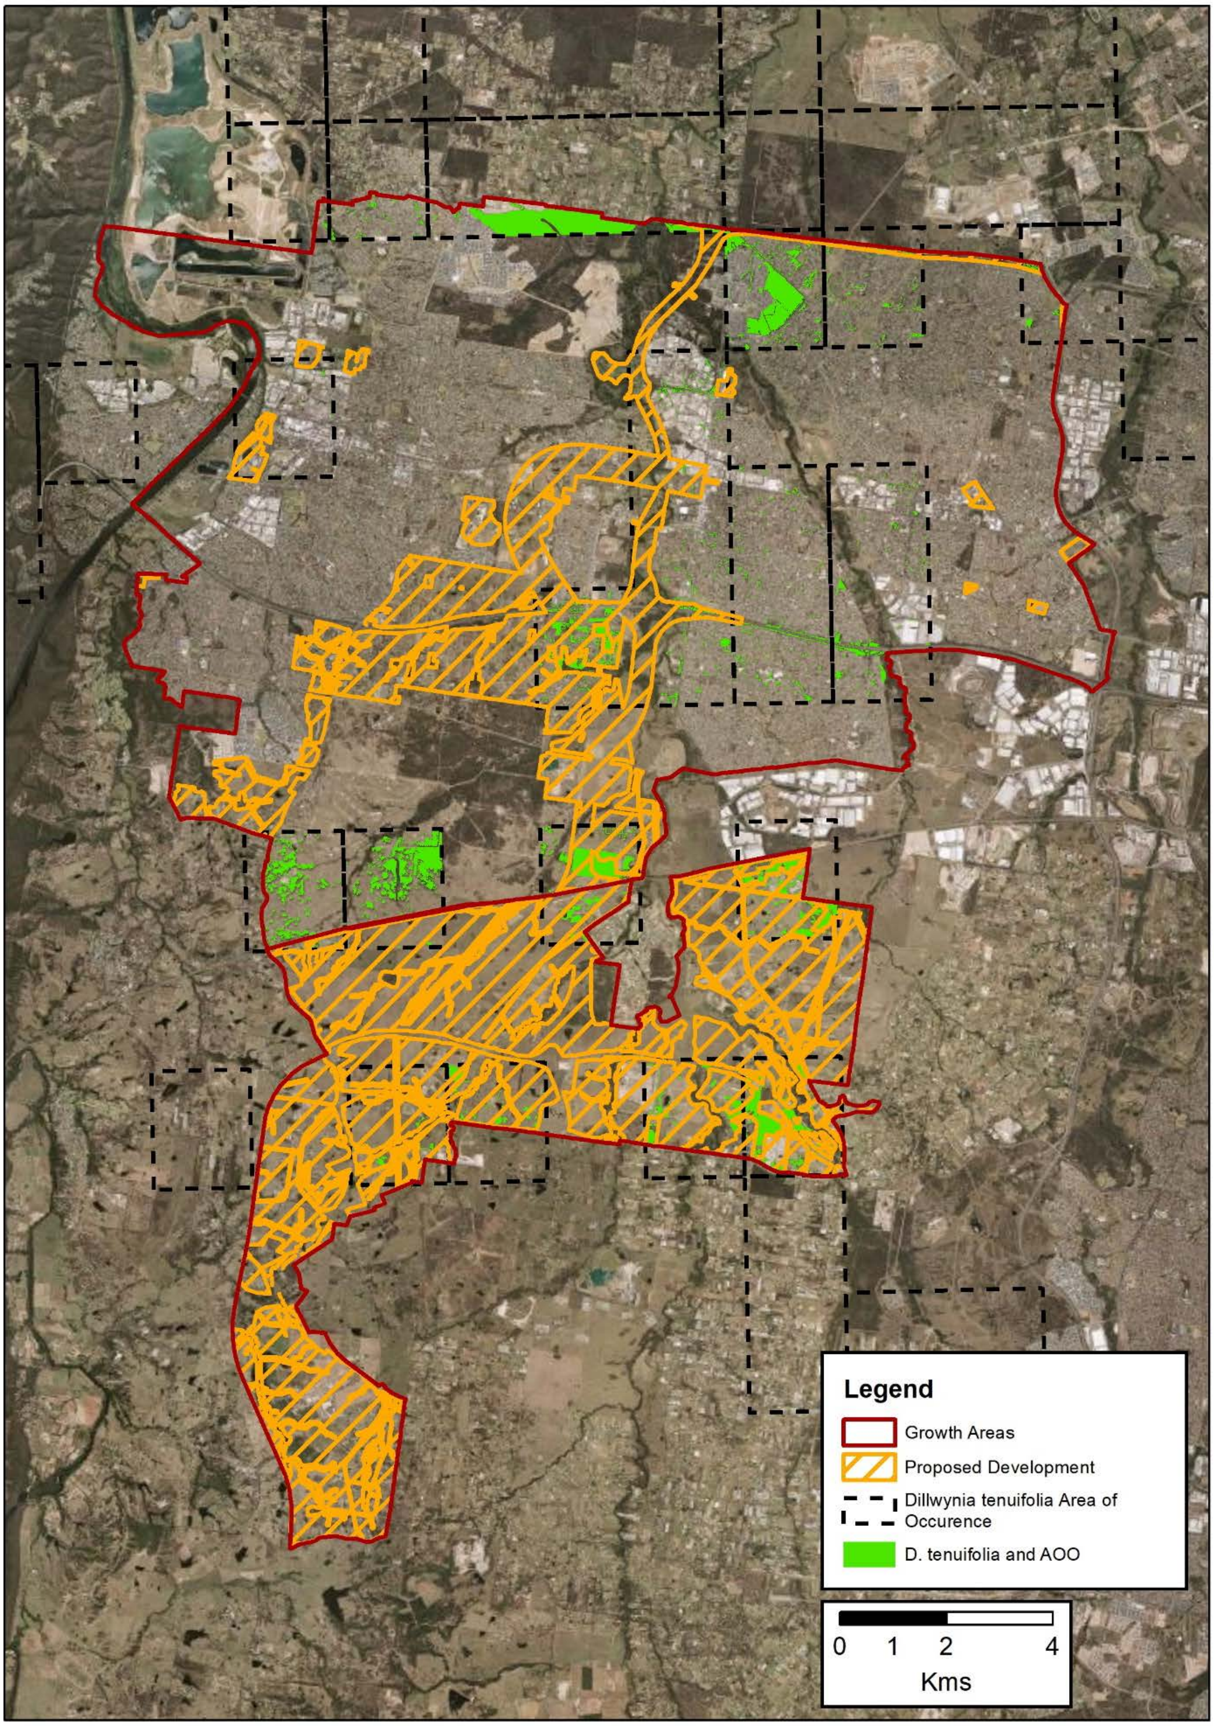

Figure 8: Map of vegetation polygons in areas and habitat that D. tenuifolia is known to occur.

5 Areas in growth areas

The total area of *D. tenuifolia* habitat within the Greater Penrith and Eastern Creek (GPEC), and Western Sydney Airport Growth Areas is estimated to be 606 ha and 225 ha, respectively (total 831 ha; Table 3). *Dillwynia tenuifolia* had the greatest habitat area within the growth areas in the Grey Box - Forest Red Gum grassy woodland (68% total area; 564 ha PCT 849), with intermediate habitat area in Cooks River Castlereagh Ironbark Forest and Broad-leaved Ironbark - Grey Box vegetation (16% [133 ha] PCT 725; 15% [127 ha] PCT 724), and less than 1% in Hard-leaved Scribbly Gum Parramatta Red Gum woodland (6.5 ha PCT 883) (Table 3). The majority of vegetation was in the condition thinned or scattered trees (Table 3). This reflects the overall abundance of the PCTs in the growth areas (Table 1).

Table 3: The total area of D. tenuifolia habitat within the Greater Penrith and Eastern Creek (GPEC), and Western Sydney Airport Growth Areas by vegetation zone (PCT) and condition.

PCTs	Condition	GPEC	Western Sydney Airport Growth Area	Grand Total
724	Intact	21.5	3.3	24.8
724	Scattered Trees	3.1	0.1	3.2
724	Thinned	53.5	45.8	99.3
725	Intact	59.4	21.1	80.5
725	Scattered Trees	6.0	2.8	8.8
725	Thinned	29.3	14.4	43.7
849	DNG	4.8	24.5	29.2
849	Intact	11.0	22.2	33.2
849	Scattered Trees	33.7	40.9	74.6
849	Thinned	377.2	50.0	427.2
883	Intact	6.4	0.0	6.4
883	Thinned	0.1	0.0	0.1
Grand Total		**605.9**	**225.0**	**830.9**

The habitat area impacted was greater in the Western Sydney Aerotropolis Growth Area (121.3ha) than the Greater Penrith and Eastern Creek Growth Area (101.2 ha) (total 222.5 ha; Table 4), despite only representing approximately a quarter of the total habitat area for *D. tenuifolia* in the urban growth areas (Table 3). The Grey Box - Forest Red Gum grassy woodland is the most impacted (164.4 ha PCT 883) then Broad-leaved Ironbark - Grey Box (39.1 ha PCT 724) followed by Cooks River Castlereagh Ironbark Forest (18.1 ha PCT 725). Overall 26% of the habitat would be impacted within the growth areas; 29% PCT 883, 30% PCT 724 and 14% PCT 725. The majority of the vegetation condition was thinned.

Table 4: The D. tenuifolia habitat area impacted in the growth areas by PCT and condition.

PCT	Condition	GPEC	Western Sydney Airport Growth Area	Grand Total
724	Intact	1.0	0.0	1.0
724	Scattered Trees	0.1	0.1	0.2
724	Thinned	19.6	18.3	37.9
725	Intact	2.8	0.4	3.2
725	Scattered Trees	0.0	2.5	2.5
725	Thinned	7.0	6.4	13.4
849	DNG	4.8	21.5	26.3
849	Intact	1.4	6.6	8.0
849	Scattered Trees	1.6	34.7	36.3
849	Thinned	62.9	30.9	93.8
Grand Total		**101.2**	**121.3**	**222.5**

Brief career history of Dr Paul Rymer

Research Interests: Ecology and evolution, biodiversity hotspots, weeds, and climate change.

Qualifications

- PhD, University of Wollongong, 2006
- BSc (Honours), University of Western Sydney, 2000

Employment

- Lecturer in Ecological Genetics, Western Sydney University, 2014
- Research Lecturer, University of Western Sydney, 2011
- Associate Researcher, Royal Botanic Gardens Sydney, 2010
- Marie Curie Incoming International Fellow, Imperial College London, 2008
- Postdoctoral Researcher, University of Oxford, 2006

Main Research grants

2017 NSW Environmental Trust “Assisted migration under climate change”

2016 HIA Green Cities “Which plant where and why database”

2016 HIA Pollination “Healthy bee populations for sustainable pollination in horticulture”

2015 ARC Linkage “Do hotter and drier regions harbour adaptive variation for climate change?”

2014 ARC Linkage “Identifying regions of high drought mortality risk for tree species in NSW”

2013 NSW Environmental Trust “Grey Box psyllid induced mortality”

2013 UWS Partnership Program “Adaptive potential to climate change” DPaW

2012 UWS Partnership Program “Genetic issues in restoration” Greening Australia

2009-2007 Marie Curie Fellowship “Pollinators drive flora speciation”

Evidence for quality of research outputs:

I have published 33 peer-reviewed scientific journal articles, with an H-index of 11. My work on plant speciation and population genomics attracted some attention, with Linder (Molecular Ecology DOI: 10.1111/j.1365-294X.2010.04798.x) highlighting its importance in the field. My recent work has been published in several high quality journals, including Molecular Ecology, Molecular Phylogenetics and Evolution, New Phytologist and Global Change Biology. A book chapter on plant markers for conservation genetics was requested by the preeminent Geneticist Robert Henry.

Teaching

I have actively contributed to undergraduate and postgraduate teaching at several institutions, and currently I am teaching Botany, Principles of Evolution, and Biological Adaptation to Climate Change at WSU. I have supervised six MSc research projects at Imperial College London, University of Oxford, and University of Wollongong. I am currently supervising five PhD, three Masters, and several undergrad research projects.

Other research leadership and community roles:

Much of my research has been applied to understanding plant rarity (and conversely invasiveness), which has produced valuable information for land managers. The findings of my work have been directly incorporated in recovery plans for endangered species. My work on neotropical trees has been used to develop best practice guidelines for seed sourcing for natural restoration. I have contributed as a scientific expert to the Priorities Action Statement 2 process for OEH management of threatened species. I have taken up a committee positions for the development of recovery plans, Cumberland Conservation Corridor Reference Group (Department of the Environment), and Greening Australia’s Grassy Groundcover Research Project advisory group (Greening Australia). Outreach to high school students through the development of material for the HSC Agriculture syllabus (Department of Education).

Dr Paul Rymer – ten most relevant publications

1. Flores-Rentería L, Rymer PD, Riegler M. (2017) Unpacking boxes: integration of molecular, morphological and ecological approaches reveals extensive patterns of reticulate evolution in the box eucalypts. Molecular Phylogenetics and Evolution, 108, pp. 70-87

Complex evolutionary histories are unpacked through a multi-faceted approach where incomplete lineage sorting is the dominant pattern in widespread species.

2. Blackman CJ, Aspinwall MJ, Tissue DT, Rymer PD (2017) Genetic adaptation and phenotypic plasticity contribute to greater leaf hydraulic tolerance in response to drought in warmer climates. Tree Physiology https://doi.org/10.1093/treephys/tpx005

Intraspecific variation in hydraulic traits are revealed among provenances and growth temperatures. We show support for local adaptation to hot climates through enhanced resilience to drought.

3. Huang G, Rymer PD, Duan H, Smith RA, Tissue DT (2015) Elevated temperature is more effective than elevated [CO2] in exposing genotypic variation in *Telopea speciosissima* growth plasticity: Implications for woody plant populations under climate change. Global Change Biology 21 (10), pp. 3800-3813 [Cited 1, JIF 8.044]

Coastal genotypes from mesic climates were found to have a greater capacity to increase growth in response to warming and elevated CO2 campared the non-responsive upland genotype. The finding support the prediction that upland taxa will be under threat with climate change.

4. Drake JE, Aspinwall MJ , Pfautsch S, **Rymer PD**, Reich PB, Smith RA, Crous KY, Tissue DT , Ghannoum O & Tjoelker MG (2014) The capacity to cope with climate warming declines from temperate to tropical latitudes in two widely distributed *Eucalyptus* species. Global Change Biology, 21 (1), pp. 459-472 [Cited 15, JIF 8.044]

This paper provides support for the hypothesis that climate change will negatively affect the warm edge of a species' distribution more than trees from moderate- or cool origins. The climatic gradient explored along the east coast of Australia provides insights into the importance of physiological tolerance and gene flow for resilience to climate change.

5. **Rymer PD**, Sandiford M, Harris SA, Billingham MR, Boshier DH (2013) Remnant *Pachira quinata* pasture trees have greater opportunities to self and suffer reduced reproduction due to inbreeding depression. *Heredity* doi: 10.1038/hdy.2013.73 [Cited 9, JIF 3.805]

Habitat fragmentation is a key threatening process. This study shows how trees can respond to altered mate availability through labile selfing and enhanced pollen movement with implication for conservation.

A comparative study that identifies broad patterns of genetic structure in rainforest trees. We explored the effect of different life-histories and geographic barriers were shown to determine gene flow.

Expert report – Green and Golden Bell Frog

Expert report for the Green and Golden Bell Frog (*Litoria aurea*), Francis Lemckert, 2019

Strategic assessment for Cumberland Plain Conservation Plan - Expert report for the Green and Golden Bell Frog (*Litoria aurea*)

Francis Lemckert

Principal Ecologist

Level 5, 20 Berry Street, North Sydney, NSW

0408340084

1. Introduction

The NSW Government is identifying areas for future urban development and associated infrastructure in Western Sydney. Four priority Growth Areas (GA) have been nominated in South Western Sydney:

- Wilton Growth Area
- Greater Macarthur Growth Area (Campbelltown and Appin)
- Western Sydney Airport Growth Area (Aerotropolis)
- Greater Penrith to Eastern Creek Growth Area.

The locations of these four GAs are provided in Figure 1. All are located within the Cumberland Subregion Interim Biogeographic Regionalisation for Australia sub-region.

1.1 Purpose of the expert report

Section 6.5.2 of the Biodiversity Assessment Method sets out the following essential requirements for the preparation of an expert report:

- identify the relevant species or population
- justify the use of an expert report
- indicate and justify the likelihood of presence of the species or population
- estimate the number of individuals or area of habitat (whichever unit of measurement applies to the species/individual) for the biodiversity certification assessment area, including a description of how the estimate was made
- demonstrate what information was considered, rejected and discounted in relation to the determination made in the expert report
- identify the expert and provide evidence of their expert credentials.

The report needs to determine whether:

- The species is unlikely to be present, in which case no further assessment is required, or
- The species is likely to be present in which case the expert report must provide estimates of habitat area within the biodiversity certified development footprint.

1.2 Project context

The Department of Planning and Environment (DPE) has been tasked with preparing the Cumberland Plain Conservation Plan (the Plan) that will identify development and conservation outcomes within each of the above four listed GAs. The Plan will be strategically assessed and approved using Biodiversity Certification (Biocertification) enabled under the *Biodiversity Conservation Act 2016* (BC Act) and strategic assessment and approval to be carried out under *the Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act).

The strategic assessment process will lead to:

- the identification of a preferred conservation outcome for the Cumberland Subregion
- an assessment of the likely impacts of proposed urban development
- identification of mitigation measures that deliver good conservation outcomes
- a streamlined development approval processes.

A biodiversity assessment report will be pepared to assess the conservation benefits and development impacts of the Plan and determine the acceptability of the conservation outcomes in the context of the above state and national legislation. The current approach is that DPE will prepare a single, integrated assessment report that addresses the requirements of both the BC Act and the EPBC Act. A core aspect of the conservation program will be the development of offsets for impacts on threatened biodiversity.

Biocertification is being used to identify conservation areas within the Cumberland Subregion that meet the criteria to be purchased for the required offsetting. Biocertification will ensure that biodiversity values are assessed, and conservation issues resolved early in the planning process. Certification supports a more streamlined and cost-effective land-release process than site-by-site assessment.

1.3 The study area

The location of the Cumberland Subregion and the four Growth Areas is provided in Figure 1. Information for each of these areas was determined from a range of data layers including:

- Native vegetation: CumberlandPlainWest_2013_E_4207 & SydneyMetroArea_2013_v2_0_E_3817
- LEP Layers Land Zoning (LZN)
- Altitude: Central West Sydney Surrounds 2m Contours & Contours 50m, Outer Sydney South 2m Contours, Central West Sydney Surrounds 2m Contours and Outer Sydney North 2m Contours
- Waterbodies: Roadnet MDS 2018
- Biodiversity Certification Land: Subject Lands for the Biocertification of Sydney Region Growth Centres SEPP and related EPIs (GrowthCentreLandCertification)

The Wilton Growth Area (hereafter WGA) is centred around the township of Wilton, which is approximately 63 km southwest of Sydney and covers an area of approximately 4082 ha. The WGA is approximately 23 km from the coast at its eastern boundary and covers an altitudinal range of 64 to 300 m ASL. Approximately 1824 ha (45%) of the WGA is covered in retained native vegetation, which is essentially confined to the southern end of the GA adjacent to an area of dissected escarpment. The majority of the WGA is rural agricultural land used for a variety of activities including grazing, hobby farming and cropping (Figure 2). There is relatively little road development across the majority of the WGA, with the major roads being restricted to the northern end where there is also the main centre of urbanisation (accounting for approximately 20% of the WGA). The WGA contains significant permanent streams in the form of the Nepean River that runs along or within its western and northern boundaries and Allens Creek that forms the northern half of its eastern boundary. Shepherds Creek runs off Allens Creek and into the central part of the GA. These stream all have largely retained riparian vegetation, albeit often highly disturbed, and so retain the potential to serve as significant corridors for vegetation dependent biodiversity. Numerous artificial water bodies (> 200) are mapped throughout the GA, with the exception of the area of the Wilton Township itself. Many more unmapped water bodies are present through the creation of farm dams and reservoirs (Figure 2).

The Greater Macarthur Growth Area (GMGA) is centred around the township Campbelltown-Macarthur, approximately 43 km southwest of Sydney, but extending from West Appin in the South to Glenfield in the north (Figure 3). The GMGA covers an area of approximately 11046 ha, is approximately 24 km from the coast on its eastern border and covers an altitudinal range of 4 to 262 m ASL. Approximately 3038 ha (28%) of this GA remains covered in retained native vegetation, which is also concentrated at the southern end, with the southern half dominated by land used for rural agricultural purposes and, as for the WGA, there is relatively little road development across this area. The M1 motorway runs along the western edge of the GMGA and likely represents a significant barrier to dispersal for biodiversity. The northern half of the GMGA is highly developed and heavily fragmented by numerous roads. Urbanisation covers approximately 35% of the GMGA area. The most significant river within the GMGA is the Nepean River and its tributaries that are located in the southern end of the GCMA, with the main River forming a large part of the western boundary of the GA. Sections of the Nepean have retained riparian vegetation, but large parts of the banks are essentially cleared or the vegetation highly degraded. Peter Meadows Creek flows east to west in the northern part of the GA and ultimately joins into the Georges River and so also provides some degree of potential connectivity as a corridor for movement. Numerous artificial water bodies have been created within the rural portion of the GMGA (Figure 3).

The Western Sydney Aerotropolis Growth Area (WSAGA) is centred around the township of Badgery's Creek, approximately 41 km west of Sydney and so the coast (Figure 4). The WSAGA covers an altitudinal range of 32 to 120 m ASL. The WSAGA includes a section that is outside the current GAs that is excluded from assessment in this expert report (area indicated in Figure 4). Within the assessed area, there is relatively little retained natural vegetation (approximately 865 ha or 13%) that is highly fragmented and with no patch larger than 137 ha. The WSAGA is predominantly rural agricultural land, with overall percentages being 83% rural lands and 11% urbanised. Road development follows the same pattern being very limited across the WSAGA. There creeks present within the WSAGA have patchy retained riparian vegetation. As for the other GAs there are numerous artificial water bodies present in the rural land-use areas (Figure 4).

The Greater Penrith to Eastern Creek Growth Area (GPEC) is located approximately 50 km west of Sydney (Figure 5). The GPEC is relatively flat, covering an altitudinal range of 8 to 102 m ASL. Retained native vegetation cover is minimal (3229 ha = 17%) and fragmented, but with a largest retained area of 549 ha. Unlike the other GAs, the majority of the GPEC is urbanised land (11867 ha = 64%) and rural lands account for only 3501 hectares (18%). There is substantial road development across the majority of the GPEC, which is likely to form a barrier to movement for any species existing within this GA. The Penrith Lakes form an obvious area of once natural wetlands (Figure 5), but much is highly modified for recreational use and this modification continues to increase. This system only partially falls in the GPEC. Major creeks or rivers within the GPEC are the Nepean River on the western boundary, the Ropes Creek system that runs through the eastern part of the GPEC and South Creek that runs through the centre of the GPEC. The riparian vegetation along these larger streams varied in extent and condition and they run usually through highly urbanised environments, preventing frogs from moving between them or to any other water bodies within the matrix, reducing their value as corridors. Artificial water bodies are scattered across the GPEC, but are not in the same numbers as to for the other GAs (Figure 5).

1.4 Reasons for use of an expert report

Section 6.5.2.8 b of the Biodiversity Assessment Method (OEH 2017) places two specific requirements for where an expert report can be used instead of surveys:

- an expert report can only be used instead of a survey for species to which species credits apply
- an expert report may be obtained instead of undertaking a species survey at a development site, clearing site, land to be biodiversity certified or a biodiversity stewardship site.

The GGBF meets the first criteria, being a species credit species under the *Biodiversity Conservation Act 2016*. For the second point, this report is being prepared for the consideration of impacts in the area of the Cumberland Plain Conservation Plan as part of a strategic biodiversity assessment involving biodiversity certification under the *Biodiversity Conservation Act 2016* and Strategic assessment and approval under the *Environment Protection and Biodiversity Conservation Act 1999*. The strategic biodiversity assessment is an integral part of the Cumberland Plain Conservation Plan that will determine the impact of urban development on threatened species and ecological communities within these growth areas. Hence it meets the criteria as land to be biodiversity certified.

The GGBF is known to inhabit the types of landscapes present within all four of the GAs and records exist across much of the Cumberland Subregion (Figure 1). Insufficient field survey has been carried out to adequately assess the presence of the GGBF within the GAs, with extensive areas of potential habitat occurring on private lands that cannot be accessed. In addition, the spring/summer period over 2017/2018 had below average rainfall and rainfall is critical to initiate calling and reproduction in the GGBF. The conditions were sufficiently unfavourable to prevent an adequate survey outcome even in those areas that could be accessed (see Section 1.6). Activity of the GGBF at the best available reference site of Sydney Olympic Park indicated that very little calling took place over the designated survey period, minimising the chances of detecting any populations present within the four Growth Areas.

On that basis, an expert report was determined to be required for this species.

Credentials of expert

Dr Lemckert is an Ecologist that has been undertaking studies into the ecology and management of frogs since 1986 and has been a principal ecological consultant since 2011. His skills include survey design/ implementation/ targeted species surveys, data handling, analysis and interpretation and the production of high level reports including papers published in international peer-reviewed journals and technical reports and recovery plans for the Commonwealth and NSW Governments. He has also been an expert witness for the assessment of the impacts of alleged illegal clearing for the Commonwealth, NSW and Local Governments (Hornsby Council) and provided expert advice to NSW DPI for legal considerations over the potential for forestry operations to impact on rock outcrop dependent species. At the broadest level Dr Lemckert represented Forests NSW (now Forestry Corporation NSW) as a reptile and amphibian expert in the Comprehensive Regional

Assessments and Regional Forest Agreement Process carried out between 2000 and 2002 and as an expert in fauna management for negotiations over a new Threatened Species License for harvesting operations in 2014. He provided an expert review of the developed assessment process for impacts on Matters of National Environmental Significance for two proposed Coal Seam Gas Developments in Queensland and has completed two rounds of expert review of the status of Australia's amphibians for the IUCN.

Dr Lemckert is an acknowledged expert on eastern Australian frogs having completed his MSc and PhD on the ecology and management of frogs in this region and has published over 70 papers (or book chapters) in Australian and International peer-reviewed journals. He has been used by both the NSW and Commonwealth Governments as an expert witness in court cases assessing the impacts of land clearing on threatened frogs. He is member of the Amphibian Specialist Group of the IUCN, secretary of the NSW Declining Frog Working Group of NSW and past president of the Australian Society of Herpetologists. He co-supervised two PhD students, a Master of Applied Science Student and three Bachelor of Science (Honours) students who completed theses addressing issues of frog biology and conservation.

Dr Lemckert can demonstrate his expertise on the GGBF through the following publications and reports:

Lemckert, F.L., & Mahony, M.J. 2018. The status of Decline and Conservation of Frogs in Temperate Coastal South-eastern Australia. **Pp 59-72** In: *Amphibian Biology Volume 11 - Conservation and Decline of Amphibians: Eastern Hemisphere (Australia, New Zealand and Pacific Islands)*. In addition, he is recognised as an expert in the species having been engaged by:

- NSW Office of Environment and Heritage to be part of the expert panel determining the categorisation of this species under the Saving Our Species (SOS) program and in determining the populations requiring specific management to meet the SOS requirement to have a viable population maintained 100 years into the future.
- NSW Roads and Maritime Services to conduct expert surveys for this species in the area around Sydney Airport, Gerringong, Shortland to Sandgate, South Nowra and Berry to Bomaderry, locating the species at Gerringong and South Nowra (2011-2016).
- Port Kembla Coal Terminal to conduct annual ongoing monitoring of this species as part of a Green and Golden Bell Frog Management Plan (2014-2017).
- John Holland Group and Daracon to provide expert advice and survey for this species at Kooragang Island for a rail and road corridor upgrade (2015-2016).
- EPBC surveys for the GGBF at Port Kembla to determine the presence/absence of this species in relation to a proposed development along Masters Road (2014).
- Repeat surveys at Wollongong Golf Course as part of pre-clearing of drainage culverts (2013).
- Provided expert opinion on the status of this species during assessments undertaken for the IUCN in 2001 and 2016.
- Provided expert opinion on the habitat requirements, sub-population status and reservation requirements for the Green and Golden Bell Frog during the NSW Government's Comprehensive Regional Assessment program (2000-2001).
- Distribution surveys through its historic range between Sydney, NSW, and the Gippsland area of eastern Victoria, as part of a project to look at overlap zones and pre-mating isolating mechanisms between the GGBF and the Southern Bell Frog (*Litoria raniformis*) (1986-1987).

Specific to the Growth Areas, Dr Lemckert has:

- Carried out a series of surveys for the GGBF to meet EPBC standards for the development of the Franciscan Monastary Site on Narrellan Road at Blair Athol.
- Undertaken a survey for the GGBF in the study area for the proposed second airport at Badgery's Creek.
- Conducted biodiversity surveys in the Cordeaux catchment area as part of mine site impact assessments.

Dr Lemckert's full CV is provided as Appendix A of this report.

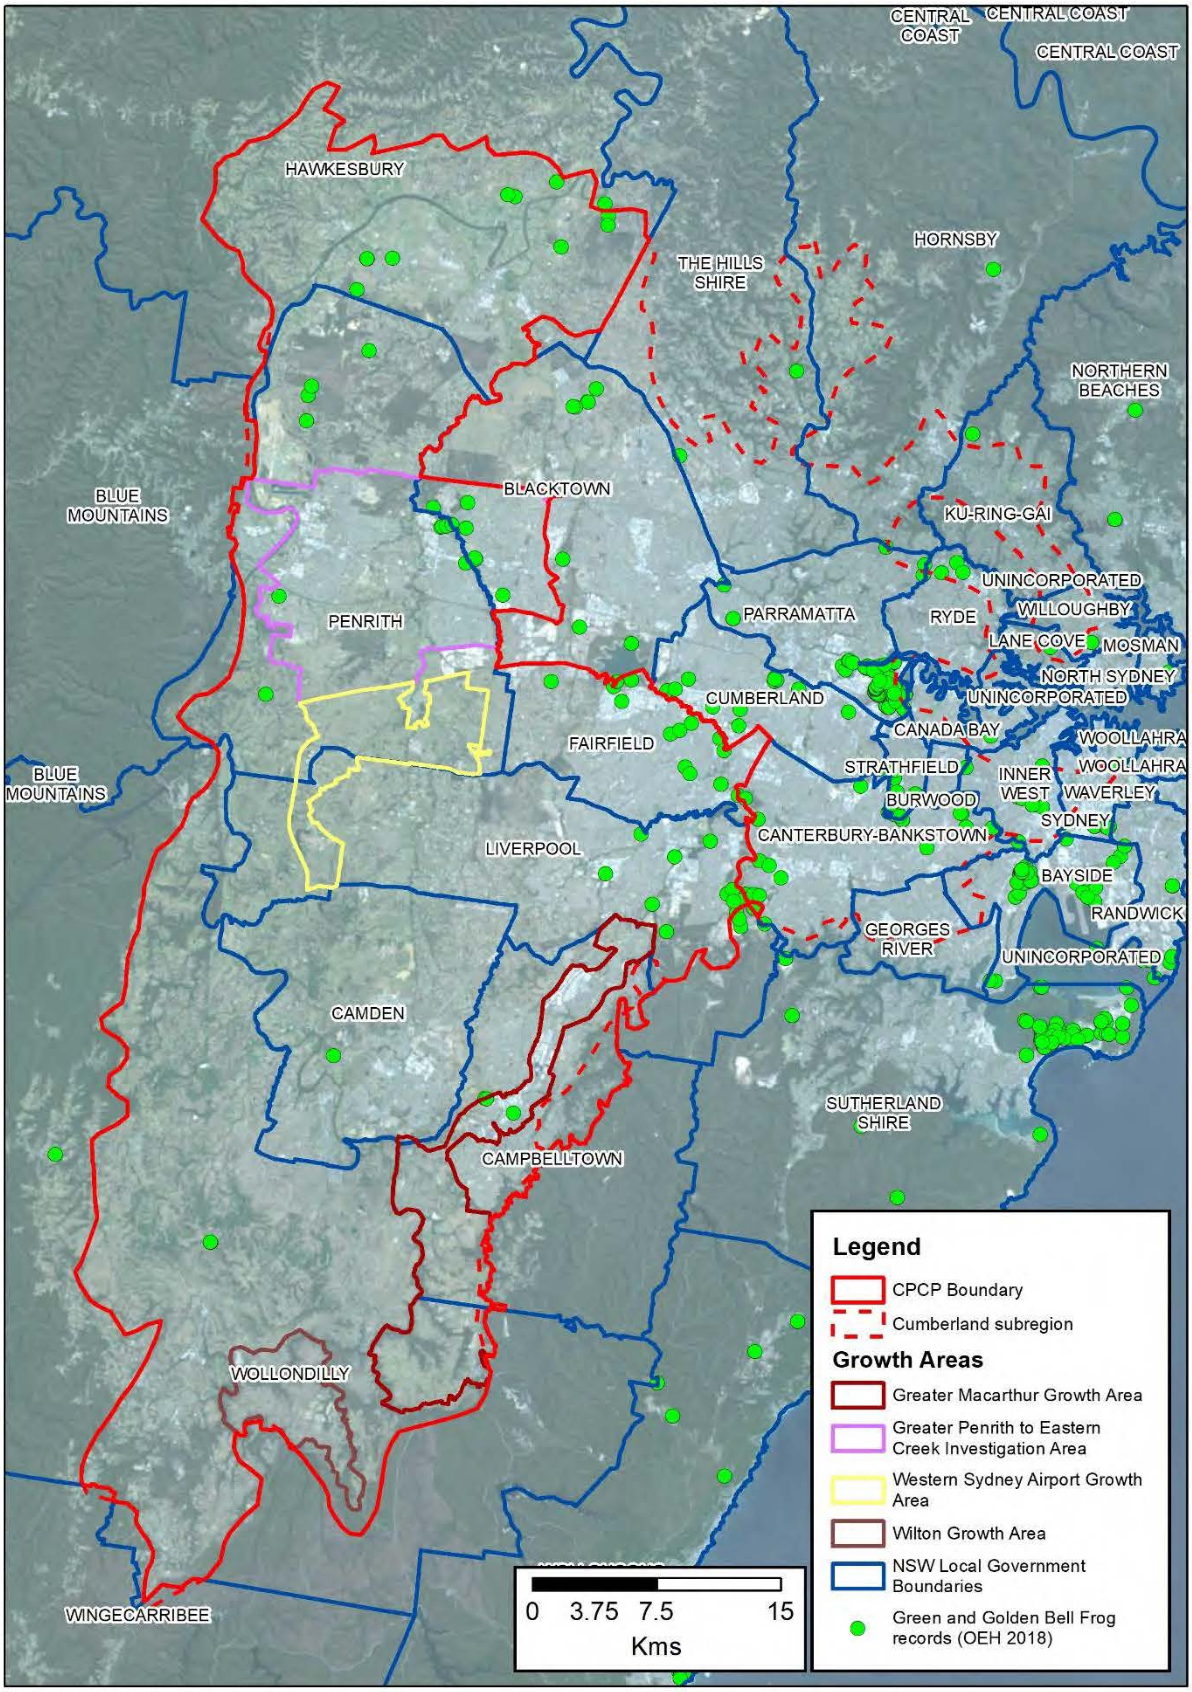

Figure 1. Location of the Cumberland Subregion and associated records for the Green and Golden Bell Frog

1.5 Species surveys conducted on behalf of the Department of Planning and Environment

The following information was provided for the survey process adopted for this project.

Land Access

The Department of Planning and Environment (DPE) sent letters to all landholders within the development footprint.

An initial 726 letters were sent to landholders within the Wilton and Greater Macarthur Growth Areas in late 2017 with a second letter following in March 2018. To increase the response rate, Biosis commenced targeted door-knocking in May 2018. From these efforts, just under 20% of landholders within these growth areas allowed access to their property. However, this included access to large parcels of land owned by major developers which allowed a reasonable amount of access, particularly for the Wilton Growth Area.

A total of 432 letters were sent to landholders across the WSAGA between November 2017 and August 2018 with 84 landholders responding positively to provide access. A further seven properties were accessed after doorknocking, resulting in a response rate of 21%.

Targeted letters were sent to landholders in the GPEC from November 2017 and August 2018 and 177 landholders provided access to their properties. An additional three landholders provided permission via doorknocking (12% response rate). The Open Spaces Team at Penrith Council facilitated access to 64 lots owned by Council.

Targeted survey for threatened species

Field sampling was undertaken across the four growth areas by consulting ecologists from Biosis and Ecoplanning. Targeted survey for threatened fauna species has been conducted on lands where access has been granted, or through ‘drive by’ and ‘over the fence’ assessments. Targeted fauna survey conducted by Biosis focused on Gang-gang Cockatoo, Glossy Black-Cockatoo, Large-eared Pied Bat, White-bellied Sea-Eagle, Little Eagle, Square-tailed Kite, Cumberland Plain Land Snail, Southern Myotis, Squirrel Glider and Greater Glider. No frogs were included in this survey, but there was still the potential for the GGBF to be detected incidentally.

Extent of surveys

The extent of the surveys undertaken for fauna have been provided by Biosis and are provided in Appendix 1. The survey tracks indicate that a relatively broad area set of surveys have been conducted in each of each GAs, but that still extensive sections of each GA have had no coverage.

2 Species information

2.1 Species description

The GGBF is an endemic Australian tree frog that is a member of the family Hylidae. It is a relatively large species, ranging in an adult size for males of 57-69 mm and females 65-108 mm snout to vent length (Tyler and Knight 2009). The species gets its name from the typical colour of the body which is often a vivid green splotched with gold. However, in some individuals the back may be almost entirely green whereas other have dominant gold markings (See Plates 1-3 in Appendix 2). There is a pale creamish-white stripe running along the side, extending from the upper eyelids usually almost to the groin. The species also has blue or bluish-green markings in the thighs and groin. The snout is relatively pointy and the belly granular. There is rarely a mid-dorsal stripe, which distinguishes this frog from the Southern Bell Frog, *Litoria raniformis*.

Plate 1. Typical adult Green and Golden Bell Frog

2.2 Life cycle

The GGBF is considered to have a calling season that extends from spring to autumn (Lemckert and Mahony 2008). Within that period of time calling is tied strongly to rainfall events. The advertisement call is a “whaaark whaaark whaark whark” that is produced by the male. Calling occurs mainly at night, but occasionally males will call during the day when conditions are especially favourable (DEC 2005). The males call in groups floating on the surface of the water usually holding on to emergent vegetation, with males synchronising their calls with a lead calling male so that they all call essentially at the same time (Barker et al, 1995; Pyke and White 2001). This may help to confuse predators by masking individual calls. Male GGBF reach sexual maturity at around 45–50 mm snout-vent length (DEC 2005), which would usually be reached in the first season after metamorphosis.

Females of the GGBF reach sexual maturity at a snout-vent length of around 65 mm, which usually takes to their second season after metamorphosis (DEC 2005). Female GGBF produce a particularly large number of eggs for an Australian species, with Pyke and White (2001) suggesting an average clutch size is about 3700 eggs, but with van de Mortel & Goldingay (1996) recording a maximum clutch of 11,682 eggs. Egg size is around 4 mm in diameter.

Spawn is laid among aquatic vegetation, with it initially floating on the water surface as a mass, but sinking within 24 hours of being laid. The eggs typically hatch 2–5 days after ovipositing/fertilisation (Anstis 2013) with water temperature playing a role in development time (eggs hatch faster in warmer water) and can hatch in less than one day.

The tadpoles can tolerate salinity levels of six parts per thousand (ppt) without any apparent effects, while salinity of 8 ppt or higher decreases growth rates and increases mortality rates (Christy and Dickman 2002). The pH of a pond does not appear to affect the likelihood of the eggs to hatch (Pyke and White 2001).

Tadpoles grow at variable rates depending on conditions and availability of food. They can reach up to 80 mm in length before metamorphosis, although they will do so at smaller body lengths. Time to metamorphosis is variable and dependent on conditions and time of year, taking between two and eleven months, but with a mean of three months (Anstis 2013). Tadpoles may overwinter if breeding occurs late in autumn. They would be expected to typically eat algae and other aquatic vegetation and can often be seen sucking at the surface of the water, presumably to take in organic material floating on the water surface. But their actual diet has not been studied. As for most species, it is likely that tadpoles will also eat dead animal material if it is available, including other tadpoles.

2.3 Distribution and abundance

Broad distribution

The distribution has been recorded as from Yuraygir National Park on the far North Coast of NSW to around Lakes Entrance in south-eastern Victoria (White and Pyke 2008). Notably, Courtice and Grigg (1975) completed a detailed study of the distribution of the GGBF and in Gippsland found it only as far west as Marlo where it abutted and had a potential hybrid zone with *Litoria raniformis*, which was the species found to the west of that point. In the mid-1980s the species was recorded at least 60 km further west at Nowa Nowa and *Litoria raniformis* were no longer present in that location (F. Lemckert Pers. Obs.) and then 15 km further west at Lakes Entrance by White and Pyke (2008). This may suggest a slight westward expansion of the species in Victoria since the 1970s. Historically the species was known from a number of sites at least 50 km inland into the NSW ranges including at Bathurst (White and Pyke 1999), Bungendore (Humphries 1979) and 30 km inland at Ulong on the NSW north coast (Moore 1961). The furthest and now only extant “inland” population is near Hoskinstown in the Southern Tablelands of NSW (Osborne et al. 2008). Natural GGBF populations are also known from three islands off the coast of NSW; Bowen Island, Kooragang Island and Broughton Island (DEC 2005). Extra-limital populations have been introduced to New Zealand (Pyke et al. 2002), and New Caledonia and Vanuatu (Pyke and White 2001) with the species occurring in high densities in some areas (M. Mahony Pers. Comm.).

The extent of occurrence of the species in 1999 within Australia was estimated to be approximately 150,000 km² (Mahony 1999), but there are no more recent estimate and the extent of occurrence is probably continuing to reduce as populations are known to be continuing to decline (Mahony et al. 2013).

Distribution one the Cumberland Subregion

A total of 13146 records for the GGBF are available on the Cumberland Subregion (based on NSW BioNet records), with the broad distribution of these records being shown in Figure 1. This is a large number of records, but is highly skewed by the records from Sydney Olympic Park and the majority (>95 %) come from the eastern third of the Cumberland Subregion, none of which is included in the GAs. The records from the actual GAs are very limited, with just 12 record sites being available from the GPEC and two from the GMGA. The limited number of records in the western half of the Cumberland Subregion suggests that the GGBF may never have been common or widespread across this region, despite the apparently adaptable nature of this frog (see Section 2.4) and the presence of habitat that otherwise looks suitable for the GGBF.

The Draft NSW GGBF Recovery Plan (DEC 2005) lists one core populations for this species located within or near a Growth Area, being the St Marys population centred around St Marys, Mt Druitt, Prospect and Riverstone that is part of the GPEC.

Abundance

The GGBF was recorded as once being a very abundant and widespread frog (Goldingay 1996). Fletcher (1889) stated that this species was commonly be encountered in the Sydney area and Harrison (1922) noted that this species was "probably our best known frog" and was "known to me since childhood". Extensive surveys for the species by Courtice and Grigg (1975) in the early 1970s recorded it very regularly and abundantly across coastal NSW and into southeast Victoria. However, there was a serious decline of the species in the 1980s, with the timing being uncertain, but with frogs having disappeared from many historic sites by 1987 (F. Lemckert Pers. Obs.). By 1996 the GGBF was regarded as rare by White & Pyke (1996) and its recorded declines recognised to be of concern (White 1995). Populations of over 1000 frogs were (and likely still are) present at Kooragang Island, Broughton Island and Homebush (Hamer et al. 2002), but the other locations it is known from are much smaller populations (DEC 2005). Even in 2005 the GGBF was recognised as having declined to less than 50 populations in NSW (DEC 2005) and the declines have been continuing (Mahony et al. 2013). The amphibian chytrid fungus has been implicated as the main driver of these severe declines (Mahony et al. 2013), although habitat loss (Goldingay 1996) and introduced predatory fish (Pyke and White 1999, Goldingay 2008) have also been suggested to have played significant roles in population declines and losses.

Over the short-term the GGBF can exhibit significant local population fluctuations when conditions result in high tadpole survivorship (eg, Daly 2014). The GGBF has a life cycle that fits what is termed to be an R-selected species (Hamer and Mahony 2007), producing large numbers of offspring and adults have relatively shorter lifespans. Hence, there is a relatively rapid turnover of individuals and survival of the local population depends on occasional very successful seasons, when population size and area utilised rapidly increase, interspersed with years of low recruitment when numbers fall away and there are local extinctions in less favourable areas of habitat. This is considered to be a typical pattern for amphibians (Alford and Richards 1999). In fact, The GGBF has been suggested to be a colonising species with a series of its attributes suit this lifestyle: habitat generalist, high fecundity, rapid growth, early sexual maturity, and relative high dispersal ability (Hamer & Mahony 2007). White and Pyke (1999) suggests that the GGBF rapidly move into areas of newly created breeding habitat that represent sites with little competition for the developing tadpoles from other species, are open and so provide good thermal environments and lack or have minimal predators such as dragonfly larvae or fish present. Such a lifestyle is atypical of frog species that have undergone significant broader declines.

Nearly all currently known populations within Australia are located within 10 kilometres of coastal locations (Mahony et al., 2013). This is most likely due to the inhibition of the amphibian chytrid fungus by salt, either through flooding or windborn, as the fungus in relatively intolerant of salt (Stockwell et al 2012). Hence more coastal locations are relative havens from the impacts of chytrid. As, salinity levels of at least 1–2 ppt can be beneficial to the GGBF because this kills pathogens such as the chytrid fungus. Interestingly, Christy and Dickman (2002) identified saltwater intrusion in coastal wetlands due to landscape changes to be a potential threat to GGBF breeding sites. Dryland salinity might then also represent a threat to GGBF should it occur, but this seems to be a minimal issue based on current evidence.

Plate 2. Examples of typical breeding habitat for the Green and Golden Bell Frog at: a) Wilton and b) Penrith Lakes – large permanent ponds with emergent and/or fringing vegetation.

Plate 3. Examples of habitat at Ropes Creek: a) Bushland for foraging and b) Dry creek bed that would flood to form breeding habitat.

2.4 Habitat requirements

Breeding Habitat

Breeding sites for the GGBF include a wide range of natural water bodies and the species has been recorded inhabiting all but fast flowing streams (Pyke & White 1996). It also inhabits many human-created environments, including highly disturbed sites such as abandoned mines and quarries (Pyke et al. 2002), as well as artificial wetlands that have been created at both Kooragang Island (Hamer et al. 2002) and Sydney Olympic Park (Darcovich and O'Meara 2008). Pyke & White (1996) undertook a review of the known breeding habitat of the GGBF and found that they preferred to breed in water bodies that were still, shallow, ephemeral, unshaded, with aquatic plants and free of the Plague Minnow (*Gambusia holbrooki*) and other predatory fish. This study also found that breeding occurs in a significantly higher proportion of sites with ephemeral (temporary) ponds, rather than sites with fluctuating or permanent ponds. Hamer et al. (2002) found a similar result for the GGBF populations at Kooragang Island where larger males would move to ephemeral water bodies to opportunistically breed at them, although reproduction was also associated with permanent water bodies. The frogs in that study also tended to remain relatively faithful to one water. The presence of the Plague Minnow does not exclude GGBF from breeding in a water body, but success appears to be dependent on the presence of more complex aquatic vegetation, which allows the GGBF to breed successfully (Hamer et al. 2002). Hence the Plague Minnow does still appear to have a significant role in determining the likely presence of the GGBF in most situations.

Non-breeding habitat

Non-breeding habitat for the GGBF is unusual for an Australian frog in that the species appears to remain generally associated with water bodies (remain within 50 metres) rather than dispersing away from water bodies into more terrestrial non-breeding habitats (100-300 metres from the breeding site), which is typical of most frogs (Lemckert 2004). Terrestrial habitats immediately adjacent to water bodies are used for foraging and shelter and preferably consist of grassy areas and vegetation no higher than woodlands and contain a range of diurnal shelter sites such as logs, rocks or dense vegetation (Pyke and White 1996). However, there are observations of GGBF using taller forests (eg. dry sclerophyll forest at Nowra; M. Greenlees Pers. Comm. and dense woodlands at Meroo, FL Pers. Obs.) and foraging in suburban backyards (DEC 2005), again demonstrating the apparent adaptability and lack of habitat specificity of this frog. Females have been observed to show site fidelity for shelter and foraging sites in areas adjacent to breeding sites (Hamer 1998, Pyke and White 2001).

Shelter sites are used when GGBFs are inactive and so vulnerable and are of added importance in providing secure over-wintering locations. Studies at Kooragang Island have suggested that females may use slightly different non-breeding areas to males and may have very important and specific over-wintering areas located in dense vegetation (M. Mahony Pers. Comm.). Whether this is the same for other populations is unknown, but there is evidence from Sydney Olympic Park that females there also concentrate in certain locations (J. O'Meara Pers. Com.).

Another unusual aspect of the GGBF is its well known habit of basking, typically within areas of aquatic vegetation, apparently to increase body temperatures (Pyke and White 2001). Basking in frogs is unusual (being generally nocturnal), but such activities in ectotherms typically allow for periods of greater activity or faster digestion of food items and, whilst the importance of this activity for its physiological requirements is not known, individual GGBF appear to bask regularly. On this basis, it is likely that basking is an important physiological activity for the GGBF. Basking typically occurs within or on the edge of emergent aquatic vegetation, which likely allows individuals the option to make a rapid escape from diurnal predators. The presence of water bodies that contain emergent vegetation are known important determinants of the presence of GGBF (Pyke and White 1996; Hamer et al. 2002) and form an important resource for the GGBF and in the consideration of their potential presence.

Whilst GGBF may retain a closer association with water bodies and appear to generally be faithful to a single water body for their general activities, they can move along and between different water bodies, particularly as part of migrations to and from breeding sites (Hamer et al. 2002). Studies have revealed that the species move distances of up to 1 kilometre (Hamer et al. 2008) and mark/recapture studies have found individuals moved up to 3 kilometres (Pyke & White 2001). Individual GGBF even have the potential to disperse as far as 10 kilometres (White & Pyke 2008). There are records of GGBFs several hundred metres from major drainage lines or other waterbodies (Gillespie 1996) and this may represent long-distance dispersal between water bodies. Hamer et al. (2008) noted that male GGBFs at Kooragang Island often moved > 200 metres to reach an ephemeral breeding site, crossing over extended grassland areas and other habitats including disturbed habitats.

Christy (2001) and Muir (2008) indicated that terrestrial movements of the GGBF are primarily undertaken through more open environments that contained patches of shelter such as rocks, logs or ponds or areas of thick vegetation. Such habitats provide relatively little impediment to the movements of frogs, but allow for individuals to seek shelter as required. Terrestrial movements are typically undertaken at night and are most likely associated with rainfall events (F. Lemckert Pers. Obs.) which would provide protection against desiccation.

Mahony (1999) cautions that the studies that have been carried out since the declines of the GGBF do not necessarily identify the actual preferred requirements of the species. He notes that the changed environment and factors causing the declines may have “altered” the optimal habitats for the species in comparison to their habitat use patterns prior to the declines. This is based on the fact that the use of ephemeral breeding sites was not noted for the bell frog group in earlier habitat descriptions. Such altered habitat use has been noted for other species such as *Litoria lorica* that now is only present in open rocky streams whereas it was once known as a rainforest stream species (Puschendorf 2011). This change is attributed to the impacts of the chytrid fungus, with the frog only surviving in a relatively extreme environment where the fungus is affected by the hotter conditions. Given the chytrid fungus appears also to have been at least a significant contributor (and probably the major one) to the decline of the GGBF, there is a significant potential that the GGBF is now living successfully only in a different set of environments to what it historically did. However, that is unlikely to ever be confirmed.

Metapopulation dynamics

A critical consideration in the likely presence/absence of the GGBF are metapopulation dynamics. The GGBF is considered to follow a classical metapopulation structure with the “local” population consisting as a series of patchy populations within the larger metapopulation. Individuals move regularly between a mosaic of wetlands across a broad area throughout a single breeding season (Hamer et al. 2008; Hamer & Mahony 2010). There is high site-specific population turnover with local extinctions being balanced by colonisations by regularly dispersing individuals, but with the overall population remaining stable. There are core sites that provide ongoing and regular reproductive success and that maintain long-term populations, but the major part of the population dynamics is driven by inter-year success of breeding at a range of available breeding sites, with years of very good reproductive success leading to opportunities to expand ranges and colonise new sites. On Kooragang Island, GGBF typically reside in permanent waterbodies where they exhibit high site fidelity, but during periods of high rainfall disperse over several hundred metres to breed at ephemeral water bodies that have flooded (Hamer et al. 2008). Reproductive activity (e.g. calling) typically occurs over several nights at these ephemeral waterbodies, with individuals returning to core permanent waterbodies. In times of poor rainfall, the core sites become the refuges for the species and Valdez et al. (2015) found that probability of occupancy of a site increased at large and permanent wetlands.

Following on from this is the identified need for connected sites to allow this population interaction. Hamer (2016) found that the presence of the GGBF at sites at Nowra was dependent on accessibility of ponds, a factor mediated both by the presence of vegetation and the extent of roads in the area, with the presence of roads providing a likely serious barrier to pond use. The presence of vegetation directly around ponds correlated significantly with the potential for greater species diversity. The type of pond available also was important, with the species avoiding steep sided concrete ponds. The apparent negative impacts of roads was confirmed in follow up work (Hamer 2018) where it was again found that the extent of accessible habitat (habitat close to ponds and not isolated from the pond by a road) positively influenced the likelihood of pond occupancy. Extinctions of GGBF were significantly more likely to occur at ponds in areas with higher densities of roads, but were significantly less likely at ponds with higher aquatic vegetation cover. The spatial arrangement of wetlands and the extent of wetlands measured in a 1 kilometre radius has been found to be an important predictor of pond occupancy by GGBF in studies by Hamer et al. (2002), Hamer and Mahony (2010) and Valdez et al. (2015) with more ponds, closer together ponds and already occupied ponds increasing the potential for the GGBF to be present or occupy a previously unoccupied pond (Puschendorf et al. 2011).

This information provides the following important points when trying to assess the potential presence of the GGBF in any area:

- The GGBF is more likely to be present where multiple suitable breeding sites are within a close enough proximity for frogs to migrate between them with relative ease
- The GGBF is more likely to be present where multiple non-breeding water bodies are present in an area and within close enough proximity to allow migration between them (and breeding sites) with relative ease
- The GGBF is more likely to be present where the connectivity of breeding and non-breeding habitat contains a matrix (vegetation and shelter) that facilitates migration
- The GGBF is more likely to be present at a location when there are other GGBF occupied ponds in close proximity.

Vegetation associations

The OEH profile records the GGBF to be associated with a broad range of vegetation formations and classes within the Sydney Basin Interim Biogeographic Region, the location of the GAs (https://www.environment.nsw.gov.au/threatenedspeciesapp/profileData.aspx?id=10483&cmaName=Sydney+Basin). These are:

Dry sclerophyll forests (shrub/grass sub-formation)

Cumberland Dry Sclerophyll Forests

Dry sclerophyll forests (shrubby sub-formation)

Sydney Coastal Dry Sclerophyll Forests
Sydney Hinterland Dry Sclerophyll Forests

Forested wetlands

Coastal Floodplain Wetlands

Freshwater wetlands

Coastal Freshwater Lagoons

Grassy woodlands

Coastal Valley Grassy Woodlands

Miscellaneous ecosystems

Highly disturbed areas with no or limited native vegetation
Water bodies, rivers, lakes, streams (not wetlands)

Rainforests

Dry Rainforests

The most important feature to note is that this list of vegetation associations is relatively broad covering wetlands and swamps, woodlands, dry sclerophyll forests and dry rainforest. That is essentially all possible environments present within the Cumberland Subregion and reflects the understanding that the GGBF is a very adaptable species with little in the way of habitat limitations. This also conforms with the GGBF being recognised for its use of highly disturbed environments and areas without native vegetation. In the context of assessing the likely presence/absence and, if present, the abundance of this species, the type of vegetation present has little relevance. The value of vegetation is it being present to provide GGBF shelter and locations where food may be found.

2.5 Threats

The GGBF is listed as is listed as endangered under the BC Act and vulnerable under EPBC Act.

The IUCN lists the threats to the GGBF as "IUCN: "*The cause(s) of the apparent declines observed in populations of all taxa within the L. aurea complex are unclear (Gillespie et al. 1995).*

Investigations of disappearances among the group have primarily focused on L. aurea and L. castanea and two major directions in research have been pursued: the role of increased ultraviolet radiation; and the impact of the introduced fish, Gambusia (Mahony 1999). It is also possible that disease, such as a viral infection or chytrid fungus, might have contributed to the decline of this species (W. Osborne pers. comm.). Chytrid fungus was detected in this species in Hoskinstown and Homebush Bay in Sydney, New South Wales".

The OEH profile for this species lists the following as threats to this species:

- Alteration of drainage patterns and stormwater runoff.
- Frog Chytrid Fungus, a fungal pathogen.
- Predation by feral animals such as foxes.
- Herbicides and other weed-control measures.
- Road mortality, where populations are already small due to other threats.
- Predation by exotic fish such as Plague Minnow.
- Loss of suitable breeding habitat through alteration by infilling and destruction of wetlands.
- Current knowledge of the status of the population and threats to the population is poor.
- Species occurs on private land where land management practices may not be suitable for the species, e.g. grazing and loss of breeding habitat.
- Changes in salinity due to sea level rise. Frogs are unable to breed in waters with salt concentrations of greater than 6 parts per 1000.
- Overgrowth of pond vegetation leading to declining water temperature.
- Small population size.
- Lack of information regarding habitat permanency.
- Drying of breeding habitat as a result of increased temperatures and more frequent droughts.
- Lack of landscape connectivity leading to isolation of small populations.
- Heavy metal pollution.
- Four-wheel drives impacting habitat.

The SPRAT profile for this species lists the following threats:

- Habitat removal.
- Habitat degradation (which includes siltation, changes to aquatic vegetation diversity or structure reducing shelter, increased light and noise, grazing, mowing, fire).
- Habitat fragmentation.
- Reduction in water quality and hydrological changes (for example, pollution, siltation erosion and changes to timing, duration or frequency of flood events).
- Disease (for example, infection of the frog with chytrid fungus (*Batrachochytrium dendrobatidis*) resulting in chytridiomycosis).
- Predation by introduced predators including the Plague Minnow (*Gambusia holbrooki*), Cats (*Felis catus*) or Foxes (*Vulpes vulpes*).
- Introduction or intensification of public access to GGBF habitats.

In regards to the GAs, the following would be of relevance when considering impacts:

- habitat loss (through changes resulting from flooding)
- fuel reduction burning
- introduced aquatic predators (access to breeding streams)
- spread of the amphibian chytrid fungus.

One specific consideration for the likely presence and abundance of the GGBF is the location of a site relative to the coast with essentially all currently known populations located within 10 kilometres of the ocean (Mahony et al. 2013). This is likely to be a result of the impacts of the amphibian chytrid fungus, with the influence of salt closer to the coast inhibiting the growth of the fungus to a sufficient degree to minimise its otherwise very serious negative effects.

3 Description of the study area

3.1 Land use history

The following information has been derived from the Cumberland Plain Recovery Plan (DECCW 2010a). At the time of European settlement, the Cumberland Subregion would have consisted of extensive areas of grassy woodlands were present along with wooded areas including ironbark and turpentine forests, dry rainforests, and floodplain communities. Agricultural development commenced before 1800 and by the middle of the 19th century most of the region was either being grazed or was cultivated. Clearing for agriculture was later supplemented by clearing for residential, commercial and industrial purposes.

NPWS (2002) noted that only 13% of the pre-1750 extent of the region's vegetation remained as intact bushland, with an additional 12% occurring as scattered trees in disturbed areas. The majority (76%) of the remaining bushland is privately owned, and only 8% is protected within the formal reserve system. The region's bushland is also highly fragmented, comprising 2,446 individual remnants (DECCW 2010b), but the 81 largest remnants contain 51% of the remaining bushland. Many of these large, intact remnants occupy public land and so can be expected to be maintained into the foreseeable future. Larger remnants are typically more diverse and resilient than smaller remnants, being less susceptible to 'edge effects' and being less likely to be fully subjected to catastrophic events. Biodiversity loss caused by habitat fragmentation has been demonstrated to significantly increase once clearing levels exceed 70% of the landscape (Freudenberger et al. 1997; WALGA 2004) and this threshold has been passed on the Cumberland Subregion.

3.2 Landscape context

Cumberland Subregion

Tozer (2003) notes that the Cumberland Plain is based on the extent of soils derived from three main geological units: Wianamatta group shales, Tertiary alluvium and Holocene alluvium (in areas draining Wianamatta group shales). Tozer states that:

"*West of Parramatta, the Cumberland Plain forms an elongated ellipse stretching from Sackville in the north to Thirlmere in the south, with the western boundary marked by the monocline of the Blue Mountains to the west of Penrith. East of Parramatta the Plain is truncated by the*

Hornsby Plateau in the north and the Woronora Plateau to the south, and finally terminates near the city centre.

The Cumberland Plain comprises gently undulating plains and low hills, rising gradually from the flat, low lying areas just above sea level in the north to an altitude of around 350 m on the rolling hills of the Razorback Range in the south. Two low ridgelines project northward from this elevated southern region as far as Mount Druitt and Orchard Hills respectively. The eastern ridge forms a watershed between the drainage channels flowing north to the Hawkesbury River and those draining east into the Georges River. Separating the two ridges is the upper catchment of South Creek, which forms the major drainage channel of the Plain. Rising gradually to the north-west of the Plain, the broadly dissected Hornsby Plateau lies between 100 to 200 m above the northern half of the Plain. On the Hornsby Plateau, Wianamatta Shale soils are located predominantly along three broad ridgelines running approximately north-west from North Sydney to Hornsby and from Ryde to Castle Hill, and north from Castle Hill to Arcadia."

Tozer 2004 also provides the following summary of geology and soils, which in turn is derived from Chapman and Murphy (1989), Hazelton et al. (1990) and Bannerman and Hazelton (1990).

"*The oldest geological units outcropping within the study area are of sedimentary origin and were laid down during the middle Triassic period. Of these, the Wianamatta group is the dominant feature and occurs throughout the Cumberland Plain and on plateau tops and ridges on the Blue Mountains and Hornsby plateaus. It comprises claystone, siltstone, laminite and fine to medium grained lithic sandstone weathering to low fertility soils ranging in texture from loam to heavy clay. The Wianamatta group conformably overlies the discontinuous Mittagong Formation and Hawkesbury Sandstone. The former comprises inter-bedded and laminated, fine to medium-grained quartz sandstone and siltstone, and constitutes passage beds between the Wianamatta Group and the Hawkesbury Sandstone.*

Hawkesbury Sandstone weathers to form sandy–loam soils of very low fertility. The Mittagong Formation and Hawkesbury Sandstone outcrop on the margins of the study area especially along watercourses where the overlying shale has eroded during the development of a streambed.

On the Cumberland Plain, the Wianamatta group is overlain by unconsolidated sediments deposited in two geological periods. The deposition and reworking of silty-clayey sands and gravels along watercourses has been ongoing throughout the Quaternary period. These constitute some of the most fertile soils of the Plain and are particularly extensive on the floodplains of the Hawkesbury–Nepean River in the north of the study area. Sediments dating from the Tertiary Period occur in two main localities: to the south of Richmond in the north-west part of the study area and south of Liverpool in the south-east. These comprise sand, clay, gravel and volcanic breccia of both colluvial and alluvial origin and give rise to soils of low fertility. In the vicinity of Agnes Banks tertiary sediments are overlain by low parallel dunes of quartz sand eroded from the upper catchment of the Hawkesbury–Nepean and deposited by wind during the quaternary period. These sandy soils are of very low fertility."

Key climate statistics for the weather stations located within each GA are shown in Table 1. These data show a decreasing mean maximum from north to north and a corresponding increase in mean minimum temperatures, which is mainly due to the north to south increase in elevation.

Rainfall is relatively similar across the range except that the far northern area at Penrith Lakes has a distinctly lower mean rainfall.

The NSW BAM provides no mandatory applicable habitat constraints for the GGBF, but includes following indicative habitat constraints as being within 1 kilometre of semi-permanent/ephemeral wet areas, within 1 kilometre of swamps and within 1 kilometre of water bodies. This mirrors the understanding of the requirements of the species provided in Section 2.4.

Table 1. Key climatic statistics for weather stations in the Growth Areas (taken from the Bureau of Meteorology).

Weather station	Mean annual rainfall (mm)	Mean maximum temperature (°C)	Mean minimum temperature (°C)
Penrith Lakes AWS	718.6	31.0	5.3
Orchard Hills Treatment Works	832.7	28.5	5.3
Badgerys Creek McMasters F	794.3	28.6	3.8
Camden Airport	782.1	23.8	10.3
Picton Council Depot	800.9	23.4	8.8

Growth Areas

All four GAs contain at least some parts that provide a diversity of water bodies including streams and rivers in dissected gorges, streams on more open floodplains (historically probably chains of ponds), large numbers of farms dams and reservoirs and numerous ephemeral water bodies located amongst pasture lands. The lands also include industrial sites that may hold settling ponds and bunded areas for water collection as well as old quarries and excavations that hold water. All of these water bodies form potentially suitable breeding and shelter sites for the GGBF

3.3 Native vegetation communities

The remnant native vegetation of the Cumberland Subregion is very varied in nature and consists of wet and dry forests, woodlands with grassy and shrubby understories and wetland and riparian vegetation communities. The different PCTs listed as occurring across the four GAs are:

Dry sclerophyll forests (shrub/grass sub-formation)

- 724 Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion;
- 725 Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion;
- 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion.

Freshwater wetlands

- 781 Freshwater wetland.

Grassy woodlands

- 830 Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion;
- 835 Forest Red Gum - Rough Barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion;
- 849 Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion;
- 850 Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion.

Dry sclerophyll forests (shrubby sub-formation)

- 774 Coast Banksia scrub on sand of the Elderslie area, Sydney Basin Bioregion;
- 883 Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion;
- 1081 Red Bloodwood - Grey Gum woodland on the edges of the Cumberland Plain, Sydney Basin Bioregion;
- 1181 Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion.

Forested wetlands

- 1105 River Oak open forest of major streams, Sydney Basin Bioregion and South East Corner Bioregion;
- 1292 Water Gum - Coachwood riparian scrub along sandstone streams, Sydney Basin Bioregion;
- 1800 Swamp Oak open forest.

4 Assessment of species presence and habitat

4.1 Existing records and surveys

The records of the GGBF available within the boundaries of the priority GAs are shown in Figures 2-5. These figures also provide the locations of records from areas immediately adjacent to the GAs, which are also be important to consider when meeting the requirement that multiple pond populations exist in close proximity and need to be linked in order to maintain metapopulation processes. The existing records demonstrate that:

- There are no records present within the Wilton GA itself or within 5 kilometres of its boundaries.
- The GMGA has a series of 4-5 GGBF records restricted to a very small area around Blair Athol. There are no other records inside or within 5 kilometres of the GA.
- The WSAGA has no records within its boundaries and only two individual records within 5 kilometres of its boundaries: one to the north east and the other the north west.
- The GPEC has a series of 11 records associated with Ropes Creek in its eastern half and a single record from Glenmore Park in its western half. There are also a series of other records scattered to the north east and west indicating that this GA is central to the records of the GGBF on the Cumberland Subregion.

The concentration of 4-5 very recent (2012-2014) records from a very small area at Blair Athol (Figure 3) provides some very recent records for the species. However, indications from the environmental officer at Campbelltown Council (Alex Cave) are that these records are of frogs that escaped a captive colony and that no original natural population was present. A population could potentially have established in that location, but all of the animals captured were juvenile frogs and no records have been obtained after 2014 indicating that the population disappeared.

The absence of records from some parts of the Cumberland Subregion may possibly be due to a lack of survey works, especially prior to the decline of the species in the 1980s. Various historic surveys will have been conducted across the region, although the extent of this work is poorly documented and generally unavailable to view. This will include surveys have been carried out around Badgery's Creek as part of a succession of assessments for the proposed second Sydney Airport site. I have personally conducted surveys in this area in the late 1990s as well as surveys at Orchard Hills, Blair Athol, Macarthur and along the Nepean River near Picton in areas included as part of this Biocertification process. None of these surveys provided any records of the GGBF and none of the surveys are freely available to the public to view. There would certainly be many more such surveys for developments that have no means of being accessed to properly assess survey effort. However, any records of GGBF should have been provided to the NSW BioNet and it would seem highly likely that the survey effort has been sufficient to reasonably indicate that the GGBF is at best rarely present within the assessed Biocertification lands.

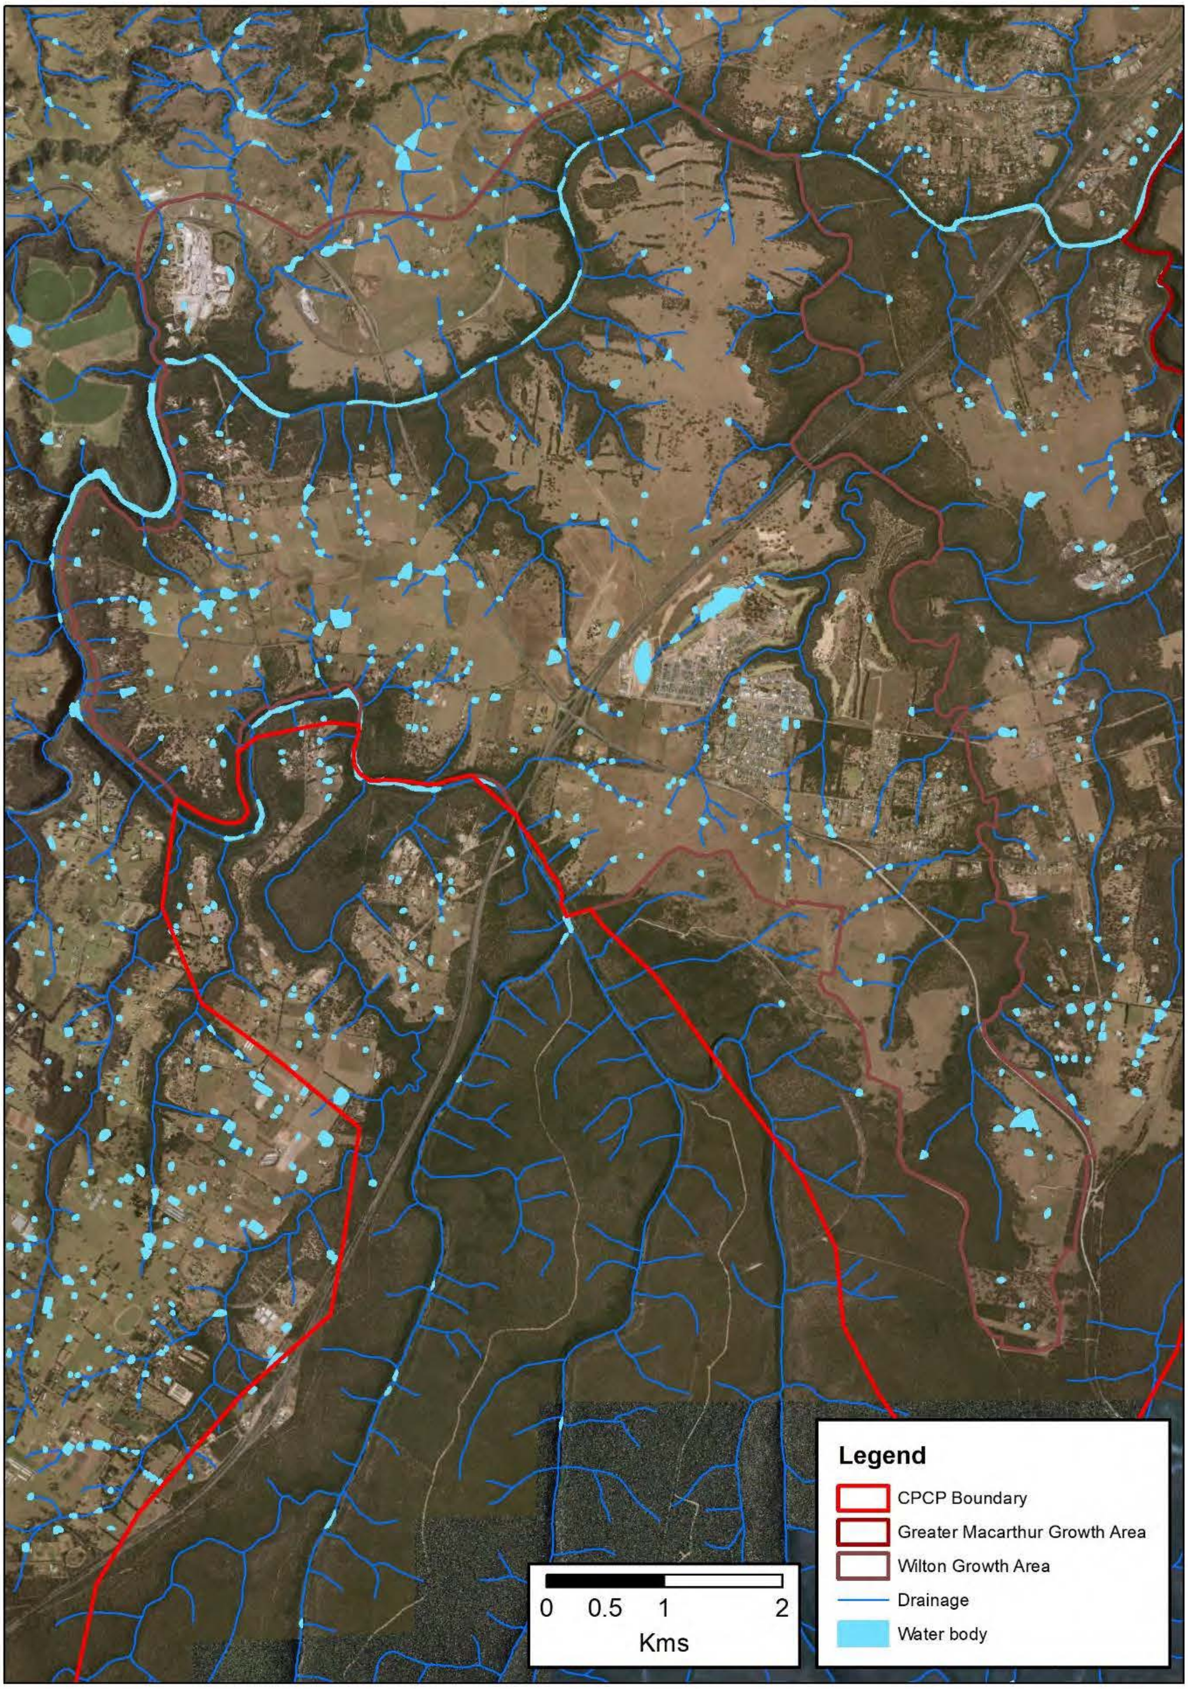

Figure 2. GGBF records from and mapped water bodies for the Wilton Growth Area

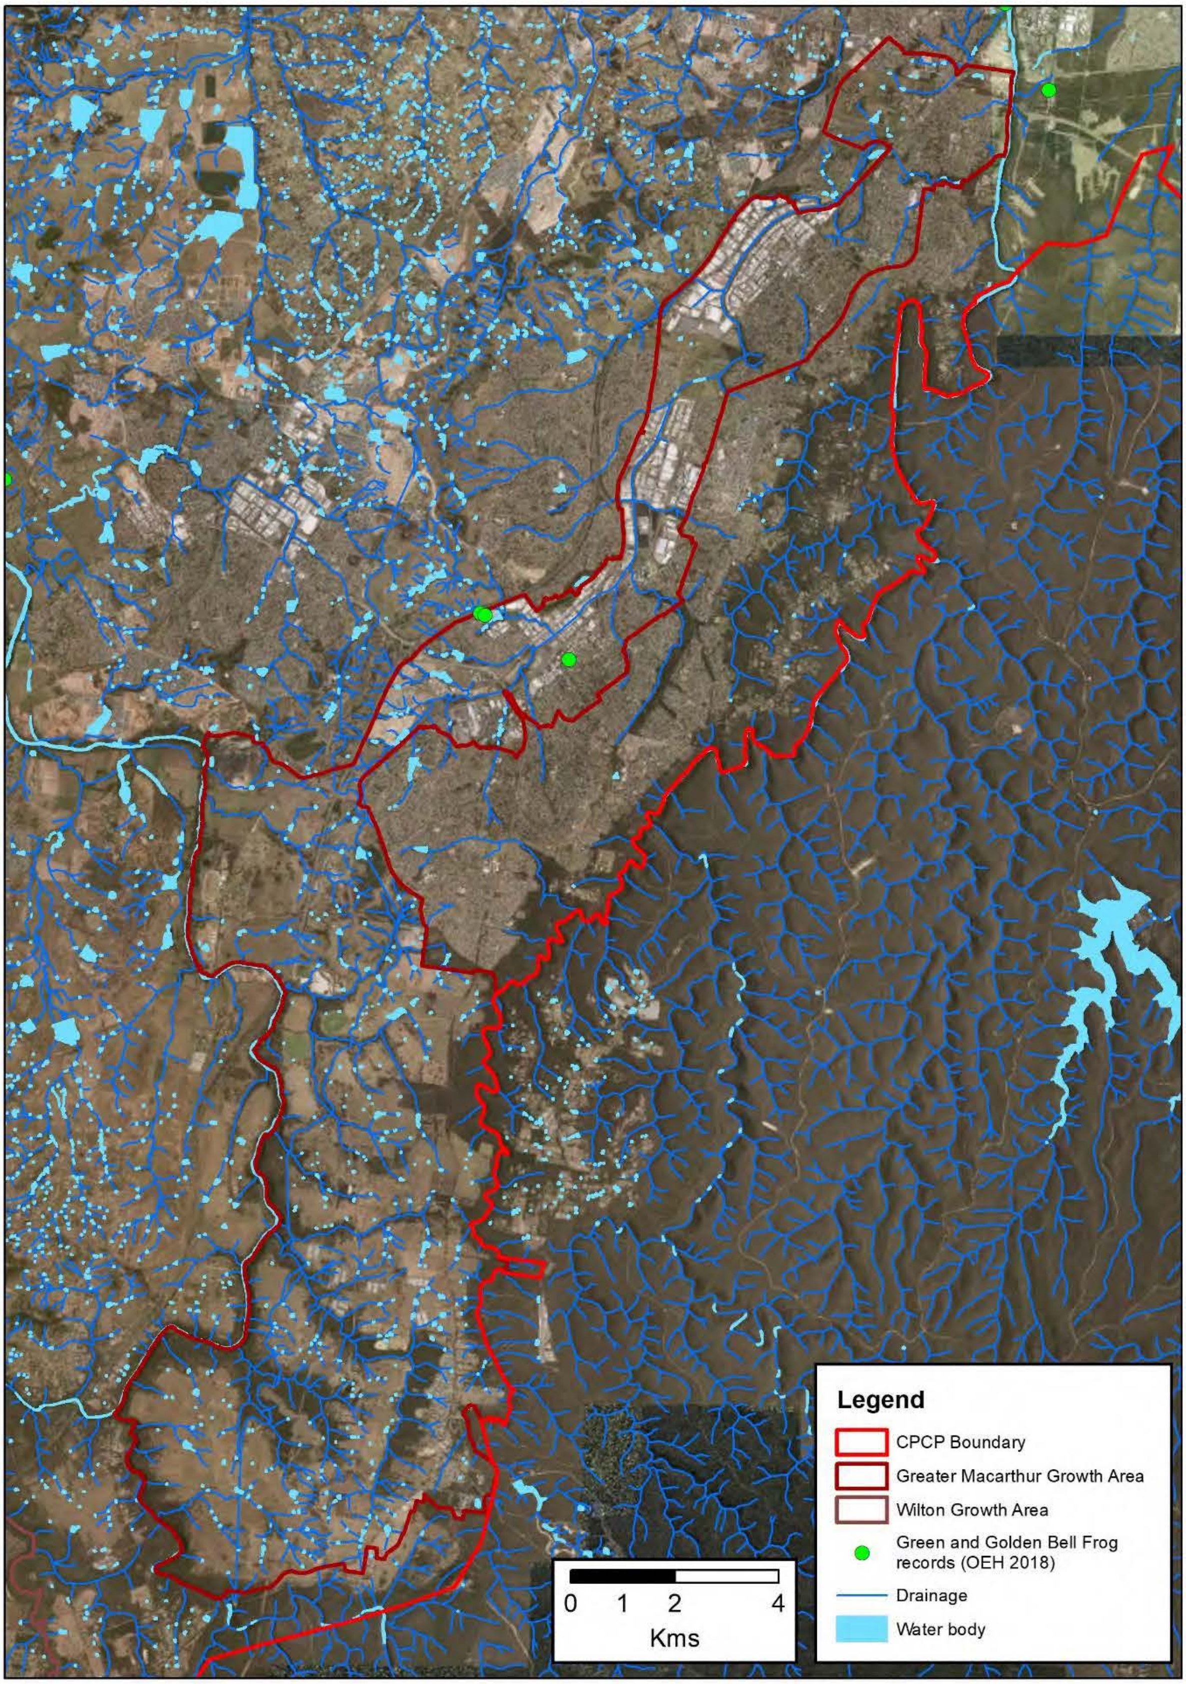

Figure 3. GGBF records from and mapped water bodies for the Greater Macarthur Growth Area

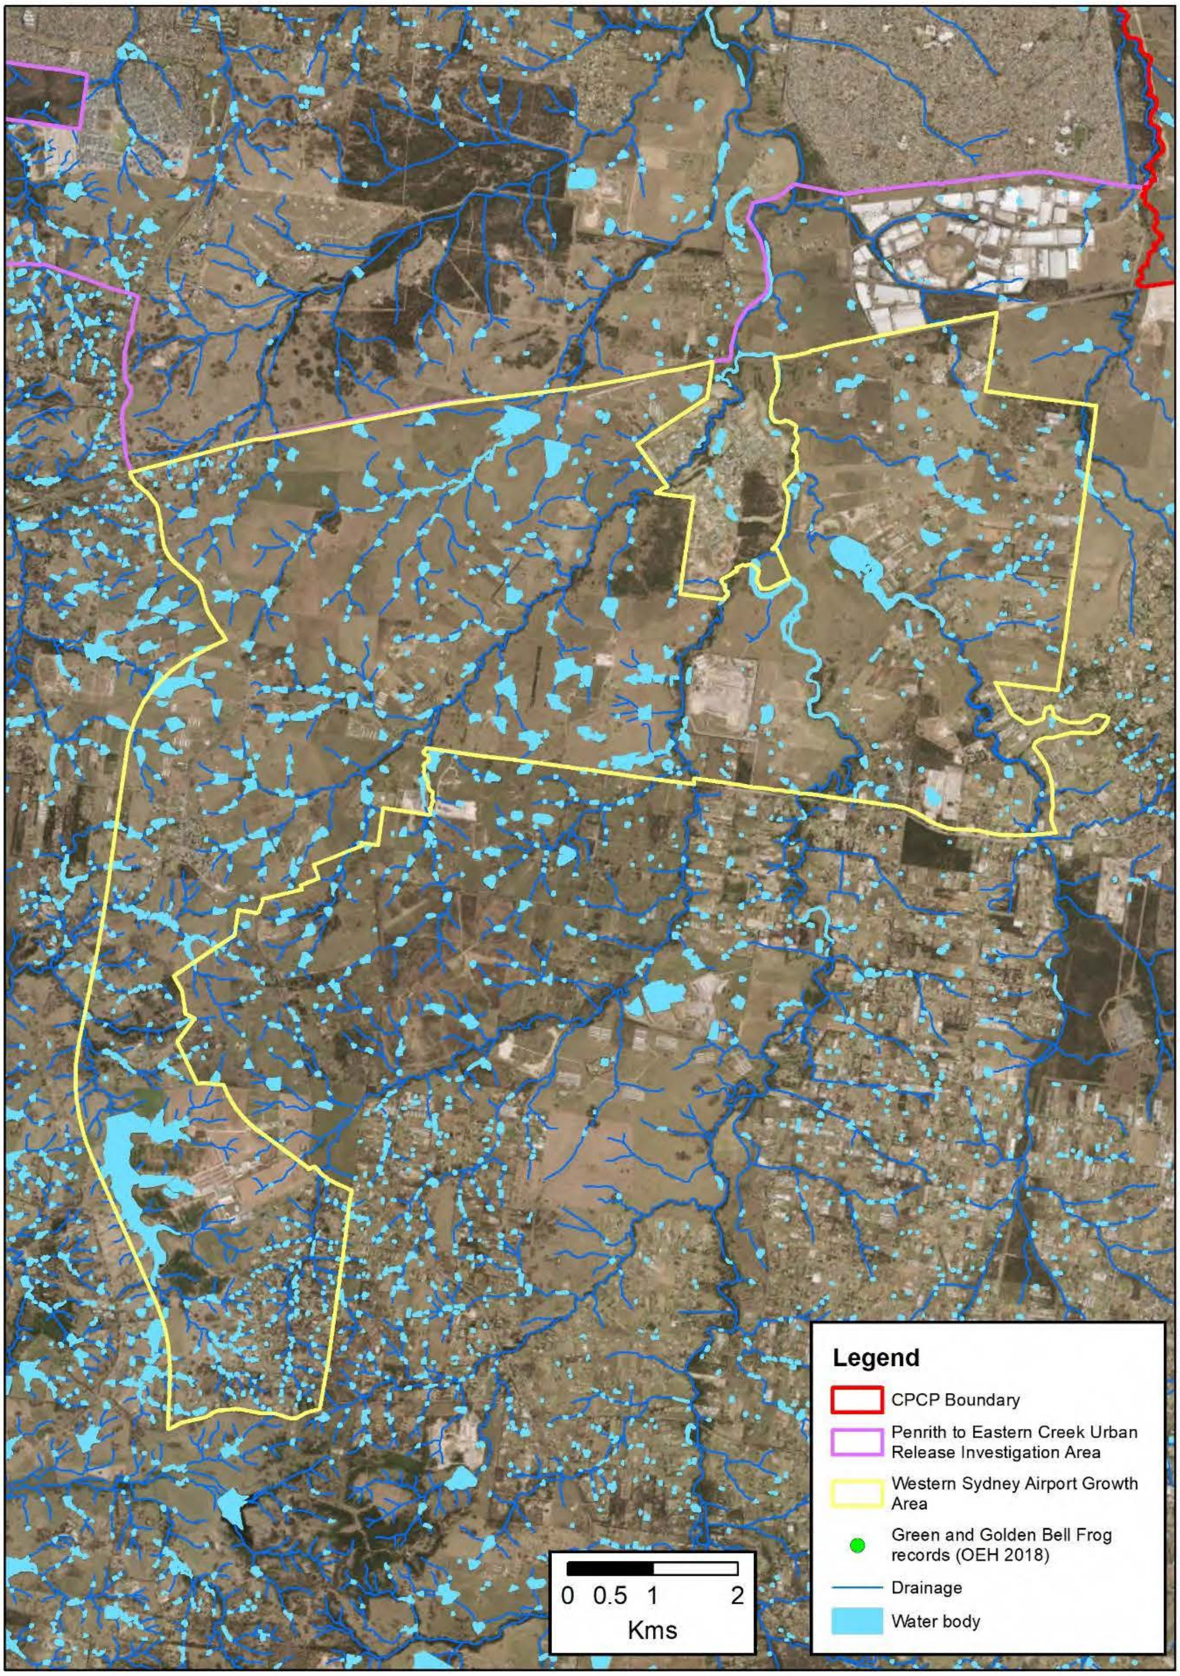

Figure 4. GGBF records from and mapped water bodies for the Aerotropolis Growth Area (Map provided by DoPE)

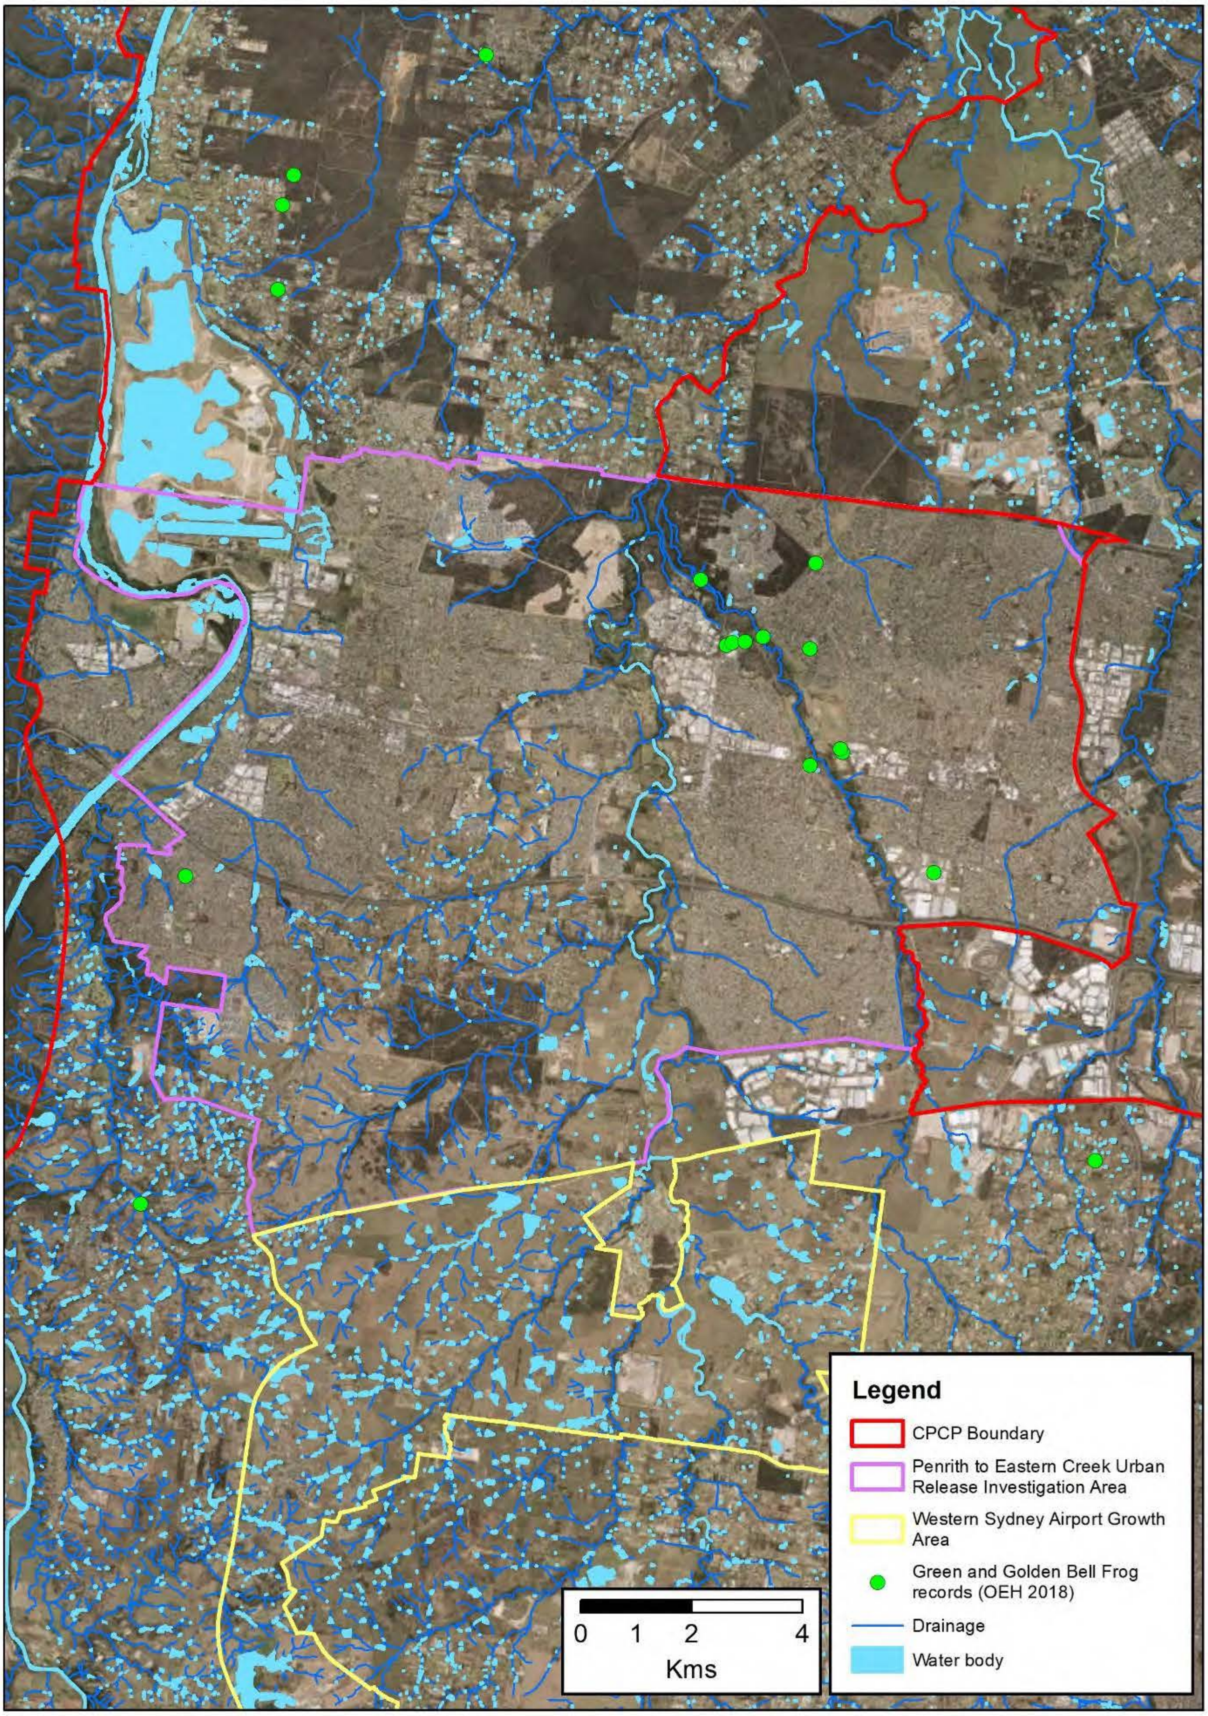

Figure 5. GGBF records from and mapped water bodies for the Greater Penrith to Eastern Creek Growth Area (Map provided by DoPE)

Three points are clearly evident. Firstly, that few actual records have been obtained for the GGBF on the area of the Cumberland Subregion under consideration and it would appear that the species has never been common in this area. Secondly, the majority of records are from prior to 1990, indicating that most populations are likely to now be extinct. This fits in with the pattern of declines noted for the GGBF by Mahony et al. (2013) that noted populations to rarely persist more than 10 kilometres from the coast. The entire study area meets this criterion. Thirdly, the few records that are available tend to be clustered into discrete areas. This is typical of the GGBF that is more likely to be found at sites where there are other nearby records (Hamer and Mahony 2010; Hamer 2018) and is attributed to the metapopulation structure of this species that requires a series of supporting and interacting sub-populations (in this case based around water bodies) in order for the species to have long-term success.

4.2 Surveys completed for the Biocertification

Surveys were completed by Biosis and Ecoplanning on behalf of DPE. The extent of the surveys are provided in the maps listed in Appendix 2.

4.3 Surveys completed for this assessment

No field surveys were specifically completed for this assessment to locate GGBF. As noted before, access to most of the potential breeding habitat is not available and time did not allow for this outcome. Instead, brief and broad habitat assessments were conducted within each of the four priority GAs to provide an understanding of the available habitats and their quality. This looked for features such as the availability and proximity of natural and artificial water bodies and the matrix of vegetation or other habitats between water bodies. These assessments confirmed the initial assessment that the built up areas provide little suitable habitat of any type for the GGBF, but the more rural locations are broadly suitable for GGBF populations to persist and include large numbers of human created water bodies.

4.4 Assessment of species presence

Likelihood of species presence

Studies have demonstrated a strong relationships to exist between the probability of occupancy of a pond by GGBF and the connectivity of wetland sites within the landscape. This relationship is evident in two forms. Firstly, in the spatial arrangement of permanent wetlands, allowing a short enough distance and suitable matrix of intervening habitat for frogs to move between ponds. Secondly, in the total area of wetlands within a 1 km-radius around a pond, which provides multiple interactive breeding sites within an area (Hamer et al. 2002; Hamer & Mahony 2010; Valdez et al. 2015; Hamer 2018). Hence consideration of the presence of the GGBF at a local scale is based on the presence of a high density of water bodies that are well connected by both proximity and suitable habitat to move through.

A second consideration is that at a much larger scale where water bodies greater than 10 kilometres from coast are unlikely to contain the frog, presumably because salinity levels are too low to play any significant role in attenuating chytrid. Sites greater than 10 kilometres from the coast may still be viable where they have an “anti-fungicidal” environment (ie, have chemical properties that inhibit growth). It is not feasible to map such locations based on historic use and it would be unlikely that such site properties would be extensive enough to provide clear guidance that the species would be present. If such did exist, it would seem very likely that the species would already have been recorded there. Hence the best understanding of the suitability of sites is based on previous records of the GGBF.

Justification for determining presence

Wilton

It has been determined that the GGBF is not likely to currently be present within the WGA. Copland (1957) records a specimen from the Picton area and so the GGBF was once present at least immediately adjacent to the WGA. However, there are no available records specific to the WGA and the distance to the coast indicates it is unlikely the GGBF would persist in the WGA.

No species polygon is provided as the species is not considered present within the WGA. The majority of the available habitat (rural lands) is suitable for this species and it could potentially return or colonise the WGA if the impacts of the amphibian chytrid fungus can be overcome.

Greater Macarthur Growth Area

It has been determined that the GGBF is not likely to currently be present within the broad GMGA. The only records of the species within the area are the very recent records of juvenile GGBF from around the Blair Athol area (Figure 3). As noted, these records are believed to be of individuals that escaped from a semi-captive colony and no extant "native" population was likely present. There are also no indications that a population has established as a result of the escape these individuals. Whilst, as for the Wilton area, it would seem likely that the GGBF was once present within the WGA, there is no evidence that it is currently present and the distance to the coast of the GMGA indicates it is unlikely to be able to persist in the current environment without some known source populations.

Figure 7 provides the species polygon of determined habitat area for the GGBF in the GMGA, although I again note that this is based on likely escaped frogs. This covers the locations of known records, the riparian zone joining those records and a buffer of 1000 m around that riparian zone and records that is the area deemed likely for GGBF to use for foraging, shelter, breeding and as migratory habitat as they move between water bodies and riparian areas.

Western Sydney Aerotropolis Growth Area

It has been determined that there is not likely to be a population of the GGBF currently present within the WSAGA. There are no records from within the GA, despite the presence of suitable habitat in rural areas in the form of a high density of water bodies. There is no evidence that it is currently present and the distance to the coast indicates it is unlikely that the GGBF would persist in this area. The two most closely associated records (Figure 4) are single records not closely aligned with other records and so it is unlikely that a larger stable population has been or is present within the WSAGA.

Greater Penrith to Eastern Creek Growth Area

It has been determined that a population of the GGBF may remain present within the GPEC. There are a number relatively recent records from within and immediately adjacent to the GPEC located along the Ropes Creek corridor (Figure 8) and areas of suitable habitat remain along that corridor in the form of a high density of water bodies within undeveloped lands. It is not certain that the population still remains, given the ongoing declines noted for the GGBF, but the survey completed for the Biocertification has not been adequate to establish the current status of the GGBF population.

Figure 8 provides a species polygon for the GGBF within the GPEC. This covers the locations of known records, the riparian zone joining those records and a buffer of 1000 m around that riparian zone and records that is the area deemed likely for GGBF to use for foraging, shelter, breeding and as migratory habitat as they move between water bodies and riparian areas.

4.5 Assessment of suitable habitat

The information in Section 2 demonstrates the ability of the GGBF to use a broad range of habitats and only urbanised areas represent unsuitable habitat, mainly because of the absence of breeding ponds and the high density of roads and buildings that form barriers to movements.

All four GAs contain suitable habitat matrix in the form of rural areas with a numerous water bodies within close proximity (< 500 metres). This should provide both breeding and non-breeding water bodies sufficiently close to allow GGBF to migrate between them and with adjacent vegetation and shelters that they would allow them to successfully do so. These surrounding areas would also provide over-wintering sites and vegetated areas to provide supplies of invertebrates as food for GGBF. The presence of the Plague Minnow would potentially limit the presence of the GGBF in some or most areas, but it is not possible to determine the extent of this effect without visiting the water bodies and the GGBF can still inhabit sites with the Plague Minnow where there is suitable emergent vegetation and where fish free ephemeral sites develop, which could be in most places across the broad landscape.

Habitat only is likely to be unsuitable where there is a matrix of roads of more than single carriageways in both directions. Larger roads represent barriers in both distances that frogs must cover in exposed conditions and carry volumes of traffic that may prohibit the successful crossing by frogs. The more rural areas of the GAs generally do not have many or even any such roads traversing them and so they should provide a suitable environment for the GGBF in at least this respect.

Species polygons

Predicted polygons for the GGBF are provided only for the GMGA (Figure 7) and GPEC (Figure 8). This is because it is considered that only these two areas may contain extant populations of the GGBF with evidence to demonstrate that they have historically been present within the two GAs. The species polygon that indicates the distribution of GGBF populations within the GA, with the polygons being based on the presence of known populations or recent records. The polygon covers the locations of known records, the riparian zone joining those records and a buffer of 1000 m around that riparian zone and records that is the area deemed likely for GGBF to use for foraging, shelter, breeding and as migratory habitat as they move between water bodies and riparian areas. The extent that these overlap with proposed development areas are also indicated.

As noted before, the figures also include highlighted areas that have been designated as potential migratory corridors for GGBF should populations return to the landscape in the future. These represent areas that GGBF would be predicted to use to move around and recolonise the GAs, if this was able to take place. They essentially follow the known riparian strips associated with rivers or where a series of identified water bodies provide the opportunity for GGBF to migrate through a series of stepping stones. These corridors do not represent current habitat that needs consideration under the Biocertification process and they do not constitute polygons of habitat for the GGBF. Rather they have been noted simply for consideration for broader scale conservation planning, should that be of interest, under the premise that the GGBF will ultimately recover from its current declined state (through disease immunity or behavioural changes) that will allow them to recolonise suitable habitats. I note that I have included a broad corridor of non-riparian area as a potential movement corridor on the western side of the WGA, as the loop of the river provides for a broad patch of land that may provide a means of the GGBF migrating across that patch if it were ever to recover.

Estimate of area of habitat

The estimated area of suitable GGBF habitat in each GA (the species polygon) and the area of this habitat expected to be impacted by development (falls within the footprint) is provided in Table 2. The latter is minimal and only exists for the GPEC.

Realistically all of the rural landscape contains suitable habitat with a range of suitable breeding ponds providing habitat for the GGBF. However, it is expected the GGBF will only persist in areas with known populations and that can maintain a metapopulation structure. Sufficient historic survey has been conducted to conclude that additional significant populations are not now present within the GAs.

Table 2. Areas of identified suitable habitat and area of habitat within each Growth Area

Growth Area	**Area of habitat (ha)**	**Area within development footprint (ha)**
Wilton	0	0
Greater Macarthur	238.8	0
Western Sydney Aerotropolis	0	0
Greater Penrith to Eastern Creek	1421.6	13.1

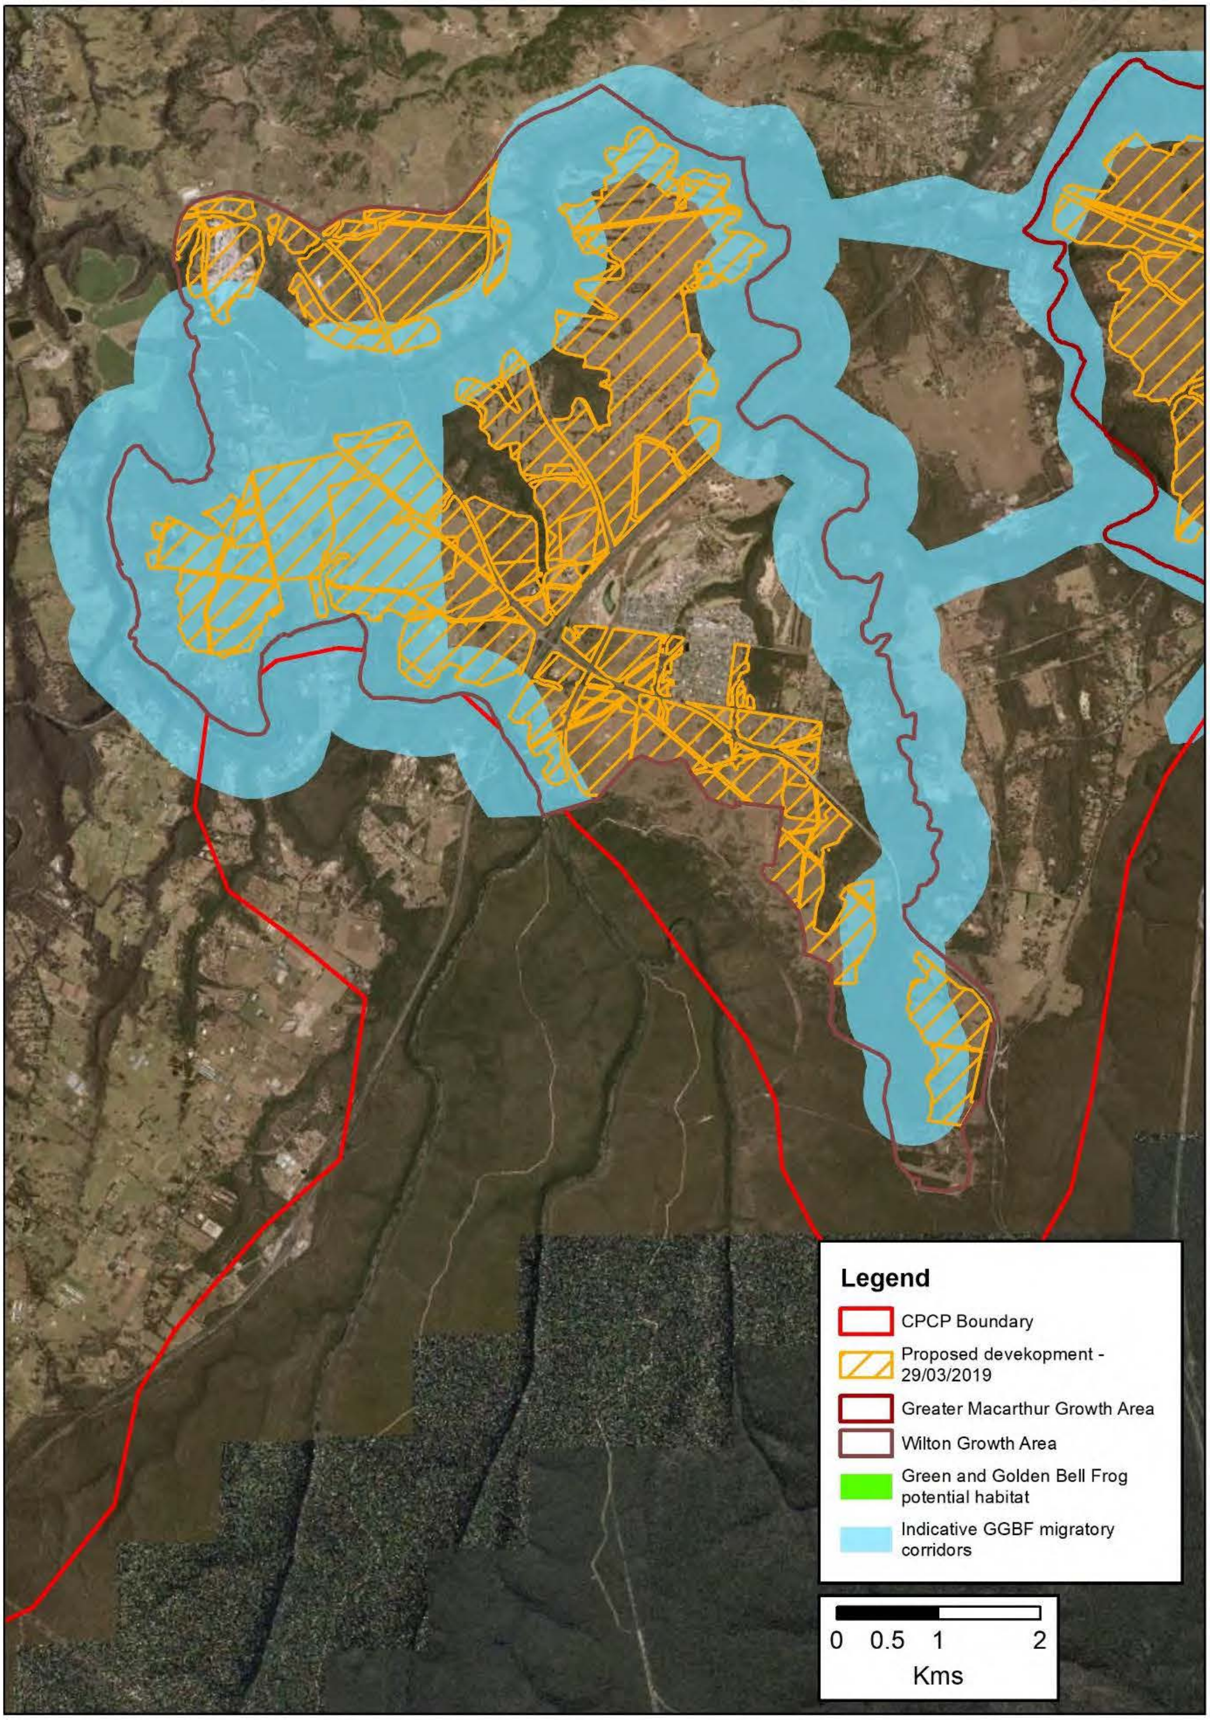

Figure 6. Polygon and potential migratory habitat for the Green and Golden Bell Frog relative to the Wilton Growth Area (Map provided by DPE)

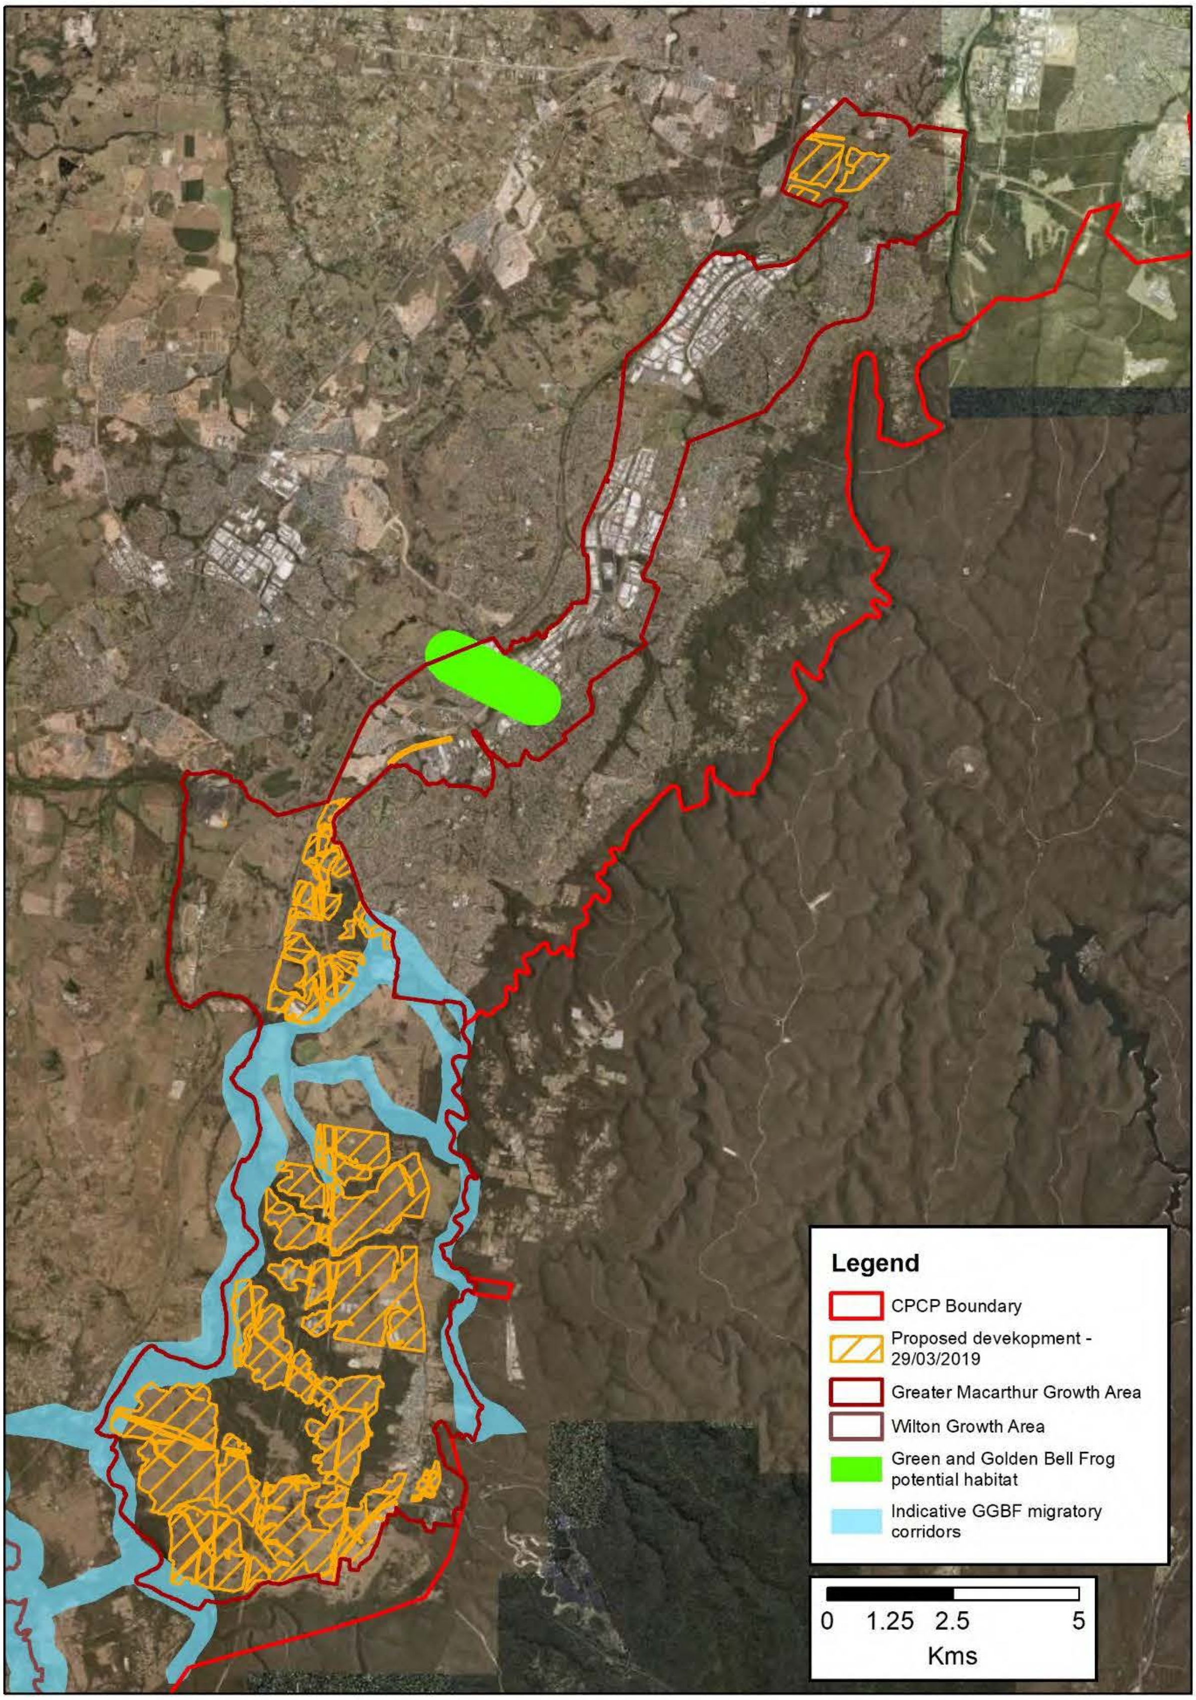

Figure 7. Polygon for Green and Golden Bell Frog habitat within the Greater Macarthur Growth Area (Map provided by DPE)

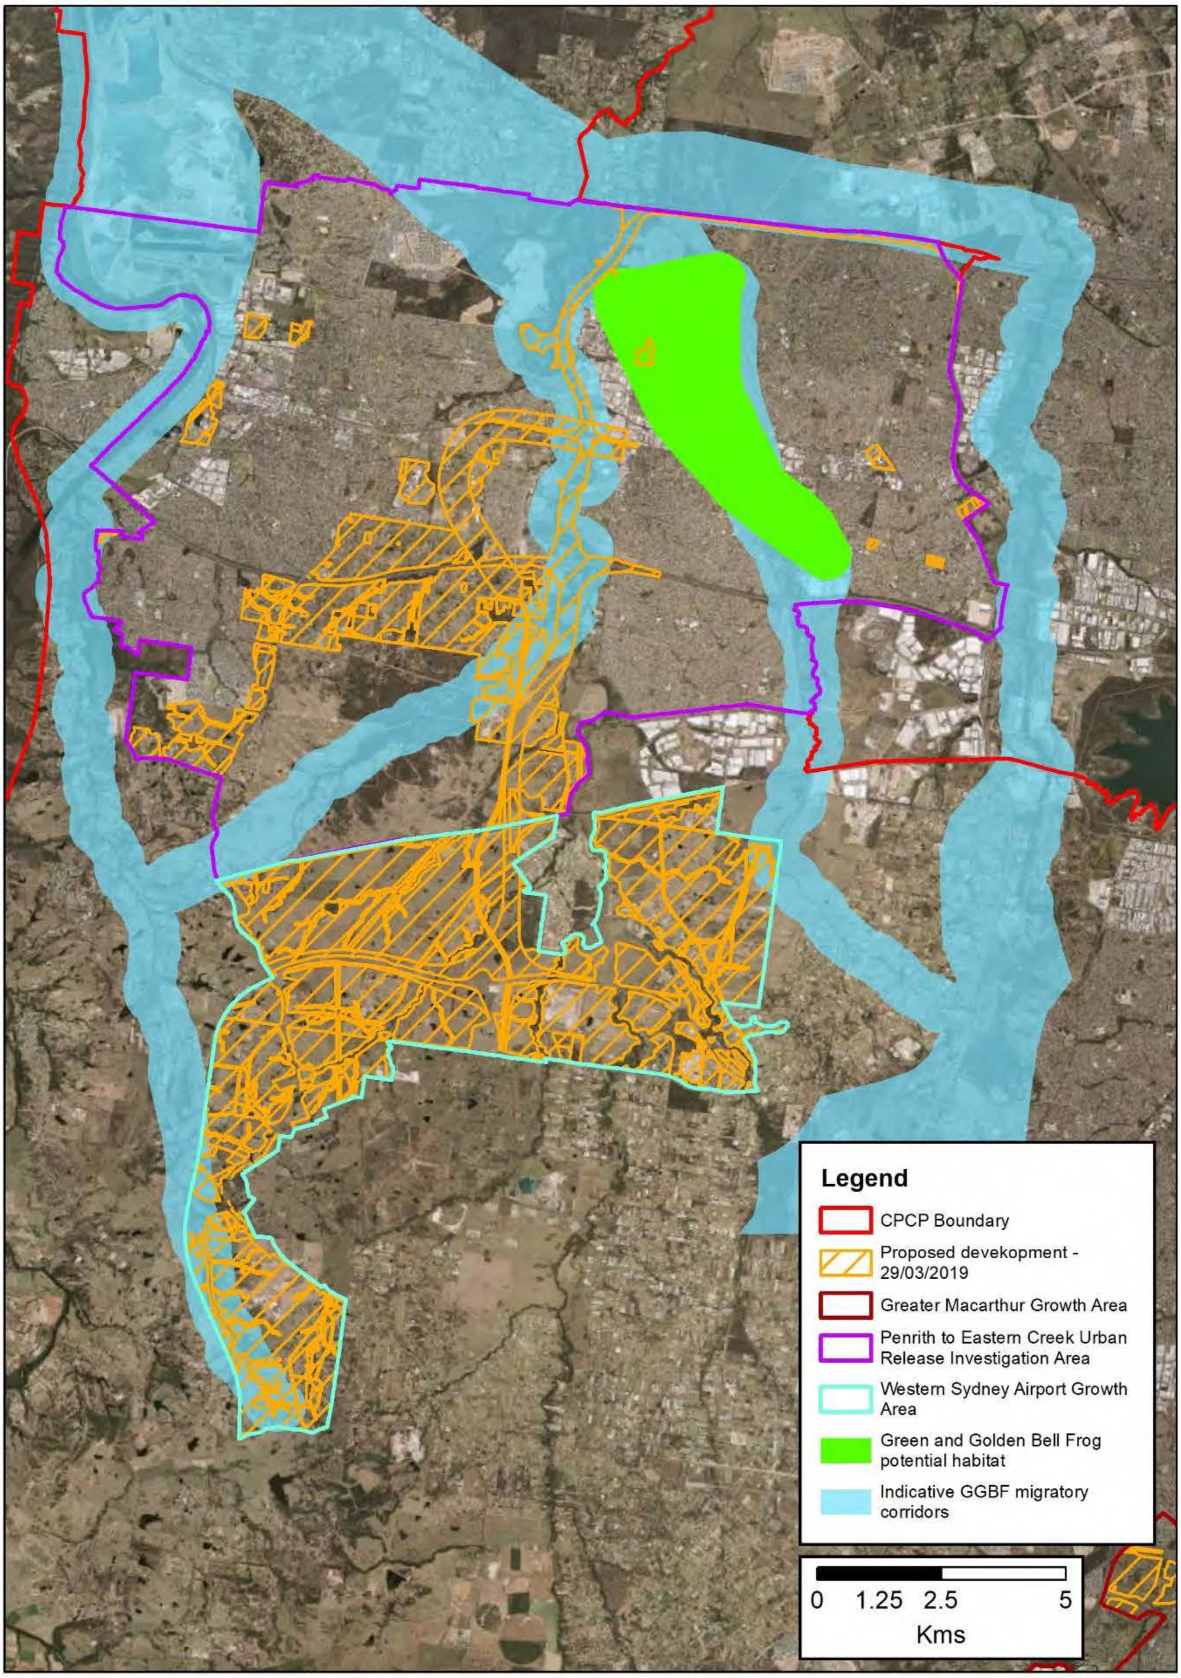

Figure 8. Habitat polygons and identified likely future migration corridors for the Green and Golden Bell Frog relative to the Greater Penrith to Eastern Creek and Western Sydney Aerotropolis Growth Areas (Map provided by DPE)

5 Information used in this assessment

Data, maps and information provided by DPE and project partners are noted through the report

7 Appendices

Appendix 1: Curriculum vitae

Member of the Surbana Jurong Group

Dr Francis Lemckert

Principal Environmental Scientist - Environment

Years of Industry Experience

- 30+ Years

Qualifications, Training and Memberships

- PhD University of Newcastle
- Master of Science, University of Sydney
- Bachelor of Science, University of Sydney
- Australian Society of Herpetologists (Past-President, Vice-President and Secretary)
- NSW Declining Frogs Working Group (Secretary)
- Amphibian Specialist Group of the IUCN
- Conjoint University of Newcastle, Australian Museum

Key Skills and Competencies

- Fauna and flora monitoring
- Fauna survey
- Fauna research
- Expert reporting under the BAM
- Specialist fauna knowledge
- Impact and ecological assessment
- Wildlife survey training
- Government agency consultation
- Herpetology

Professional Overview

Frank has been a professional scientist since 1992, specialising in the ecology and management of threatened vertebrates, particularly frogs. Frank has conducted ecological work throughout eastern Australia (NSW, Victoria, Queensland) establishing long-term research programs into the management of forest fauna and developing strategies to mitigate the impacts of human disturbances. His specialty is the ecology and management of frogs, but he also has detailed knowledge of threatened reptiles and microbat management, and has conducted hundreds of surveys for all of the vertebrate groups. Frank has worked extensively with the NSW state and federal Governments on varying issues of fauna management and is experienced in the application of NSW and federal legislation regarding the conservation of threatened species and communities. At a technical level he has participated in the preparation of a draft NSW/National recovery plan for *Heleioporus australiacus*, expert advice and review on Impact Assessment Guidelines for the *Litoria aurea*, *Litoria raniformis* and *Litoria olongburensis* and a review of the National Recovery Plan for the stream frogs of SE Queensland. He also assisted in assessing the Vic Forests fauna survey and assessment program for threatened fauna. Frank has also worked extensively with the Australian Biological Resources Study to undertake biodiversity surveys across NSW and into far southern Queensland.

Frank has a long history in fauna monitoring and management having developed broad scale monitoring strategies for vertebrate fauna when at NSW DPI. He completed a review of the methods available to undertake frog monitoring, including linking in with current river monitoring programs and developed a pilot reptile survey program for the Pilliga State Forests. He monitoring works included using both traditional population counts and consideration of more recently developed presence-absence modelling and his works included using mark-recapture techniques. He has published papers on optimal monitoring methods and its analysis and has been an author on more than 90 peer-reviewed national and international scientific publications and has undertaken presentations at more than 50 conferences across the world.

Finally, Frank has had a long history in wildlife management education, having been the lead on the wildlife training school program conducted in NSW continuously since 1993. This program has provided in-depth training on fauna and flora survey, management and identification in all parts of NSW and has been attended by more than 1000 people including government regulators, consultants and NGO staff. The courses have emphasised practical hands-on demonstrations of survey techniques to demonstrate the most effective use of the different traps and monitoring methods and approaches available and included recognised experts on the target groups. Information lessons also included talks on the ecology and management of target threatened species for any given area and course.

Relevant Project Experience

Mona Vale Road Upgrades

In regards to Mona Vale Road, Frank worked as a sub-contractor to Ecosure to provide expert surveys and technical advice on the survey and impact assessment for the Red-crowned Toadlet and Giant Burrowing Frog for both the Mona Vale Road East and Mona Vale Road West upgrade projects. This provided the first records for the Giant Burrowing Frog (*Heleioporus australiacus*) in that area and also recorded several locations for the Red-crowned Toadlet (*Pseudophryne australis*) as well as records of the Eastern Pygmy Possum (*Cercartetus nanus*) as part of nocturnal surveys. He also provided reviews of impact assessments for the Mona Vale Road west report covering all aspects of the surveys and the assessments for all of the threatened fauna. It also considered the impacts of fragmentation of the proposed upgrade and methods to mitigate impacts.

Warringah Council Crown Lands surveys

Between 2011-2013 Frank also completed a detailed reptile and frog survey of the available crown lands in the Warringah Council (now part of Northern Beaches Council) Local Government Area. This included targeted surveys for all reptiles and frogs likely to be present and provided detailed information to the Council to inform planning of development proposals into the future. These surveys provided additional record sites for the Giant Burrowing Frog and Red-crowned Toadlet in the LGA.

Saving our Species targeted surveys – Green and Golden Bell Frog (*Litoria aurea*)

Frank was engaged by the NSW Office of Environment and Heritage to undertake four rounds of targeted surveys for the Green and Golden Bell Frog in the area around Meroo Lake on the south coast of NSW. This required repeat surveys of transects to count the frogs and the collection of site data to be used in a broader analysis of Green and Golden Bell Frog habitat preferences. Frank completed the surveys successfully, locating hundreds of individuals and provided a report on time as required.

Princes Highway upgrade at South Nowra

Frank completed targeted and monitoring surveys and EPBC and EP&A/TSC Act assessments for the Green and Golden Bell Frog and hollow using fauna and was the appointed Project Herpetologist. He also produced two EPBC Referrals for the Green and Golden Bell Frog, guided the development of mitigation works, produced fauna rescue guidelines and advised on the ongoing scientific monitoring program.

Dee Why Town Centre Bat Management

Frank was the technical lead on several projects managing the impacts of drainage culvert upgrades on threatened microbats present in Dee Why. This included the identification of bats present, mapping of bat roosting sites, completion of an SIS and ongoing monitoring of the bats through the works to ensure impacts remained within acceptable limits. The bats present proved to be Eastern Bentwing-bats (*Miniopterus schreibersii oceanensis*) and the works times to minimise impacts at sensitive times for the bats.

Pacific Highway upgrade for Oxley Highway to Kempsey and Frederickton to Eungai

Frank has been involved in a diversity of fauna related work for this project including population and mitigation monitoring surveys for the Giant Barred Frog (*Mixophyes iteratus*) and Green-thighed Frogs (*Litoria brevipalmata*) and provided review and quality assurance for reports on monitoring for Giant Barred Frogs, Green-thighed Frogs, Brush-tailed Phascogales, Squirrel Gliders, Hairy Joint Grass, *Maundia triglochinoides*, Koalas and Glossy Black Cockatoos. He also reviewed works on water quality, underpass use, fauna crossings, nest box use and road-kill.

Expert Witness Somersby land clearing

In 2016 Frank provided expert advice to DoEE on the potential impacts of alleged illegal land-clearing on the Giant Burrowing Frog at Somersby on the NSW Central Coast. This includes a site search to locate the presence of tadpoles (located in the central stream) and an assessment of the value of the cleared habitat to this frog and the likely long-term effects on the local population.

Threatened Frog Monitoring and Modelling – Hornsby Council

In 2015-2016 Frank completed surveys of known record sites for the Red-crowned Toadlet and the Giant Burrowing Frog in the Hornsby Local Government Area to provide data on the location of these two species within areas adjacent to areas of housing and in undeveloped locations. The data provided the basis for an ongoing monitoring program to be carried out by Council and assess if housing was impacting the local water quality and the frogs. Habitat modelling was also produced for the Giant Burrowing Frog, allowing Council to better target assessment requirements for development applications.

Expert review - Pacific Highway threatened frog monitoring program

Frank was commissioned to provide an expert review of the proposed frog monitoring program to assess the impacts and success of mitigation for approximately 130 km of the Pacific Highway in northern NSW. This expert review considered the thoroughness and technical relevance of the proposed program and covered Giant Barred Frogs, Green-thighed Frogs, Wallum Sedge Frogs Brush-tailed Phascogales, Squirrel Gliders, Hairy Joint Grass, *Maundia triglochinoides*, Koalas and Glossy Black Cockatoos. He also reviewed works on water quality, underpass use, fauna crossings, nest box use and road-kill.

Forests NSW fauna monitoring strategy

Between 2008 and 2011 Frank assisted in developing a state-wide fauna monitoring strategy for Forests NSW, concentrating on the herpetological component. This lead to a working paper on options for frog monitoring and undertaking a pilot program for reptile monitoring in the Pilliga Forests of northwest NSW.

1. Introduction

PURPOSE

I was engaged by the Department of Planning and Envionment in early June 2018, to produce an expert report on the distribution and abundance of *Grevillea juniperina* subsp. *juniperina* (Proteaceae) within the proposed Greater Macarthur and Wilton Growth Areas (collectively termed "the study area"). The aim of this exercise was to assess whether *Grevillea juniperina* subsp. *juniperina* (the "focal taxon") is native to either of the Growth Areas and, if so, to assess where suitable habitat is located and to estimate the numbers of plants of *Grevillea juniperina* subsp. *juniperina* that are likely to occur there.

According to Section 6.5.2 of the Biodiversity Assessment Method, an expert report must:

- identify the relevant species or population
- justify the use of an expert report
- indicate and justify the likelihood of presence of the species or population
- estimate the number of individuals or area of habitat (whichever unit of measurement applies to the species/individual) for the biodiversity certification assessment area, including a description of how the estimate was made
- demonstrate what information was considered, rejected and discounted in relation to the determination made in the expert report, and
- identify the expert and provide evidence of their expert credentials.

PROJECT CONTEXT

The Department of Planning and Environment is leading a strategic biocertification of several identified growth areas within Western Sydney, including the two growth areas that define the geographic scope of this report: the Greater Macarthur Growth Area and the Wilton Growth Area. The strategic biodiversity assessment is an integral part of the Cumberland Plain Conservation Plan that will determine the impact of urban development on threatened species and ecological communities within these growth areas. The Plan will also provide conservation measures to mitigate any impact, as specified by NSW and Commonwealth environmental legislation.

STUDY AREA

The Greater Macarthur and Wilton Growth Areas are located in the south western part of the Sydney Metropolitan Area, between latitudes 33°57'29"S and 34°16'44"S and longitudes 150°37'12"E and 150°54'47"E.

CREDENTIALS OF EXPERT

I prepared this report as an independent botanical consultant but I am also currently an Honorary Research Associate at the at the New South Wales state herbarium (the National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust). In 2016, I retired from my role as a Senior Principal Research Scientist at the state herbarium, having worked there since 1982 as a Systematic Botanist and as curator of the herbarium's collections of specimens of Proteaceae (including *Grevillea juniperina*) (see my *Curriculum Vitae*, attached). I now work, part-time at the National Herbarium of New South Wales as an Honorary Research Associate. I have published, either as sole author or as a co-author, 50 papers on the systematics and ecology of the Proteaceae in the peer-reviewed scientific literature, including the most comprehensive phylogenetic analysis of the genus *Grevillea* yet published (Mast *et* al. 2015). As curator of Proteaceae at the state herbarium, I examined all specimens of *Grevillea juniperina* subsp. *juniperina* incorporated into the collection between 1982 and 2016. I was invited to contribute to floristic treatments of the Proteaceae for *Flora of New South Wales*, *Flora of Australia*, *Flora of the Perth Region*, *Flora of China*, *Flora of North America*, and to write the treatments of Proteaceae for *Families and Genera of Vascular Plants* and *Flowering Plant Families of the World* (see my *Curriculum Vitae*, attached). I was also asked to conduct a peer review of the essay on the ecology of the Proteaceae that accompanied the "Ecology of Sydney Plants" (Myerscough *et al.* 2000). Throughout my career I have participated in numerous collecting trips in the field, collecting specimens in all Australian states for the state herbarium. In documenting these specimens I had to describe the habitat at each collecting site, including associated plant species, substrate, aspect, degree and kind of disturbance. On some of those trips, I observed and collected *Grevillea juniperina* growing in the wild.

JUSTIFICATION FOR USE OF EXPERT REPORT

Grevillea juniperina subsp. *juniperina* has never been collected within, nor reported as growing as a native, in the study area. However, The OEH Threatened Species Data Collection indicates that *Grevillea juniperina* subsp. *juniperina* has the potential to occur in the following plant communities within the Wilton and Greater Macarthur Growth Areas:

- 849 Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain
- 850 Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain
- 883 Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain

Moreover, a specimen of *G. juniperina* subsp. *juniperina* held by the state herbarium (B. Towle, NSW999291) was collected in June 2017, in a bushland remnant only 3.6 km west of the study area, raising the possibility that suitable habitat for *G. juniperina* subsp. *juniperina* might exist there. If this were so, *G. juniperina* subsp. *juniperina* might once have lived there, or even still exist in the study area as small, unrecorded populations.

Grevillea juniperina subsp. *juniperina* is a perennial shrub that is readily recognised at any time of year by its distinctive vegetative morphology. Conventional surveying would therefore be the most appropriate way to test for its presence, if unlimited access to the study area were allowed. Surveys were undertaken on all areas of land where landowners granted access. However, the survey effort for this species did not meet the recommendations in the OEH threatened species guidelines (OEH 2016) for field traverse surveys due to limitations imposed by land access.

These limitations and the possibility that *G. juniperina* subsp. *juniperina* might be native to the Greater Macarthur and Wilton Growth Areas triggered the need for an expert report.

SPECIES SURVEYS

An initial 726 letters were sent to landholders within the Growth Areas in late 2017. A second letter was sent in March 2018, and targeted door knocking occurred in May 2018. From this, just under 20% of landholders have responded. Surveys were undertaken on all areas of land where landowners granted access. Of the 14,984 hectares within the Wilton and Macarthur Growth Areas, of which 5,385 ha is potential native vegetation that could be impacted by development, DPE has completed surveys across 3,360 hectares (62% of the total survey area). Surveys for *Grevillea juniperina* subsp. *juniperina* were undertaken from November 2017 to May 2018, resulting in no sightings of the species recorded from the survey areas.

2. Species information

SPECIES DESCRIPTION

The following morphological description was produced by merging information from Makinson's (2000) descriptions of the Linearifolia Group, the Speciosa Subgroup, *Grevillea juniperina*, and *Grevillea juniperina* subsp. *juniperina*:

More or less erect to spreading dense divaricate shrub 0.5–1.5 m tall, to 3 m across; major branches appearing subcolumnar (leaves clustered on short lateral branchlets); foliage dense. Branchlets terete, tomentose to villous. Leaves spreading to ascending, often crowded on short lateral branchlets, usually rigid, often dark green with paler veins, entire, narrowly ovate to subulate or linear, angularly deltoid to trigonous in cross-section, 10–22 mm long, 0.6–0.8 mm wide, pungent, needle-like, with dissimilar upper and lower surfaces; upper surface usually with 3–5 longitudinal veins, the midvein and intramarginal veins usually very prominent, sparsely covered with appressed hairs; margins strongly and angularly revolute; lower surface usually fully enclosed, usually densely sericeous or occasionally openly so, rarely glabrous, or open-tomentose; juvenile leaves scarcely broader than adults. Conflorescence terminal, occasionally also axillary and subterminal, usually simple or occasionally 2 (–4)-branched; unit conflorescence erect or slightly decurved, acropetal, subsecund; floral rachis 1–17 mm long. Flowers zygomorphic; torus slightly oblique. with perianth style similar to perianth or a little paler. Perianth densely to openly subsericeous outside with biramous hairs only, bearded inside between 2.5 and 9 mm above base, red, yellow, pale orange, or rarely greenish; tepals remaining coherent over at least the basal third, independently recoiled above (usually the ventral pair more strongly so). Pistil (13–) 20–25 mm long; style glabrous except for minute scattered erect simple hairs extending from back of style-end down at least 3 mm and sometimes almost to ovary, similar colour to perianth or a little paler; pollen-presenter usually oblique or occasionally lateral. Follicles narrowly ovoid or oblong-ellipsoidal, 10–18 mm long, colliculose to smooth, not ridged. Seeds ellipsoidal; margins revolute, a waxy strip on one side extending into a short apical elaiosome.

LIFE CYCLE

Grevillea juniperina subsp. *juniperina* is a perennial, woody plant that germinates from an ellipsoidal seed (Makinson 2000). Germination is significantly enhanced by fire: in a germination experiment, a treatment of smoke plus heat raised the germination percentage from 5-13% observed in the control treatment to 60% (Morris 2000). Seedlings are readily identifiable because their leaves differ minimally from adult leaves and the characteristic growth pattern with abundant lateral short shoots starts when seedlings are less than 10 cm tall. The duration of the juvenile growth phase and the longevity of plants are unknown (Benson & McDougall 2000). Plants are known to be killed by fire (Olde & Marriott 1995, Makinson 2000) and are not known to spread vegetatively (Benson & McDougall 2000), so this taxon can be classed as an obligate seeder. Flowering occurs mainly from August to September, with sporadic flowers appearing in other months (Makinson 2000).The flowers of all subspecies of *Grevillea juniperina* are visited by nectar-feeding birds (Olde & Marriott 1995), which are presumed to be their pollinators (Benson & McDougall 2000). Fertilized carpels develop into follicular fruits that open at maturity, releasing one or two flat seeds, each of which bears a wing-like terminal elaiosome. The seeds are dispersed by wind and also possibly by ants, which may collect the seeds for their edible elaiosomes.

DISTRIBUTION AND ABUNDANCE

Grevillea juniperina subsp. *juniperina* occurs naturally on the northern Cumberland Plain, in Sydney's Western Suburbs, in an area bounded by Scheyville National Park, Agnes Banks Nature Reserve, Mulgoa, Kemps Creek, and Blacktown (OEH Wildlife Atlas, accessed 2/7/2018, Atlas of Living Australia, accessed 3/7/2018). Within this polygon, it is sporadically distributed but often locally abundant in both intact native vegetation and in highly disturbed habitats such as pastures and road cuttings. Collectors' notes on local abundance usually note multiple plants at collecting sites and vary in their estimates of plant numbers from solitary individuals to populations of over 1000. At my site GJ5 (Appendix 1, figure 3), an embankment of a road cutting that is being recolonised by native vegetation, I estimated a population of 5000 plants (including seedlings) in an area of less than one hectare.

A herbarium specimen collected from Gundungarra Reserve, Spring Farm, 4 km north west of the "waist" in the study area (NSW999291), is a geographic outlier that is unlikely to represent a natural occurrence of *Grevillea juniperina* subsp. *juniperina*. Herbarium records that were classed as naturalised occurrences by their collectors, and by R.O. Makinson in curatorial notes, include one from the Melbourne suburb of Heathmont (NSW 834413) and another from Penrose, 67 km south west of the study area (NSW971120).

HABITAT REQUIREMENTS

Makinson (2000: 210) notes that *Grevillea juniperina* subsp. *juniperina* "grows in open dry sclerophyll (eucalypt-dominated) forest or woodland at altitudes of less than about 50 m, in sandy to clay-loam soils and red pseudolateritic gravels." The substrates on which *Grevillea juniperina* subsp. *juniperina* most frequently occurs are sandy to gravelly Cenozoic alluvia, although it also grows on soils derived from Bringelly Shale (Wianamatta Group) and interfaces between these substrates. It has not been recorded on Ashfield Shale, which has a significantly higher phosphate content than Bringelly Shale (Martyn 2018). The vegetation associations in which it has been recorded include

Cumberland Plain Woodland (e.g. figure 1), Castlereagh Ironbark Woodland, Castlereagh Scribbly Gum Woodland (e.g. figure 2) and Shale/Gravel Transition Forest.

Makinson (2000: 211) also notes that “this subspecies shows some ability to colonise mechanically disturbed areas where open ground surface persists; repeated disturbance appears to eliminate it. Populations are often restricted to infrequently managed road verges [e.g. figure 3] or ungrazed semi-cleared land [e.g. figure 4].” At two such disturbed sites where I observed it to be growing (sites GJ2, GJ5, Appendix 1), *Grevillea juniperina* subsp. *juniperina* had vigorously colonised the habitat, with plants representing all life cycle stages from seedlings less than 7 cm tall (e.g. , figure 5) to large, reproductively mature shrubs .

Figure 1. *Grevillea juniperina* subsp. *juniperina* growing in Cumberland Plain Woodland on Bringelly Shale on the eastern side of Park Road, Marsden Park (site GJ1, Appendix 1).

3. Description of the study area

LAND USE HISTORY

The following account is based largely on information gathered from Liston (1988), except where otherwise stated. The first human inhabitants of the study area were Aborigines who moved there many thousands of years ago. People of the Dharawal group were occupants of the study area when Europeans first started to settle in the Sydney Region in 1788. These hunter-gatherers would have managed the grassy woodlands that grew on Wianamatta Shales of the area using fire-stick farming methods (Benson & Howell 1990). In 1816 a large group of them were massacred by soldiers at Appin and by 1830 their community life in the Campbelltown area had disintegrated.

In 1788, six months after Sydney was founded, two bulls and four cows escaped from Sydney Cove. European exploration of the study area commenced in 1795, when 61 naturalised descendants of

Figure 2. *Grevillea juniperina* subsp. *juniperina* growing in Castlereagh Scribbly Gum Woodland on Tertiary alluvium at The Northern Road, Castlereagh Nature Reserve (site GJ3, Appendix 1).

Figure 3. *Grevillea juniperina* subsp. *juniperina* has colonised about 0.4 km of the north eastern embankment of a road cutting through Bringelly Shale on Richmond Road at Marsden Park (site GJ5, Appendix 1) .

Figure 4. A population of *Grevillea juniperina* subsp. *juniperina* plants growing in semi-cleared land on the western side of Park Road, Marsden Park (site GJ2, Appendix 1).

Figure 5. Two seedlings of *Grevillea juniperina* subsp. *juniperina* plants growing in semi-cleared land on gravelly Tertiary alluvium on the western side of Park Road, Marsden Park (site GJ2, Appendix 1) .

those bulls and cows were discovered near Menangle, in an area that became known as "the Cowpastures". Those cattle had discovered a plentiful source of fodder on the alluvial flats of the Nepean River and adjacent grassy woodlands on Wianamatta Shales, which also proved to offer more fertile farming land than sandy soils derived from Hawkesbury Sandstone. By the end of 1809, 34 settlers had been granted land at Minto and Glenfield for farming. Further land was granted to settlers at Appin in 1811, Macquarie Fields and Airds in 1816 and at Campbelltown in 1820. From then to the 1950s, land use in both growth areas was dominated by agriculture, which necessitated extensive clearing of native vegetation from the more fertile alluvial and clayey soils. Agricultural activities conducted in the areas have included the cultivation of wheat (which was curtailed in 1864 when the whole crop was destroyed by an infestation of rust disease) and other cereal crops, grazing of sheep, cattle and horses, intensive production of pigs and poultry, and the cultivation of fruit and vegetables. Campbelltown grew slowly as an urban centre during the 19th century and first half of the 20th century, but population growth accelerated after 1950 due to the rezoning of agricultural land for housing development in the northern part of the Macarthur Growth Area, electrification of the railway line as far south as Macarthur in 1963, the release of the Three Cities Plan (Campbelltown-Camden-Appin) in 1972 and subsequent construction of a number of large-scale housing commission projects from 1973.

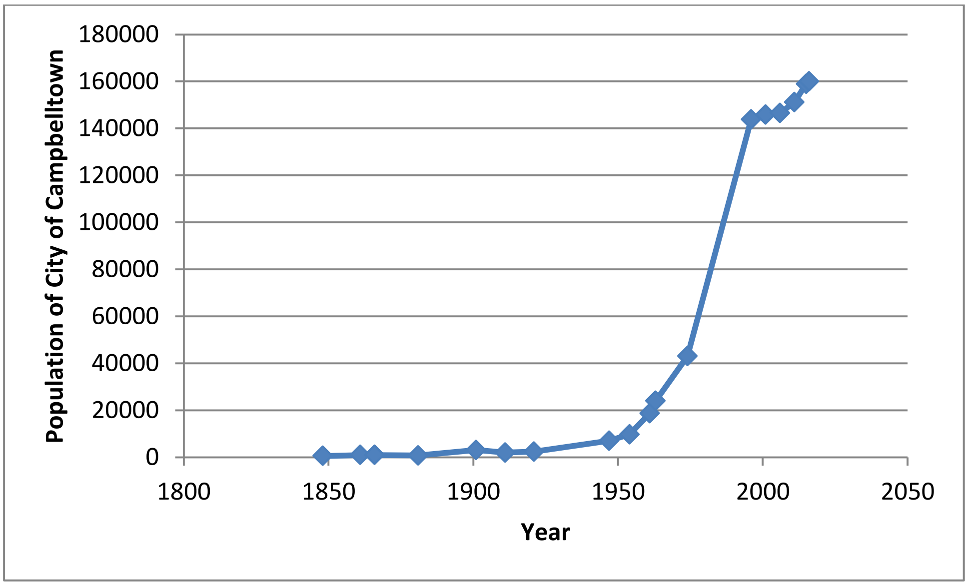

Figure 6. Population growth of Campbelltown, 1848-2016, assembled from data presented at https://www.campbelltown.nsw.gov.au/AboutCampbelltown/History/Campbelltowntimeline

Land use in the northern part of the Macarthur Growth Area is now dominated by residential housing, light industry and transport infrastructure, with only small pockets of pasture and urban bushland remaining intact, albeit weed-infested. In the southern half of the Macarthur Growth Area, south of the "waist" between Mt Annan and Glen Alpine, and in the Wilton Growth Area, land use is still largely rural, with the exception of limited residential and industrial development around Appin and Wilton. Agriculture has been largely restricted to soils derived from Wianamatta Shales and alluvium. Most areas of exposed Hawkesbury Sandstone either still support native vegetation or have been cleared for residential development.

HISTORY OF BOTANICAL EXPLORATION IN THE GROWTH AREAS

The first botanist to collect plant specimens in the same region as the growth areas was Joseph Banks' employee, George Caley, who in 1802 made several expeditions from Prospect through the Cowpastures, reaching Mount Hunter, Menangle and Thirlmere Lakes (Webb 1995). Caley returned to the area in 1803, 1804, 1805 and 1807, once in the company of the great Scottish botanist Robert Brown. Caley mapped a section of Georges River near Ingleburn, following it to Appin, and explored the upper Nepean River system as far as Douglas Park and Appin Falls on the Cataract River (Webb 1995). On these trips, Caley and Brown made extensive botanical collections, from which Brown described numerous species that were new to science, including *Grevillea juniperina*, which they collected near Prospect in 1803. The next botanical collector to visit the area was Franz Sieber, an Austrian who spent six months in the Sydney Region in 1823, during which time he collected specimens of 300 plant species (Ducker 1990), including many that are native to the study area. Botanical exploration of the area then became almost dormant until the late 19th century, when it intensified under the influence of J.H. Maiden, curator of the new Technological Museum, and later director of the Sydney Botanic Gardens. Botanists associated with Maiden, including R.T. Baker, J.L. Boorman, A.A. Hamilton, W.F. Blakely and E. Cheel made several thousand collections in the study area in the late 19th and early 20th centuries (National Herbarium of N.S.W. specimen database), long after much of the native vegetation on Wianamatta Shales and alluvia had been cleared for agriculture. Botanical exploration of the remnant vegetation of the study area has continued to the present day

LANDSCAPE CONTEXT

The Greater Macarthur and Wilton Growth Areas are located on the southern to south eastern rim of the Cumberland Plain, the central part of the saucer-shaped sedimentary Sydney Basin. Here, the uppermost strata of the Sydney Basin, Cenozoic alluvia patchily overlie the Triassic Wianamatta Group, mostly comprising Bringelly and Ashfield Shales, which, in turn overlie Triassic Hawkesbury Sandstone (Martyn 2018). Scattered small volcanic intrusions occasionally pierce the sedimentary strata, such as at Mt Annan, 0.7 km west of the "waist" in the middle of the Greater Macarthur Growth Area.

The most commonly exposed substrate in the northern part of the Greater Macarthur Growth Area is Ashfield Shale, over which patches of Bringelly Shale have been preserved on the western side, while Quaternary alluvia have accumulated in the valleys of Bow Bowing and Bunbury Curran Creeks (NSW Department of Minerals and Energy 1991, NSW Department of Mineral Resources 1985). Here, minor tributaries of the Georges River, such as Redfern, Smiths and McBarrons Creeks have exposed Hawkesbury Sandstone in narrow, shallow but steep-sided valleys.

In the southern half of the Greater Macarthur Growth Area, Bringelly Shale and Quaternary alluvium are restricted to the north west at Menangle Park. Further south, the Nepean and Georges Rivers and their tributaries have cut deep gorges through the Ashfield Shale, exposing large areas of Hawkesbury Sandstone on the steep valley sides and on the adjacent, flat to gently sloping valley borders. Large areas of transitional substrate exist here, where Ashfield Shale colluvium thinly covers Hawkesbury Sandstone or mixes with sandstone-derived soil. The landscape of the Wilton Growth Area resembles that of the southern half of the Greater Macarthur Growth Area but here the predominant substrate is Hawkesbury Sandstone over which an archipelago of thin islands of Ashfield Shale are preserved.

As the Greater Macarthur and Wilton Growth Areas are located on the southern to south eastern rim of the Cumberland Plain, they are gently tilted from south south west to north north east. However, topography also varies locally, with erosion having produced gently rolling landscapes over much of the area but steep-sided valleys contain the major water courses. The lowest point is in the far north east at Glenfield, where the banks of the Georges River are at 15 m altitude, but the land nearby rises to an altitude of 60 m at the junction of Campbelltown Road and Camden Valley Way. In the southern end of the Greater Macarthur Growth Area, just south east of Appin, the altitude reaches 260 m but drops to 230 m on the banks of the Georges River . The Wilton Growth Area varies in altitude from 105 m in the bottom of the Nepean Gorge to 305 m near its southern tip on the Picton Road.

Topographic variation as well as distance from the sea influences climate. The area just west of the Greater Macarthur Growth Area has the lowest average annual rainfall and the highest average January maximum temperature in the Sydney Region (Benson & Howell 1990). Both growth areas are subject to winter frosts.

NATIVE VEGETATION

In terms of the plant community types recognised in the Bionet Vegetation Classification and the vegetation maps that were prepared for this project, the remnant native vegetation of the growth areas consists of:

- 830 Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain;
- 835 Forest Red Gum – Rough Barked Apple grassy woodland on alluvial flats of the Cumberland Plain;
- 849 Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain;
- 850 Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain;
- 1081 Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain;
- 1181 Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney;
- 1292 Water Gum – Coachwood riparian scrub along sandstone streams;
- 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain.

Plant community types 830, 849 and 850 grow on Wianamatta Shales, 835 on quaternary alluvium, 1081 and 1395 on Hawkesbury Sandstone under a thin layer of Ashfield Shale or shale colluvium and 1181 and 1292 on Hawkesbury Sandstone.

In the course of this project, I visited 23 sites in the field, 19 of which were either in, or adjacent to, the Growth Areas, 20 of which I characterised in detail (Appendix 1).

In the northern half of the Greater Macarthur Growth Area, native vegetation is restricted to small, mostly long, narrow patches of urban bushland, most of which line water courses. A few of these are conserved as council reserves. I visited four bushland remnants either in, or close to the northern part of the Greater Macarthur Growth Area (sites N1, N7, N13, N14, Appendix 1), two of which I characterised in detail (N1, N7). I found all of these to include substantial weed infestation, especially close to water courses. Two species of privet, *Ligustrum sinense* and *L. lucidum*, were the most common woody weeds growing on sandstone, while African Olive (*Olea europea* subsp. *cuspidata*) was common on Wianamatta Shales. Common herbaceous weeds included naturalised grasses, Bridal Creeper (*Asparagus asparagoides*) and, near watercourses, Wandering Jew (*Tradescantia fluminensis*). Dumped household and garden rubbish was common near road access points in most patches of remnant bushland.

In the southern half of the Greater Macarthur Growth Area, and in the Wilton Growth Area, patches of remnant native vegetation become progressively more plentiful, on larger blocks of land, as one moves south but they are still mostly associated with water courses. According to the vegetation maps that were prepared for this project, by far the most abundant plant community type here is 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain. This community type occurs on flat to gently sloping land, on clayey to loamy soils derived from Asfhield shale or shale colluvia over Hawkesbury Sandstone, often adjacent to steep-sided gorges of exposed Hawkesbury Sandstone (e.g. site N8, figure 7).

Figure 7. Plant community type 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain, on Ashfield shale colluvium over Hawkesbury Sandstone at Shingle Hill, Wilton (site N10, Appendix 1).

Although almost all of this community type is coded as "intact" in the vegetation maps, I found the condition of these remnants variable, depending on the extent of grazing by stock to which they had been subjected. At one of my sites (site N3, Appendix 1), a shrub stratum was completely absent and all herbaceous plants had been grazed close to the ground (figure 8).

The sides of the gorges of the Nepean and Georges Rivers and their major tributaries are typically covered by plant community type 1181 Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney (e.g. site N11, figure 9). In some places this forms a mosaic with plant community type 1081 Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain.

Figure 7. Heavily grazed understory vegetation in plant community type 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain at Allen Creek, Wilton (site N3, Appendix 1).

Small, mostly degraded remnants of plant community types 849 and 850 are scattered on Ashfield Shale in the Wilton Growth Area and southern part of the Macarthur Growth Area.

POTENTIAL HABITAT

In its core distribution, *Grevillea juniperina subsp. juniperina* on sandy to gravelly Tertiary alluvia, although it also grows on soils derived from Bringelly Shale (Wianamatta Group) and Quaternary alluvia and interfaces between these substrates. It is recorded from Cumberland Plain Woodland, Castlereagh Ironbark Woodland, Castlereagh Scribbly Gum Woodland and Shale/Gravel Transition Forest.

Figure 8. Plant community type 1181 Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney east of Appin (site N11, Appendix 1).

Figure 9. Plant community type 1081 Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain east of Appin (site N12, Appendix 1).

The OEH Threatened Species Data Collection indicates that *Grevillea juniperina subsp. juniperina* has the potential to occur in the following plant community types within the Wilton and Greater Macarthur Growth Areas:

- 849 Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain;
- 850 Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain;
- 883 Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain.

Plant community types 849 and 850 are represented in the Growth Areas mostly as small, degraded fragments. Plant community type 883 is absent from the Wilton Growth Area and is represented in the Greater Macarthur Growth Area by a tiny, degraded fragment totalling less than one hectare at Macquarie Fields.

4. Assessment of species presence and suitable habitat

SPECIES RECORDS AND HABITAT ASSESSMENTS

Grevillea juniperina subsp. juniperina has never been recorded in the study area, nor has any formal habitat assessment ever been conducted there. However, on 19 June 2017 the focal taxon was collected adjacent to the study area by Brian Towle at Gundungarra Reserve, Spring Farm, 4 km north west of the “waist” in the Greater Macarthur Growth Area (specimen NSW999291), in a disturbed remnant of Grey Box – Forest Red Gum grassy woodland on Bringelly Shale.

I interviewed two botanists who have published comprehensive taxonomic treatments of *Grevillea*, Robert O. Makinson and Peter M. Olde, to ask for their personal opinions on the likelihood of *Grevillea juniperina subsp. juniperina* being native to the study area. Both are familiar with, and have described the morphology, distribution and ecology of this taxon and Olde has also written on its horticultural attributes. Both consider the core of its distribution to be the area bounded by Scheyville, Richmond, Penrith and Blacktown. Makinson has observed one plant of *Grevillea juniperina subsp. juniperina* growing at Bill Anderson Reserve, Kemps Creek, and thought that this was most probably a wild occurrence, representing the southern limit of distribution of the taxon. Makinson had determined the identity of Towle’s collection from Spring Farm as *Grevillea juniperina subsp. juniperina* but was ambivalent about whether this represented a wild record or garden escape. Olde believes that the southern limit of *Grevillea juniperina subsp. juniperina* is north of Luddenham and considers the Kemps Creek and Spring Farm occurrences both to represent garden escapes.

PRIOR SPECIES SURVEYS

Grevillea juniperina subsp. *juniperina* is a perennial shrub that is readily recognised at any time of year by its distinctive vegetative morphology. Conventional surveying would therefore be the most appropriate way to test for its presence, if unlimited access to the study area were allowed. Surveys were undertaken on behalf of DPE on all areas of land where landowners granted access, amounting to 3,360 hectares (62% of the urban development footprint). However, the survey effort for this species did not meet the recommendations in the OEH threatened species guidelines for field traverse surveys due to limitations imposed by land access. No sightings of the species were recorded from the survey areas.

ASSESSMENT OF SPECIES PRESENCE

Grevillea juniperina subsp. *juniperina* is unlikely to be growing wild in either the Greater Macarthur Growth Area or the Wilton Growth Area and has probably never been native to either of these areas.

JUSTIFICATION FOR DETERMINATION

Evidence and arguments supporting the hypothesis that *Grevillea juniperina* subsp. *juniperina* is, or once was native to the study area

There is some evidence that suitable habitat for *Grevillea juniperina subsp. juniperina* exists in the study area. Two of the substrate classes on which *Grevillea juniperina subsp. juniperina* is found growing within its core distribution, Bringelly Shale and Cenozoic alluvia, occur patchily in the Greater Macarthur Growth Area north of Gilead and as a small patch of Bringelly Shale 3 km SW of Appin (NSW Department of Minerals and Energy 1991, NSW Department of Mineral Resources 1985). The focal taxon is therefore adapted to growing on soils that occur in part of the study area. Three of the plant community types in which *Grevillea juniperina subsp. juniperina* grows in its core distribution are also represented in the study area and some of these patches occur on the focal taxon's preferred substrates.

The population of four plants of *Grevillea juniperina subsp. juniperina* that was recently discovered at Gundungarra Reserve, in a patch of degraded remnant Grey Box – Forest Red Gum grassy woodland on Bringelly Shale, just outside the study area, might be native there. This habitat closely resembles small remnant patches of Cumberland Plain woodland that are scattered through the western side of the Greater Macarthur Growth Area north of Gilead and south west of Appin. It is conceivable that small populations of *Grevillea juniperina subsp. juniperina* like the one at Gundungarra Reserve might have survived in patches of remnant bushland on private property that have never been accessible to botanical collectors, including those who have surveyed parts of the growth areas for this project. The presence of *Grevillea juniperina subsp. juniperina* at Gundungarra Reserve also shows that it is capable of growing in the study area.

Most native vegetation originally growing on Bringelly Shale and alluvia in the study area was cleared for agriculture before intensive botanical exploration of the area commenced in the late 19th century, potentially destroying populations of the taxon before they could be discovered. Thus absence of evidence for the presence of the focal taxon in the study area should not be construed as evidence of original absence.

Evidence and arguments against the hypothesis that *Grevillea juniperina* subsp. *juniperina* is, or once was native to the study area

The history of botanical exploration of the study area suggests that if *Grevillea juniperina subsp. juniperina* had originally been native there, then it would probably have been collected or reported there at some time in the last 210 years. George Caley made multiple botanical collecting expeditions through the study area before any land had been granted to settlers and did not collect

Grevillea juniperina subsp. *juniperina* there, although he had earlier collected it near Prospect. One would expect Caley to have collected it if it had been as abundant here as it is in remnant bushland in its core distribution. Franz Sieber collected plant specimens in the study area in 1823, shortly after land started to be cleared there but did not collect *Grevillea juniperina* subsp. *juniperina* either. Intensive botanical exploration of the study area began in the late 19th century, and has continued to the present day and yet none of the numerous botanists who worked there have collected or reported it.

Two of the three plant community types that are potential habitat for *Grevillea juniperina* subsp. *juniperina* in the study area (849 Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain, 850 Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain) were originally common and widespread between the core distribution of the taxon and the study area 24 km to the south east (Benson 1992). Moreover, two of the substrates on which *Grevillea juniperina* subsp. *juniperina* is known to occur, Bringelly Shale and Cenozoic alluvia, collectively underlie almost the whole area separating the study area from the core distribution of the focal taxon. If *Grevillea juniperina* subsp. *juniperina* had originally been native to the study area, one would expect some evidence of its existence in this intervening area to have accumulated since intensive botanical exploration of the Cumberland Plain commenced in the late 19th century. The only such evidence that I could find from the Wildlife Atlas and herbarium records was one observation of two plants at Bill Anderson Reserve, Kemps Creek and the recent discovery of four plants at Gundungarra Reserve, Spring Farm. The former of these records arguably represents a native occurrence at the margin of the focal taxon's natural distribution but the latter is very dubious as a native occurrence.

I visited Bill Anderson Reserve, Kemps Creek (sites GJ6-GJ8, Appendix 1), and spent a total of 3 hours and 45 minutes searching for *Grevillea juniperina* subsp. *juniperina* and characterising three sites there, including sites at which R.O. Makinson and G. Steenbeeke had told me that they had previously seen individual plants. The whole of this reserve could be classed as suitable habitat for the focal taxon on the basis of substrate (Bringelly Shale) and associated plant species but I could find no plants of it there. This reserve varies in altitude from 50 to 70 m, which is higher than anywhere within the core distributional range of *Grevillea juniperina* subsp. *juniperina*, where it is typically locally abundant in suitable habitats. Its rarity at Kemps Creek is consistent with this locality being at the limit of its ecological tolerance.

Brian Towle reported finding four healthy plants growing in a thicket of *Bursaria spinose* at Gundungarra Reserve, Spring Farm in June 2017 but when I visited this site 12 months later I found all four plants dead (site GJ9, Appendix 1). Their cause of death is most likely to have been water stress caused by drought: in the period May 2017 to June 2018, Campbelltown weather station recorded 317.2 mm of rainfall, less than half the mean annual rainfall of 824 mm (Bureau of Meteorology 2018). The death of these plants calls into question the bioclimatic suitability of this site as a sustainable habitat for *Grevillea juniperina* subsp. *juniperina.* This population was unlike any I had seen in the focal taxon's core distributional range. The plants were all very large, reproductively mature shrubs varying from 1.3 to 2.0 m tall and therefore at least 10 years old if one assumes a rate of growth in height of 13 to 20 cm per year. There was no evidence of seedling recruitment, unlike the populations that I had examined in the Castlereagh –Marsden Park – Shanes Park area, all of which included plants of diverse size classes.

The unusual size distribution and unexpected location of this population seem best explained by an anthropogenic origin. These plants might all be of the same or similar age, having germinated from seeds that escaped here from a local garden after construction of the suburb began in the early 1990s (https://profile.id.com.au/camden/about/?WebID=230, accessed, 21/7/2018). Two collections from naturalised populations of *Grevillea juniperina* subsp. *juniperina* are held by the National Herbarium of NSW – one from Heathmont, a suburb of Melbourne (NSW834413), the other from Penrose, 67 km south west of the study area (NSW971120), demonstrating that garden escapes of this species are likely. A notable feature of both of those collections was the observation of the presence of seedlings, unlike the population at Gundungarra Reserve. Alternatively, the plants at Gundungarra Reserve might have been planted there when the park was established at the same time as the suburb of Spring Farm. Plants used for landscaping purposes are often vegetatively propagated from single, selected clones and this could explain the absence of seedlings, if *Grevillea juniperina* subsp. *juniperina* is reproductively self-incompatible like some other species of *Grevillea* (Smith & Gross 2002). A third plausible scenario is that the plants at Gundungarra Reserve established there from dumped garden waste. The western side of this park, bordering a powerline easement, is an informal garbage dump, with abundant household refuse and garden waste, including discarded plant pots and plant material strewn through this side of the reserve.

The main reason for requiring an expert report on *Grevillea juniperina* subsp. *juniperina* is that three plant community types in which it is typically found in its core range occur in the study area. These were inferred to be potential habitat for the focal species, implying that it might occur, as yet undiscovered, in remnants of those community types within the growth areas. However, the distribution of *Grevillea juniperina* subsp. *juniperina* is also correlated with other environmental variables, such as substrate and altitude. In its core distributional range, it occurs below 50 m altitude (Makinson 2000), but records from Kemps Creek that were unknown to Makinson in 2000, extend its altitudinal range to 70 m. Land under 70 m occurs in two parts of the study area. In the northern half of the Greater Macarthur Growth Area, such low lying land occurs on substrates such as Ashfield Shale and Hawkesbury Sandstone on which *Grevillea juniperina* subsp. *juniperina* has never been recorded and where blocks of intact native vegetation seldom exceed 10 ha in area. Land below 70 m altitude is also found on the banks of the Nepean River between Menangle and Spring Farm but here the land is vegetated with a plant community type in which *Grevillea juniperina* subsp. *juniperina* has not been recorded: 835 Forest Red Gum – Rough Barked Apple grassy woodland on alluvial flats of the Cumberland Plain. None of the sites that I visited and characterised in or near the study area matched the habitat of the focal species in its core distributional range (Appendix 1). It is reasonable to conclude that no suitable habitat for *Grevillea juniperina* subsp. *juniperina* now occurs within the study area.

Even if suitable habitat did occur in the study area prior to clearance of land for agriculture, this would not be compelling evidence supporting the former presence of *Grevillea juniperina* subsp. *juniperina* there. Other causal factors such as biogeographic history are also important determinants of plant distributions. Absence of the focal taxon from Bringelly Shale and Cenozoic alluvia south of Kemps Creek might reflect a history of incomplete range expansion: it might have originated on the northern Cumberland Plain but not yet dispersed into all of the habitats in which it was capable of growing and competing. Alternatively, it might have once covered a much larger area from which it later contracted as a result of stochastic processes such as high bushfire frequency in the southern Cumberland Plain.

LIKELIHOOD OF SPECIES PRESENCE

Figure 10 shows a frequency histogram of records of *Grevillea juniperina* subsp. *juniperina* from the OEH Wildlife Atlas, with the herbarium specimen from Spring Farm added into the data set, categorised in latitudinal samples 0.05 degrees wide. If the Spring Farm record is rejected as native, as I have recommended, then the frequency distribution resembles a unimodal Gaussian curve, which is typical of many plant species, as well as other kinds of organisms (Brown 1984). If we make the simplifying assumption that surveying and specimen collecting efforts have been unbiased across this range of latitudes within the Cumberland Plain, then this frequency distribution can be treated as a probability distribution. If this argument is accepted, then the whole of the study area lies outside of the curve enclosing all 1488 records. The probability of *Grevillea juniperina* subsp. *juniperina* occurring in the study area can then be conservatively estimated as less than 1/100.

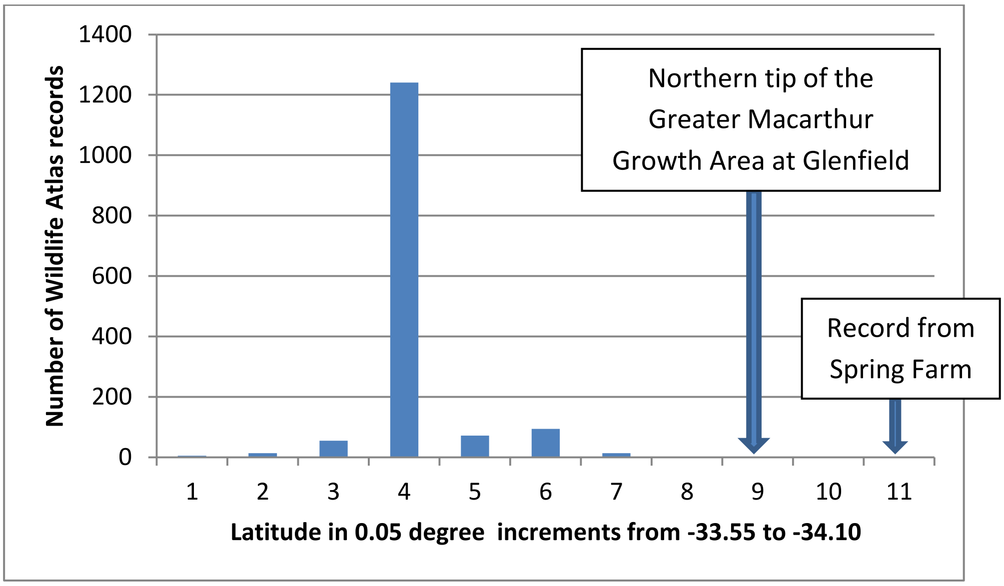

Figure 10. Frequency histogram of records of *Grevillea juniperina* subsp. *juniperina* from the OEH Wildlife Atlas classified according to latitude.

6. Acknowledgements

I am grateful to Teresa James, Bob Makinson, Peter Olde, and Brian Towle for happily being interviewed, and for generously sharing their knowledge about *Grevillea juniperina* subsp. *juniperina*. Alison Butler (Camden Council) kindly provided information about the history of suburban development at Spring Farm and adjacent suburbs.

8. Appendices

APPENDIX 1: Characterisation of habitat at selected sites

The tables on following pages record data that I collected at sitews both within and outside the study area. Several of these sites received “over the fence” assessments and were not characterised in detail. Each site that was characterised in detail was centred on an arbitrarily selected plant of *Grevillea juniperina* subsp. *juniperina* (sites numbered GJ1-GJ5, GJ9) or at places where the focal taxon had previously been reported (sites GJ6-GJ8) or at an arbitrarily point in the case of sites examined in or near the growth areas (sites N1-N14). At each site the precise latitude and longitude, altitude, substrate, soil description, slope and aspect were also recorded. Also, at each site all woody plant species and a few species of herbaceous plants that could be reliably identified from vegetative characters were recorded within a radius of 30 metres. Attributes of sites at which *Grevillea juniperina* subsp. *juniperina* was found (sites GJ1-GJ5, GJ9) were compared with comparable attributes of sites in or near the growth areas to assess whether any sites in the growth areas closely matched *Grevillea juniperina* subsp. *juniperina* sites.

APPENDIX 2: PETER WESTON'S CURRICULUM VITAE

Personal details

Name: Peter Henry Weston.

Address: 18 Lyle Avenue, Lindfield, New South Wales 2070, Australia.

Date and place of birth: 22 October 1956, Lower Hutt, New Zealand.

Immediate family: wife (Susan) and three children (Timothy 33, Caitlin 31, Nicholas 27).

Nationality: Australian.

Interests: soccer, reading, guitar, orchid growing, cross-country skiing, bush walking.

Academic Qualifications

i) **B.Sc.** (first class honours; equal first in order of merit) School of Biological Sciences, University of Sydney; 1975-78, conferred 7 April 1979.
Thesis title: "The evolution and classification of *Boronia* Sm."

ii) **Ph.D.**, School of Biological Sciences, University of Sydney, 1979-83; conferred 18 May 1985.
Thesis title: "Systematics and biogeography of the Persooniinae (Proteaceae)".

Awards, Fellowships and Scholarships

2014	Nancy Burbidge Medal (awarded by the Australasian Systematic Botany Society to a person who has made a longstanding and significant contribution to Australasian systematic botany. It is the foremost award that can be conferred by ASBS).
2014	Australian Biological Resources Study-sponsored Winston Churchill Fellowship for an established career researcher in taxonomy.
2009	Grady L. Webster Structural Botany Publication Award for 2008 and 2009 from the Botanical Society of America. The BSA component of the award (it is awarded in alternate years by the BSA and the American Society of Plant Taxonomists) recognizes the most outstanding paper published in the *American Journal of Botany* in the field of structural and developmental botany (i.e., anatomy and morphology) over a two-year period. It was awarded to Gregory J. Jordan, Peter H. Weston, Raymond J. Carpenter, Rebecca A. Dillon and Timothy J. Brodribb for: "The evolutionary relations of sunken, covered, and encrypted stomata to dry habitats in Proteaceae," American Journal of Botany, Volume 95, Issue 5; May 2008.
2006	Carrick Award for Australian University Teaching from the Australian Learning and Teaching Council (one of five members of a teaching

team from the University of New England cited for Outstanding Contributions to Student Learning).

1992-93 Posting to Royal Botanic Gardens, Kew, as Australian Botanical Liaison Officer.

1982 Charles Gilbert Heydon Travelling Fellowship for the biological sciences (not taken up).

1980-82 University of Sydney Postgraduate Scholarship.

1979-82 Commonwealth Postgraduate Award.

1977 G.S. Caird Scholarship for Third Year Botany, University of Sydney.

1976 Slade Prize for Practical Plant Biology, University of Sydney.

Employment

Present Position: Honorary Research Associate, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney and independent botanical consultant.

Previous positions held:
2008-2016 Senior Principal Research Scientist, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

2000-2008 Principal Research Scientist, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

1994-2000 Senior Research Scientist, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

1989-1994 Research Scientist, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

1982-1989 Scientific Officer, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

1979-82 Part-time demonstrator, School of Biological Sciences, University of Sydney.

Adjunct and visiting university appointments

2013- Adjunct Associate Professor, La Trobe University.

2011- Adjunct Associate Professor, University of New South Wales.

2006 Visiting Lecturer, Rhodes University, Grahamstown, South Africa.

2004-2009 Adjunct Associate Professor, University of New England.

2000-2004 Adjunct Senior Lecturer, University of New England.

Administrative/management experience

2009 Acting Manager Plant Diversity

2002-2003 Member, Plant Diversity Research Program Leaders Committee
1998-99 Systematics Liaison Officer
1997-98 Member RBGS Market testing working party
1997 Member, RBGS advisory committee for restructuring senior management
1990-91 Systematics Co-ordinator
1996-98 Member, RBGS Joint Consultative Committee

Membership of Learned Societies

1996- Society of Australian Systematic Biologists
1984- Willi Hennig Society (Elected Fellow, 1992-, Council member, 1998-2000)
1979- Society of Systematic Biologists (member, Editorial Board 1993-95)
1978- Australasian Systematic Botany Society (formerly Australian Systematic Botany Society: President, 2009-2012, Vice President, 2008-2009, Chairman, Hansjörg Eichler Research Fund Committee, 1998-2002, Council member, 1996-2002)

Membership of External Committees

2015- Financial Grants Standing Committee (formerly the Grants Policy Standing Committee) of the Australasian Systematic Botany Society
2012-2013 Conference Organising Committee of *Systematics Without Borders*, a joint conference of the Australasian Systematic Botany Society, Society of Australian Systematic Biologists and Invertebrate Biodiversity and Conservation, University of Sydney (Chairman)
2011- Editorial Board, *Phytotaxa*
2008-2009 Corresponding Member, Editorial Advisory Committee, *Australian Systematic Botany*
2006-2014 Ira Butler Memorial Trophy Committee (a joint committee of the Australasian Native Orchid Society and the Orchid Society of New South Wales) (Chairman)
2004- Editorial Advisory Board, *Kew Bulletin*
2001-2006 Panel of Judges, Eureka Prize for Biodiversity Research
2000-2012 Bushland Management Advisory Committee, Lane Cove Council (Chairman, 2008-2010)
1999-2004 Editorial Advisory Committee, *Australian Systematic Botany*

Spoken presentations at conferences (not including presentations delivered by others)

2015 Building Our Botanical Capital, annual conference of the Australasian Systematic Botany Society: “A database of variation in floral characters in the Proteaceae, and implications for key questions in floral evolution”.
2014 Next Generation Systematics, annual conference of the Australasian Systematic Botany Society: Nancy Burbidge Memorial

Lecture: “Problems and progress in plant systematics since Nancy Burbidge”

2013 Genetics Society of Australasia conference, Sydney *Genetics in the Harbour City*: “Molecular phylogeny of the subtribe Hakeinae (Green Plants: Proteaceae tribe Embothrieae) and its implications”.

2013 Joint conference of the Australasian Systematic Botany Society, Society of Australian Systematic Biologists and Invertebrate Biodiversity and Conservation, Sydney, *Systematics Without Borders*: “Molecular phylogeny of the subtribe Hakeinae (Green Plants: Proteaceae tribe Embothrieae) and its implications”.

2012 Australasian Systematic Botany Society conference, Perth, *Local knowledge, global delivery*: “Contested, Uncontested and Potentially Controversial Taxonomic Changes in the Proteaceae: How Do They Differ?”

2011 37th annual conference of the South African Association of Botanists, *Plants in a Changing World* and 9th conference of the South African Society of Systematic Biologists, *Biodiversity Matters*; plenary address: “Cenozoic environmental change and the systematics of southern hemisphere plants”

2011 XVIII International Botanical Congress, Melbourne: “Floral evolution in animal-pollinated Australian angiosperm clades: patterns and potential explanations”.

2010 VI Southern Connection Congress, Bariloche: “Cladistic biogeography, molecular dating, fossils and the Proteaceae”

2010 VI Southern Connection Congress, Bariloche: “Diversification of the Proteaceae in Mediterranean hotspots of the Southern Hemisphere and in tropical rainforests”

2010 Australian Systematic Botany Society conference *Systematic Botany Across the Ditch: Links Between Australia and New Zealand*; Keynote address: “Cenozoic environmental change and the systematics of southern hemisphere plants”

1999 XVI International Botanical Congress, Saint Louis: “Historical biogeography of Proteaceae”.

1997 II Southern Connection Congress, Valdivia: “Cladistic biogeography of a key woody group: Proteaceae”.

1997 First Biennial International Conference of the Systematic Association, Oxford: “Rolf Sattler’s Plant Morphology and Cladistic Analysis”.

1996 *An International Symposium on the Biology of Proteaceae*, Melbourne: “ITS squence variation in the Proteaceae and what it tells us about phylogeny”.

1993 Joint conference of The Systematics Associations and The Linnean Society on *Models in Phylogeny Reconstruction*, London: “Direct methods for polarising character transformation series”.

1990 IXth meeting of the Willi Hennig Society, Canberra: “Transoceanic cladistic patterns in the Proteaceae”.

2003 The Third International Conference on *the Comparative Biology of the Monocotyledons*, Ontario: “Co-evolution of *Chiloglottis* (Orchidaceae) and its Thynnine wasp pollinators”.
2005 XVII International Botanical Congress, Vienna: “Food is good but sex is better: the evolution of deceptive pollination in the tribe Diurideae (Orchidaceae)”.
2006 Australian Systematic Botany Society conference, Cairns, *Plant Diversity in the Tropics*: “A new suprageneric classification of the Proteaceae”.
2007 5th Southern Connection Congress, Adelaide: “‘I’m not dead yet’ – Gondwana (the Proteaceae are at least partially congruent with Gondwanic fragmentation)”.
1989 Australian Systematic Botany Society symposium, on *Gondwanan Elements in the Australian Flora*, Sydney: “Transpacific cladistic patterns in the Proteaceae and Elaeocarpaceae”.
1988 Symposium on *Panbiogeography of New Zealand*, Wellington: “Problems with the statistical testing of panbiogeographic hypotheses”.
1985 Australian Flora Foundation Symposium on *Waratahs*, Canberra: “Drifting waratahs or continents?”
1984 Australian Systematic Botany Society symposium on *Cladistics, Systematics and Phylogeny*, Canberra: “A reappraisal of Nelson's direct method of character analysis”.

Refereeing manuscripts, grant applications, reports and examining postgraduate theses (last five years)

2016: *Australian Systematic Botany*; *Botanical Journal of the Linnean Society*, *National Research Foundation* (South Africa).
2015: *American Journal of Botany*; Australian Research Council (4); *Australian Systematic Botany*; *Muelleria*; *Nuytsia*; *Phytotaxa*; *PLOS One*; *Telopea* (6).
2014: Australian Research Council (3); *Australian Systematic Botany* (2); *Cunninghamia*; *Journal of Biogeography* (2); *Muelleria*; National Research Foundation (South Africa); *Orchadian*; *Perspectives in Plant Ecology, Evolution and Systematics*; *Plant Systematics and Evolution*; *Telopea* (3).
2013: Australian Research Council; *Australian Systematic Botany*; *Biology Letters*; *Cladistics*; *Diversity and Distributions*; *Evolution*; *Journal of Biogeography*; *New Zealand Journal of Botany*; *Taxon*; *Telopea*.
2012: Australian Research Council (3); *Australian Systematic Botany*; “Darwin, Then and Now” (chapter of book published by University of Chicago Press); *Diversity and Distributions*; *Journal of Biogeography*; National Research Foundation (South Africa); *Phytokeys*.

Research

My research has been in the theoretical and practical aspects of systematic botany, with emphasis on the theory and practice of phylogenetic analysis, and the broader uses to which phylogenetic knowledge may be applied. I have phylogenetically analysed groups in the plant families Proteaceae, Fabaceae, Orchidaceae, Rutaceae, Winteraceae and Lauraceae, contributed to more general analyses of angiosperm phylogeny, and used the results of these analyses to improve biological classification and to test theories of historical biogeography, trait evolution, co-evolution and adaptation. I have earned an international reputation for my contributions to both theoretical and empirical developments in this field.

Herbarium curation and collections

My curatorial responsibilities at the National Herbarium of New South Wales have included the families Rutaceae (1982-1998), Proteaceae (1982-2016), Orchidaceae (1986-2016) and Fabaceae subfamily Faboideae (1986-2016). I have collected plant specimens (mostly angiosperms) in Australia, England, New Zealand, New Caledonia, Chile, South Africa, and Argentina, mostly for the herbarium and living collections of the Royal Botanic Gardens and Domain Trust, Sydney. Duplicates of my collections have been distributed to over 20 herbaria in 8 different countries.

Teaching

I have been actively involved in the preparation and teaching of four third year undergraduate courses in biosystematics:
Western Sydney University (2015-2017): “Principles of Evolution” (unit 300980), “Botany” (unit 300836).
University of New South Wales (2010-2016): “Assembling the Tree of Life” (BIOS3221)
University of New England (2000-2010): Biosystematics (Biosyst 301, Biosyst 302, Evol 301/501).
Botany Department, Rhodes University, Grahamstown, South Africa (February-March 2006): “Plant Biodiversity” course in collaboration with Associate Professor Nigel Barker.

I am currently co-supervising one postgraduate student:
Nanette Thomas (Ph.D., University of New England): Systematics of *Tasmannia* informs Biogeography of Winteraceae.

Postgraduate and honours students I have previously co-supervised include:
Margaret Stimpson (Ph.D., University of New England): Systematics, evolution and ecology of the *Banksia spinulosa* complex (graduated 2017).
Melita Milner (Ph.D., Australian National University): Phylogeography of *Lomatia and Telopea* (Proteaceae) in south eastern Australia (graduated 2015).
Samanta Oon (B.Sc. Honours, University of New South Wales): *Lomatia* likes it both ways: rampant bidirectional introgression of chloroplast genomes between two morphologically distinct species of Lomatia (Proteaceae) (graduated 2015).
Zoe Reynolds (B.Sc. Honours, Australian National University): Phylogenetic, taxonomic and functional turnover in Proteaceae assemblages (graduated 2013).

Emma McIntosh (B.Sc. Honours, University of Sydney): Hybridization and introgression between *Lomatia myricoides* and *L. silaifolia* (Proteaceae) (graduated 2011).
Margaret Stimpson (M.Sc.Stud., University of New England): Review of the *Banksia spinulosa* species complex (Proteaceae) (graduated 2011).
James Indsto (M.Sc., University of Wollongong): Pollination Ecology and Molecular Systematics of *Diuris* (Orchidaceae) of the Sydney Region (graduated 2010).
Nanette Thomas (Grad.Dip.Sci., University of New England): Phylogenetic analysis of Winteraceae (graduated 2009).
David McKenna (Ph.D., University of Wollongong: Demographic and ecological indicators for rarity in obligate-seeding *Persoonia* (Proteaceae) shrubs of the Sydney region, graduated 2007).
Paul Rymer (Ph.D., University of Wollongong: Plant rarity: species distributional patterns, population genetics, pollination biology and seed dispersal in *Persoonia* (Proteaceae), graduated, 2006).
Georgina Lloyd (B.Sc. Honours, University of Sydney: Pseudocopulation in two species of *Cryptostylis*: Implications for maintaining species integrity, graduated 2004)
Andrew Perkins (Ph.D., University of Sydney: Phylogenetic Systematics of the Genus *Calochilus* (Orchidaceae), graduated 2002).
Jim Mant (Ph.D., Australian National University: Comparative biology of *Chiloglottis* (Orchidaceae) and its thynnine wasp pollinators (Tiphiidae), graduated 2002).
Siegfried Krauss (Ph.D., University of Wollongong: Systematic pattern and evolutionary process in the complex species *Persoonia mollis* (Proteaceae), graduated 1995).

I have examined 14 honours and postgraduate theses:
Australian National University (Ph.D., 2003, 2007, 2008)
University of Melbourne (Ph.D., 1995, 2011)
University of Newcastle (M.Phil., 2003)
University of Queensland (Ph.D., 2003)
University of Sydney (Ph.D., 1991, 1994, 1997, 2009)
University of Wollongong (B.Sc. Hons., 2001, 2003)
Victoria University (Ph.D., 2007)

Competitive Research and Infrastructure Grants

Peakall, R., Pichersky, E., Linde, C., Weston, P.H. (2015-2019) The biosynthesis and evolution of novel semiochemicals in orchids. $644,800, Australian Research Council Discovery Grant DP150102762.

Hoebee, S.E., Weston, P.H., & Edwards, T.J. (2015-18) Evolution in action or the demise of iconic Australian flora? $217,700, Australian Research Council Discovery Grant DP150100508.

He, T., Lamont, B., Weston, P.H., & Cowling, R. (2012-2014) Origin and evolution of plant functional traits in relation to fire. $310,000, Australian Research Council Discovery Grant DP120103389.

Rossetto, M., Crayn, D.M. & Weston, P.H. (2008-2010) Integrating molecular and morphological data for generic delimitation and species identification in Lauraceae. $73,333, Australian Biological Resources Study.

Cantrill, D., Murphy, D. & Weston, P.H. (2008-10) Understanding the origins of the Australian flora by integrating molecular phylogenies and fossil data in the Proteaceae. $88,900, Hermon Slade Foundation.

Rossetto, M. & Weston, P.H. (2007-2009) Speciation in the Australian flora: testing explanatory hypotheses in waratahs and their allies. $78,000, Hermon Slade Foundation.

Considine, J.A., Krauss, S.L. & Weston, P.H. (2002-2004) A biological basis for the efficient breeding of native plants for export markets: a case study with the Australian Goodeniaceae. $168,126, ARC – Linkage (Krauss and Weston representing industry partners)

Whelan, R.J., Ayre, D.J., England, P., Auld, T.D., & Weston, P.H. (2000-2002) Ecology and genetics of fire-sensitive *Persoonia* species: threatened species recovery and management. $126,480, Australian Research Council (ARC– SPIRT, Auld and Weston representing industry partners).

Trent, R. *et al.* (2000) Enhancement of DNA sequencing equipment for the Sydney University and Prince Alfred Molecular Analysis Centre. $600,000, Australian Research Council (ARC-REIF).

Weston, P.H. (1999-2001) Comparative biology of *Chiloglottis* (Orchidaceae) and its thynnine wasp pollinators (Tiphiidae). $75,000, Hermon Slade Foundation.

Weston, P.H. (1997-2000) Taxonomic revision of *Dillwynia* (Fabaceae: Faboideae: Mirbelieae). $62,836, Australian Biological Resources Study.

Weston, P.H. & Thomson, J.A. (1993) A molecular approach to the evolution and biogeography of the Queensland tree waratahs. $4000, Queensland Wet Tropics Management Authority

Weston, P.H. & Thomson, J.A. (1991-92) A molecular approach to the evolution and biogeography of the waratahs. $80,100, Australian Research Council (large grants scheme).

Weston, P.H. (1984) Establishment of a data bank for eucalypt specimens held by NSW. $20,000, Australian Biological Resources Study.

Scientific Publications

[the numbers in square brackets following a reference indicates: 1. the journal's 2016-17 impact factor according to ISI Web of Knowledge, then the number of literature citations for the paper found by Google Scholar, as of 23 May 2018]

H-index = 32, total number of citations = 3831 as of 24 May 2018

Table of Contents

1. Introduction

1.1 Purpose of the expert report

I was engaged by the Department of Planning and Envionment in September 2018, to produce an expert report on the distribution and abundance of *Grevillea juniperina* subsp. *juniperina* (Proteaceae) within the proposed Western Sydney Aerotropolis Growth Area, and Greater Penrith to Eastern Creek Urban Release Investigation Area (collectively termed "the study area"). This immediately followed my submission of a similar report on the same species for the Greater Macarthur and Wilton Growth Areas (Weston unpublished) The aim of this exercise was to assess whether *G. juniperina* subsp. *juniperina* is native to either of the Growth Areas and, if so, to assess where suitable habitat is located and to estimate the area occupied by *G. juniperina* subsp. *juniperina* in the study area and within the development footprint.

According to Section 6.5.2 of the Biodiversity Assessment Method, an expert report must:
- identify the relevant species or population
- justify the use of an expert report
- indicate and justify the likelihood of presence of the species or population
- estimate the number of individuals or area of habitat (whichever unit of measurement applies to the species/individual) for the biodiversity certification assessment area, including a description of how the estimate was made
- demonstrate what information was considered, rejected and discounted in relation to the determination made in the expert report, and
- identify the expert and provide evidence of their expert credentials.

1.2 Project context

The Department of Planning and Environment is leading a strategic biocertification of several identified growth areas within Western Sydney, including the two growth areas that define the geographic scope of this report: the Western Sydney Aerotropolis Growth Area and the Greater Penrith to Eastern Creek Urban Release Investigation Area. The strategic biodiversity assessment is an integral part of the Cumberland Plain Conservation Plan that will determine the impact of urban development on threatened species and ecological communities within these growth areas. The Plan will also provide conservation measures to mitigate any impact, as specified by NSW and Commonwealth environmental legislation.

1.3 Study area

The study area is located in the western to south western part of the Sydney Metropolitan Area, between latitudes 33.712°S and 33.941°S and longitudes 150.654°E and 150.857°E (figure 1).

1.4 Reasons for use of expert report

Grevillea juniperina subsp. *juniperina* is represented by numerous collections and observations within the Greater Penrith to Eastern Creek Urban Release Investigation Area, and from at least one observation in the Western Sydney Aerotropolis Growth Area. *G. juniperina* subsp. *juniperina* is a perennial shrub that is readily recognised at any time of year by its distinctive vegetative morphology. Conventional surveying would therefore be the most appropriate way to test for its presence, if unlimited access to the study area were allowed. Although sizeable blocks of the

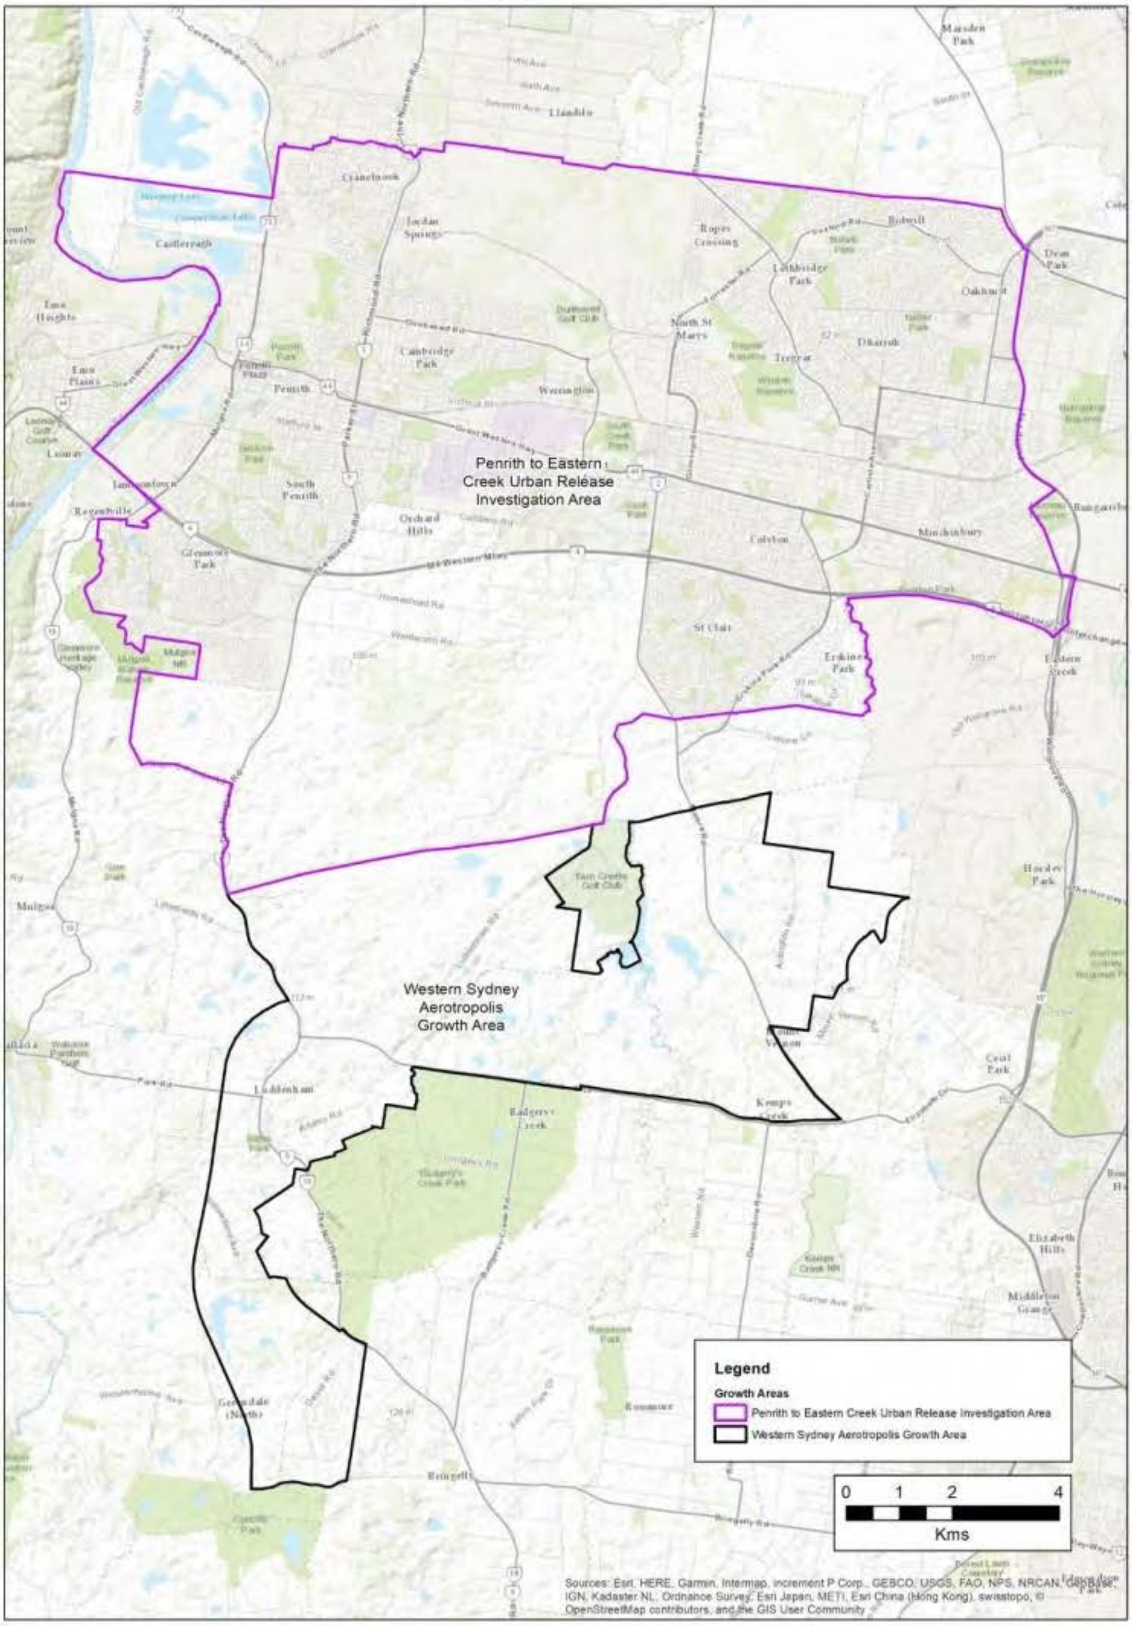

Figure 1. The Greater Penrith to Eastern Creek Urban Release Investigation Area (outlined in purple) and the Western Sydney Aerotropolis Growth Area (outlined in black). © OpenStreetMap contributors.

remnant bushland are found in public reserves, most of the native vegetation occurs on private land or land managed by the Australian Department of Defence. Only 13.5% of landowners granted permission for surveys to be conducted on their land and the Australian Department of Defence was not one of them. An alternative approach involves the construction of a general habitat model for *Grevillea juniperina* subsp. *juniperina*, which can then be used to identify suitable habitat on all land tenures across the two Growth Areas. The limitations of land access necessitated the latter approach. The need for expert knowledge of the ecology of *Grevillea juniperina* subsp. *juniperina* in creating a habitat model triggered the need for an expert report.

1.5 Credentials of expert

I prepared this report as an independent botanical consultant but I am also currently an Honorary Research Associate at the at the New South Wales state herbarium (the National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust). In 2016, I retired from my role as a Senior Principal Research Scientist at the state herbarium, having worked there since 1982 as a Systematic Botanist and as curator of the herbarium's collections of specimens of Proteaceae (including *Grevillea juniperina*) (see my *Curriculum Vitae*, attached). I now work, part-time at the National Herbarium of New South Wales as an Honorary Research Associate.

I have published, either as sole author or as a co-author, 50 papers on the systematics and ecology of the Proteaceae in the peer-reviewed scientific literature, including the most comprehensive phylogenetic analysis of the genus *Grevillea* yet published (Mast *et* al. 2015). As curator of Proteaceae at the state herbarium, I have examined all specimens of *G. juniperina* subsp. *juniperina* in the collection. I was invited to contribute to floristic treatments of the Proteaceae for *Flora of New South Wales*, *Flora of Australia*, *Flora of the Perth Region*, *Flora of China*, *Flora of North America*, and to write the treatments of Proteaceae for *Families and Genera of Vascular Plants* and *Flowering Plant Families of the World* (see my *Curriculum Vitae*, attached). I was also asked to conduct a peer review of the essay on the ecology of the Proteaceae that accompanied the "Ecology of Sydney Plants" (Myerscough *et al.* 2000). Throughout my career I have participated in numerous collecting trips in the field, collecting specimens in all Australian states for the state herbarium. In documenting these specimens I had to describe the habitat at each collecting site, including associated plant species, substrate, aspect, degree and kind of disturbance. On some of those trips, I observed and collected *Grevillea juniperina* growing in the wild.

In June 2018 I was appointed to prepare an expert report on *Grevillea juniperina* subsp. *juniperina* in the Greater Macarthur and Wilton Growth Areas (Weston unpublished), during the preparation of which I characterised in detail the associated plant species and other ecological attributes of five plots, each of 30 metre radius at which I found *G. juniperina subsp. juniperina*. I am personally familiar with this taxon and the habitats in which it lives.

In November 2018 I was approved by the Office of Environment and Heritage as a species expert for *Grevillea juniperina* subsp. *juniperina* under section 6.5.2 of the Biodiversity Assessment Method. This approval is current for a period of six years.

1.6 Species surveys

Letters were sent by the Department of Planning and Environment to all landholders within the development footprint to request access. A total of 432 letters were sent to landholders across the Western Sydney Aerotropolis Growth Area between November 2017 and August 2018 with 84 landholders responding positively to provide access. A further seven properties were accessed after doorknocking, resulting in a response rate of 21%.

A small number of targeted letters were sent to landholders in the Greater Penrith to Eastern Creek Urban Release Investigation Area from November 2017. However, most letters (more than 1500) were sent in August 2018, which included many urban and small acreage landholders. From this, 177 landholders provided access to their properties and an additional three landholders provided permission via doorknocking (12% response rate). Not all of these properties were surveyed as some did not support vegetation patches of interest. In addition, the Open Spaces Team at Penrith Council facilitated access to 64 lots owned by Council. Surveys were undertaken on all areas of land where landowners granted access. Access to the Defence Establishment Orchard Hills, which includes large patches of native vegetation, was not provided.

A targeted survey for threatened species was conducted on lands where access was granted. Vegetation transects and random meanders for threatened flora were conducted by the Ecoplanning Pty Ltd and Biosis Pty Ltd in accessible areas proposed for certification, with particular attention to areas of likely habitat. The survey included effort through each plant community type and vegetation zone, and extended into suitable habitat adjacent to the edge of the future urban area where potential indirect impacts to high quality habitat may occur (up to ~50m). Likely habitat for most flora species comprised areas of lower disturbance. This included areas with a predominantly native understorey (with or without a canopy), the base of scattered trees in paddocks, paddocks with an apparent low grazing pressure, and known topographic/habitat preferences for certain flora. One incidental observation of *Grevillea juniperina* subsp. *juniperina* was made in the study area during this survey, at North St Marys.

The percentages of remnant native vegetation in the growth areas that were sampled in the threatened species survey were 1.0% in Greater Penrith to Eastern Creek and 7.1% in the Western Sydney Aerotropolis. The percentages of sampled remnant native vegetation that were covered by the urban development footprint were 7.9% in Greater Penrith to Eastern Creek and 18.4% in the Western Sydney Aerotropolis. These data include a 20 m buffer from survey tracks.

2. Species information

2.1 Species description

The following morphological description was produced by merging information from Makinson's (2000) descriptions of the Linearifolia Group, the Speciosa Subgroup, *Grevillea juniperina*, and *G. juniperina subsp. juniperina*:

More or less erect to spreading dense divaricate shrub 0.5–1.5 m tall, to 3 m across; major branches appearing subcolumnar (leaves clustered on short lateral branchlets); foliage dense (see figure 2). Branchlets terete, tomentose to villous. Leaves spreading to ascending, often crowded on short lateral branchlets, usually rigid, often dark green with paler veins, entire, narrowly ovate to subulate or linear, angularly deltoid to trigonous in cross-section, 10–22 mm long, 0.6–0.8 mm wide, pungent, needle-like, with dissimilar upper and lower surfaces; upper surface usually with 3–5 longitudinal veins, the midvein and intramarginal veins usually very prominent, sparsely covered with appressed hairs; margins strongly and angularly revolute; lower surface usually fully enclosed, usually densely sericeous or occasionally openly so, rarely glabrous, or open-tomentose; juvenile leaves scarcely broader than adults. Inflorescence terminal, occasionally also axillary and subterminal, usually simple or occasionally 2 (–4)-branched; unit conflorescence erect or slightly decurved, acropetal, subsecund; floral rachis 1–17 mm long (see figure 3). Flowers zygomorphic; torus slightly oblique. with perianth style similar to perianth or a little paler (see figure 3). Perianth densely to openly subsericeous outside with biramous hairs only, bearded inside between 2.5 and 9 mm above base, red, yellow, pale orange, or rarely greenish; tepals remaining coherent over at least the basal third, independently recoiled above (usually the ventral pair more strongly so). Pistil (13–) 20–25 mm long; style glabrous except for minute scattered erect simple hairs extending from back of style-end down at least 3 mm and sometimes almost to ovary, similar colour to perianth or a little paler; pollen-presenter usually oblique or occasionally lateral. Follicles narrowly ovoid or oblong-ellipsoidal, 10–18 mm long, colliculose to smooth, not ridged. Seeds ellipsoidal; margins revolute, a waxy strip on one side extending into a short apical elaiosome.

2.2 Life cycle

Grevillea juniperina subsp. *juniperina* is a perennial, woody plant that germinates from an ellipsoidal seed (Makinson 2000). Germination is significantly enhanced by fire: in a germination experiment, a treatment of smoke plus heat raised the germination percentage from 5-13% observed in the control treatment to 60% (Morris 2000). Seedlings are readily identifiable because their leaves differ minimally from adult leaves and the characteristic growth pattern with abundant lateral short shoots starts when seedlings are less than 10 cm tall. The duration of the juvenile growth phase and the longevity of plants are unknown (Benson & McDougall 2000). Plants are known to be killed by fire (Olde & Marriott 1995, Makinson 2000) and are not known to spread vegetatively (Benson & McDougall 2000), so this taxon can be classed as an obligate seeder. Flowering occurs mainly from August to September, with sporadic flowers appearing in other months (Makinson 2000).The flowers of all subspecies of *Grevillea juniperina* are visited by nectar-feeding birds (Olde & Marriott 1995), which are presumed to be their pollinators (Benson & McDougall 2000). Fertilized carpels develop into follicular fruits that open at maturity, releasing one or two flat seeds, each of which bears a wing-like terminal elaiosome. The seeds are dispersed by wind and also possibly by ants, which may collect the seeds for their edible elaiosomes. A buried soil seed bank accumulates at a site after plants reach reproductive maturity.

2.3 Distribution and abundance

Grevillea juniperina subsp. *juniperina* occurs naturally on the northern part of the Cumberland Subregion of the Sydney Basin IBRA Bioregion, in Sydney's Western Suburbs, in an area bounded by Pitt Town, Agnes Banks, Castlereagh, Mulgoa, Kemps Creek, and Blacktown (OEH Wildlife Atlas, accessed 2/7/2018, Atlas of Living Australia, accessed 3/7/2018). Within this polygon, it is sporadically distributed but often locally abundant in both intact native vegetation (figure 4) and in highly disturbed habitats such as pastures (figure 5), road cuttings, and abandoned railway platforms (figure 6). Collectors' and observers' notes on local abundance usually note multiple plants at recording sites and vary in their estimates of plant numbers from solitary individuals to populations of over 1,000. At some sites its population density is high. For example, between my sites PEC1 and PEC2, in Wianamatta Regional Park, I conducted a survey of reproductively mature plants of *G. juniperina subsp. juniperina* along two transects that were 1 m wide and a total of 1,285 m long (Appendix 1), in which I recorded 246 plants, a density of 1,914 mature plants per hectare.

A herbarium specimen collected from Gundungarra Reserve, Spring Farm, 11 km south south west of the study area (NSW999291), is a geographic outlier. In my earlier expert report on *Grevillea juniperina* subsp. *juniperina* in the Greater Macarthur and Wilton Growth Areas (Weston unpublished a), I argued that this population is unlikely to represent a natural occurrence of *G. juniperina subsp. juniperina*. Herbarium records that were classed as naturalised occurrences by their collectors, and by R.O. Makinson in curatorial notes, include one from the Melbourne suburb of

Figure 2. A large plant of *Grevillea juniperina* subsp. *juniperina* growing on the road verge in front of 327 Luddenham Road, Orchard Hills.

Figure 3. A branchlet of *Grevillea juniperina* subsp. *juniperina* showing lateral short shoots, bearing crowded, needle-like leaves and an inflorescence of greenish-yellow flowers terminating a short shoot.

Heathmont (NSW 834413) and another from Penrose, 94 km south west of the study area (NSW971120).

2.4 Habitat requirements

Makinson (2000: 210) notes that *Grevillea juniperina* subsp. *juniperina* "grows in open dry sclerophyll (eucalypt-dominated) forest or woodland at altitudes of less than about 50 m, in sandy to clay-loam soils and red pseudolateritic gravels." Makinson (2000: 211) also notes that "this subspecies shows some ability to colonise mechanically disturbed areas where open ground surface persists; repeated disturbance appears to eliminate it. Populations are often restricted to infrequently managed road verges or ungrazed semi-cleared land." At two such disturbed sites where I observed it to be growing (sites GJ2, GJ5, Appendix 1), *Grevillea juniperina* subsp. *juniperina* had vigorously colonised the habitat, with plants representing all life cycle stages from seedlings less than 7 cm tall (e.g. , figure 5) to large, reproductively mature shrubs.

The threatened species profile of *Grevillea juniperina* subsp. *juniperina*, published online by OEH (2018) describes its habitat as follows:

- Grows on reddish clay to sandy soils derived from Wianamatta Shale and Tertiary alluvium (often with shale influence), typically containing lateritic gravels.
- Recorded from Cumberland Plain Woodland, Castlereagh Ironbark Woodland, Castlereagh Scribbly Gum Woodland and Shale/Gravel Transition Forest.

Figure 4. A population of *Grevillea juniperina* subsp. *juniperina* growing in intact PCT 849 on Bringelly Shale at Plumpton Park, Plumpton.

Figure 5. A population of *Grevillea juniperina* subsp. *juniperina* that has established in cleared pasture on St Marys Formation alluvium at Marsden Park.

Figure 6. A population of *Grevillea juniperina* subsp. *juniperina* that has established on the platform of the abandoned Dunheved Railway Station, North St Marys.

- Associated canopy species within Cumberland Plain Woodland and Shale/Gravel Transition Forest include *Eucalyptus tereticornis*, *E. moluccana*, *E. crebra*, *E. fibrosa* and *E. eugenioides*. Understorey species include *Bursaria spinosa*, *Dillwynia sieberi*, *Ozothamnus diosmifolius*, *Daviesia ulicifolia*, *Acacia falcata*, *Acacia parramattensis*, *Themeda australis*, *Aristida ramosa*, *Cymbopogon refractus*, *Eragrostis brownii*, *Cheilanthes sieberi*, *Dianella revoluta* and *Goodenia hederacea*.
- In Castlereagh Woodland on more sandy soils the dominant canopy species are *Eucalyptus fibrosa*, *E. sclerophylla*, *Angophora bakeri* and *Melaleuca decora*. Understorey species include *Melaleuca nodosa*, *Hakea sericea*, *Cryptandra spinescens*, *Acacia elongata*, *Gonocarpus teucrioides*, *Lomandra longifolia* and the threatened species *Dillwynia tenuifolia*, *Pultenaea parviflora*, *Micromyrtus minutiflora* and *Allocasuarina glareicola*.

The OEH Threatened Species Data Collection indicates that *Grevillea juniperina* subsp. *juniperina* has the potential to occur in the following plant community types within the Greater Penrith to Eastern Creek Urban Release Investigation Area and Western Sydney Aerotropolis Growth Area:

- 724 Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion;
- 725 Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion;
- 806 Derived grasslands on shale hills of the Cumberland Plain (50-300m asl);
- 807 Derived grasslands on shale plains of the Cumberland Plain (<100m asl);
- 808 Derived shrubland on Tertiary Gravels of the Cumberland Plain;
- 849 Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion;
- 850 Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion;
- 883 Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion.

3. Description of the study area

3.1 Land use history

This section is based primarily on information from penrithhistory.com, a website maintained by Penrith Library (Penrith Library 2018), except where other sources are explicitly cited. The first human inhabitants of the study area were Aborigines who moved there many thousands of years ago. People of the Darug language group were occupants of the study area when the British first started to settle in the Sydney Region in 1788 (Logan 2011). These hunter-gatherers would have managed the grassy woodlands that grew on Bringelly Shale and Cenozoic alluvia of the area using fire-stick farming methods (Benson & Howell 1990). They used the natural landscape seasonally, taking advantage of different food sources depending on availability, establishing temporary open camps of simple gunyahs on higher ground near water courses. The Nepean River and its tributaries were significant sources of fish, shellfish and useful plants while the wooded plains and gentle hills were sources of game, edible tubers, seeds, fruits and materials for making clothing, tools and shelters (Logan 2011).

In 1789, 18 months after the founding of Sydney, Captain Watkin Tench led a group from Rose Hill to the Nepean River, followed soon by further expeditions from there to Razorback in the south and downstream to the Hawkesbury River in the north (Fitzhardinge 1967). The alluvial flats of the Nepean River and adjacent grassy woodlands on Wianamatta Shales, offered more fertile farming land than sandy soils derived from Hawkesbury Sandstone surrounding the Cumberland Subregion. However, violent clashes between the British and the Darug people led by Pemulwuy delayed settlement west of Prospect until 1802, when Governor King built a headquarters for his government stock reserve at what is now Rooty Hill (NSW Office of Environment and Heritage 2018). King went on to issue land grants at what are now Penrith and Cranebrook in 1804, and Orchard Hills, St Marys and Badgerys Creek in 1806. Further land grants were made in what are now Mulgoa and Greendale in 1810, and Luddenham in 1813. In 1815 the Great Western Road was completed between Parramatta and Bathurst, placing the northern part of the study area on what soon became a major transport artery. Completion of the western railway line from Sydney to Penrith in 1867 and its extension to Bathurst in 1876 significantly enhanced accessibility of the northern part of the study area. From first settlement in the early 19th century to the 1950s, land use in both growth areas was dominated by timber production, agriculture and quarrying, all of which necessitated extensive clearing of native vegetation, especially from the more fertile alluvial and clayey soils. Agricultural activities conducted in the areas have included the cultivation of wheat (which was curtailed in 1861 when the whole crop was destroyed by an infestation of rust disease) and other cereal crops, grazing of sheep, cattle and horses, intensive production of pigs and poultry, and the cultivation of fruit, vegetables, turf and cut-flowers (Wilkinson 2011). Industrial facilities that processed saw logs and agricultural produce, such as timber mills, flour mills, milk processing plants, cattle sale yards, tanneries, canneries and wineries began to be built early in the 19th century and mostly continued operating well into the 20th century. A few manufacturing plants, producing textiles, munitions and bricks were also developed in the 19th and early 20th centuries.

Penrith grew slowly as an urban centre during the 19th century and first half of the 20th century, but population growth accelerated after 1960 due to the establishment of several social housing projects by the N.S.W. Housing Commission. This was followed from the 1970s by the gradual rezoning of much of the agricultural land in the northern part of the Greater Penrith to Eastern Creek Urban Release Investigation Area is for urban development. Land use in this growth area is now dominated by residential housing, retail precincts, light industry and transport infrastructure, but Orchard Hills in the south is still largely rural. Most protected patches of remnant native vegetation are less than 20 Ha in area but the two largest reserves containing intact bushland, Wianamatta Regional Park in the north and The Defence Establishment Orchard Hills in the south, cover approximately 900 Ha and 1370 Ha respectively.

The Western Sydney Aerotropolis Growth Area is still largely rural but includes a staggeringly small area of remnant bushland in public reserves. The largest patch consists of about 3.5 hectares of weed-infested Grey Box – Forest Red Gum grassy woodland in Sales Park, Luddenham.

3.2 Landscape context

The Sydney Basin is a geological entity composed of sedimentary rocks that is shaped a bit like a tilted, triangular, art deco saucer. In the middle of this structure is the Cumberland Subregion, in the northern half of which is located the study area. Here, the uppermost strata of the Sydney Basin, Cenozoic alluvia, patchily overlie the Triassic Wianamatta Group, comprising Bringelly Shale, Minchinbury Sandstone and Ashfield Shale, which, in turn overlie Triassic Hawkesbury Sandstone, the Triassic Narrabeen Group and the Permian Shoalhaven Group (Martyn 2018). Scattered small Jurassic basalt diatremes occasionally pierce the sedimentary strata, such as at Lethbridge Park and Bidwill.

The most commonly exposed substrate in the study area is Bringelly Shale. Over this, the second most commonly exposed substrate, heavy, alluvial Quaternary clay, which has been eroded from Bringelly Shale, has accumulated in a branching pattern across the study area on the floodplains of

South Creek and its tributaries, including Kemps, Badgerys, Cosgrove, Blaxland, Claremont, Werrington and Ropes Creeks (NSW Department of Minerals and Energy 1991).

Other substrates are also exposed over a much smaller area on the northern and western margins of the Greater Penrith to Eastern Creek Urban Release Investigation Area. Two patches of Londonderry Clay, a Paleogene-Neogene alluvium, covering an area of about six square kilometres, have been preserved on the northern edge between St Marys and Shanes Park. On the western margin, between Mulgoa and the north-western corner, gravelly, sandy, silty and clayey Quaternary alluvia of the Cranebrook formation line the eastern bank of the Nepean River and its eastern tributaries, forming an extensive deposit up to four kilometres wide north of Regentville. On the western margin, several square kilometres of Ashfield Shale and a smaller area of Rickabys Creek Gravel, a Paleogene-Neogene alluvium, are exposed from Jamisontown to Glenmore Park.

The whole study area is gently tilted from south to north and all watercourses flow in that general direction. Topography varies subtly in the Greater Penrith to Eastern Creek Urban Release Investigation Area with low, rounded ridges alternating with flat-bottomed flood plains. The lowest point is in the north west corner at Upper Castlereagh, where the bank of the Nepean River is below 10 m altitude, and along the northern margin the altitude is less than 70 metres. The highest point in the Greater Penrith to Eastern Creek Urban Release Investigation Area is 93 metres in altitude at Sovereign, in the south west corner. Along the boundary between the two growth areas, altitude varies from 40 metres in the east to 90 metres in the west.

Topographic relief is still quite gentle, but more noticeable, with steeper slopes, in the Western Sydney Aerotropolis Growth Area. The altitude varies from 40 metres in the north eastern corner to 106 metres just south east of Luddenham village.

Topographic variation, as well as distance from the sea influence climate. The Cumberland Subregion is the driest part of the Sydney Region and also experiences the most extreme temperatures in the region. Key climate statistics for the three weather stations in the study area, for which data are freely available, are shown in table 1. The whole study area is subject to winter frosts.

Weather station	Mean annual rainfall (mm)	Mean maximum temperature (°C)	Mean minimum temperature (°C)
Penrith Lakes AWS (1995-)	718.6	31.0	5.3
Orchard Hills Treatment Works (1970-)	832.7	28.5	5.3
Badgerys Creek McMasters F (1995-)	794.3	28.6	3.8

Table 1. Key climatic statistics for weather stations in the growth areas.

3.3 Native vegetation communities

In terms of the plant community types recognised in the Bionet Vegetation Classification and the vegetation maps that were prepared for this project, the remnant native vegetation of the growth areas consists of:

- 724 Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain (191.3 ha);
- 725 Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain (167.4 ha);
- 781 Freshwater wetland (68.9 ha);
- 830 Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion (2.8 ha);

- 835 Forest Red Gum – Rough Barked Apple grassy woodland on alluvial flats of the Cumberland Plain (989.2 ha);
- 849 Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain (2334.1 ha);
- 850 Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain (88.5 ha);
- 883 Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain (6.5 ha);
- 1105 River Oak open forest of major streams, Sydney Basin Bioregion and South East Corner Bioregion (94.2 ha);
- 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain (2.0 ha).
- 1800 Swamp Oak open forest on river flats of the Cumberland Plain and Hunter valley (228.5 ha).

In the study area, according to the vegetation mapping that was conducted for this project, the following substrates support the following plant community types:

- Quaternary alluvium, including Cranebrook Formation: PCTs 781, 835, 849, 850, 1105, 1800;
- Londonderry Clay: PCTs 724, 725, 835, 849;
- Bringelly Shale: PCTs 724, 725, 835, 849, 883;
- Ashfield Shale: PCTs 830, 835, 849, 1395.
- Rickabys Creek Gravel: 849.

PCT 849 is the most abundant plant community type throughout both growth areas, growing on most of the uncleared land above the zone of floodwater inundation, most commonly on Bringelly Shale. Over 50% of the two largest patches of remnant bushland, Wianamatta Regional Park and the Defence Establishment Orchard Hills is covered in PCT 849 and it covers most of the smaller reserves too. PCT 835 covers the second largest area and also occurs throughout the study area, vegetating the uncleared flood plains of South Creek and its tributaries on Quaternary alluvium, as well as the lowest part of the adjacent slopes. The banks of those creeks as well as some other blocks of low-lying land on Quaternary alluvium, are dominated by PCT 1800. PCTs 724 and 725 are dominant on Londonderry Clay in the northern part of the study area but also occur patchily elsewhere on Bringelly Shale, most notably in the Kemps Creek area and on a rectangular block of regenerating vegetation 0.6-0.8 km west of Luddenham Road, 0.2-0.6 km north of the Warragamba-Prospect water pipeline. PCT 1105 dominates remnant vegetation on the banks of the Nepean River north of Penrith, on Cranebrook Formation alluvium. The remaining plant community types occur only rarely as tiny fragments in the study area. About 6.5 ha of PCT 883 occurs in two patches at the eastern end of Wianamatta Regional Park and about 15 ha remains in a block 0.6 km north of Elizabeth Drive, Kemps Creek. PCT 1395 is represented by a sliver of two hectares on Ashfield Shale at Glenmore Park. PCT 830 is restricted to a fringe of under three hectares in area on the eastern the border of Mulgoa Nature Reserve.

Weed infestation is a problem throughout the study area. This is well illustrated by two sites at Claremont Meadows. The vegetation at a site beyond the eastern end of Caddens Road, on the flood plain of South Creek, which I visited but did not include in my sampling, consisted of a closed forest of *Ligustrum sinense*, *Ligustrum lucidum* (both natives of China, the latter extending to Japan) and *Olea europaea* subsp. *cuspidata* (native of Africa), with scattered emergent trees of *Eucalyptus tereticornis* and *E. amplifoli*a. This would have been a forest of PCT 835 before weed infestation converted it into a novel, derived plant community. Only 0.6 km to the west north west of that site is a superficially pristine block of PCT 724. Even here, however, *Ligustrum sinense* and *Ligustrum lucidum* already dominate the vegetation near South Creek, *Eragrostis curvifolia* is a common component of the ground stratum and seedlings of *Olea europaea* subsp. *cuspidata* are starting to establish throughout the reserve.

4. Assessment of species presence and habitat

4.1 Existing records and surveys

A search of *Grevillea juniperina* subsp. *juniperina* in the Bionet Atlas, conducted on 12 November 2018, returned 1513 observational records. The only targeted survey of this species of which I am aware was conducted by Teresa James in Plumpton Park in October 2007 (Teresa James personal communication). However, patterns in the dates and locations of Bionet records suggest that several intensive surveys of *G. juniperina subsp. juniperina* have been conducted in the 21st century, apparently as part of more general environmental surveys. Most of those were conducted outside the study area but the following are relevant to this report:

- 12 October 2007: 5 records reporting over 700 plants from what is now Wianamatta Regional Park;
- 8-11 September 2008: 4 records reporting approximately 1250 plants from the Defence Establishment Orchard Hills;
- 25 September to 2 November 2009: 118 records from the St Marys Sewage Treatment Plant;
- 6 March to 14 December 2015: 82 records from the Dunheved development site, for the St Marys Central Precinct Project;
- 16 February 2016: 1 record reporting >1000 plants West of Luddenham Rd, north of the Warragamba-Prospect water pipelines;
- 18 October 2016: 22 records reporting 115 plants from Wianamatta Regional Park.

4.2 Surveys completed for the biocertification

Apart from the surveys conducted for this expert report, no targeted surveys for *Grevillea juniperina* subsp. *juniperina* were conducted for biocertification of the Greater Penrith to Eastern Creek Urban Release Investigation Area and Western Sydney Aerotropolis Growth Area. Several opportunistic observations were made by other consultants in the course of conducting more general surveys and expert reports on other species.

4.3 Surveys completed for this assessment

4.3.1 Survey Methods

In the course of preparing my expert reports on *Grevillea juniperina* subsp. *juniperina* and *Pterostylis saxicola* in the Greater Macarthur and Wilton Growth Areas (Weston unpublished a, b), I characterised twenty plots of native vegetation in detail, each plot being a circle of radius 30 m (an of area 2827 m^2), centred either on a plant of *G. juniperina subsp. juniperina* or *Pterostylis saxicola* or on an arbitrarily chosen point (at sites where both the *Grevillea* and the *Pterostylis* were absent). I have included data from nine of those plots as samples from outside the study area in my analyses for this report. I have also used the same methods to characterise 33 plots in and adjacent to the study area. I chose the locations with the aim of sampling patches of accessible, remnant bushland representing as broad an ecological range and geographic extent across the two Growth Areas as time would allow, sampling more plots in areas where *G. juniperina subsp. juniperina* had previously been recorded. Some habitats, such as freshwater wetlands, and substrates on which *G. juniperina subsp. juniperina* has never been recorded, such as Cranebrook Formation alluvia, were avoided. At each plot I listed all vascular plant species that could feasibly be identified, taking photographs of plants for later reference in cases where the plant's identity was in question. The latitude and longitude of the centre of each plot was determined using a GPS instrument. The altitude of each site was determined later from 1:25,000 topographic maps. The soil and topography at each site was described and the substrate identified using the Penrith 1:100,000 geological map (NSW Department of Minerals and Energy 1991) and 1:25,000 topographic maps.

I identified the plant community type in each plot using the PCT identification tool in Bionet, and my list of plant species found in each plot.

I conducted statistical analyses of association between presence or absence of *Grevillea juniperina* subsp. *juniperina* in my plots and several other binary variables using the Phi statistic and Fisher's exact test at http://vassarstats.net/tab2x2.html. The other binary variables were plant community types, and substrate Quaternary alluvium present or absent. As multiple tests were conducted, I applied a Bonferroni correction to the significance level s of the tests.

I conducted a census of reproductively mature plants of *Grevillea juniperina* subsp. *juniperina* along a pair of transects, each 1 m wide, oriented in a north-south direction in the eastern part of Wianamatta Regional Park, where multiple plants of the species had previously been recorded, to estimate population density there.

I kept an eye out for plants of *Grevillea juniperina* subsp. *juniperina* as I drove or walked from site to site within the study area. I also conducted a "drive by" survey of inaccessible properties in the southern part of the Western Sydney Aerotropolis, looking over boundary fences of private properties with remnant native vegetation on Willowdene Avenue, Luddenham, and Dwyer and Findley Roads and Francis Street, Greendale.

I developed an improved habitat model for *Grevillea juniperina* subsp. *juniperina*, using data from my own botanical surveys of 38 plots, the published literature, 1513 observers' and collectors' records of *G. juniperina subsp. juniperina* in the Bionet Atlas, vegetation mapping conducted for the Cumberland Plain Conservation Plan (Biosis unpublished), and the geological map of the area (NSW Department of Minerals and Energy 1991).

4.3.2 Results and Conclusions from my Surveys Completed for this Assessment

Site and ecological data for my plots are shown in Appendix 2. I sampled most plant community types and most substrates known in the study area in these plots. According to my identifications of plant community types, I found *Grevillea juniperina* subsp. *juniperina* in the following PCTs in my plots:

- 849 Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain (found in 17 plots, 10 of which also hosted *G. juniperina subsp. juniperina*);
- 725 Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain (found in 11 plots sampled, 9 of which also hosted *G. juniperina subsp. juniperina*);
- 883 Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain (found in 2 plots, one of which also hosted *G. juniperina subsp. juniperina*);
- 724 Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain (found in 1 plot, which also hosted *G. juniperina subsp. juniperina*).

Plant community types that I sampled, in which *G. juniperina subsp. juniperina* was absent, were the following.

- 850 Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain (3 plots);
- 1800 Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley (3 plots);
- 1081 Red Bloodwood - grey gum woodland on the edges of the Cumberland Plain (1 plot).

Substrates present in my plots were Londonderry Clay (11 plots, all with *Grevillea juniperina* subsp. *juniperina* present), Bringelly Shale (14 plots, 7 with *G. juniperina subsp. juniperina* present), Londonderry Clay-Bringelly Shale transition (1 plot, with *G. juniperina subsp. juniperina* present), St Marys Formation-Bringelly Shale transition (1 plot, with *G. juniperina subsp. juniperina* present), Quaternary Alluvium (8 plots, *G. juniperina subsp. juniperina* absent from all), Bringelly Shale-Quaternary Alluvium transition (1 plot, *G. juniperina subsp. juniperina* present).

The most striking positive association between habitat variables and presence of *Grevillea juniperina* subsp. *juniperina* was with Londonderry Clay, with all 11 plots on this substrate also hosting the grevillea, a relationship so strong that it did not need statistical testing. In contrast, none of the eight plots on Quaternary Alluvium hosted *G. juniperina subsp. juniperina*. This negative association proved to be statistically significant with a probability due to chance of 0.0013 in the 2-tailed test (significance level adjusted to 0.01 to account for multiple tests). Of the four plant community types in which *G. juniperina subsp. juniperina* was found, none turned out to be significantly associated with presence or absence of the grevillea. It seems reasonable to conclude that substrate type is a more powerful predictor of the presence or absence of *G. juniperina subsp. juniperina* than plant community type.

Comparison of observational records of *Grevillea juniperina* subsp. *juniperina* in the Bionet Atlas with the geological map shows that the association between substrates and plant records can be expressed with greater precision than has been done in the published literature. The substrates on which *G. juniperina subsp. juniperina* most frequently occurs are Londonderry Clay (a Paleogene-Neogene alluvium) and Bringelly Shale (a member of the Triassic Wianamatta Group). Most of the area of exposed Londonderry Clay occurs outside the study area but the density of observational records on this Paleogene-Neogene alluvium, both inside and outside the study area, confirms my conclusion from my plot data that this is a highly favoured substrate of *G. juniperina subsp. juniperina*. The favoured substrate that covers by far the largest area in the study area is Bringelly Shale. *G. juniperina subsp. juniperina* has also been recorded on laterised sand and clay of the St Marys Formation and on Rickabys Creek Gravel (both Paleogene-Neogene alluvia) but these substrates are much less extensive in area than either Londonderry Clay or Bringelly Shale. Rickabys Creek Gravel is very rare in, and St Marys Formation absent, from the study area.

Careful comparison of observational records of *Grevillea juniperina* subsp. *juniperina* with the distribution of Quaternary alluvia, a group of substrates that are mostly associated with the flood plains of existing watercourses in the Cumberland Subregion, supports my earlier conclusion based on my plot data that *G. juniperina subsp. juniperina* rarely, if ever, grows on these substrates. Sporadic inundation of these soils and the higher fertility of many of them, relative to Bringelly Shale and Paleogene-Neogene alluvia, probably explain why *G. juniperina subsp. juniperina* is absent from Quaternary alluvia. *G. juniperina subsp. juniperina* is also conspicuously absent from Ashfield Shale, another member of the Wianamatta Group, small outcrops of which occur on the western margin of the Greater Penrith to Eastern Creek Urban Release Investigation Area. Ashfield Shale has a significantly higher phosphate content than Bringelly Shale (Martyn 2018), which possibly explains the absence of *G. juniperina subsp. juniperina* from soils derived from it. All Proteaceae are highly efficient accumulators of soil phosphate, and moderate levels of this nutrient are toxic to many of them (Lambers *et al.* 2015).

The northern, eastern and western limits of the natural distribution of *Grevillea juniperina* subsp. *juniperina* can be explained simply by the distributions of its favoured substrates. However, its southern limit is much less well defined and I cannot explain it with confidence. The most dense populations of *G. juniperina subsp. juniperina* are found on Paleogene-Neogene alluvia, north of 33° 45' S. South of this latitude, the taxon occurs more patchily, forming sizeable populations at some suitable sites such as Pennard Crescent Luddenham (my plot GJ10), but being absent from other apparently suitable bushland remnants on Bringelly Shale nearby, such as the patch between Cosgrove Creek and Halmstad Boulevard, Luddenham (my plot WSA2). South of 33° 51' S, all known populations are small (fewer than 10 plants), sporadically distributed, and absent from most apparently suitable habitats.

Remnants of plant community type 849 growing on Bringelly Shale are liberally scattered between 33° 53' S and 34° 05' S but only one of these patches of bush is known to support a population of *Grevillea juniperina* subsp. *juniperina*. This is at 34° 03' 38.8'' S 150° 44' 15.5'' E, at Gundungarra Reserve, Spring Farm (my plot GJ9), approximately 14 km south of the southern end of the Western Sydney Aerotropolis Growth Area, where a population of four mature plants of *G. juniperina subsp. juniperina* was discovered in 2017. I have argued elsewhere (Weston unpublished a) that the population at Gundungarra Reserve is probably naturalised, resulting from a garden escape. However, this and other putatively naturalised populations are potentially informative about the limits of the taxon's ecological tolerance, so they should not be dismissed as irrelevant. The Gundungarra Reserve population is at 130 m altitude, which is higher than anywhere in the study area. However, a putatively naturalised population of eight plants from near Penrose grows at 650 m altitude, so altitude seems unlikely to be a limiting factor in the study area. The Penrose population occurs on "residual deposits of unconsolidated clayey coarse- to fine-grained sands to weakly consolidated sandy clay layers" (Triggs & Campbell 2016), analogous to Londonderry Clay, on which *G. juniperina subsp. juniperina* grows within its natural distribution. Whether the gradual thinning of the metapopulation of *G. juniperina subsp. juniperina* from north to south is due to ecological factors or to historical processes is unknown. Nevertheless, the probability of finding this species clearly declines as one moves south of 33° 45' S.

A historical process that may partly explain the patchy distribution of *Grevillea juniperina* subsp. *juniperina* within its distributional range is the potential effect of frequent fires. As plants of *G. juniperina subsp. juniperina* are killed by fire and populations regenerate by germinating from a buried seed bank in response to fire (see section 2.2), this species can be exterminated locally by frequent fires exhausting the soil seed bank. This can happen when a succession of fires occurs with an interval between fires that is less than the average time between germination and reproductive maturity. However, while such a process could explain the contrast mentioned above, between my plots GJ10 and WSA2, it seems unlikely to have affected an area as extensive as the whole southern half of the taxon's distribution.

Another historical process that could have produced the observed distribution is range expansion. If *Grevillea juniperina* subsp. *juniperina* originated in the northern part of the Cumberland Subregion and is still expanding into unfilled niche space in the southern Cumberland Subregion, then we would expect its populations to be smaller and scarcer than those in the north. This hypothesis could be tested using population genetic techniques but such a study is beyond the scope of this project.

4.4 Assessment of species presence

4.4.1 Likelihood of species presence

Grevillea juniperina subsp. *juniperina* is known with confidence in both the Greater Penrith to Eastern Creek Urban Release Investigation Area and Western Sydney Aerotropolis Growth Area.

4.4.2 Justification for determining presence

The presence of *Grevillea juniperina* subsp. *juniperina* in the Greater Penrith to Eastern Creek Urban Release Investigation Area is uncontroversial, supported by hundreds of observational and collection records, as well as my observations at 16 of my survey plots there. Its presence in the Western Sydney Aerotropolis Growth Area appears to be marginal but at least one observational record from the western side of Luddenham Road, just south of the northern border of this Growth Area (0.2 km south of my plot PEC25), documents its presence there. The probability of it occurring naturally elsewhere not far inside the northern border of the Western Sydney Aerotropolis Growth Area (the Warragamba to Prospect water pipeline) is high, but most of that border was inaccessible to botanical surveys for this project. The probability of its presence south of Luddenham village seems low, given the evident thinning of its population density towards the south, but it is not zero. Small patches of apparently suitable habitat are scattered through this Growth Area, especially south of Luddenham, but almost all of them were inaccessible for surveying for this project.

4.5 Assessment of suitable habitat

4.5.1 Suitable habitat within the study area

Grevillea juniperina subsp. *juniperina* is known to occur naturally in four plant community types recognised in the Bionet Vegetation Classification. They are:

- 724 Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain;
- 725 Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain;
- 849 Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain;
- 883 Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain.

All of these plant community types have been recorded in the study area.

Grevillea juniperina subsp. *juniperina* also occurs on the margins of a fifth plant community type, 835 Forest Red Gum – Rough Barked Apple grassy woodland on alluvial flats of the Cumberland Plain. This community usually grows on Quaternary alluvium, a substrate on which *G. juniperina subsp. juniperina* does not grow. However, ecological gradients between PCT 835 and adjacent plant community types, particularly PCT 849, are not clear-cut and do not always correspond exactly to transitions between substrate types. PCT 835 growing on Bringelly Shale should be included in the habitat model for *G. juniperina subsp. juniperina* to avoid excluding populations on the margins of alluvial flats.

Most records of *Grevillea juniperina* subsp. *juniperina* report populations living in intact native vegetation but it is also capable of surviving in, and even invading highly disturbed landscapes (see section 2.4)

Grevillea juniperina subsp. *juniperina* is known to occur naturally on four substrate types recognised by the Geological Survey of New South Wales. They are:

- Triassic Bringelly Shale (Wianamatta Group);
- Paleogene-Neogene Londonderry Clay;
- Paleogene-Neogene St Marys Formation;
- Paleogene-Neogene Rickabys Creek Gravel.

The intersection of any of the above plant community types with any of the above substrates indicates suitable habitat for *Grevillea juniperina* subsp. *juniperina*.

4.5.2 Species polygons

My species polygons for *Grevillea juniperina* subsp. *juniperina* (figure 7) include all patches of PCTs 724, 725, 833, 835 and 849 growing on Londonderry Clay, Rickabys Creek Gravel or Bringelly Shale in the study area. They were prepared with the assistance of Darren James (DAJ Environmental), using the ArcMap software package, from vegetation maps of the study area produced by Biosis Pty Ltd. A shape file for these polygons is held by the Biodiversity and Sustainability Branch of the NSW Department of Planning and Environment. My arguments justifying these polygons have been set out in sections 2.3, 2.4, 4.1, 4.3, 4.4 and 4.5.1.

4.5.3 Estimate of area of habitat

The areas estimated to represent suitable habitat for *Grevillea juniperina* subsp. *juniperina* in figure 7 are as follows:

- Greater Penrith to Eastern Creek Area Urban Release Investigation Area
    - Habitat mapped – 1989.8 ha
    - Habitat impacted by development footprint – 93.4 ha
- Western Sydney Aerotropolis Growth Area
    - Habitat mapped – 683.5 ha
    - Habitat impacted by development footprint – 310.4 ha

These estimates were calculated with the assistance of Darren James (DAJ Environmental), using the ArcMap software package, from vegetation maps of the study area produced by Biosis Pty Ltd. My arguments justifying the polygons from which these estimates were calculated have been set out in sections 2.3, 2.4, 4.1, 4.3, 4.4 and 4.5.1.

5. Information used in this assessment

My assessment was based on information obtained from a diversity of sources:

- Databases of observational and vouchered specimen records of *Grevillea juniperina* subsp. *juniperina*:
    - National Herbarium of New South Wales specimen database;
    - Bionet Wildlfie Atlas;
- Interviews with collectors, observers, propagators and scientists of *Grevillea juniperina* subsp. *juniperina* (see section 6, acknowledgements);
- Fieldwork at 42 sites (see Appendix 1):
    - Five sites at which *P. saxicola* had previously been collected;
    - 14 sites in or near the study area that had potentially suitable habitat;
- The scientific and scholarly literature (see section 7, references);
- A GIS map of the study area with layers representing the boundaries, plant community types, development footprint, and the results of flora and fauna surveys, prepared by Biosis Pty Ltd, provided through the Biosis spatial viewer;
- Background information on the study area provided by the Biodiversity and Sustainability Branch of the NSW Department of Planning and Environment;

- My personal knowledge and experience, gained from 40 years as a professional botanist specialising in the systematics and ecology of the Proteaceae.

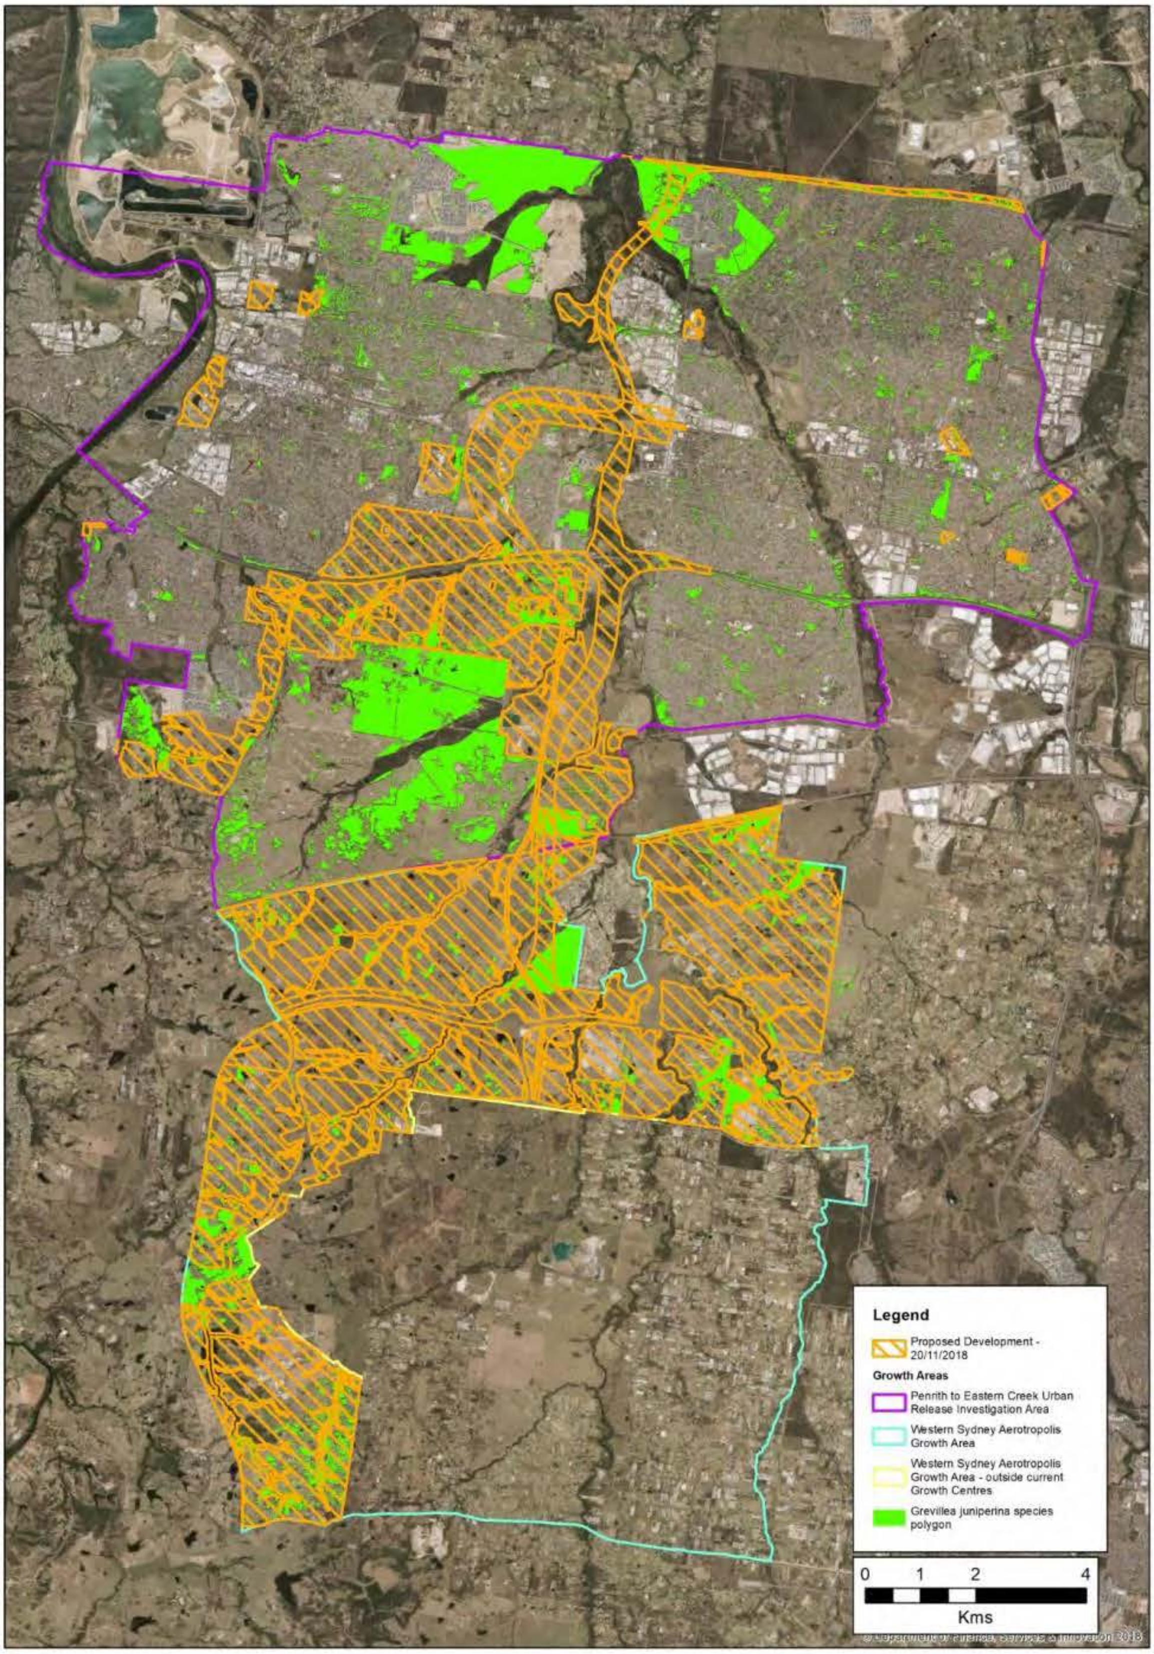

Figure 7. Polygons of suitable habitat for *Grevillea juniperina* subsp. *juniperina* across its whole distribution.

6. Acknowledgements

I am grateful to Teresa James, Bob Makinson, Peter Olde, Brian Towle and Greg Steenbeeke for happily being interviewed, and for generously sharing their knowledge about *Grevillea juniperina* subsp. *juniperina* with me. Darren James (DAJ Environmental) and Phillip Rofe (Biodiversity and Sustainability Branch, NSWDPE) kindly assisted me in producing species polygons and area estimates using the ArcMap software package. I am grateful to Laura Torrible, Dayle Green and Greg Steenbeeke for the provision of support and advice throughout this project.

8. Appendices

8.1 Appendix 1: Characterisation of habitat at selected sites

The tables on following pages record data that I collected at sites both within and outside the study area. Each site was centred on an arbitrarily selected plant of *Grevillea juniperina* subsp. *juniperina*, or at an arbitrarily chosen point where the focal taxon was absent from the site. At each site the precise latitude and longitude, altitude, substrate, soil description, slope and aspect were also recorded. Also, at each site all plant species that could be reliably identified were recorded within a radius of 30 metres.

Site	Gjj present?	Location	Latitude	Longitude	Altitude (m)	substrate

8.2 Appendix 2: Peter Weston's curriculum vitae

Personal details

Name: Peter Henry Weston.

Address: 18 Lyle Avenue, Lindfield, New South Wales 2070, Australia.

Date and place of birth: 22 October 1956, Lower Hutt, New Zealand.

Immediate family: wife (Susan) and three children (Timothy 34, Caitlin 32, Nicholas 29).

Nationality: Australian.

Interests: soccer, reading, guitar, orchid growing, cross-country skiing, bush walking.

Academic Qualifications

i) **B.Sc.** (first class honours; equal first in order of merit) School of Biological Sciences, University of Sydney; 1975-78, conferred 7 April 1979.
Thesis title: "The evolution and classification of *Boronia* Sm."

ii) **Ph.D.**, School of Biological Sciences, University of Sydney, 1979-83; conferred 18 May 1985.
Thesis title: "Systematics and biogeography of the Persooniinae (Proteaceae)".

Awards, Fellowships and Scholarships

2014	Nancy Burbidge Medal (awarded by the Australasian Systematic Botany Society to a person who has made a longstanding and significant contribution to Australasian systematic botany. It is the foremost award that can be conferred by ASBS).
2014	Australian Biological Resources Study-sponsored Winston Churchill Fellowship for an established career researcher in taxonomy.
2009	Grady L. Webster Structural Botany Publication Award for 2008 and 2009 from the Botanical Society of America. The BSA component of the award (it is awarded in alternate years by the BSA and the American Society of Plant Taxonomists) recognizes the most outstanding paper published in the *American Journal of Botany* in the field of structural and developmental botany (i.e., anatomy and morphology) over a two-year period. It was awarded to Gregory J. Jordan, Peter H. Weston, Raymond J. Carpenter, Rebecca A. Dillon and Timothy J. Brodribb for: "The evolutionary relations of sunken, covered, and encrypted stomata to dry habitats in Proteaceae," American Journal of Botany, Volume 95, Issue 5; May 2008.
2006	Carrick Award for Australian University Teaching from the Australian Learning and Teaching Council (one of five members of a teaching team from the University of New England cited for Outstanding Contributions to Student Learning).
1992-93	Posting to Royal Botanic Gardens, Kew, as Australian Botanical Liaison Officer.
1982	Charles Gilbert Heydon Travelling Fellowship for the biological sciences (not taken up).
1980-82	University of Sydney Postgraduate Scholarship.

1979-82	Commonwealth Postgraduate Award.
1977	G.S. Caird Scholarship for Third Year Botany, University of Sydney.
1976	Slade Prize for Practical Plant Biology, University of Sydney.

Employment

Present Position: Honorary Research Associate, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney and independent botanical consultant.

Previous positions held:
2008-2016 Senior Principal Research Scientist, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

2000-2008 Principal Research Scientist, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

1994-2000 Senior Research Scientist, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

1989-1994 Research Scientist, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

1982-1989 Scientific Officer, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

1979-82 Part-time demonstrator, School of Biological Sciences, University of Sydney.

Adjunct and visiting university appointments

2013-	Adjunct Associate Professor, La Trobe University.
2011-2016	Adjunct Associate Professor, University of New South Wales.
2006	Visiting Lecturer, Rhodes University, Grahamstown, South Africa.
2004-2009	Adjunct Associate Professor, University of New England.
2000-2004	Adjunct Senior Lecturer, University of New England.

Administrative/management experience

2009	Acting Manager Plant Diversity
2002-2003	Member, Plant Diversity Research Program Leaders Committee
1998-99	Systematics Liaison Officer
1997-98	Member RBGS Market testing working party
1997	Member, RBGS advisory committee for restructuring senior management
1990-91	Systematics Co-ordinator
1996-98	Member, RBGS Joint Consultative Committee

Membership of Learned Societies

1996-	Society of Australian Systematic Biologists
1984-	Willi Hennig Society (Elected Fellow, 1992-, Council member, 1998-2000)
1979-	Society of Systematic Biologists (member, Editorial Board 1993-95)

1978- Australasian Systematic Botany Society (formerly Australian Systematic Botany Society: President, 2009-2012, Vice President, 2008-2009, Chairman, Hansjörg Eichler Research Fund Committee, 1998-2002, Council member, 1996-2002)

Membership of External Committees

2015- Financial Grants Standing Committee (formerly the Grants Policy Standing Committee) of the Australasian Systematic Botany Society

2012-2013 Conference Organising Committee of *Systematics Without Borders*, a joint conference of the Australasian Systematic Botany Society, Society of Australian Systematic Biologists and Invertebrate Biodiversity and Conservation, University of Sydney (Chairman)

2011- Editorial Board, *Phytotaxa*

2008-2009 Corresponding Member, Editorial Advisory Committee, *Australian Systematic Botany*

2006-2014 Ira Butler Memorial Trophy Committee (a joint committee of the Australasian Native Orchid Society and the Orchid Society of New South Wales) (Chairman)

2004- Editorial Advisory Board, *Kew Bulletin*

2001-2006 Panel of Judges, Eureka Prize for Biodiversity Research

2000-2012 Bushland Management Advisory Committee, Lane Cove Council (Chairman, 2008-2010)

1999-2004 Editorial Advisory Committee, *Australian Systematic Botany*

Spoken presentations at conferences (not including presentations delivered by others)

2015 Building Our Botanical Capital, annual conference of the Australasian Systematic Botany Society: “A database of variation in floral characters in the Proteaceae, and implications for key questions in floral evolution”.

2014 Next Generation Systematics, annual conference of the Australasian Systematic Botany Society: Nancy Burbidge Memorial Lecture: “Problems and progress in plant systematics since Nancy Burbidge”

2013 Genetics Society of Australasia conference, Sydney *Genetics in the Harbour City*: “Molecular phylogeny of the subtribe Hakeinae (Green Plants: Proteaceae tribe Embothrieae) and its implications”.

2013 Joint conference of the Australasian Systematic Botany Society, Society of Australian Systematic Biologists and Invertebrate Biodiversity and Conservation, Sydney, *Systematics Without Borders*: “Molecular phylogeny of the subtribe Hakeinae (Green Plants: Proteaceae tribe Embothrieae) and its implications”.

2012 Australasian Systematic Botany Society conference, Perth, *Local knowledge, global delivery*: “Contested, Uncontested and Potentially Controversial Taxonomic Changes in the Proteaceae: How Do They Differ?”

2011 37th annual conference of the South African Association of Botanists, *Plants in a Changing World* and 9th conference of the South African Society of Systematic Biologists, *Biodiversity Matters*; plenary address: “Cenozoic environmental change and the systematics of southern hemisphere plants”

2011 XVIII International Botanical Congress, Melbourne: “Floral evolution in animal-pollinated Australian angiosperm clades: patterns and potential explanations”.

2010 VI Southern Connection Congress, Bariloche: “Cladistic biogeography, molecular dating, fossils and the Proteaceae”

2010 VI Southern Connection Congress, Bariloche: “Diversification of the Proteaceae in Mediterranean hotspots of the Southern Hemisphere and in tropical rainforests”

2010 Australian Systematic Botany Society conference *Systematic Botany Across the Ditch: Links Between Australia and New Zealand*; Keynote address: “Cenozoic environmental change and the systematics of southern hemisphere plants”
1999 XVI International Botanical Congress, Saint Louis: “Historical biogeography of Proteaceae”.
1997 II Southern Connection Congress, Valdivia: “Cladistic biogeography of a key woody group: Proteaceae”.
1997 First Biennial International Conference of the Systematic Association, Oxford: “Rolf Sattler’s Plant Morphology and Cladistic Analysis”.
1996 *An International Symposium on the Biology of Proteaceae*, Melbourne: “ITS squence variation in the Proteaceae and what it tells us about phylogeny”.
1993 Joint conference of The Systematics Associations and The Linnean Society on *Models in Phylogeny Reconstruction*, London: “Direct methods for polarising character transformation series”.
1990 IXth meeting of the Willi Hennig Society, Canberra: “Transoceanic cladistic patterns in the Proteaceae”.
2003 The Third International Conference on *the Comparative Biology of the Monocotyledons*, Ontario: “Co-evolution of *Chiloglottis* (Orchidaceae) and its Thynnine wasp pollinators”.
2005 XVII International Botanical Congress, Vienna: “Food is good but sex is better: the evolution of deceptive pollination in the tribe Diurideae (Orchidaceae)”.
2006 Australian Systematic Botany Society conference, Cairns, *Plant Diversity in the Tropics*: “A new suprageneric classification of the Proteaceae”.
2007 5th Southern Connection Congress, Adelaide: “‘I’m not dead yet’ – Gondwana (the Proteaceae are at least partially congruent with Gondwanic fragmentation)”.
1989 Australian Systematic Botany Society symposium, on *Gondwanan Elements in the Australian Flora*, Sydney: “Transpacific cladistic patterns in the Proteaceae and Elaeocarpaceae”.
1988 Symposium on *Panbiogeography of New Zealand*, Wellington: “Problems with the statistical testing of panbiogeographic hypotheses”.
1985 Australian Flora Foundation Symposium on *Waratahs*, Canberra: “Drifting waratahs or continents?”
1984 Australian Systematic Botany Society symposium on *Cladistics, Systematics and Phylogeny*, Canberra: “A reappraisal of Nelson's direct method of character analysis”.

Refereeing manuscripts, grant applications, reports and examining postgraduate theses (last five years)

2018: *Candollea*; *Flora of the Hunter Region*; *Journal of Biogeography.*

Research

My research has been in the theoretical and practical aspects of systematic botany, with emphasis on the theory and practice of phylogenetic analysis, and the broader uses to which phylogenetic knowledge may be applied. I have phylogenetically analysed groups in the plant families Proteaceae, Fabaceae, Orchidaceae, Rutaceae, Winteraceae and Lauraceae, contributed to more general analyses of angiosperm phylogeny, and used the results of these analyses to improve biological classification and to test theories of historical biogeography, trait evolution, co-evolution and adaptation. I have earned an international reputation for my contributions to both theoretical and empirical developments in this field.

Herbarium curation and collections

My curatorial responsibilities at the National Herbarium of New South Wales have included the families Rutaceae (1982-1998), Proteaceae (1982-2016), Orchidaceae (1986-2016) and Fabaceae subfamily Faboideae (1986-2016). I have collected plant specimens (mostly angiosperms) in Australia, England, New Zealand, New Caledonia, Chile, South Africa, and Argentina, mostly for the herbarium and living collections of the Royal Botanic Gardens and Domain Trust, Sydney. Duplicates of my collections have been distributed to over 20 herbaria in 8 different countries.

Teaching

I have been actively involved in the preparation and teaching of four third year undergraduate courses in biosystematics:
Western Sydney University (2015-2018): “Principles of Evolution” (unit 300980), “Botany” (unit 300836).
University of New South Wales (2010-2016): “Assembling the Tree of Life” (BIOS3221)
University of New England (2000-2010): Biosystematics (Biosyst 301, Biosyst 302, Evol 301/501).
Botany Department, Rhodes University, Grahamstown, South Africa (February-March 2006): “Plant Biodiversity” course in collaboration with Associate Professor Nigel Barker.

I am currently co-supervising one postgraduate student:
Nanette Thomas (Ph.D., University of New England): Systematics of *Tasmannia* informs Biogeography of Winteraceae.

Postgraduate and honours students I have previously co-supervised include:
Margaret Stimpson (Ph.D., University of New England): Systematics, evolution and ecology of the *Banksia spinulosa* complex (graduated 2017).
Melita Milner (Ph.D., Australian National University): Phylogeography of *Lomatia and Telopea* (Proteaceae) in south eastern Australia (graduated 2015).
Samanta Oon (B.Sc. Honours, University of New South Wales): *Lomatia* likes it both ways: rampant bidirectional introgression of chloroplast genomes between two morphologically distinct species of Lomatia (Proteaceae) (graduated 2015).
Zoe Reynolds (B.Sc. Honours, Australian National University): Phylogenetic, taxonomic and functional turnover in Proteaceae assemblages (graduated 2013).
Emma McIntosh (B.Sc. Honours, University of Sydney): Hybridization and introgression between *Lomatia myricoides* and *L. silaifolia* (Proteaceae) (graduated 2011).
Margaret Stimpson (M.Sc.Stud., University of New England): Review of the *Banksia spinulosa* species complex (Proteaceae) (graduated 2011).
James Indsto (M.Sc., University of Wollongong): Pollination Ecology and Molecular Systematics of *Diuris* (Orchidaceae) of the Sydney Region (graduated 2010).
Nanette Thomas (Grad.Dip.Sci., University of New England): Phylogenetic analysis of Winteraceae (graduated 2009).

David McKenna (Ph.D., University of Wollongong: Demographic and ecological indicators for rarity in obligate-seeding *Persoonia* (Proteaceae) shrubs of the Sydney region, graduated 2007).
Paul Rymer (Ph.D., University of Wollongong: Plant rarity: species distributional patterns, population genetics, pollination biology and seed dispersal in *Persoonia* (Proteaceae), graduated, 2006).
Georgina Lloyd (B.Sc. Honours, University of Sydney: Pseudocopulation in two species of *Cryptostylis*: Implications for maintaining species integrity, graduated 2004)
Andrew Perkins (Ph.D., University of Sydney: Phylogenetic Systematics of the Genus *Calochilus* (Orchidaceae), graduated 2002).
Jim Mant (Ph.D., Australian National University: Comparative biology of *Chiloglottis* (Orchidaceae) and its thynnine wasp pollinators (Tiphiidae), graduated 2002).
Siegfried Krauss (Ph.D., University of Wollongong: Systematic pattern and evolutionary process in the complex species *Persoonia mollis* (Proteaceae), graduated 1995).

I have examined 14 honours and postgraduate theses:
Australian National University (Ph.D., 2003, 2007, 2008)
University of Melbourne (Ph.D., 1995, 2011)
University of Newcastle (M.Phil., 2003)
University of Queensland (Ph.D., 2003)
University of Sydney (Ph.D., 1991, 1994, 1997, 2009)
University of Wollongong (B.Sc. Hons., 2001, 2003)
Victoria University (Ph.D., 2007)

Competitive Research and Infrastructure Grants

Peakall, R., Pichersky, E., Linde, C., Weston, P.H. (2015-2019) The biosynthesis and evolution of novel semiochemicals in orchids. $644,800, Australian Research Council Discovery Grant DP150102762.

Hoebee, S.E., Weston, P.H., & Edwards, T.J. (2015-18) Evolution in action or the demise of iconic Australian flora? $217,700, Australian Research Council Discovery Grant DP150100508.

He, T., Lamont, B., Weston, P.H., & Cowling, R. (2012-2014) Origin and evolution of plant functional traits in relation to fire. $310,000, Australian Research Council Discovery Grant DP120103389.

Rossetto, M., Crayn, D.M. & Weston, P.H. (2008-2010) Integrating molecular and morphological data for generic delimitation and species identification in Lauraceae. $73,333, Australian Biological Resources Study.

Cantrill, D., Murphy, D. & Weston, P.H. (2008-10) Understanding the origins of the Australian flora by integrating molecular phylogenies and fossil data in the Proteaceae. $88,900, Hermon Slade Foundation.

Rossetto, M. & Weston, P.H. (2007-2009) Speciation in the Australian flora: testing explanatory hypotheses in waratahs and their allies. $78,000, Hermon Slade Foundation.

Considine, J.A., Krauss, S.L. & Weston, P.H. (2002-2004) A biological basis for the efficient breeding of native plants for export markets: a case study with the Australian Goodeniaceae. $168,126, ARC – Linkage (Krauss and Weston representing industry partners)

Whelan, R.J., Ayre, D.J., England, P., Auld, T.D., & Weston, P.H. (2000-2002) Ecology and genetics of fire-sensitive *Persoonia* species: threatened species recovery and management. $126,480, Australian Research Council (ARC– SPIRT, Auld and Weston representing industry partners).

Trent, R. *et al.* (2000) Enhancement of DNA sequencing equipment for the Sydney University and Prince Alfred Molecular Analysis Centre. $600,000, Australian Research Council (ARC-REIF).

Weston, P.H. (1999-2001) Comparative biology of *Chiloglottis* (Orchidaceae) and its thynnine wasp pollinators (Tiphiidae). $75,000, Hermon Slade Foundation.

Weston, P.H. (1997-2000) Taxonomic revision of *Dillwynia* (Fabaceae: Faboideae: Mirbelieae). $62,836, Australian Biological Resources Study.

Weston, P.H. & Thomson, J.A. (1993) A molecular approach to the evolution and biogeography of the Queensland tree waratahs. $4000, Queensland Wet Tropics Management Authority

Weston, P.H. & Thomson, J.A. (1991-92) A molecular approach to the evolution and biogeography of the waratahs. $80,100, Australian Research Council (large grants scheme).

Weston, P.H. (1984) Establishment of a data bank for eucalypt specimens held by NSW. $20,000, Australian Biological Resources Study.

Scientific Publications

[the numbers in square brackets following a reference indicate: 1. the journal's 2016-17 impact factor according to ISI Web of Knowledge, then the number of literature citations for the paper found by Google Scholar, as of 13 Feb 2019]

H-index = 34, total number of citations = 4081 as of 13 Feb 2019

Expert report – *Hibbertia fumana*

Hibbertia fumana – Wilton and GMAC, Robert Miller, September 2018

Hibbertia fumana – WSA and GPEC, Robert Miller, December 2018

Strategic assessment for Cumberland Plain Conservation Plan
Hibbertia fumana

Hibbertia fumana, Moorebank, R. Miller September 2017.

Report prepared for Department of Planning and Environment

By

Cumberland Flora & Fauna Interpretive Services

Robert Miller - September 2018

Executive Summary

Hibbertia fumana is listed as a Critically Endangered Species under the *Biodiversity Conservation Act 2016*. There are two known populations of the species, one at Moorebank and the other at Bankstown Airport. The species is assessed as data-poor.

Survey for this report was limited by time constraints, lack of access to private property, survey outside the species flowering season and years of preceding drought conditions.

Assessment relied on the expected presence of “likely habitat”, based on extant population habitat, and “potential habitat”, based on speculation of historic record habitat.

The probability of the species to occur in the likely habitat is considered low due to site disturbance, however, cannot be ruled out as the Bankstown population survives in highly modified mown derived grassland environment. The probability of the species to occur in potential habitat is considered to be very low. However, a precautionary approach is recommended. Locating and protecting new populations, no matter how small, is significant to the survival of this species.

H. fumana is a small shrub that could be severely affected by anthropogenic impacts resulting from development edge effects, particularly in areas downhill of development.

The assessment identified:

- at Menangle Park an area of approximately 92ha that could contain likely habitat niches within the growth area footprint, and a further 31 ha of land containing likely habitat niches adjacent to the footprint.
- at Kayess and Milton Parks areas of likely habitat that are not affected by the growth area footprints.
- at Bunbury Curran Creek vicinity areas of potential habitat are not affected by the growth area footprints.
- in the Gilead and Appin areas approximately 8ha of land containing potential habitat niches within the growth area footprint and a further 380ha of land containing potential habitat niches adjacent to the footprint.
- in the Wilton growth area, approximately 65ha of land containing potential habitat niches within the footprint and a further 680ha of land containing potential habitat niches adjacent to the footprint.

Note that the likely and potential habitats are niches within the overall landscape, generally associated with localised soil and drainages within transition vegetation.

Although the species occurrence is assessed as low, it is recommended that further survey be carried out in the likely habitat and some of the potential habitat areas during the species’ flowering season.

1. Introduction

1.1 PURPOSE

The purpose of this expert report is to determine the potential for future urban development in identified growth areas of Western Sydney to impact on *Hibbertia fumana*, which is listed as a Critically Endangered Species under the *Biodiversity Conservation Act 2016*. This report forms part of the Cumberland Plain Conservation Plan, which will be assessed under the:

- Biodiversity certification under the *Biodiversity Conservation Act 2016* (BC Act)
- Strategic assessment and approval under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act).

The Biodiversity Assessment Method (BAM) sets out the framework and methods to be used for assessment of impacts to biodiversity to provide preferred conservation outcomes while also supporting the development approval process. Under the BAM an expert report can be used when adequate survey is not possible. An expert report can only be used for species to which species credits apply.

The expert report must document the information that was considered, and/or rejected as unsuitable for consideration, to reach the determination made in the expert report. The report must set out whether the subject species is likely to be present at the development site, and if present then the report must estimate, in the case of a species such as *Hibbertia fumana*, the area of habitat where the species is likely to be impacted, as well as areas from which it is known to occur in which it will be impacted.

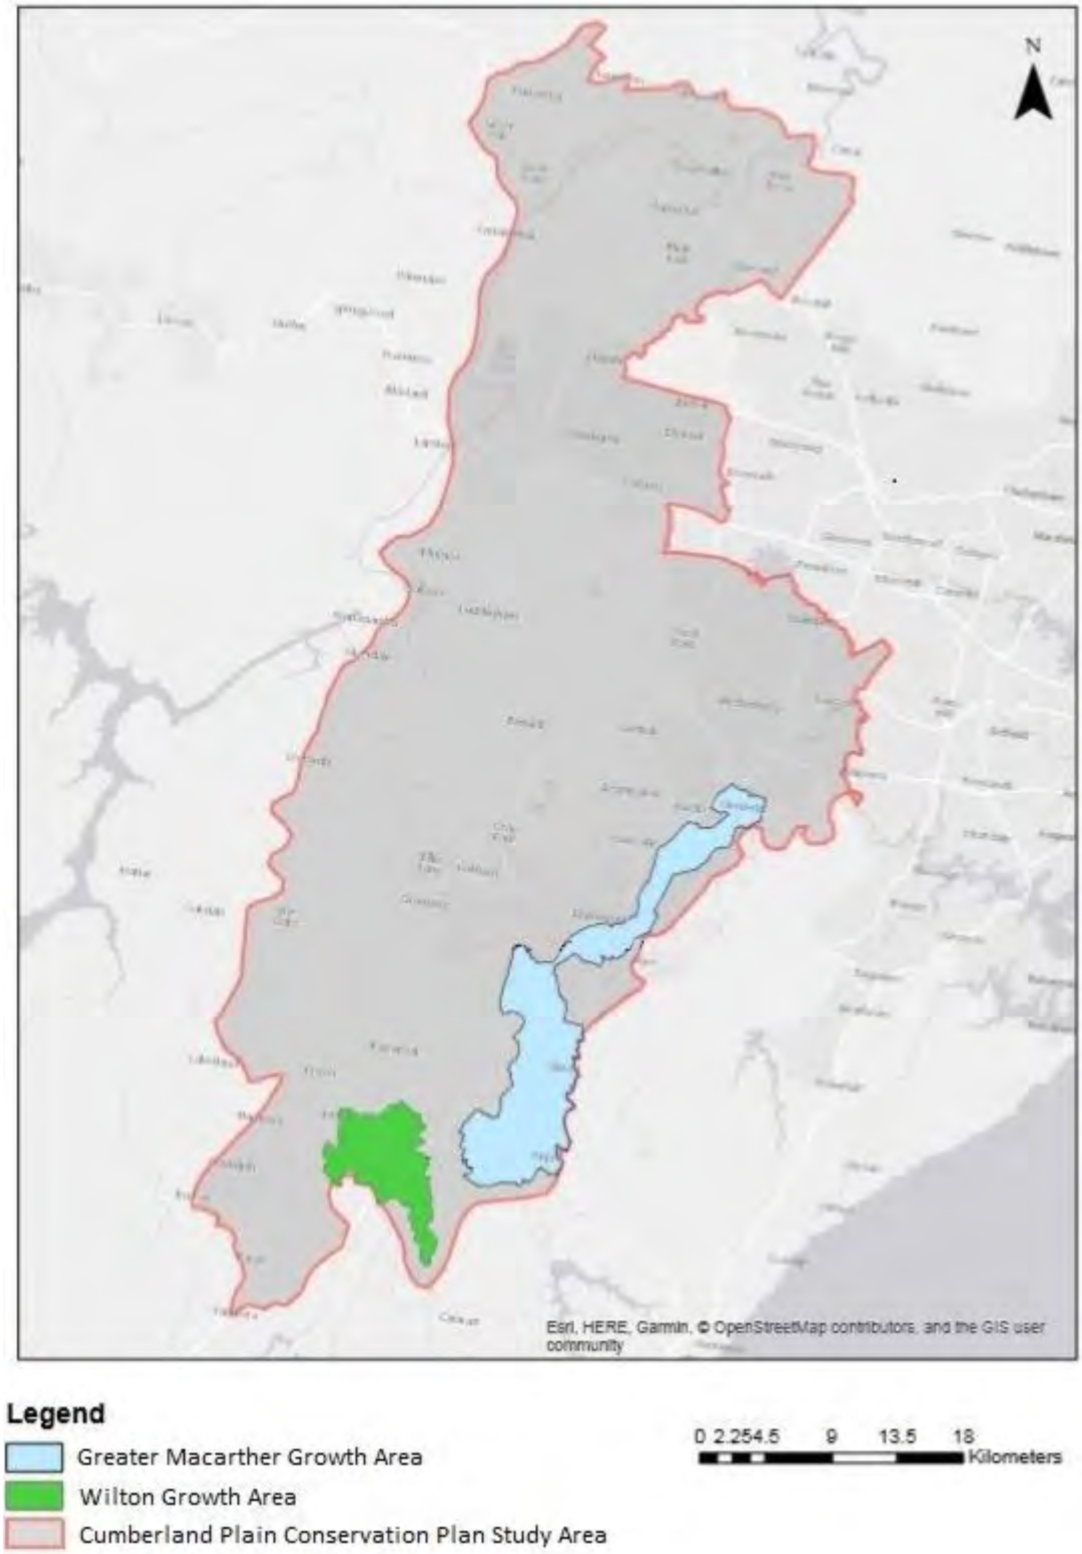
1.2 PROJECT CONTEXT

The NSW Government is planning for future urban development in Western Sydney. Four growth areas have been identified, these are Wilton, Greater Macarthur (Campbelltown and Appin), Western Sydney Airport, and Greater Penrith to Eastern Creek. These growth areas are all located within the Cumberland Subregion in version 7 of the Interim Biogeographic Regionalisation for Australia (IBRA) (2016).

As part of the planning for this future development, the Department of Planning and Environment (DPE) is preparing the Cumberland Plain Conservation Plan. This is a strategic regional assessment that will lead to the identification of preferred conservation outcomes for the Cumberland subregion.

1.3 STUDY AREA

The Map 1 shows the Cumberland Plain Conservation Plan Study Area and the two growth areas of Greater Macarthur (GMGA) and Wilton (WGA).



Map 1: Cumberland Plain Conservation Study Area and Growth Areas

Map source: NSW Department of Planning and Environment.

1.4 SPECIES SURVEYS

Past collections

This species was first collected by George Caley from “near South Head” in 1802 and was subsequently collected by Robert Brown “in occidental (western) Sydney” in 1804.

The type specimen is a F. W. Sieber collection Australia near Sydney. His expedition was from June until December 1823 when he collected 645 local plant specimens (Council of Heads of Australasian Herbaria Australian National Herbarium Biographical Notes Extracted from: A.E.Orchard (1999)).

One collection by Keith Ingram at Connells Point in 1941 is also thought to be that species but a degree of uncertainty prevails (refer to specimen label notes by Orme in Appendix 3). No precise locality details nor habitat information was recorded on these historic specimens.

Presumed extinct when first published in 2012, the species was re-discovered at the Moorebank Intermodal site in October 2016. It has also been recorded at Bankstown Airport in November 2017 (AVH) as part of environmental assessment of an infrastructure proposal. It is not known to occur at any other locations.

Surveys for this Bio Assessment

Surveys for the biodiversity assessment informing the development of the biocertification were constrained by private lands access issues, time and the overall size of the biocertification area.

Surveys undertaken by Ecoplanning and Biosis consultancies since 2017 have largely been confined to the deemed “development footprint” and appear to have been undertaken predominantly to comply with the BAM protocols for vegetation sampling for assessment purposes with little survey for threatened species. As such, no new occurrences of threatened *Hibbertia* species including *Hibbertia fumana* were recorded by Biosis or Ecoplanning through their survey efforts.

One site was identified by DPE and Biosis as having potential to support the species, an area mapped as PCT 883 Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain.

Access to a spatial viewer was provided by DPE to assist in the expert assessment. Whilst this tool has been useful in gaining a general overview, the information presented is limited and is acknowledged to “have been acquired and developed from numerous sources of differing dates, accuracy and completeness and may include errors in extent and content”. CFFIS are not aware of any surveys performed specifically for *Hibbertia fumana* by DPE, Ecoplanning or Biosis Consultancies. The broadscale vegetation mapping of PCTs that was provided to assist with this assessment cannot identify the habitat niches that may be present on a localised scale.

The surveys undertaken by Miller as part of this expert report relied on assessment of known habitat traits of extant sites and, although highly speculative, inferred habitat traits from historic records. PCT mapping and aerial digitised photography were used to select potential habitat areas for targeted surveys. Priority was given to finding the same habitat as occurs at the Moorebank and Bankstown Airport sites, although a variety of vegetation associations that are known habitat of other *Hibbertia* species such as *H. puberula* were surveyed to include inferred habitat from historic records. *Hibbertia puberula* co-occurs with *H. fumana* at the Moorebank site.

Map 2**Error! Reference source not found.** and Map 3 **Error! Reference source not found.**show the sites that were surveyed for this assessment.

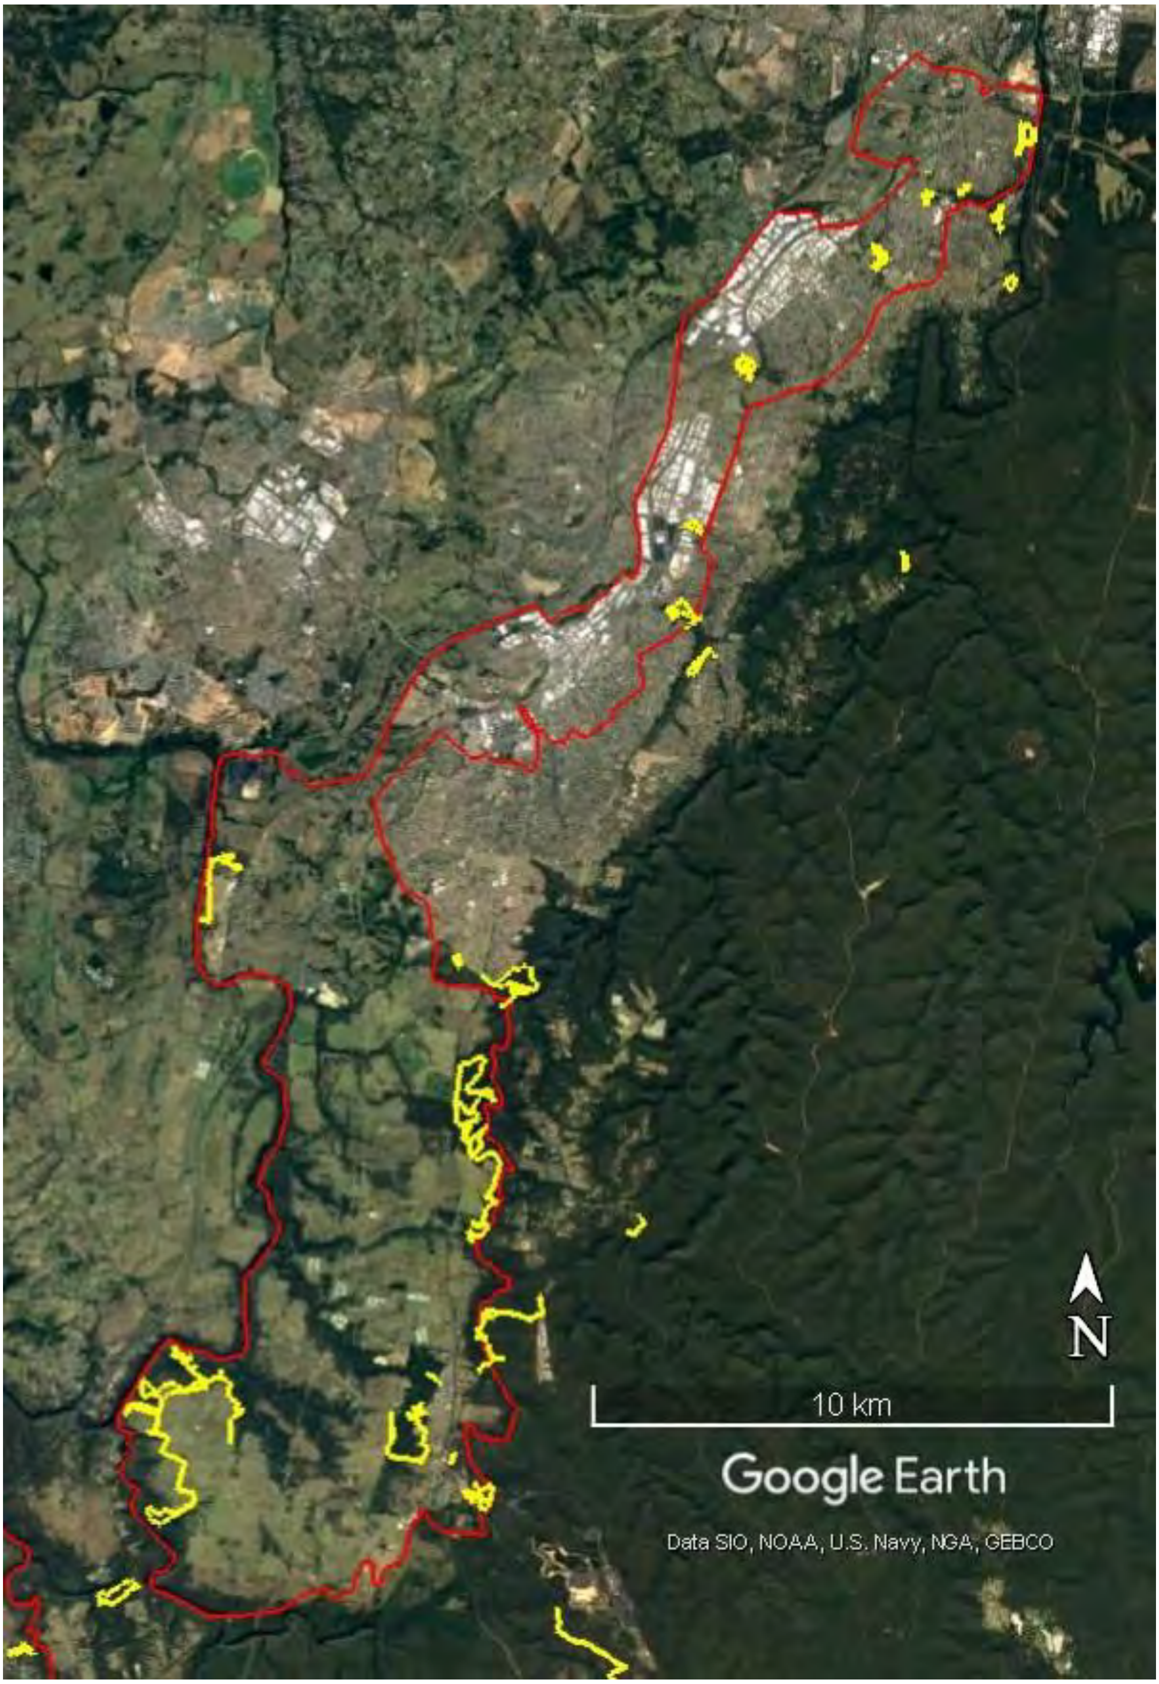

Map 3: Google Earth Image of Greater Macarthur Growth Area and CFFIS survey tracks.

Key: Growth area approximate boundary shown in red, survey tracks shown in yellow.

<u>Species identification</u>

If a small-leaved *Hibbertia* was located that had macro morphological features resembling that of *Hibbertia fumana* then a specimen would be retained for later microscopic examination. CFFIS has also assessed the likelihood of *Hibbertia puberula* to occur in the GMGA and the WGA. *Hibbertia puberula* co-occurs with *H. fumana* at Moorebank and as both species are small-leaved, diminutive plants it is possible to misidentify *H. fumana* as *H. puberula* or other small-leaved species without careful examination (refer Photo 2). Selected specimens taken as part of the *Hibbertia puberula* assessment were microscopically examined to ensure that *Hibbertia fumana* was not inadvertently collected and dismissed as *Hibbertia puberula* or another small-leaved species. Due to the time of the year and prevailing drought conditions, plants were not in flower and depauperate, such that any specimens removed consisted of very small fragments (eco-scraps) most only a few cm in length.

The survey during June and July is not the flowering season for this species, so identification relied on stem and leaf characteristics, shown in Figure 1, Figure 2, Appendix 2 and microscopic comparison with voucher specimens. Note that positive identification of the species requires flowering parts, however, some species of *Hibbertia* can be ruled out based on stem and leaf characteristics.

Figure 1 drawing depicts *Hibbertia fumana* in bud where those buds appear +/- sessile. During the Moorebank surveys it was purported by a consultant that pedunculate flowers are a key field identification tool even in bud. This is clearly erroneous and should not be used as the sole identifying feature (refer also to Photo 3**Error! Reference source not found.** R.T. Miller and photo of the Isotype in Figure 3**Error! Reference source not found.**).

Peduncle elongation is clearly related to and is proportional to the developmental progression from buds to seed formation. Anecdotal observation by Miller suggests peduncle development is also related to environmental conditions such as moisture content of the soil and degree of exposure, for example, extended periods of low soil moisture and /or in combination with exposure appears to reduce peduncle length.

The species profile for *Hibbertia fumana* identifies some of the *Hibbertia* species with which it might be confused: "species with which it may be confused include *Hibbertia aspera* (peduncle of *H. fumana* is shorter, especially in flower, the foliage is more persistently hairy, and there are fewer stamens), *H. empetrifolia* (*H. fumana* is much more prominently stellate-hairy) and *H. riparia* (*H. fumana* has much shorter leaves). *Hibbertia superans* is another possible species for confusion, though *H. fumana* has smaller leaves" (OEH 2018).

It is unlikely that an expert would misidentify large / mature flowering plants of the above species with *Hibbertia fumana*. Confusion / unreliability is likely to arise if a population census is undertaken outside of optimal flowering time and/or the survey site is recovering from fire when high proportion of the plants will be small and immature, or if depauperate in drought conditions.

There are several other small leaved diminutive Hibbertias that could be confused including *Hibbertia dispar*, *H. pedunculata*, *H. calycina* s.str. and other undescribed taxa.

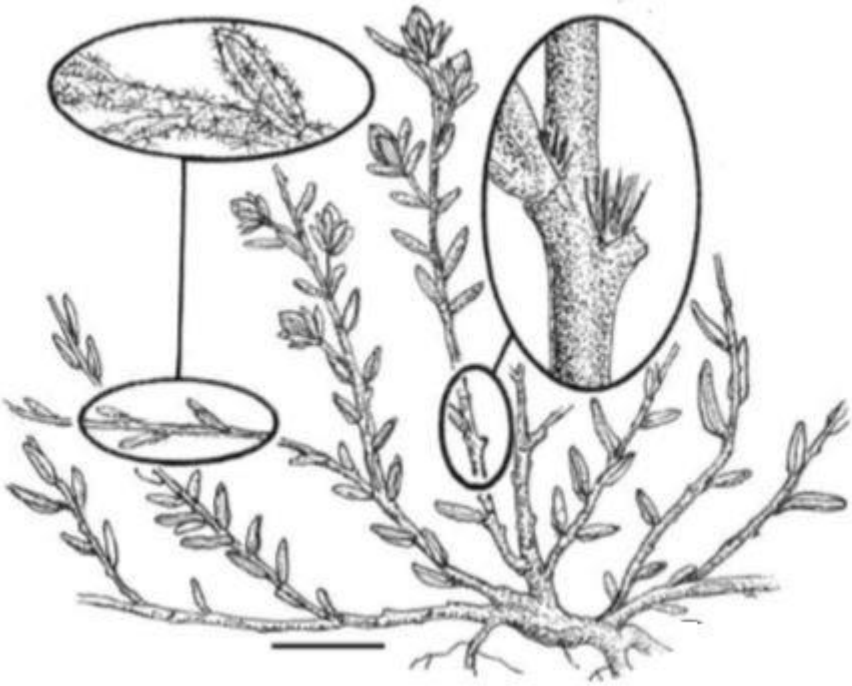

Figure 1: Stem and leaf characteristics of a flowering *Hibbertia fumana* specimen.

F.W. Sieber 147 (MEL 3111616) (Toelken and Miller 2012)

Relying solely on stem and leaf characteristics in field survey can lead to mis-identification. *Hibbertia fumana*, *H*. *aspera* and *H*. *empetrifolia* have discolorous leaves and using this character alone on non-flowering specimens without a high resolution microscopic examination could result in dismissing or mis-identifying a plant to be *H*. *fumana*. The discoloration of the under surface of the leaves in both *Hibbertia fumana* and *H*. *aspera* is due to the presence of a usually dense white/silvery tomentum whilst the leaf under surface of *H*. *empetrifolia* lacks dense tomentum but it is of a similar whitish coloration.

Apparent tomentum density and type on the stems and leaves will vary according to the section of branchlet examined and the prior climatic conditions. New growth is likely to have a higher density and a fuller range of hair types present whereas on older growth much of this tomentum will have "worn off" (Toelken), especially the longer simple hairs. Drought condition will see a marked reduction in new growth. *Hibbertia aspera*, like *H. empetrifolia*, shows much variation in different local populations as well as sometimes on the same plant (Toelken).

Both *Hibbertia aspera* and *H*. *empetrifolia* were frequently observed during the CFFIS survey, whilst *H. ericifolia* subsp. *acutifolia* was noted to be locally common in the south-eastern sector of the GMGA mostly associated with Scribbly Gum Woodland.

Microscope photographs of *H. fumana* characteristic features used during this survey by CFFIS are provided in Appendix 2 and includes comparison photos of *Hibbertia aspera*, *H*. *empetrifolia* and *H*. *dispar*.

<u>Survey assumptions</u>

The survey was carried out in June to August, during the non-flowering period, and it was not possible to access and survey all the many bushland remnants within the Wilton and Greater Macarthur growth areas. As such, the first assumption was:

Assumption 1. *Hibbertia fumana* would not be found growing in bushland that is unlikely to be suitable habitat.

The author is familiar with the type of habitat at the Moorebank Intermodal and Bankstown sites. Using this knowledge of geology, soil and vegetation type that is the known occupied habitat of the species, areas of bushland that would not be suitable habitat were ruled out of the assessment.

Using this knowledge of habitat requirement, the second assumption was:

Assumption 2. *Hibbertia fumana* is likely to be present in areas that are known to be suitable habitat. While surveys in suitable PCTs since the species was described in 2012 have failed to find *H. fumana*, this is a cryptic plant and the precautionary principle should be applied to the potential for the species to occur in suitable habitat.

The survey was carried out following several years of drought in western Sydney, and many shrubs, forbs and grasses were dead. This led to the third assumption:

Assumption 3. In areas of suitable habitat, where *Hibbertia fumana* specimens have not been found, the species could be present in the soil seed bank.

Identification to species of the *Hibbertia* relies on characters of the flowers. The survey was carried out in the non-flowering period which led to the fourth assumption:

Assumption 4. That specimens matching the stem and leaf characteristics of *Hibbertia fumana* could possibly be that species. Small narrow-leaved specimens were examined under the microscope to determine if the stem and leaf characteristics matched those of *Hibbertia fumana.*

1.5 JUSTIFICATION FOR USE OF EXPERT REPORT

The BAM allows for situations where an expert report will be required to replace or complement survey effort at a development site. While there has been some field survey for the Strategic Biocertification assessment, the area covered by the proposed GMGA and WGA are extensive and there have been issues with gaining access to some of the private properties.

An expert report is required to assess potential impact to *Hibbertia fumana* for the following reasons:

Insufficient survey: A large extent of the identified growth areas could not be surveyed because it was on private property and could not be accessed within the project timeframe. Expertise was required to identify and survey potential species habitat and propose additional habitat based on extant and historic records.

Survey out of flowering season: Survey during June and July is at the non-flowering period for the species, so finding cryptic species of *Hibbertia* in the field is difficult even for an expert and more so for someone who is not an expert (refer Photo 1).

1.6 CREDENTIALS OF EXPERT

Robert Miller has over 30 years' experience in field botany. Over this time Robert has identified many rare and endangered plant species and has contributed to the scientific knowledge of native flora distribution and habitat in NSW.

Robert has worked with Hellmut Toelken of the State Herbarium of South Australian, locating, collecting and identifying undescribed or rare species of *Hibbertia*. Some of these taxa were known only from historic records with non-precise locality details and depauperate or non-existent habitat information. Many of the specimens have been used for the taxonomic revision of the genus and are cited in various taxonomic publications including "Notes on *Hibbertia* subg. *Hemistemma* (Dilleniaceae) 9. The eastern Australian *H. vestita* group, including *H. pedunculata* and *H. serpyllifolia*" published in the *Journal of the Adelaide Botanic Gardens* 26 (2013). Examples of the cited specimens include: *Hibbertia ericifolia* subsp. *acutifolia* Toelken, subsp. nov. Type: New South Wales, Sarahs Knob, R. & J. Miller s.n., 21.x.2006 (holo.: AD; iso.: BRI, CANB, NSW, PERTH) and *Hibbertia dispar* R.T.Miller s.n., 0.5 km S of Penrose Rest area, along western boundary track, Penrose State Forest, 12.x.2010 (AD, NSW).

Robert and Hellmut's paper "Notes on *Hibbertia* (Dilleniaceae) 8. Seven new species, a new combination and four new subspecies from subgen. *Hemistemma*, mainly from the central coast of New South Wales", was published in the *Journal of the Adelaide Botanic Gardens* in 2012. The paper describes 13 new taxa including *Hibbertia fumana* Toelken and *Hibbertia puberula* subsp. *puberula,* – subsp. *extensa* R.T.Mill. and – subsp. *glabrescens* Toelken*.*

In 2017 Robert was called as an expert to identify the species of *Hibbertia* on the Moorebank bushland site that is the subject of the Intermodal development proposal.

Robert is also a recognised expert for other threatened taxa including *Pomaderris adnata*, *Solanum celatum*, *Epacris purpurascens* var. *purpurascens*, and the genus *Prostanthera* including the threatened taxa *Prostanthera discolor*, *P. stricta*, *P. densa*, *P. junonis* and has provided expertise to the OEH Saving our Species programs.

Photo 1: Very cryptic by its diminutive nature *Hibbertia fumana.*

H. fumana is difficult to detect even just prior to full petal expansion. Refer Photo 3 for close-up showing morphological features.

<u>Survey during drought</u>

The Western Sydney region has been experiencing dry conditions for several years, which means that the *Hibbertia fumana* plants are likely to be under severe drought stress and partially defoliated making this small and cryptic species more difficult to locate. It requires an expert in the species to locate and identify rare *Hibbertia* under these conditions.

<u>Reliable species identification</u>

Identification of the genus *Hibbertia* to species level requires examination of flower parts in combination with stem and leaf characters, especially tomentum type and density. It is not practical nor reliable to identify small leaved species in the field as many of these morphological features require microscopic examination and comparison to known voucher specimens.

The use of an expert report to complement survey of the growth areas avoids the problems associated with *Hibbertia* misidentifications. *Hibbertia* species can be misidentified in vegetation assessments, frequently being dismissed as “common” species.

The misidentification of both *Hibbertia puberula* and presumably *Hibbertia fumana as Hibbertia riparia* during past surveys raises the possibility that other records of *Hibbertia riparia* may in fact be *Hibbertia fumana*. Searches of the databases revealed prior surveys undertaken for various projects have recorded *Hibbertia riparia* to occur at a number of locales within the GMGA and WGA.

The *Hibbertia riparia / H. calycina / H. hirsuta* groups are currently under further detailed evaluation (Toelken pers. comm.). *Hibbertia riparia* R.Br. s. str. occurs in Tasmania (Toelken) and is unlikely to occur in NSW, the name being misapplied (Toelken pers. comm.). It was therefore anticipated that the identifications of *Hibbertia riparia* would be found to be incorrect.

Two recorded *H. riparia* sites were inspected as part of this report, one at Douglas Park (12 June 2018) and one at Wilton on 17 August 2018. A third Site at Appin was not surveyed due to access constraints.

The *Hibbertia* sp. observed off Douglas Park Drive was found to have vegetative features consistent with *H. puberula*. No plants were noted that resembled *Hibbertia fumana*, however the site inspection was limited by the extreme drought conditions and non-flowering period for the species. It remains unknown if *Hibbertia fumana* co-occurs at the site.

The Wilton locale was inspected in August and it was found that the severity of impact to the bushland from drought had markedly increased. The site was extremely dry following the years of drought, the ground was covered with a thick layer of leaf litter, and many plants were dead including large numbers of *Hibbertia aspera*. No plants resembling *H. riparia* were found at the location, so the correct identification of the species could not be ascertained.

It is considered likely that this species is the same taxon as the proximate occurrence off Douglas Park Drive which has vegetative features consistent with *H. puberula,* however there remains a possibility although low, that the *Hibbertia* may be *H. fumana*.

Photo 2: Five species of Hibbertia, photo taken 30cm above specimens, but which one is which?

Key - A: *Hibbertia aspera*, B: *H. empetrifolia*, C1: *H*. *puberula* (Lucas Heights), C2: *H*. puberula (Moorebank), D*: H*. sp. (morphological vegetative features consistent with *H*. *puberula* (East Gilead), E: *H*. *fumana*, F: *H*. *dispar*.

2. Species information

2.1 SPECIES DESCRIPTION

Hibbertia fumana was described by Toelken and Miller (2012) in their paper "Notes on Hibbertia (Dilleniaceae) 8. Seven new species, a new combination and four new subspecies from subgen. Hemistemma, mainly from the central coast of New South Wales". At the time of writing, the species was presumed extinct and had not yet been discovered at the Moorebank Intermodal site. The description was based on three herbarium specimens collected in 1802, 1804 and 1823.

The re-discovery of the species provided a broader range of specimens and a revised description which included for the first time fruit and seed, was provided by Duretto, Orme, Rodd, Stables and Toelken (2017). The following is a direct quote from that description.

Hibbertia fumana Sieber ex Toelken, Journal of the Adelaide Botanic Gardens 25: 73 (2012).

Type: Australia, near Sydney, "F.W.Sieber Nov. Holl. No. 147"

Decumbent shrublet, prostrate to weakly ascending to 20 cm high, with many branches from the base, moderately- to much-branched; branches wiry, with raised leaf bases shortly decurrent, shortly fascicled-pubescent. Vestiture persistent, consisting of more or less coarse simple hairs over fine fascicled hairs on tubercles; on branches more or less densely covered with short subequal multiangulate fascicled hairs (4–7 equal arms) and without simple hairs except for intrapetiolar tufts of hairs in leaf axils; on leaves above scattered, short antrorse fine bi- or triforked to simple hairs, sparse becoming denser onto the petiole, few simple hairs along the flanks, all wearing off soon; on leaves below dense, with short subequal multiangulate fascicled hairs (4–12 subequal arms) particularly on central vein, overtopped by few simple hairs on the flanks of the revolute margins; on outer calyx outside moderately dense, with spreading coarse antrorse simple hairs over erect-spreading multiangulate fascicled hairs (8–15 subequal arms), inside dense, with forked to simple antrorse hairs over most of surface; on inner calyx lobes outside dense with spreading multiangular fascicled hairs (2–12 subequal or unequal arms) becoming smaller towards the membranous margins, overtopped by coarse antrorse simple hairs along the central ridge, inside glabrous except for a few simple hairs towards the apex. Leaves with intrapetiolar axillary tuft of hairs to 0.7 mm long; petiole 0.2–0.45 mm long; lamina narrowly oblong, rarely linear-elliptic, (1.9–) 2.1–6.5 × 0.5–1.2 mm, obtuse, with terminal tuft of hairs on a somewhat recurved apex of the central vein, more or less abruptly constricted into petiole, above ± flat and puberulous to glabrescent, below with broadened central vein recessed below the level of revolute margins and protruding into apex, pubescent to puberulous. Flowers single, terminal, commonly on main branches; flower stalk 2–9 mm long, recurved and elongating after flowering, pubescent; bract linear to linear-triangular, 1–1.3 mm long, sometimes leaf-like to 5.5 mm long, fascicled-pubescent, on lower third to half of flower stalk. Calyx distinctly accrescent, with lobes subequally long; outer calyx lobes lanceolate, 3.5–5.7 × 1.3–1.65 mm, enlarging to 6.1 × 2.2 mm with fruit, acute to acuminate, without ridge, outside strigose-pubescent, inside finely strigose with antrorse forked hairs on much of the surface;

inner calyx lobes oblong-ovate, 4.0–5.8 × 3.1–3.5 mm, usually cuspidate, outside strigose along the central vein and tomentose towards the margins, inside glabrous with few forked hairs at the apex. Petals obovate, 4–5.2 mm long, broadly bilobed. Stamens 5 or 6 (7), subequal, clustered on one side of the ovaries; filaments 0.4–0.6 mm long, basally connate; anthers broadly oblong, 1.3–1.4 mm long, ± abruptly constricted above and below. Pistils 2; ovaries obovoid but ± laterally compressed, each with 4 ovules, fascicled-tomentose, with style attached to the centrifugal apex of the ovary then after a short curve downwards straightening up on either side of the stamens with stigmas exposed above the anthers. Fruit puberulous with simple and multiangular hairs. Seeds oblong-obovoid to almost obloid, 1.6–2.0 × 1.4–1.5 mm, smooth, light brown; aril with fleshy base surmounted by one-sided membranous cup covering c. one quarter of one side of seed.

Additional specimens examined: NEW SOUTH WALES: Central Coast: R.Brown [J.J.Bennett 4873], "In occidental Sydney 1804" (BM); G.Caley s.n., "near South Head", viii.1802 (BM); Moorebank in western Sydney, J.Rodd & M.Stables, 19.x.2016 (NSW, 3 specimens); Moorebank in western Sydney, A.E.Orme 1572, 16.xi.2016 (AD, NSW).

2.2 LIFE CYCLE

The NSW Threatened Species Scientific Committee Final Determination for listing of *Hibbertia fumana* states that "Little is known about the life history of *Hibbertia fumana*. Seed production and plants of different ages were recorded within the only known population (A. Orme in litt. November 2016). The species does sucker (A. Orme in litt. November 2016) suggesting it may be able to resprout from rootstock following fire."

Peak flowering is recorded as spring to early summer, although the species appears to be capable of minor sporadic flowering at other times of the year as a response to suitable climatic conditions (Miller pers. obs.).

2.3 DISTRIBUTION AND ABUNDANCE

Historically the species was collected by Caley "near South Heads", eastern Sydney, in 1802, by Robert Brown in 1804 "occidental Sydney" and by Sieber 1823 "near Sydney New Holland".

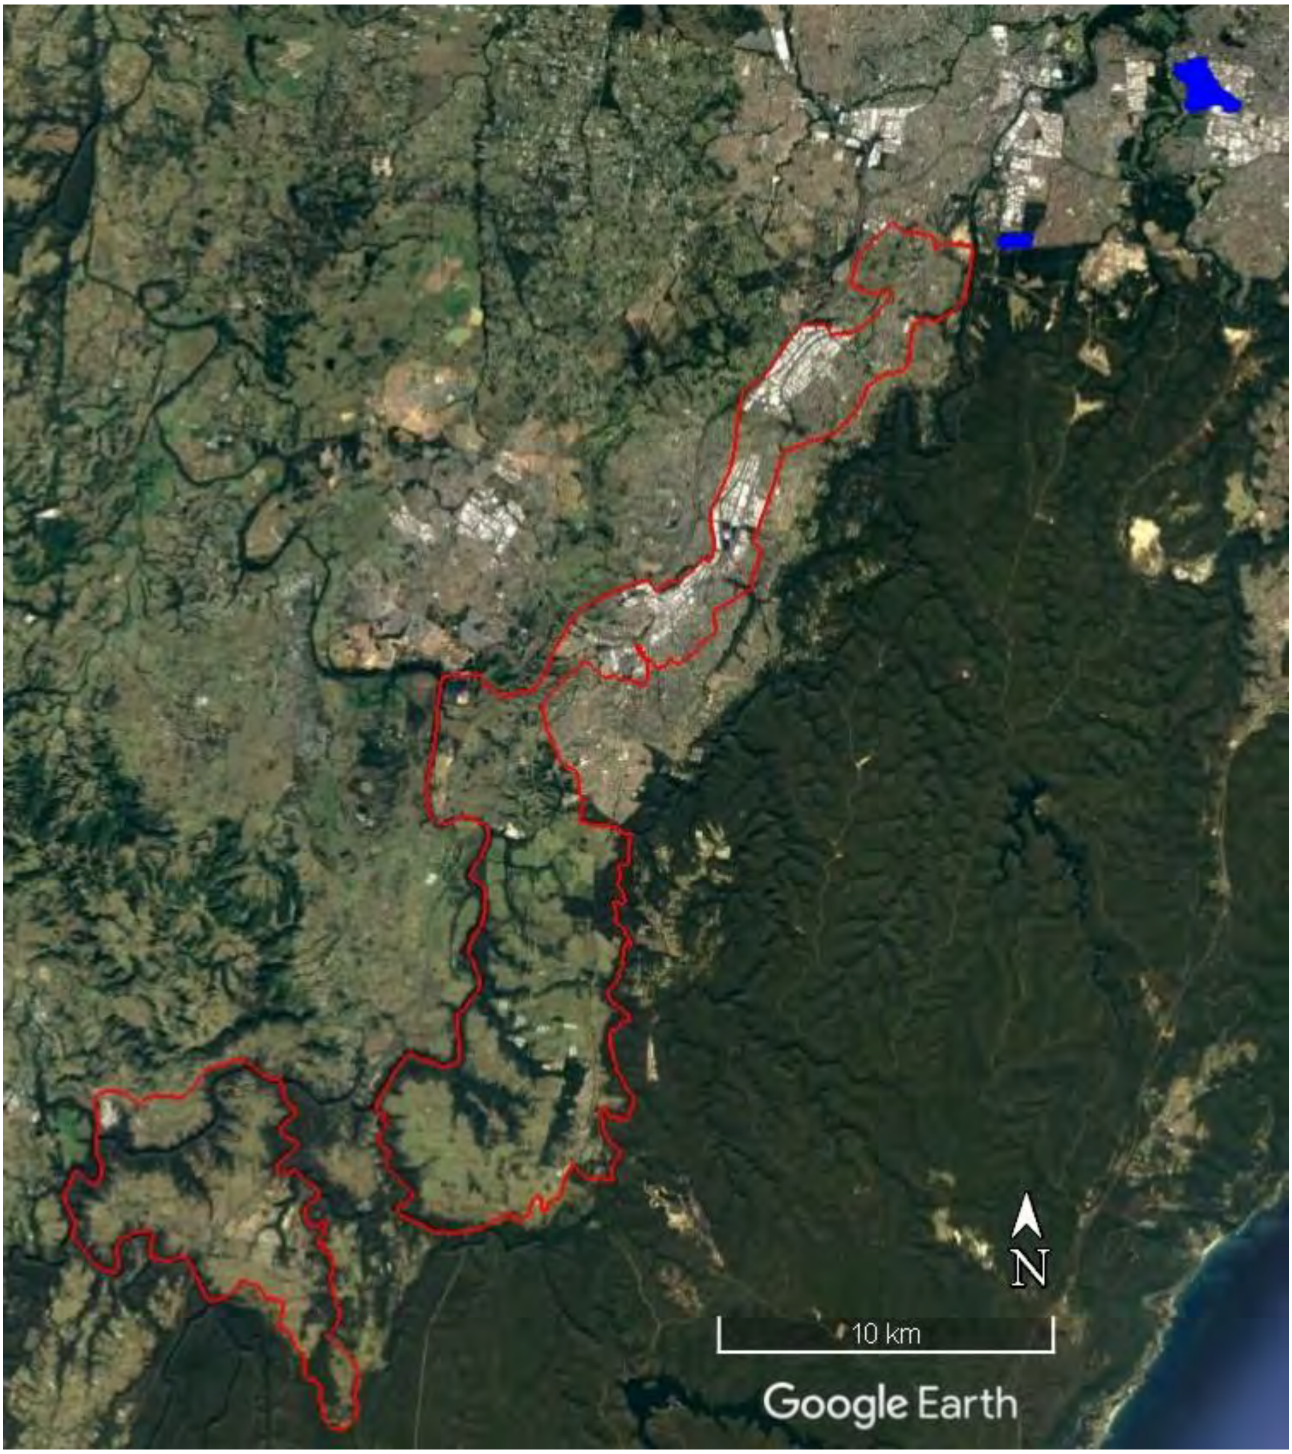
Recently a specimen from the Keith Ingram herbarium collection has been determined as most likely to be that species by Andrew Orme. It was collected at Connells Point in February 1941.

South Head and Connells Point are now highly urbanised environments and as such this diminutive species is unlikely to have persisted at either locale. If the species has persisted it is most likely so in the Connells Point environs. Targeted searches may be warranted in the Poulton Creek vicinity including Poulton Park.

Currently known from one extant population at Moorebank of c. 400 and an unknown number of plants in the Bankstown Airport vicinity.

At the time of the species listing in October-November 2016 (Arcadis and Parsons & Brinckerhoff Australia/New Zealand (WSP)) 370 plants were recorded at Moorebank and a further "approximately 29 plants" were recorded in September 2017 (Arcadis and Cumberland Ecology).

The impact upon the population at the Moorebank site from an intense fire in April 2018 is unknown.



Map 4: Indicative area of *Hibbertia fumana* populations.

Key - Areas of known *H. fumana* populations (blue) and the Wilton and Greater Macarthur growth areas (red).

2.4 HABITAT REQUIREMENTS

Historic collections

The *Hibbertia fumana* profile states: “Habitat of an 1802 Caley collection 'near South Head' are uncertain, with potential communities in that area including coastal shale sandstone communities and open forest or forest communities on lateritised shale lenses. No similar alluvial sand deposits are identified in that area.” (OEH 2018)

It is speculated by Miller that the most likely habitat for the Caley collection is transitional vegetation associated with “Swamps” or wet heath, especially the transition from shale influence communities to heath and/or open woodland. Although unsuitable habitat now, the Woollarah Golf Course site is likely to have consisted of a mosaic of vegetation types including swamp transition to woodland and the original habitat at Centennial Park is well documented “Originally a swamp and then set aside as land for the water source for Sydney, Centennial Park” (Centennial Park Trust). The diverse micro-habitats at Centennial Park supported numerous now locally rare or endangered taxa including *Hibbertia virgata E.Cheel NSW 86014*, Centennial Park, ix.1900 (NSW); and *A.A.Hamilton NSW 86016*, Centennial Park, 23.viii.1912 (AD, NSW) (Toelken in. prep.) and it is likely to have also supported *Hibbertia fumana*.

Extant populations

The OEH website states that *Hibbertia fumana* is known to be associated with the following vegetation formations and classes:

Dry sclerophyll forests (shrub/grass sub-formation) - within the Cumberland Dry Sclerophyll Forests class *Hibbertia fumana* is associated with

- Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain and Sydney Basin Bioregion and
- Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion

Dry sclerophyll forests (shrubby sub-formation) - the Vegetation Types that *Hibbertia fumana* is associated within the Sydney Sand Flats Dry Sclerophyll Forests class include

- Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion and
- Parramatta Red Gum woodland on moist alluvium of the Cumberland Plain, Sydney Basin Bioregion

At Bankstown Airport the AVH record states that the “Site is heavily managed and is routinely slashed to a height of about 10cm. Soils are grey heavy clay with ironstone fragments present at surface. Other native species observed indicate a derived form of Cooks River / Castlereagh Ironbark forest community. Main weed observed *Eragrostis curvula*.”

Photo 4: Indicative habitat of *Hibbertia fumana* at Bankstown Airport, regularly slashed.

At the Moorebank site the species is found growing in the transition zone between Castlereagh Ironbark Forest and Castlereagh Scribbly Gum woodland in open forest of *Eucalyptus sideroxylon, E. fibrosa, E. parramattensis, E. sclerophylla* and *Melaleuca decora* with a diverse understorey of shrubs including *Hakea sericea, Callistemon linearis, Bursaria spinosa, Grevillea parviflora* subsp. *parviflora, Acacia brownii, Acacia bynoeana, Pultenaea retusa, Pultenaea villosa, Hibbertia puberula* subsp. *puberula* and *H. aspera* subsp. *aspera*. The herb/grass layer is dominated by *Goodenia hederacea, Dianella revoluta, Thysanotus, Gonocarpus, Poa, Stylidium graminifolium, Patersonia, Themeda, Diuris* and *Microtis* (Telopea 2017).

Prior to the recent fire, the density of the understorey was variable across the site and ranged from sparse to extremely dense especially within the long-unburnt sections of the Castlereagh Scribbly Gum woodland. The variation in density is presumed to be due to the fire history, localised clearance events including recent remediation works, as well as minor changes in topography and drainage especially in swales.

In general, the topography of the land is described as flat although this is disrupted by the passage of Anzac Creek and by numerous minor depressions or swales likely to be remnants of past creek alignments and/or overflow channels that support Castlereagh Swamp Woodland. These swales and minor excavations / scrapings form small ephemeral pondages.

From limited brief inspections *Hibbertia fumana* was observed to be of sporadic occurrence across the site and appeared to be absent from ephemeral pondage locales preferring open slightly higher ground. Soils are described as fine sandy clay loam, grey brown in colour.

2.5 ANTHROPOGENIC THREATS TO THE HABITAT

Threats to the habitat of *Hibbertia fumana* that are relevant to sites within or adjacent to urban development include:

- Loss of habitat. Loss of the existing habitats across much of the distribution has occurred and may occur for as-yet-missed populations of the species.
- The Moorebank population consists of approximately 370 individuals only.
- Development of the adjacent lands at Moorebank for a major transport hub may affect the plants, and there is a rarely-used railway line bisecting the site. At Bankstown airport infrastructure development could impact the population.
- Fire either too frequently (limiting recruitment) or too rarely (allowing midstorey thickening) are likely to impact the species.
- Clearing for fire protection zones and infrastructure works could remove habitat.
- Damage to habitat by trail biking, 4WDs and mountain bikes.
- High densities of weeds and invasive grasses occur at the top of ridgelines; there is significant potential for encroachment into areas where the species occurs.
- A number of weeds are likely to impact on the plant, with particular concern for low shrubs, dense shrubs and smothering grasses.
- Changes to hydrological processes can impact habitat by reducing subsoil infiltration, drying out seepages, or concentrating flow paths through habitat.
- Nutrification can increase weed potential.
- Road maintenance and slashing works.

Field inspection of bushland remnants in the heavily urbanised sectors of GMGA provide irrefutable proof of severe degradation arising from anthropogenic impacts and urbanisation (refer photos 4 through 8). Without exception, all creeks and many of the remnants were heavily weed infested arising from a range of factors not limited to nutrification, stormwater discharge, garden refuse and fill dumping and exotic seed dispersal by various vectors.

Damage to zones adjacent urban development can also be caused by clearing for fire hazard reduction, control burning frequently, and recreation activities such as 4WD vehicle access, mountain bikes and kids' cubby house building.

Photo 5: Control burn at Bunbury Curran Park, Macquarie Fields.

Photo 6: Chronic weed infestations characterise the riparian zone of Bunbury Curran Creek.

The photo above was taken in the southwestern corner of Bunbury Curran Park west of TAFE NSW Macquarie Fields.

Weeds include: Balloon Vine (*Cardiospermum grandiflorum*), Fennel (*Foeniculum vulgare*), African Olive (*Olea europaea* subsp. *africana*), Large-leaved Privet (*Ligustrum lucidum*), Small-leaved Privet (*Ligustrum sinense*) Kikuyu (*Pennisetum clandestinum*), African Lovegrass (*Eragrostis curvula*), Rhodes Grass (*Chloris gayana*), Mothvine (*Araujia hortorum*), Honeysuckle (*Lonicera japonica*), Wild Tobacco (*Solanum mauritianum*) and Blackberry (Rubus fruticosus aggregate).

Hibbertia fumana is a small shrub that would not survive in bushland that is severely weed infested, or that is severely burnt on a regular basis.

Photo 7: Pembroke Park Impacts of urbanisation - invasive weed species dominate the shrub, vine and ground layers.

Photo 8: At Pembroke Park Red Ash (*Alphitonia excelsa*) and Forest Red Gum (*Eucalyptus tereticornis*) cut down to construct bike jumps and cubby houses and the shrub layer cleared.

Photo 9: Smith's Creek Reserve typical condition of bushland adjoining residential properties on the southern side of Smith's Creek, highly weed degraded, cleared for hazard reduction, fill and refuse dumping.

3. Description of the study area

3.1 LAND USE HISTORY

The Cumberland Plain was first occupied by the Aboriginal peoples, who enjoyed a plentiful supply of fresh water and foods including fruit, tubers, fish, animals, birds and honey (Hills District Council website).

With the arrival of Europeans, land-use changed to timber gathering and agriculture, permanently altering the landscape. Particularly since the end of the Second World War urban settlement and industry have expanded west from Sydney into the Cumberland subregion. Over the last 40 years many rural properties have been subdivided as lifestyle and hobby farm properties.

Currently there is great pressure for further residential development to the west of Sydney in the Cumberland subregion.

3.2 LANDSCAPE CONTEXT

The changes in land use have caused the clearing of a large proportion of the natural bushland of the Cumberland subregion. In 2011 the Cumberland Plain Recovery Plan stated “Only 13% of the pre-1750 extent of the region’s vegetation remains as intact bushland, with an additional 12% occurring as scattered trees in disturbed areas (NPWS 2002). Consequently, much of the region’s biodiversity is listed as threatened under State and/or Commonwealth legislation.”

Widespread clearing of the remaining habitat has continued with much of the extant vegetation now being assessed as Critically Endangered. Previously recorded from South Head and Western Sydney, *Hibbertia fumana* appears to have suffered a reduction in range caused by urbanisation.

3.3 NATIVE VEGETATION

Since 2011 there has been further clearing, there are now 15 vegetation communities that are listed as Critically Endangered, Endangered or Vulnerable in the Cumberland Plain.

The Cumberland Plain Recovery Plan states that “there are seven threatened species, four endangered populations and nine threatened ecological communities listed on the NSW *Threatened Species Conservation Act* 1995 that are found only on the Cumberland Plain. Seven of these are also listed as threatened under the Commonwealth *Environment Protection and Biodiversity Conservation Act* 1999.” The remaining bushland is highly fragmented and much of it occurs on private lands.

Within the GMGA and the WGA eleven Plant Community Types (PCTs) are mapped (mapping provided by the NSW Department of Planning and Environment). These PCTs are:

- Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion, PCT 830

- Forest Red Gum – Rough Barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion, PCT 835
- Grey – Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion. PCT 849
- Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion. PCT 850
- Grey Myrtle dry rainforest of the Sydney Basin Bioregion and South East Corner Bioregion. PCT 877
- Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion. PCT 883
- Red Bloodwood – Grey Gum woodland of the Cumberland Plain, Sydney Basin Bioregion. PCT 1081
- Red Bloodwood – Scribbly Gum heathy woodland on sandstone plateau of the Sydney Basin Bioregion. PCT 1083
- Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion. PCT 1181
- Water Gum- Coachwood riparian scrub along sandstone streams, Sydney Basin Bioregion. PCT 1292
- Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion. PCT 1395

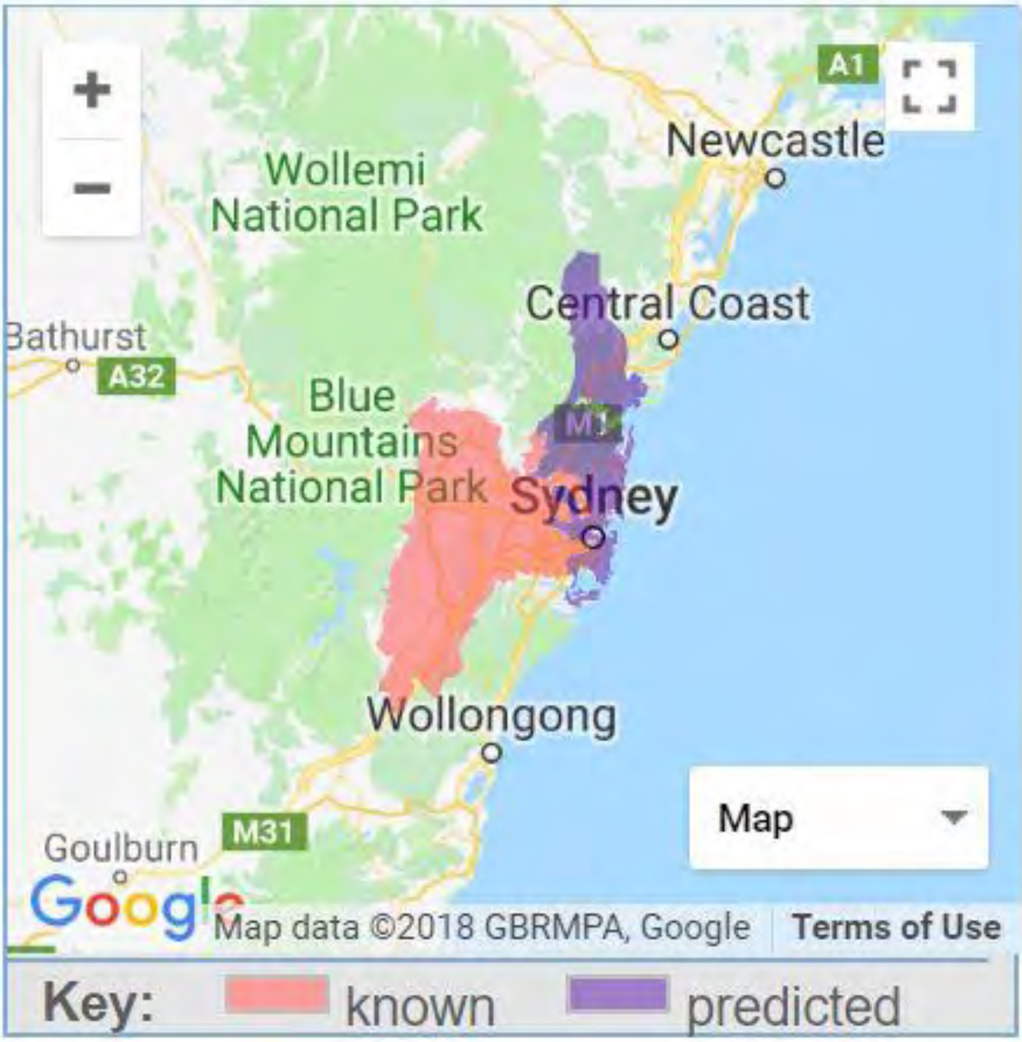
3.4 POTENTIAL HABITAT

Within the Sydney Basin bio-region *Hibbertia fumana* is known from the IBRA subregion of Cumberland and is predicted to occur in the Pittwater IBRA sub-region. No geographic constraints are currently listed for the species. The subregions of known and predicted occurrence are shown in **Error! Reference source not found.**. The areas shown in pink and purple are the sub-regions where the species or community is known or predicted to occur. They may not occur throughout the sub-region but may be restricted to certain areas.

The OEH species profile sheet states: “found in the transition zone between Castlereagh Ironbark Forest and Castlereagh Scribbly Gum woodland in open forest of *Eucalyptus sideroxylon, E. fibrosa, E. parramattensis, E. sclerophylla*”. The species has the potential to occur in similar intergrade alluvial habitats rich in sands and laterite in other parts of western Sydney.

Hibbertia fumana is currently known only from two locations in western Sydney. A single population at Moorebank and a single population in Bankstown (AVH record) but has the potential to occur elsewhere in greater Sydney.

At Moorebank it is found in areas of open woodland in a long intergrade between Castlereagh Scribbly Gum Woodland and Castlereagh Ironbark Forest. The AVH record for *Hibbertia fumana* at Bankstown records “Site is heavily managed and is routinely slashed to a height of about 10cm. Soils are grey heavy clay with ironstone fragments present at surface. Other native species observed indicate a derived form of Cooks River / Castlereagh Ironbark forest community."



Map 5: Known and predicted distribution of *Hibbertia fumana*.

Source OEH website 2018.

The habitat of an 1802 Caley collection 'near South Head' is uncertain, with potential communities in that area including coastal shale sandstone communities and open forest or forest communities on lateritised shale lenses. No similar alluvial sand deposits are identified in that area.

OEH has identified that *Hibbertia fumana* has the potential to occur in the following plant community within the Wilton and Greater Macarthur Growth Areas:

- 883 Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain

4. Assessment of species presence and suitable habitat

4.1 SPECIES RECORDS AND HABITAT ASSESSMENTS

Hibbertia fumana is poorly known and is site managed and assessed as data-poor. There are no records of the species within or adjoining the proposed growth areas. Only two known extant populations exist Moorebank c. 1.6 km to the north-east of the northern boundary of GMGA and approximately 36 km from WGA, and Bankstown Airport 9 km from the northern boundary of GMGA and approximately 41 km from WGA.

The broad scale vegetation assessment that has been carried out across the growth areas does not identify local scale habitat potential.

4.2 PRIOR SPECIES SURVEYS

Private land holdings comprise much of the lands within the GMGA and WGA, restricting access opportunities for botanical surveys and incidental sightings. This is a likely contributing reason for the lack of prior records of threatened *Hibbertia* species including *Hibbertia fumana* within the proposed growth areas.

From the information provided, no prior targeted searches have been undertaken for this species as part of the biocertification assessment process. One small area of mapped potential habitat (PCT 883) at Milton Park, Macquarie Fields was investigated by Biosis. The data provided is limited to that found within the spatial viewer.

The level of data is insufficient to base an assessment of presence/absence for a Critically Endangered species purely as a desktop study.

The Threatened Species Expert Report Overview spreadsheet, provided by DPE, shows that *Hibbertia fumana* was not recorded from the area mapped as PCT 883 in Milton Park based on the records of Bionet and Biosis and Ecoplanning consultant surveys. Nor was it found during surveys of the Greater Macarthur and Wilton Growth areas by these consultants.

CFFIS conducted a site inspection of Milton Park and the adjacent Macquarie Fields Leisure Centre. We found that the regional scale vegetation mapping could not provide the level of detail required to identify potential species habitat.

Local scale variations indicate the need for site-specific survey of the growth areas for *H. fumana* or its habitat.

Photo 10: Milton Park, the majority of the trees are *Eucalyptus tereticornis,* PCT 849 thinned.

Photo 11: Area between Macquarie Fields Leisure Centre and Macquarie Road, site is dominated by Ironbarks.

4.3 ASSESSMENT OF SPECIES PRESENCE

The previous survey data provided by Biosis and Ecoplanning Consultants was insufficient to assess the probability of occurrence of *Hibbertia fumana* from a desk top study. The species has demonstrated an ability to persist within suitable derived habitat, it was therefore appropriate to undertake specific targeted surveys.

The area mapped as PCT 883 and surrounds were surveyed by CFFIS for the species. We also surveyed for habitat appropriate to the species in areas of potential tertiary sediments and shale sandstone interface across the growth areas and adjacent lands, based on geology, soils and landform maps where access was provided.

4.3.1 LIKELIHOOD OF SPECIES PRESENCE

The possibility of *Hibbertia fumana* occurring within the GMGA is assessed as low because potential habitat sites with similar attributes to known extant sites are highly modified and of limited extent. However, the presence of this species cannot be dismissed entirely on disturbance factors because the Bankstown Airport population survives in a highly modified environment. Bannerman and Hazelton (1990) in *Soil Landscapes of the Penrith 1:100,000 Sheet* map the entire site as disturbed terrain, although field observation by Miller and others have identified areas to retain the original soil profile.

There are no habitats similar to the known extant sites mapped as occurring within the WGA. The possibility of those PCT's being undocumented within WGA is assessed as negligible.

Historic occurrence records indicate the species could also be found "in coastal shale sandstone communities and open forest or forest communities on lateritised shale lenses" (OEH Threatened Species Profile). Large tracts of shale sandstone interface exist within the WGA and GMGA. Therefore, the potential for suitable habitat for the species within the WGA, and other areas of the GMGA, although unlikely, cannot be dismissed.

Hibbertia fumana is currently assessed as being Critically Endangered and is data -poor. In this context, a precautionary approach is recommended. Locating and protecting new populations, no matter how small, is significant to the survival of this species.

4.3.2 JUSTIFICATION FOR DETERMINATION

Greater Macarthur Growth Area

Just one small area of known habitat PCT 883 is located in the Milton Park area at Macquarie Fields. This area was surveyed in June and July and the species was not found. Milton Park is intensively managed for recreation, however further survey during the species flowering period would be appropriate.

Hibbertia fumana is reported to occur at Bankstown Airport within a highly modified environment that is “routinely slashed to a height of about 10cm” resulting in a “derived form of Cooks River / Castlereagh Ironbark forest community. Main weed observed *Eragrostis curvula*.” (AVH). This new record demonstrates that the species can be found on differing soils to that of the Moorebank occurrence.

The Bankstown occurrence provides evidence that the species can persist within a suitable derived habitat. It is therefore possible that *H. fumana* could occur within the GMGA. If it does occur, it is most likely in a transitional vegetation zone either between shale / alluvial or shale / sandstone environs. Limited potential habitat areas occur within the GMGA.

Shale alluvial transitional sites may include potentially inadequately surveyed areas in the Menangle Park vicinity and other areas in the northern sector of GMGA, especially those now modified to a derived grassland environment.

Shale / Sandstone transitional vegetation occurs in the middle and southern sectors of GMGA but is mostly confined to above the escarpment edges of the various creeks and rivers. Scattered occurrences of sandstone outcroppings have been noted elsewhere including in the northern sector of the GMGA, for example, at Milton Park and Kayess Park at Ingleburn.

One record of *Hibbertia riparia* (which could potentially be *H. fumana* and/or *H. puberula*) is noted at Appin, the co-ordinates placing the occurrence in Shale / Sandstone transition.

<u>Milton Park environs</u>

The vegetation remnants in Milton Park vicinity are variously mapped as PCT 835 along the unnamed branch of Bunbury Curran Creek and PCT 849 Grey Box – Forest Red Gum grassy woodland elsewhere with the exception of a small area to the north of Macquarie Road and south of Bingara Road which is mapped as PCT 883 Hard-leaved Scribbly Gum – Parramatta Red Gum woodland.

Site inspection revealed that some areas of vegetation in the vicinity of the Macquarie Fields Leisure Centre had Ironbark species dominating the upper canopy. Areas of ironstone gravel were noted. Other species observed included Woollybutt (*Eucalyptus longifolia*), *Cryptandra spinosa*, *Daviesia ulicifolia*, *Bursaria spinosa*, *Lepidosperma laterale*, *Kunzea ambigua*, and *Melaleuca decora*.

The area north of Macquarie Road mapped as PCT 883 and PCT 849 is comprised of a few clumps and scattered remnant trees of both *Eucalyptus sclerophylla* and *E. tereticornis* in a regularly slashed recreation reserve. *Eucalyptus sclerophylla* occurs, on the higher ground to the north on soils observed to have a high quartz content in association with the underlying sandstone plates. Scribbly Gum exists as approximately 1/3 of the areas of remnant trees. Scattered trees of *E. tereticornis* dominate the ephemeral creek / drainage line and are the major tree species in the remainder of the area.

The areas of remnant *Eucalyptus sclerophylla* are characterised by scattered sandstone plate outcroppings and relatively sandy soil. Hard-leaved Scribbly and *Angophora bakeri* / *floribunda* intergrade are likely to have covered much of the site extending to the west to near the sports fields where sandstone outcropping is prominent. Dense mown swathes of *Eragrostis curvula* dominate the ground layer and unmown tussocks the tree bases. Apart from one clump of *Kunzea ambigua* and sapling Eucalypts, few other native species noted had more than one to a few individuals surviving above ground. Twelve native species were observed mostly at the bases of some remnant trees.

Map 6: Image of areas containing likely habitat at Milton Park and Macquarie Road Reserve.

The moister drainage line to the south and the gentle rise to Macquarie Road is dominated by *Pennisetum clandestina*, *Eragrostis curvula* and assorted other weeds, no native understorey species were observed in this mown environment.

It is unknown whether *Eucalyptus parramattensis* exists or existed at this site.

The polygon mapped as 883 is highly disturbed and it is unlikely that this area would now support an occurrence of *Hibbertia fumana.* However, as Ironbark is dominant in the adjoining Macquarie Field Leisure Centre area adjacent Macquarie Road, it is likely that a transitional vegetation type previously existed between the Ironbark, Forest Red Gum and Scribbly Gum Woodland in this vicinity that may have supported *Hibbertia fumana* and/or *H. puberula.*

As a precaution it is recommended that a targeted search be undertaken under non-drought conditions in the species peak flowering season by an experienced *Hibbertia* specialist.

Kayess Park environs

Biosis mapped Kayess Park environs to support Intact PCT 835 - Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion, 849 - Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion and Cumberland Plain Urban Native / Exotic.

Site inspection of the 20 July 2018 determined that PCT 835 mapped along the creek lines was unsuitable habitat for *H. fumana*.

An area of Ironbark occurs in the central area which grades into Grey Box - Forest Red Gum and Ironbark in the western portion. A fire was noted to have impacted much of the site especially the grassland area. This was evidenced by burnt Blackberry canes, bases of many Whisky Grass tussocks and dead *Acacia decurrens*.

The park is cleared and very weedy across much of the location especially on the more fertile shale derived soils. Localised sandstone outcroppings are apparent, and areas of sandy soil also present in the derived grassland. The sandstone influence extends upslope into the Ironbark forest environs but appears absent within areas supporting Grey Box and Forest Red Gum.

In general *Eucalyptus tereticornis* dominates eastern creek slopes. Ironbark species dominate sandstone influenced ridge top, including *Eucalyptus beyeriana*. The northwest corner is dominated by *Eucalyptus tereticornis, E. moluccana* and *E. crebra*?

In the context of its size and location much of the “intact” remnant vegetation is in reasonable condition. Sections of the remnants have a lot of rubbish dumping and weed invasion especially along drainage lines.

Potential threatened *Hibbertia* habitat occurs in the sandy soil at and below sandstone outcroppings including the derived grassland. Prior to clearing the sandy soil may have supported a small localised area of Scribbly Gum woodland as found at Milton Park or a localised variant of Shale Sandstone transitional vegetation.

Map 7: Image of area containing likely habitat at Kayess Park.

Species noted within the burnt derived grassland include: *Centella asiatica, Tricoryne elatior, Drosera hookeri, Goodenia paniculata, Juncus* sp., *Cheilanthes sieberi, Acacia decurrens, Themeda australis, Lomandra filiformis* subsp. *coriacea*, *L. multiflora*, *Microlaena stipoides, Eragrostis brownii*, *E. leptostachya*, *Dianella caerulea, D. revoluta, D. longifolia, Crassula sieberiana., Hibbertia diffusa*, *Opercularia diphylla*, *Helichrysum apiculatum*, *Einadia hastata*, *Bursaria spinosa.*

At the time of inspection, the most prominent weeds were African Lovegrass (*Eragrostis curvula*), Whisky Grass (*Andropogon virginicus*) and Blackberry. A wide variety of other pasture species were noted to have occasional occurrence including Fleabane (*Conyza* sp.), Fire Weed (*Senecio madagascariensis*), Catsear (*Hypochaeris* sp.) and Rambling Dock *(Acetosa sagittata)*.

<u>Menangle Park Paceway environs</u>

From data provided no targeted surveys were undertaken for threatened species within and to the north of Menangle Park Raceway environs. One BAM plot and one fauna survey within the immediate riparian zone of the Nepean River provides the only survey data undertaken for the biocertification assessment for this area.

A brief site inspection of the Menangle Paceway revealed a highly modified environment with some areas of potential habitat for the species. Relictual terraces and associated swales were noted. Native species were observed to exist in a number of locales even in areas routinely slashed and used for activities associated with horse racing. Soils ranged from alluvial to laterised clays.

The area to the north of Fitzpatrick Street was not inspected but viewed from a distance. It is assessed as likely to contain potential habitat, but the species composition of the ground layer remains unknown.

A Klaphake, V. 1992-05-10 record for *Drosera burmannii* describes land to the north in the vicinity of Fitzpatrick street as “Pasture near railway line N, 200 m below Fitzpatrick St, Menangle Park. In swampy pastureland on sloping land with *Eleocharis minuta*, *E. atricha*, *Lipocarpha microcephala*, *Ranunculus inundata*. Growing on the edge of the swamp in damp soil. Soil sand-based.”

Banksia integrifolia is the primary species for the Elderslie Banksia Scrub Forest which is described as “generally associated with alluvium of Tertiary age, on soils which are sandy, with drainage varying from good to poor (Benson 1977). *Banksia integrifolia* is a species component of the sandy tertiary sediments of Bankstown Airport environs especially adjacent to the *Hibbertia puberula* subsp. *glabrescens* population.

The known Bankstown Airport occurrence is reported from soils that are “grey heavy clay with ironstone fragments present at surface” (AVH) and sandy tertiary alluvium is known to be present at some locales.

There is a similarity between the Bankstown Airport environs and the Menangle Park site as both contain alluvial deposits adjacent shale communities.

Map 8: Image of areas containing likely habitat at and adjacent to the Menangle Park Paceway.

Bunbury Curran Creek vicinity

Several areas of Bunbury Curran Creek vicinity have potential habitat for rare *Hibbertia* based on implied habitat derived from historic records.

Map 9: Image of areas containing potential habitat at Bunbury Curran Creek, based on habitat inferred from historic collections.

Wilton Growth Area

The possibility that *Hibbertia fumana* occurs within the WGA sector is uncertain but cannot be ruled out due to the implied habitat derived from historic records. The OEH Threatened Species Profile indicates the species could be found on shale sandstone interface. Shale / Sandstone transitional vegetation is widespread throughout the WGA.

Hibbertia fumana is most unlikely to occur within the proposed urban footprint. The majority of proposed urban footprint is confined to the Wianamatta Shale derived soils which on current knowledge is unsuitable habitat for the species. Much of this land was known, in part, as the Cowpastures and were amongst the first lands to be cleared for agriculture purposes with European occupation. The native ground layer in many of these areas has been replaced by exotic species.

Within the growth area and adjacent the development footprint, we note that the Biosis quadrat Plot B27, near the Georges River at Wilton, records the following species: "Euca punc 15%, Euca fibr 1%, Ango baker 1%, Euca spar 5%, Euca parr 1%, Kunz amb 25%, Call line 1%, Ento stri 15%, Aris vagan2%, Loma fili 1%, Loma mult 0.3%, Aust pube 0.2%". The presence of *Callistemon linearis* and *Eucalyptus parramattensis* indicate a periodically moist environ within the transitional vegetation which may support several threatened taxa such as *Grevillea parviflora* and *Hibbertia puberula*. Both taxa co-occur at the Moorebank site with *H. fumana*. *Epacris purpurascens* is also likely to occur in the vicinity.

A L.A.S Johnson record for *Eucalyptus parramattensis* supports the presence of Parramatta Red Gum in the general area: Douglas Park, 0.75 miles [1.1 km] S of Nepean River, on east rim of gorge. Habitat: Somewhat lateritic soil at edge of shale and sandstone. In regrowth with *Angophora oblonga*, *E. fibrosa*, *Acacia glaucescens*.

It is unknown whether Threatened *Hibbertia* taxa exist in this general locale as access so far has not been granted.

4.4 ASSESSMENT OF SUITABLE HABITAT

The assessment of suitable habitat has been described in section 4.3, assessment of species presence, because the survey during the non-flowering period required the presumption that if suitable habitat were present then the species could also be present.

The species could be present in areas of shale / sandstone transition, in microhabitats such as seepage zones below or above sandstone outcrops. Broad scale vegetation survey and mapping do not identify habitats at this scale. Survey during the flowering season is recommended.

4.4.1 DETERMINATION OF SPECIES POLYGONS

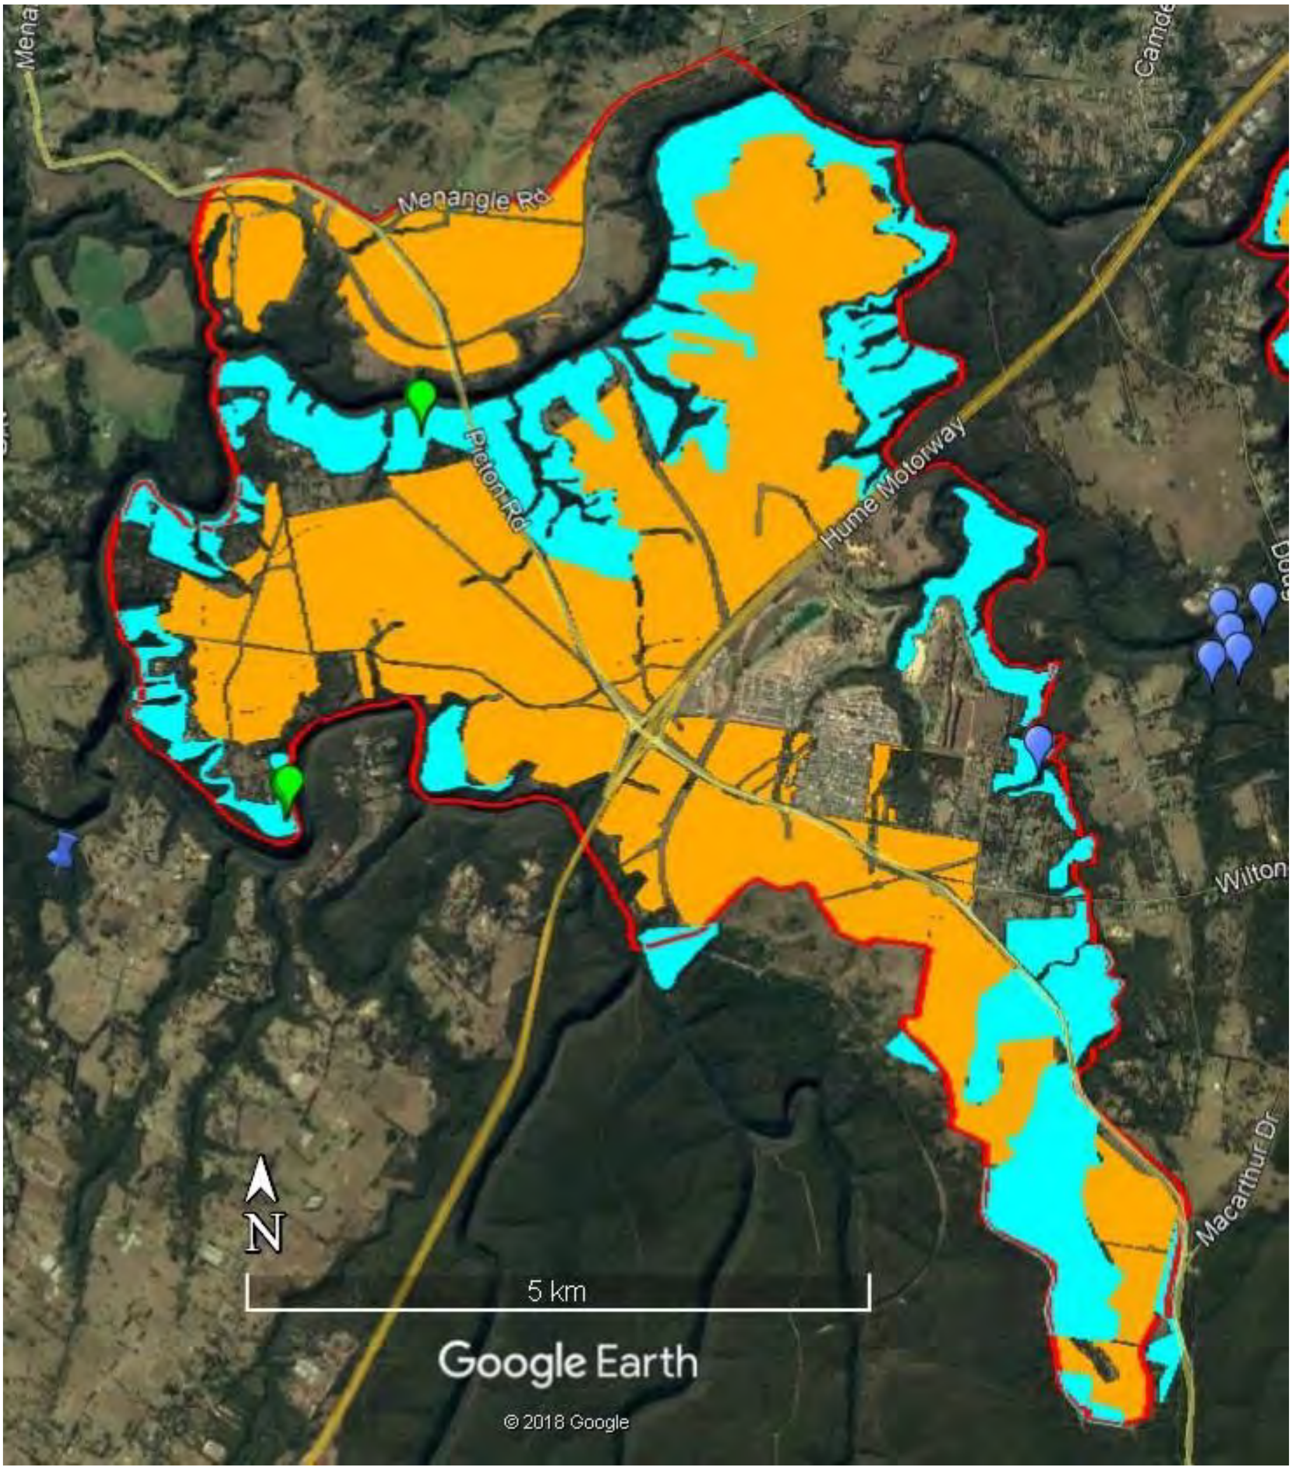
Determination of potential habitat for *Hibbertia fumana* includes areas identified outside but adjacent to the deemed biocertification area. Anthropogenic impacts are well documented to adversely affect vegetation well beyond the direct urban footprint (refer section 2.5).

Maps 10 to 13 show an overview of areas containing likely and potential habitat of *Hibbertia fumana* within the GMGA and WGA. The areas shaded in yellow are habitats assessed as having attributes similar to known extant populations and the entire area should be considered likely habitat. The polygons shaded in blue are based on broad scale mapping units both vegetation and soils and are indicative that potential habitat niches may exist within those areas. The habitat niches are inferred from historic records only.

Mixed native / exotic derived grassland / herbland including *Themeda australis* & *Hibbertia diffusa* that is likely habitat at Menangle Park Paceway vicinity.

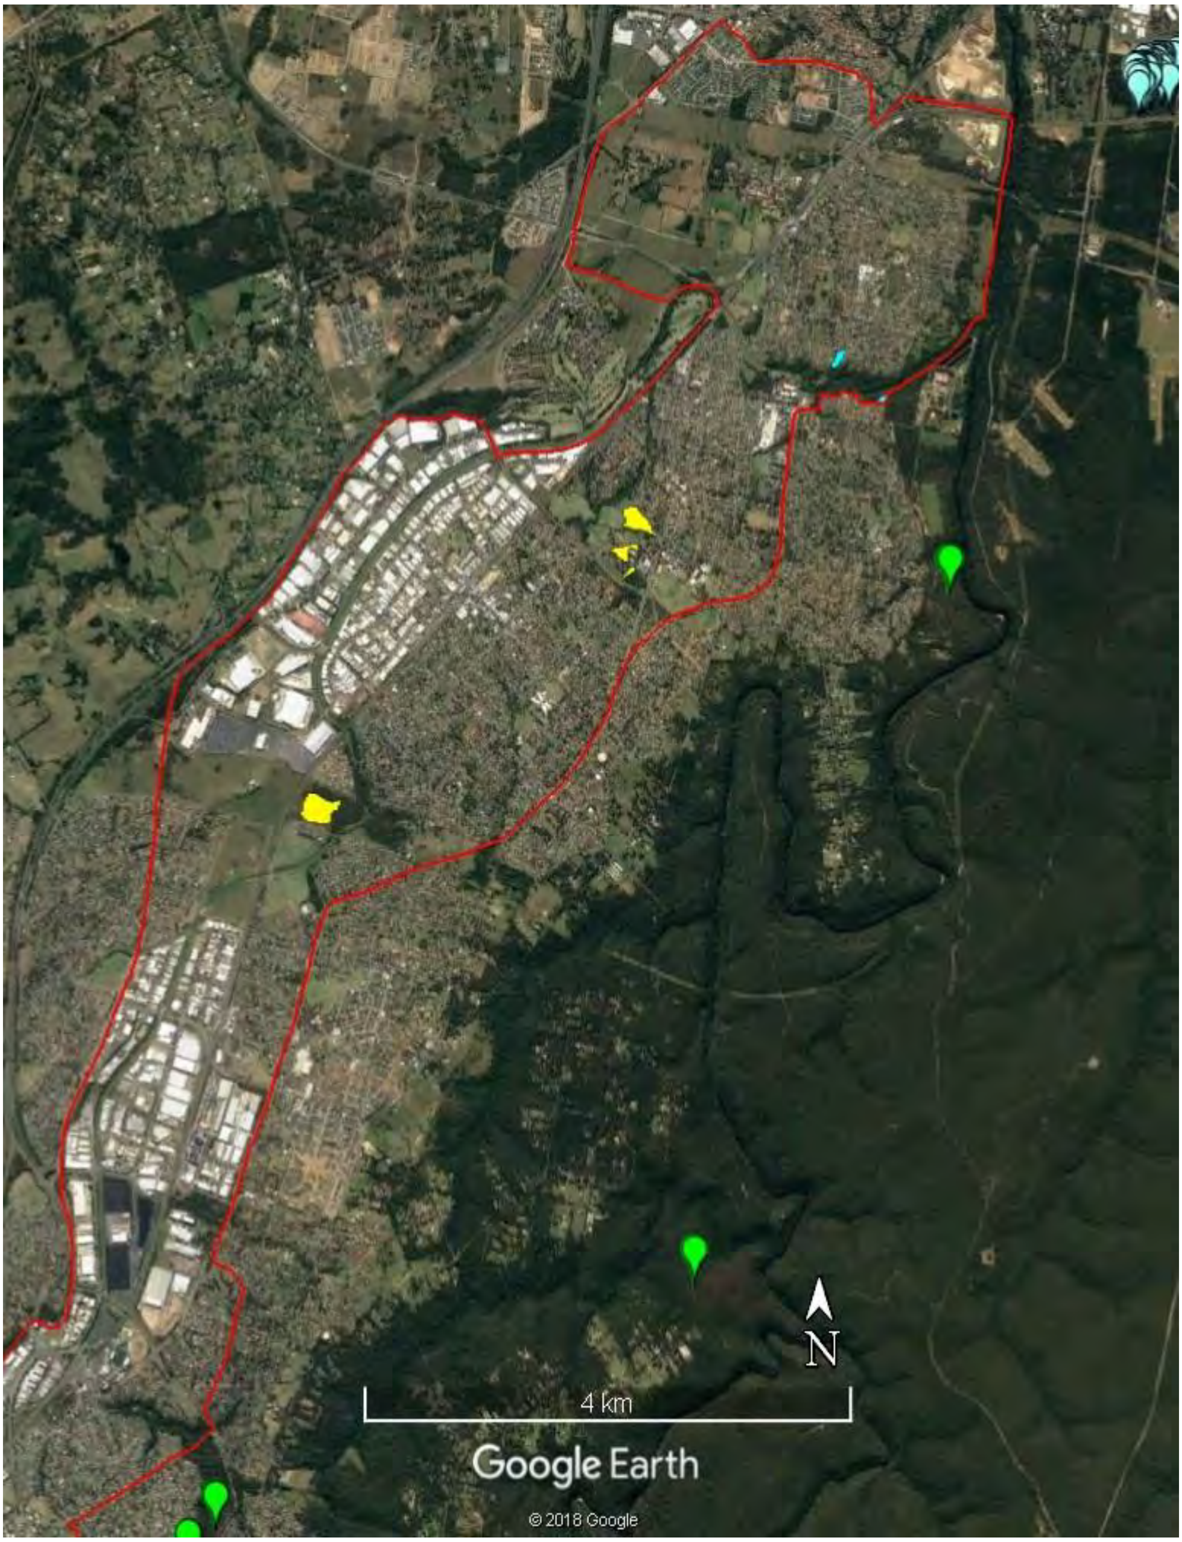
Areas of indigenous shrubs including *Melaleuca erubescens*, *Dillwynia seiberi*, *Pultenaea villosa*, *Daviesia ulicifloia.* This is a habitat that may also support *Hibbertia fumana*.

Photo 12: Indicative of likely habitat in the Manangle Park Paceway vicinity.



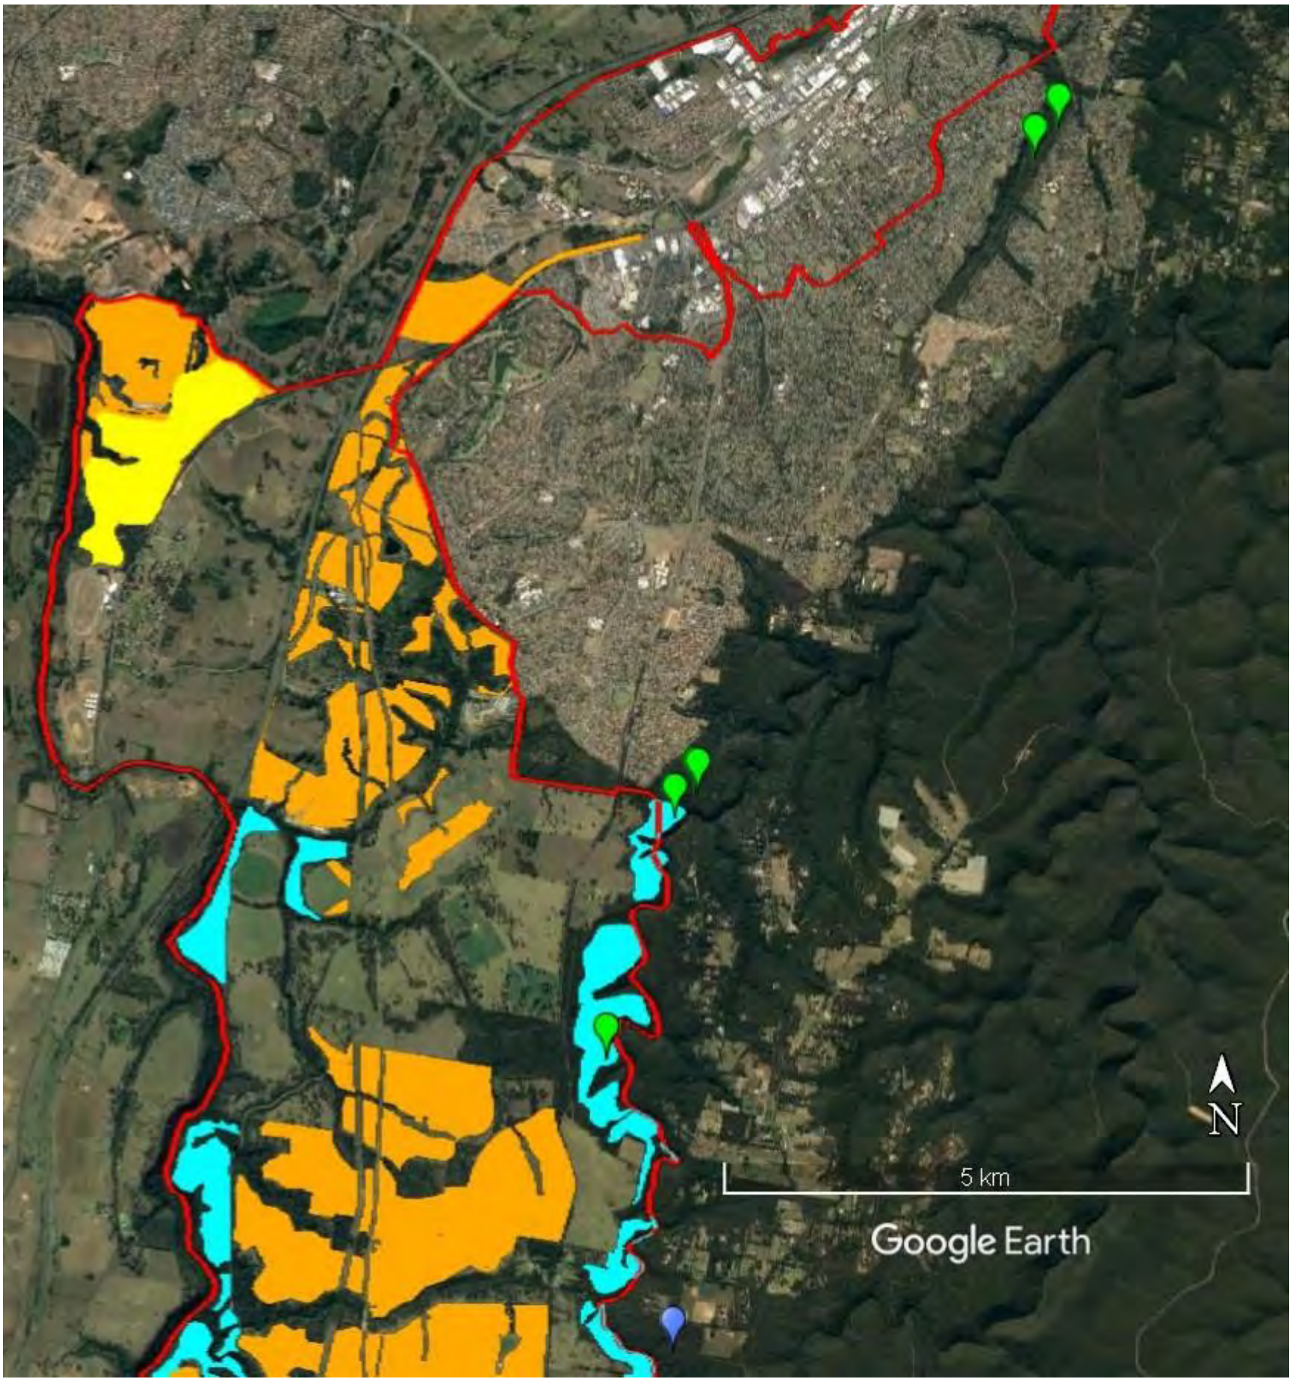
Map 10: Areas containing potential habitat in the Wilton Growth Area.

Key: Red – outline of growth area, blue – areas of potential habitat niches, orange – growth area footprint, green dots – locations of *Hibbertia puberula?* plants, purple dots – records of *Hibbertia riparia*.



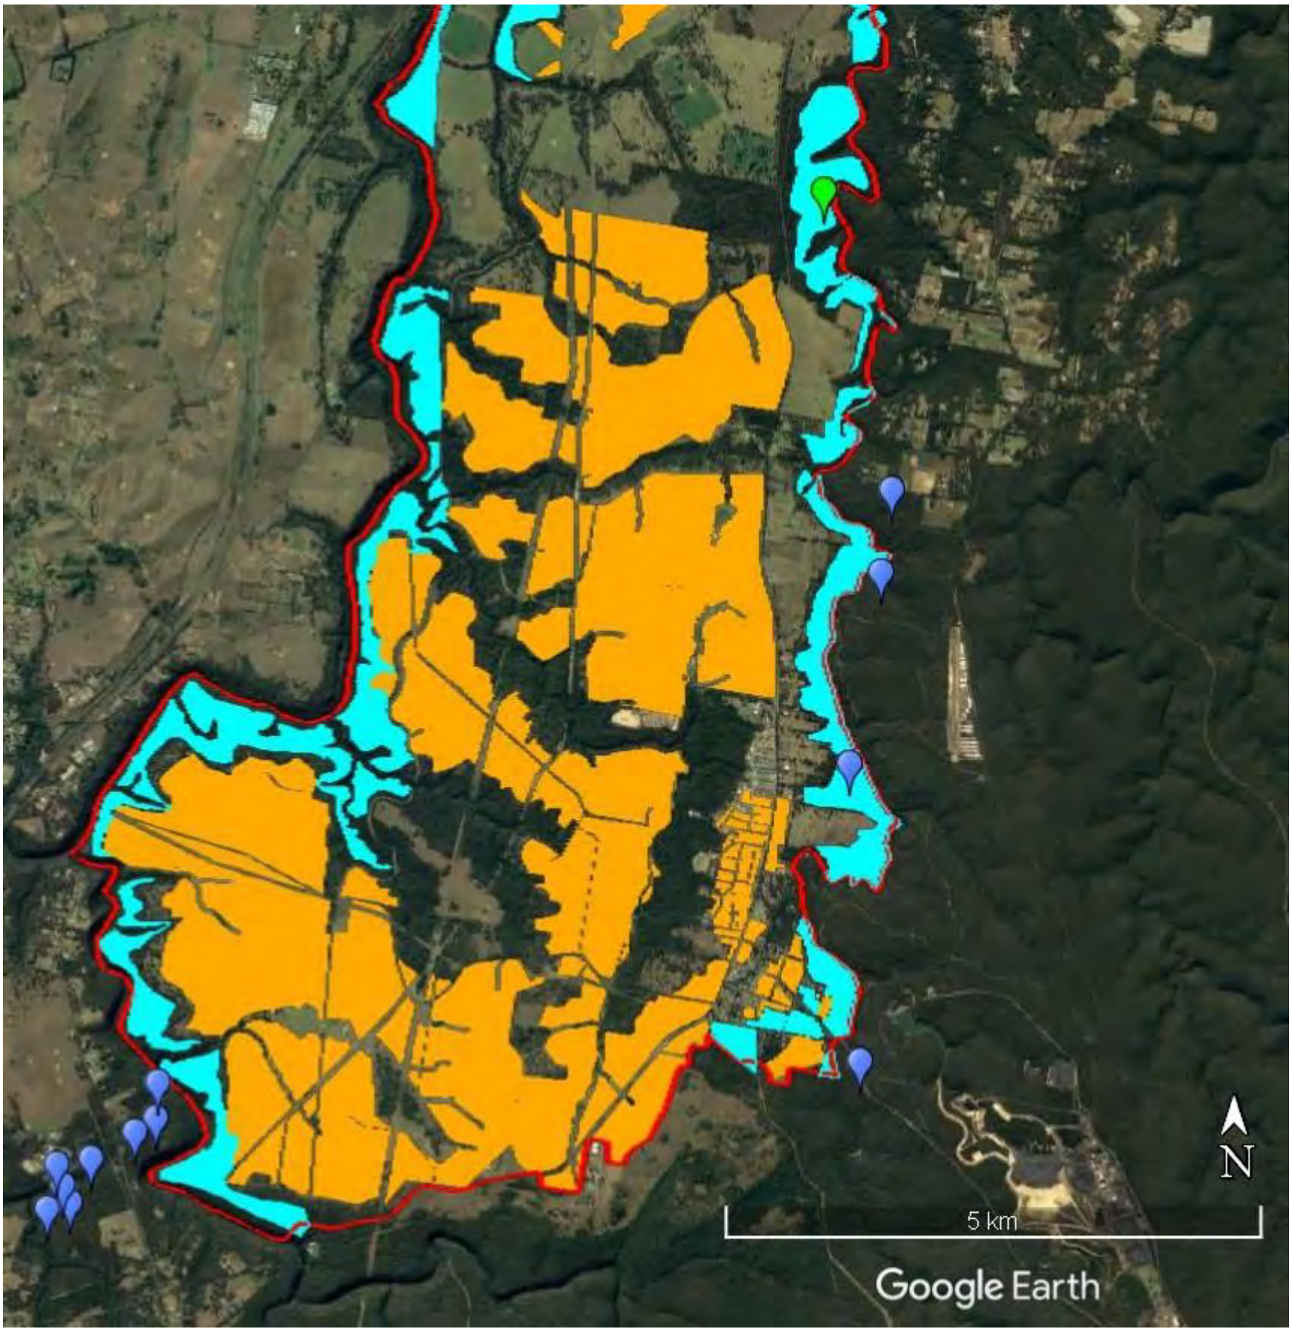
Map 11: Areas of likely habitat, north section of Greater Macarthur Growth Area.

Key: Red –outline of growth area, yellow – areas of likely habitat, blue – areas of potential habitat niches, green dots – locations of *Hibbertia puberula?* plants, blue dots (top right of map at Moorebank) – records of *Hibbertia fumana*.



Map 12: Areas of potential habitat, middle section of Greater Macarthur Growth Area.

Key: Red –outline of growth area, yellow – areas of likely habitat, blue – areas of potential habitat niches, orange – growth area footprint, green dots – locations of *Hibbertia puberula?* plants, purple dots – records of *Hibbertia riparia*.



Map 13: Areas of potential habitat, southern section of the Greater Macarthur Growth Area.

Key: Red – outline of growth area, blue – areas of potential habitat niches, orange – growth area footprint, green dots – locations of *Hibbertia puberula?* plants, purple dots – records of *Hibbertia riparia*.

4.4.2 JUSTIFICATION FOR DETERMINATION

The species likely habitat polygons for Milton Park, Kayess Park and Menangle Park in the GMGA are based on limited field inspections undertaken in adverse environmental conditions outside the flowering period. Therefore, the polygons are indicative only.

The majority of potential habitat polygons for the WGA are based on regional mapping data provided by DPE as access issues limited field inspection. Similar access issues arose with other potential habitat areas within southern and central portions of the GMGA. Unless indicated potential habitat polygons for the southern and central portions of the GMGA are also based on regional mapping data.

4.5 ESTIMATE OF AREA OF HABITAT OR NUMBER OF INDIVIDUALS

4.5.1 ESTIMATES

The assessment provides the following estimates:

- at Menangle Park an area of approximately 92ha that could contain likely habitat niches within the growth area footprint, and a further 31 ha of land containing likely habitat niches adjacent to the footprint.
- at Kayess Park and Milton Park – Macquarie Fields Leisure Centre vicinity areas of likely habitat that are not affected by the growth area footprints. However, Milton Park is managed for recreation and it is very unlikely that the species would survive at that location. Macquarie Fields Leisure Centre vicinity contains remnant bushland some of which may support the species. The derived grassland in the Kayess Park vicinity may support the species.
- at Bunbury Curran Creek vicinity areas of potential habitat are not affected by the growth area footprints.
- in the Gilead and Appin areas approximately 8ha of land containing potential habitat niches within the notional development footprint and a further 380ha of land containing potential habitat niches adjacent to the footprint.
- in the Wilton growth area, approximately 65ha of land containing potential habitat niches within the footprint and a further 680ha of land containing potential habitat niches adjacent to the footprint.

4.5.2 JUSTIFICATION FOR ESTIMATES

Assessment relied on personal knowledge of the species habitat for extant populations and speculation about the habitat of historic records, combined with vegetation mapping and soil and landscape features, to determine “likely habitat” (based on extant population habitat) and "potential habitat" (based on speculation of historic record habitat) locations within and adjacent the growth areas footprints.

The probability of the species to occur in the likely habitat is considered low due to site disturbance, however, cannot be ruled out as the Bankstown population survives in a highly modified mown derived grassland environment refer Photo 12). The probability of the species to occur in potential habitat is considered to be very low. However, a precautionary approach is recommended. Locating and protecting new populations, no matter how small, is significant to the survival of this species.

It was not possible to provide accurate habitat areas or counts due to the following:

- Access was not granted to the majority of development footprint.
- The region has undergone a period of protracted drought and small diminutive species, forbs and even many of the larger resilient shrubs were observed to be in severe drought stress or dead. *Hibbertia puberula* grows in close proximity to *Hibbertia fumana* at both extant sites. At all locations where *Hibbertia* species with vegetative morphological features consistent with *H. puberula* were found only a few individuals were noted, most were almost dead. It is well documented that the above ground populations of many genera including *Hibbertia* species fluctuate widely in response to various conditions such as rainfall and time since last fire.
- Most sites inspected within the WGA and many within GMGA were also noted to have senescing or dead shrubs, high levels of leaf, bark and branch fall and dead understorey an indication of both a long fire interval and severe drought. Apparent diversity and population numbers of many species significantly decline, retreating to the soil seedbank under such conditions. It is inconclusive to undertake population census or estimates under such circumstances.
- The cryptic nature of small-leaved *Hibbertia* when not in flower also make their detection extremely difficult and population count or area calculation unreliable.
- The use of a surrogate site(s), as a base for the estimation, in this case, is deemed not credible. *Hibbertia fumana* is a data-poor species. Insufficient or no reliable data exists in regards to population density and population fluctuation over time at any of the known sites.

5. Information used in the assessment

Information used in this assessment includes taxonomic papers, BioNet and ALA records of the target species, Critically Endangered Listing, online Threatened Species profile and associated documents, personal observations and site inspections, and the spatial viewer including the layers: survey access and coverage, (BAM plots, polygons and transects), PGA layer and geology and soils.

Employment Record

1993 – present

Cumberland Flora and Fauna Interpretive Services

Principal - flora surveys, plant identifications, vegetation assessment, project impact assessment, bush regeneration, rehabilitation, habitat enhancement, seed collection and propagation services.

1990 - 1997

Sylvan Grove Native Gardens

Curator of gardens and adjoining bushland - maintenance of and improvement to the plant collection, training and supervision of staff, liaison with other botanic gardens, guided tours, technical advice.

1982 - 1990

Sylvan Grove Native Gardens

Horticulturist Specialising in Australian Flora - collection, propagation, identification, and growing of native plants.

CUMBERLAND FLORA & FAUNA INTERPRETIVE SERVICES INFORMATION AND RELEVANT EXPERIENCE

Cumberland Flora and Fauna Interpretive Services have provided technical expertise since 1993 to numerous clients including Local Government, NSW Roads and Maritime, NSW Office Environment Heritage NPWS and community groups.   Following is a list of some of our projects and clients:

REPORT	CLIENT
Expert advice for Conservation Assessment of *Solanum celatum* Eren Delgado1 16/04/2018, Science Division, NSW Office of Environment and Heritage	OEH
Saving our Species (SoS) project for *Pomaderris adnata* a post fire population census Grid D 2018	OEH
Provision of expert advice to update the current ecological data for southern NSW threatened flora species, as part of the review of biodiversity assessments under the Biodiversity Conservation Act 2016.	OEH

REPORT	**CLIENT**
Expert witness in botany Residents Against Intermodal Development Moorebank Incorporated v NSW Minister for Planning and Anor – NSW Land & Environment Court Class 1 Proceedings No. 2017/81889. Review of project documentation, in particular the various biodiversity assessments including the BAM assessment for the project and Individual Expert Witness report of Dr David Robertson 15 October 2017; Site inspections to identify the location of and/or potential habitat for *Hibbertia fumana*, *Hibbertia puberula*, *Grevillea parviflora*, *Persoonia nutans*, *Acacia bynoeana*, provision of an expert report in accordance with Division 2 of Part 31 of the UCPR; confer with the other parties experts at a joint conference and produce a joint expert report; and f appear at the section 34 conciliation conference	EDO
Saving our Species (SoS) project for *Pomaderris adnata* a population census 2017	OEH
Central Coast Creek Monitoring Evaluating and Reporting 2016 – Vegetation Consultant	OEH
Great Lakes Creek Monitoring Evaluating and Reporting 2016 – Vegetation Consultant	OEH
Northern Beaches Creek Monitoring Evaluating and Reporting 2016 – Vegetation Consultant	OEH
Northern Beaches Creek Monitoring Evaluating and Reporting 2015 – Vegetation Consultant	OEH
Clarence Colliery Discharge Investigation April 2015	OEH
Vegetation Assessment as part of the Lachlan Wetlands Condition Assessment Project October 2013 – May 2014	Lachlan Catchment Management Authority
Field expertise and guidance in the Sydney basin to PhD candidate Karen Muscat studying the molecular phylogenetics and morphology of the genus Dianella with close scrutiny of the variation in the D. *caerulea* group of species in eastern Australia	Volunteer to University of Melbourne
Survey for *Pomaderris adnata* to determine population size, structure, occupancy and threats 2014	NPWS Illawarra Region
Survey of *Hibbertia stricta* subsp. *furcatula* (Hibbertia species ‘Menai’) to determine population size, structure, occupancy and threats. Collection of voucher herbarium material for taxonomic review June 2014	OEH
Survey of the southern populations of *Hibbertia stricta* subsp. *furcatula* (Hibbertia species ‘Menai’) to determine population size, structure, occupancy and threats May 2014	OEH
Investigation of works within the Sublime point precinct Illawarra Escarpment State Conservation Area February 2014.	NPWS Illawarra Region
Identification of Hibbertia species in proposed control burn sites Victoria Road precinct Dharawal National Park.	NPWS Illawarra Region
Assessment of impact of infrastructure upgrade Victoria Road, Dharawal National Park – location of threatened species.	NPWS Illawarra Region
APPEAL IN RESPECT OF PROPERTY AT Lot 1 and 2 DP 224431 Site 2 Sturdee Avenue, Bulli	Roy ‘Dootch’ Kennedy

REPORT	**CLIENT**
Expert Witness Report Relating to Some Environmental Issues Land & Environment Court of New South Wales PROCEEDINGS NO 10982 of 2012	Roy 'Dootch' Kennedy
Field surveys, collection, pressing, curation of botanical specimens and contributions of notes in association with the manuscript "Notes on Hibbertia subgen. Hemistemma (Dilleniaceae) 7. Eight new species, a new combination and four new subspecies from mainly central New South Wales H.R. Toelken & R.T. Miller 2006 - 10 July 2012	Volunteer to Adelaide Botanic Gardens
Vegetation Surveys and assessments & input into the preparation of REF for proposed car-park and amenities Victoria Road Precinct Dharawal National Park November 12.	NPWS Illawarra Region
Office of Environment and Heritage – Priority Action Statement Expert Consultant Interviews June 2012 – January 2013	OEH

Strategic assessment for Cumberland Plain Conservation Plan
Aerotropolis and Greater Penrith
Hibbertia fumana

Hibbertia fumana, Moorebank, R. Miller September 2017.

Report prepared for Department of Planning and Environment

By

Cumberland Flora & Fauna Interpretive Services

Robert Miller - December 2018

Executive Summary

Hibbertia fumana is listed as a Critically Endangered Species under the *Biodiversity Conservation Act 2016*. There are two known populations of the species, one at Moorebank and the other at Bankstown Airport. There is limited data on the life history and ecology of the species.

Survey for this report was restricted by time constraints, lack of access to private property, and years of preceding drought conditions. Survey targeted areas of suitable habitat identified from the habitat of extant populations and DPE vegetation mapping.

Areas adjacent to the development footprint were included in the survey because *H. fumana* is a small shrub that could be severely affected by anthropogenic impacts.

Outcomes of the assessment:

There were no prior records of the species within or adjoining the proposed growth areas.

There has been just a short period in which the species would have been formally considered in the assessment process as the species was thought to be extinct when described in 2012 and was only recently rediscovered in late 2016. This would be the primary reason for the lack of records.

No plants of *Hibbertia fumana* were found during survey for this assessment.

Non-detection should not be interpreted as the species not being present, but simply as not seen. Survey followed years of drought in Western Sydney and the species could have retreated to the soil seed bank.

The possibility of *Hibbertia fumana* occurring within the GPEC is assessed as low because potential habitat sites found within the biodiversity certification area do not have the same complexity of attributes as known extant sites.

Within the Kemps Creek area of the WSA the likelihood of *H. fumana* occurrence was assessed to range from moderate to low potential adjacent the footprint.

Note that the potential habitats are niches within the overall landscape, generally associated with localised soil and drainages within transition vegetation.

Outcomes of this assessment are that 32 ha of habitat with a low probability of the species occurring are within the development footprint, and that more than 100 ha of habitat with moderate to low probability of species occurrence are outside the footprint but are likely to suffer from anthropogenic impacts caused by the development. More than 10 ha with moderate potential have recently been partly cleared.

As *Hibbertia fumana* is a Critically Endangered species a precautionary approach is recommended. Locating and protecting new populations, no matter how small, is significant to the survival of this species.

1. Introduction

1.1 PURPOSE

The purpose of this expert report is to determine the potential for future urban development in identified growth areas of Western Sydney to impact on *Hibbertia fumana*, which is listed as a Critically Endangered Species under the *Biodiversity Conservation Act 2016*. This report forms part of the Cumberland Plain Conservation Plan, which will be assessed under the:

- Biodiversity certification under the *Biodiversity Conservation Act 2016* (BC Act)
- Strategic assessment and approval under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act).

The Biodiversity Assessment Method (BAM) sets out the framework and methods to be used for assessment of impacts to biodiversity to provide preferred conservation outcomes while also supporting the development approval process. Under the BAM an expert report can be used when adequate survey is not possible. An expert report can only be used for species to which species credits apply.

The expert report must document the information that was considered, and/or rejected as unsuitable for consideration, to reach the determination made in the expert report. The report must set out whether the subject species is likely to be present at the development site, and if present then the report must estimate, in the case of a species such as *Hibbertia fumana*, the area of habitat where the species is likely to be impacted, as well as areas from which it is known to occur in which it will be impacted.

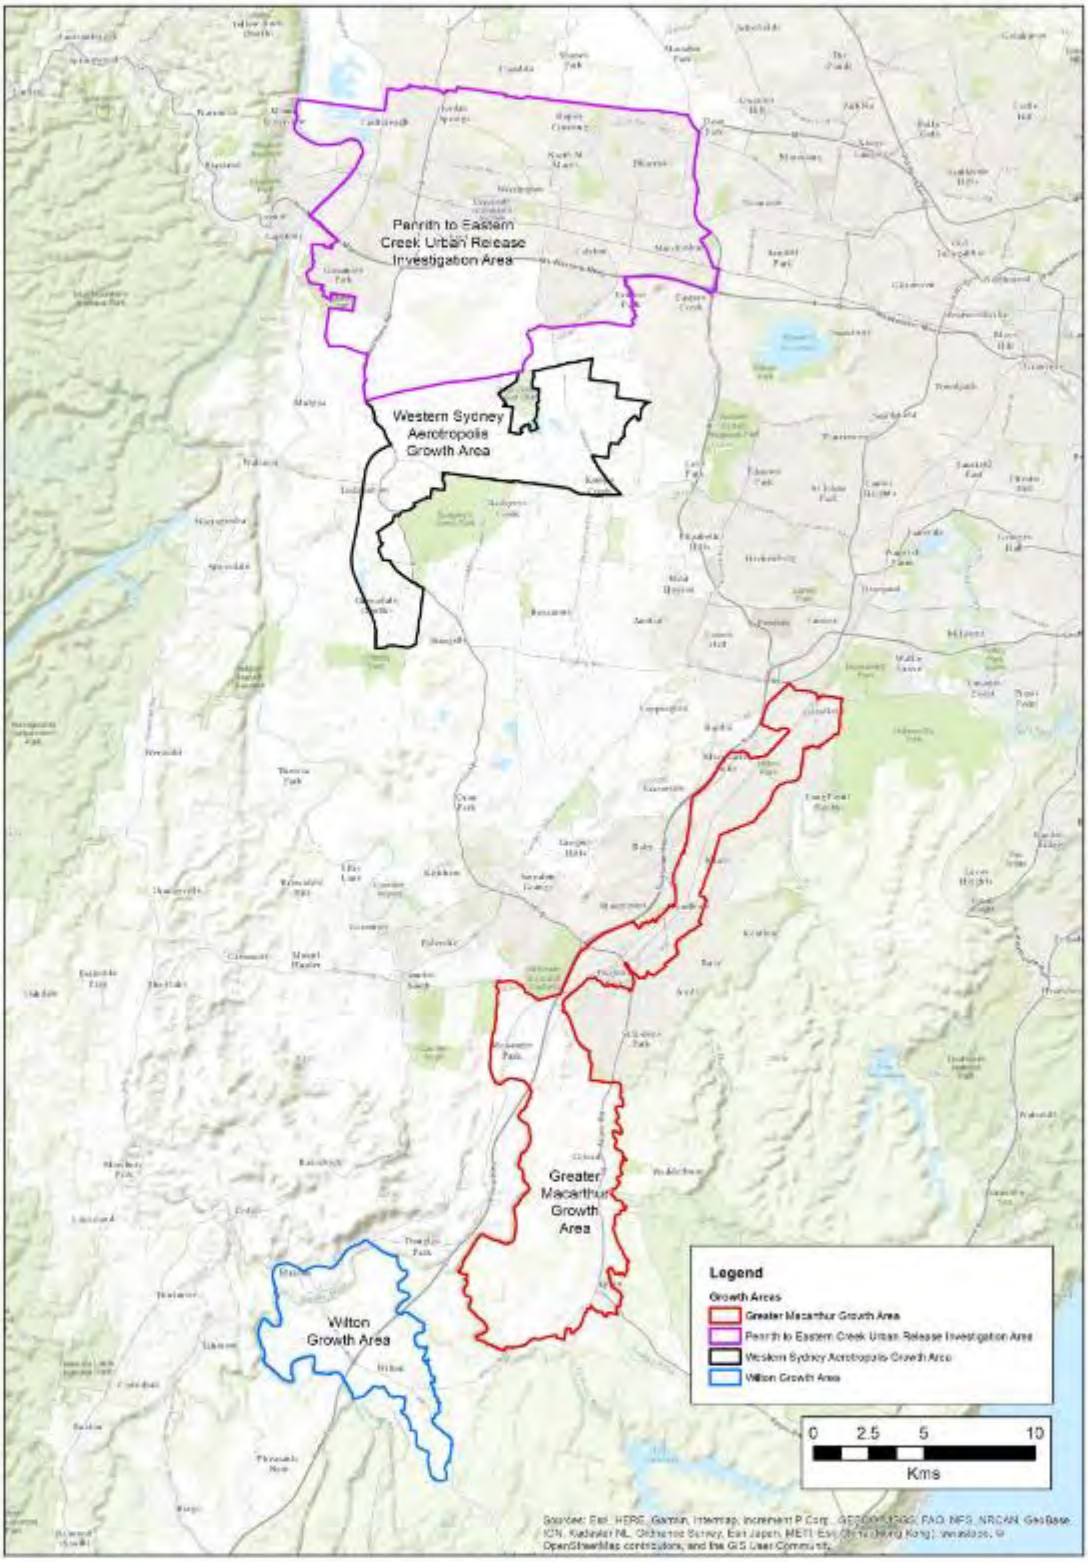
1.2 PROJECT CONTEXT

The NSW Government is planning for future urban development in Western Sydney. Four growth areas have been identified, these are Wilton, Greater Macarthur (Campbelltown and Appin), Western Sydney Airport, and Greater Penrith to Eastern Creek. These growth areas are all located within the Cumberland Subregion in version 7 of the Interim Biogeographic Regionalisation for Australia (IBRA) (2016).

As part of the planning for this future development, the Department of Planning and Environment (DPE) is preparing the Cumberland Plain Conservation Plan. This is a strategic regional assessment that will lead to the identification of preferred conservation outcomes for the Cumberland subregion.

1.3 STUDY AREA

The Map 1 shows the growth areas of Greater Penrith to Eastern Creek (GPEC) and Western Sydney Aerotropolis (WSA) which are the subject of this report, and the Greater Macarthur and Wilton growth areas which are the subject of a separate report.



Map 1: The four Western Sydney Growth Areas

Map source: NSW Department of Planning and Environment.

1.5 JUSTIFICATION FOR USE OF EXPERT REPORT

The BAM allows for situations where an expert report will be required to replace or complement survey effort at a development site. While there has been some field survey for the Strategic Biodiversity Certification assessment, the area covered by the proposed GPEC and WSA growth areas are extensive and there have been issues with gaining access to some of the private properties.

An expert report is required to assess potential impact to *Hibbertia fumana* for the following reasons:

Insufficient survey: A large extent of the identified growth areas could not be surveyed because it was on private property and could not be accessed within the project timeframe. Expertise was required to identify and survey potential species habitat and propose additional habitat based on extant and historic records.

Survey following extended drought conditions: Western Sydney has been experiencing dry to drought conditions for several years. Numerous usually resilient native trees and shrubs were observed to have experienced severe drought stress causing partial and/or full defoliation and many had died. Although unknown, it is likely that a large proportion of the *Hibbertia fumana* population could be reduced to the soil seed bank in these circumstances. As such, expertise is required to identify potential habitat for the species.

Compounding the effect of reduced soil moisture, following drought many areas have a significant increase in leaf, twig and branch drop making this small and cryptic species more difficult to locate or possibly covering them completely. The discernible population is likely to be significantly reduced from this cause.

Herbivory of a wide range of native species can severely impact small plants during dry conditions.

Rainfall events in months prior to this assessment allowed many *Hibbertia* species to produce new growth and therefore flowers. However, the rainfall was insufficient to replenish subsoil moisture. A dry period and unusually hot conditions prior to, and during, this assessment resulted in moisture stress for many plants. In the case of some *Hibbertia* species this is noticeable by unusually early petal dehiscence making their detection difficult.

It requires an expert in the species to locate and identify rare *Hibbertia* under these conditions.

Reliable species identification: Identification of the genus *Hibbertia* to species level requires examination of flower parts in combination with stem and leaf characters, especially tomentum type and density. It is not practical nor reliable to identify small leaved species in the field as many of these morphological features require microscopic examination and comparison to known voucher specimens. The use of an expert report to complement survey of the growth areas avoids the problems associated with *Hibbertia* misidentifications.

1.6 CREDENTIALS OF EXPERT

Robert Miller has over 30 years' experience in field botany. Over this time Robert has identified many rare and endangered plant species and has contributed to the scientific knowledge of native flora distribution and habitat in NSW.

Robert has been certified as an expert for *Hibbertia fumana* and *H. puberula* under the Biodiversity Assessment Methodology.

Robert has worked with Hellmut Toelken of the State Herbarium of South Australian, locating, collecting and identifying undescribed or rare species of *Hibbertia*. Some of these taxa were known only from historic records with non-precise locality details and depauperate or non-existent habitat information. Many of the specimens have been used for the taxonomic revision of the genus and are cited in various taxonomic publications including "Notes on *Hibbertia* subg. *Hemistemma* (Dilleniaceae) 9. The eastern Australian *H. vestita* group, including *H. pedunculata* and *H. serpyllifolia*" published in the Journal of the Adelaide Botanic Gardens 26 (2013). Examples of the cited specimens include: *Hibbertia ericifolia* subsp. *acutifolia* Toelken, subsp. nov. Type: New South Wales, Sarahs Knob, R. & J. Miller s.n., 21.x.2006 (holo.: AD; iso.: BRI, CANB, NSW, PERTH) and *Hibbertia dispar* R.T.Miller s.n., 0.5 km S of Penrose Rest area, along western boundary track, Penrose State Forest, 12.x.2010 (AD, NSW).

Robert and Hellmut's paper "Notes on *Hibbertia* (Dilleniaceae) 8. Seven new species, a new combination and four new subspecies from subgen. *Hemistemma*, mainly from the central coast of New South Wales", was published in the Journal of the Adelaide Botanic Gardens in 2012. The paper describes 13 new taxa including *Hibbertia fumana* Toelken and *Hibbertia puberula* subsp. *puberula,* – subsp. *extensa* R.T.Mill. and – subsp. *glabrescens* Toelken*.*

In 2017 Robert was called as an expert to identify the species of *Hibbertia* on the Moorebank bushland site that is the subject of the Intermodal development proposal.

Robert has recognised expertise for other threatened taxa including *Pomaderris adnata*, *Solanum celatum*, *Epacris purpurascens* var. *purpurascens*, and the genus *Prostanthera* including the threatened taxa *Prostanthera discolor*, *P. stricta*, *P. densa*, *P. junonis* and has provided expertise to the OEH Saving our Species programs.

2. Species information

2.1 SPECIES DESCRIPTION

Hibbertia fumana was described by Toelken and Miller (2012) in their paper "Notes on Hibbertia (Dilleniaceae) 8. Seven new species, a new combination and four new subspecies from subgen. Hemistemma, mainly from the central coast of New South Wales". At the time of publishing, the species was presumed extinct and had not yet been discovered at the Moorebank Intermodal site. The description was based on three herbarium specimens collected in 1802, 1804 and 1823.

The re-discovery of the species provided a broader range of specimens and a revised description which included for the first time fruit and seed, was provided by Duretto, Orme, Rodd, Stables and Toelken (2017). The following is a direct quote from that description.

Hibbertia fumana Sieber ex Toelken, Journal of the Adelaide Botanic Gardens 25: 73 (2012).

Type: Australia, near Sydney, "F.W. Sieber Nov. Holl. No. 147"

Decumbent shrublet, prostrate to weakly ascending to 20 cm high, with many branches from the base, moderately- to much-branched; branches wiry, with raised leaf bases shortly decurrent, shortly fascicled-pubescent. Vestiture persistent, consisting of more or less coarse simple hairs over fine fascicled hairs on tubercles; on branches more or less densely covered with short subequal multiangulate fascicled hairs (4–7 equal arms) and without simple hairs except for intrapetiolar tufts of hairs in leaf axils; on leaves above scattered, short antrorse fine bi- or triforked to simple hairs, sparse becoming denser onto the petiole, few simple hairs along the flanks, all wearing off soon; on leaves below dense, with short subequal multiangulate fascicled hairs (4–12 subequal arms) particularly on central vein, overtopped by few simple hairs on the flanks of the revolute margins; on outer calyx outside moderately dense, with spreading coarse antrorse simple hairs over erect-spreading multiangulate fascicled hairs (8–15 subequal arms), inside dense, with forked to simple antrorse hairs over most of surface; on inner calyx lobes outside dense with spreading multiangular fascicled hairs (2–12 subequal or unequal arms) becoming smaller towards the membranous margins, overtopped by coarse antrorse simple hairs along the central ridge, inside glabrous except for a few simple hairs towards the apex. Leaves with intrapetiolar axillary tuft of hairs to 0.7 mm long; petiole 0.2–0.45 mm long; lamina narrowly oblong, rarely linear-elliptic, (1.9–) 2.1–6.5 × 0.5–1.2 mm, obtuse, with terminal tuft of hairs on a somewhat recurved apex of the central vein, more or less abruptly constricted into petiole, above ± flat and puberulous to glabrescent, below with broadened central vein recessed below the level of revolute margins and protruding into apex, pubescent to puberulous. Flowers single, terminal, commonly on main branches; flower stalk 2–9 mm long, recurved and elongating after flowering, pubescent; bract linear to linear-triangular, 1–1.3 mm long, sometimes leaf-like to 5.5 mm long, fascicled-pubescent, on lower third to half of flower stalk. Calyx distinctly accrescent, with lobes subequally long; outer calyx lobes lanceolate, 3.5–5.7 × 1.3–1.65 mm, enlarging to 6.1 × 2.2 mm with fruit, acute to acuminate, without ridge, outside strigose-pubescent, inside finely strigose with antrorse forked hairs on much of the surface;

inner calyx lobes oblong-ovate, 4.0–5.8 × 3.1–3.5 mm, usually cuspidate, outside strigose along the central vein and tomentose towards the margins, inside glabrous with few forked hairs at the apex. Petals obovate, 4–5.2 mm long, broadly bilobed. Stamens 5 or 6 (7), subequal, clustered on one side of the ovaries; filaments 0.4–0.6 mm long, basally connate; anthers broadly oblong, 1.3–1.4 mm long, ± abruptly constricted above and below. Pistils 2; ovaries obovoid but ± laterally compressed, each with 4 ovules, fascicled-tomentose, with style attached to the centrifugal apex of the ovary then after a short curve downwards straightening up on either side of the stamens with stigmas exposed above the anthers. Fruit puberulous with simple and multiangular hairs. Seeds oblong-obovoid to almost obloid, 1.6–2.0 × 1.4–1.5 mm, smooth, light brown; aril with fleshy base surmounted by one-sided membranous cup covering c. one quarter of one side of seed.

Additional specimens examined: NEW SOUTH WALES: Central Coast: R.Brown [J.J.Bennett 4873], “In occidental Sydney 1804” (BM); G.Caley s.n., “near South Head”, viii.1802 (BM); Moorebank in western Sydney, J.Rodd & M.Stables, 19.x.2016 (NSW, 3 specimens); Moorebank in western Sydney, A.E.Orme 1572, 16.xi.2016 (AD, NSW).

Figure 1 shows taxonomic features of *H. fumana*, and Figure 2 shows an image of the species isotoype.

2.2 LIFE CYCLE

The NSW Threatened Species Scientific Committee Final Determination for listing of *Hibbertia fumana* states that “Little is known about the life history of *Hibbertia fumana*. Seed production and plants of different ages were recorded within the only known population (A. Orme in litt. November 2016). The species does sucker (A. Orme in litt. November 2016) suggesting it may be able to resprout from rootstock following fire.”

Peak flowering is recorded as spring to early summer, although the species appears to be capable of minor sporadic flowering at other times of the year as a response to suitable climatic conditions (Miller pers. obs.).

2.3 DISTRIBUTION AND ABUNDANCE

Historically the species was collected by Caley “near South Heads”, eastern Sydney, in 1802, by Robert Brown in 1804 “occidental Sydney” and by Sieber 1823 “near Sydney New Holland”.

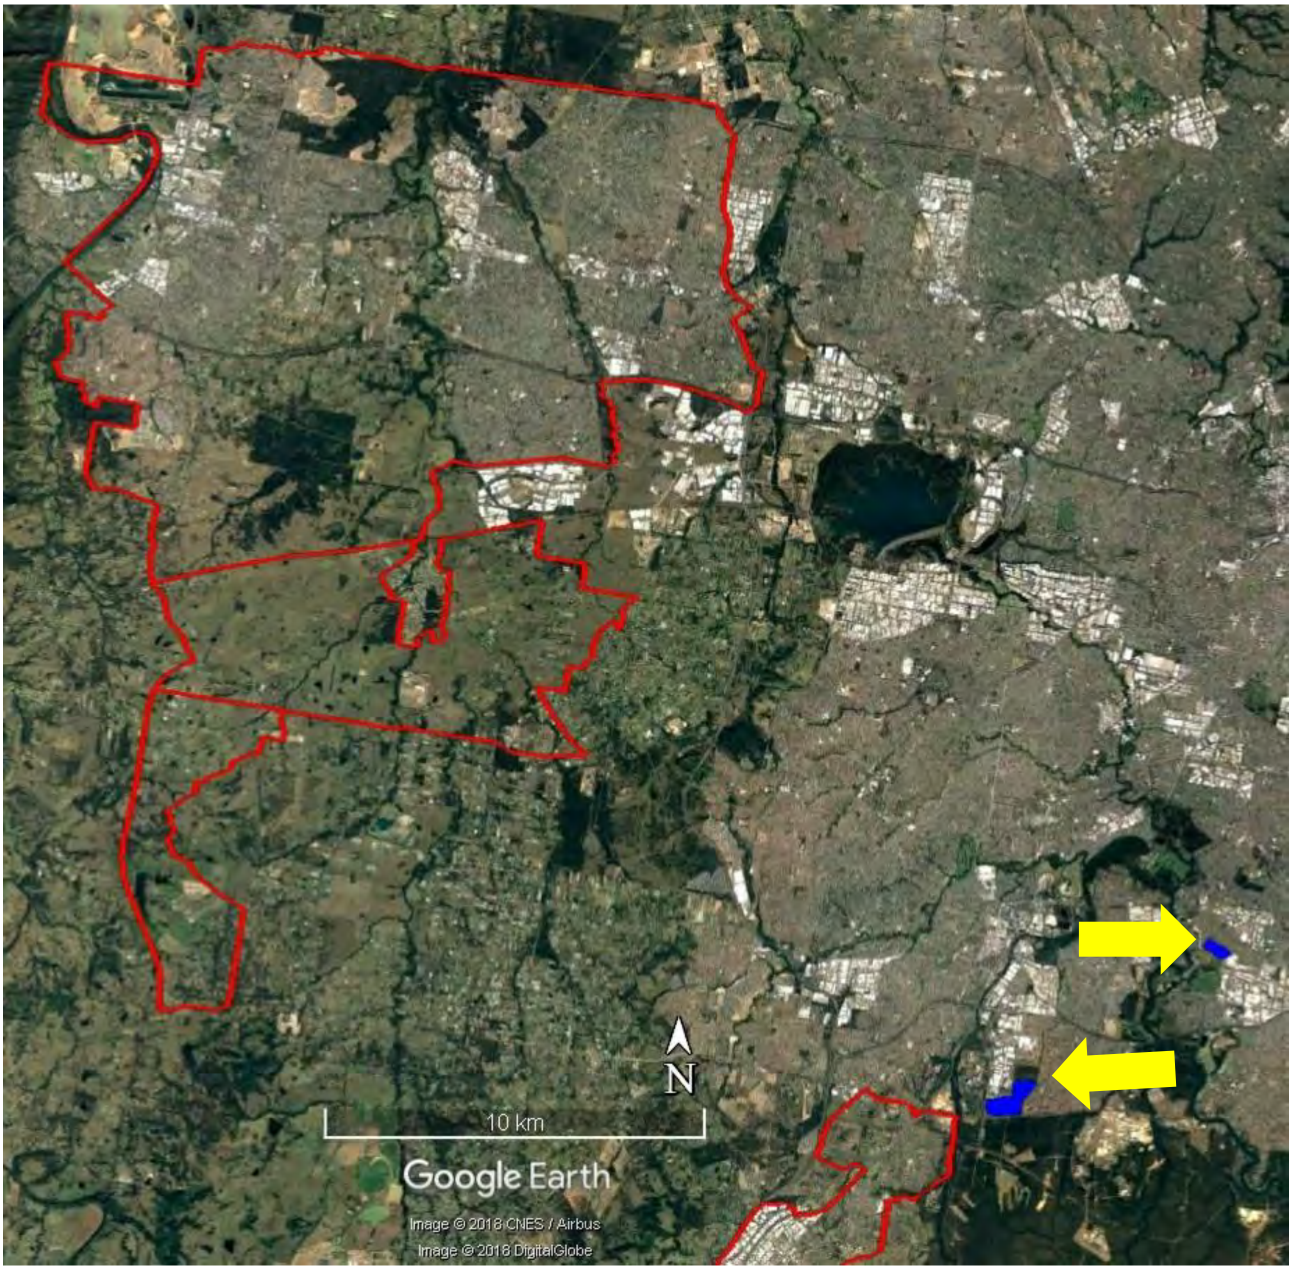
Recently a specimen from the Keith Ingram herbarium collection has been determined as most likely to be that species by Andrew Orme. It was collected at Connells Point in February 1941.

South Head and Connells Point are now highly urbanised environments and as such this diminutive species is unlikely to have persisted at either locale. If the species has persisted it is most likely so in the Connells Point environs. Targeted searches may be warranted in the Poulton Creek vicinity including Poulton Park.

Currently known from one extant population at Moorebank of c. 400 and an unknown number of plants in the Bankstown Airport vicinity.

At the time of the species listing in October-November 2016 (Arcadis and Parsons & Brinckerhoff Australia/New Zealand (WSP)) 370 plants were recorded at Moorebank and a further "approximately 29 plants" were recorded in September 2017 (Arcadis and Cumberland Ecology).

The impact upon the population at the Moorebank site from an intense fire in April 2018 is unknown.



Map 2: Indicative area of known *Hibbertia fumana* populations.

Key - Areas of known *H. fumana* populations (blue) and the Western Sydney growth areas (red).

Fig. 1. *Hibbertia fumana*. **a**, habit; **b**, branch; **c**, branch detail showing tufts of hairs in leaf axil; **d**, leaf, adaxial surface; **e**, leaf, abaxial surface; **f**, flower; **g**, flower, petals removed; **h**, inner sepal, abaxial surface; **i**, inner sepal, adaxial surface; **j**, outer sepal, abaxial surface; **k**, outer sepal, adaxial surface; **l**, flower with fruit; **m**, seed. Scale bar: **a** = 80 mm; **b** = 15 mm; **c** = 2.5 mm; **d & e** = 4 mm; **f** = 6 mm; **g & l** = 8 mm; **h–k** = 5 mm; **m** = 3 mm. Drawn from *Orme 1572*.

Figure 2: Isotype of *Hibbertia fumana.*

F.W Sieber held within the William and Lynda Steere Herbarium as digitised imagery in the C. V. Starr Virtual Herbarium New York Botanic Gardens showing apparent +/- sessile flower buds.

2.4 HABITAT REQUIREMENTS

Historic collections

The *Hibbertia fumana* profile states: "Habitat of an 1802 Caley collection 'near South Head' are uncertain, with potential communities in that area including coastal shale sandstone communities and open forest or forest communities on lateritised shale lenses. No similar alluvial sand deposits are identified in that area." (OEH 2018)

It is speculated by Miller that the most likely habitat for the Caley collection is transitional vegetation associated with "Swamps" or wet heath, especially the transition from shale influence communities to heath and/or open woodland. Although unsuitable habitat now, the Woollarah Golf Course site is likely to have consisted of a mosaic of vegetation types including swamp transition to woodland and the original habitat at Centennial Park is well documented "Originally a swamp and then set aside as land for the water source for Sydney, Centennial Park" (Centennial Park Trust). The diverse micro-habitats at Centennial Park supported numerous now locally rare or endangered taxa including *Hibbertia virgata* E.Cheel *NSW 86014*, Centennial Park, ix.1900 (NSW); and A.A.Hamilton *NSW 86016*, Centennial Park, 23.viii.1912 (AD, NSW) (Toelken in prep.) and it is likely to have also supported *Hibbertia fumana*.

Extant populations

The OEH website states that *Hibbertia fumana* is known to be associated with the following vegetation formations and classes:

Dry sclerophyll forests (shrub/grass sub-formation) - within the Cumberland Dry Sclerophyll Forests class *Hibbertia fumana* is associated with

- Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain and Sydney Basin Bioregion and
- Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion

Dry sclerophyll forests (shrubby sub-formation) - the Vegetation Types that *Hibbertia fumana* is associated within the Sydney Sand Flats Dry Sclerophyll Forests class include

- Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion and
- Parramatta Red Gum woodland on moist alluvium of the Cumberland Plain, Sydney Basin Bioregion

At Bankstown Airport the AVH record states that the "Site is heavily managed and is routinely slashed to a height of about 10cm. Soils are grey heavy clay with ironstone fragments present at surface. Other native species observed indicate a derived form of Cooks River / Castlereagh Ironbark forest community. Main weed observed *Eragrostis curvula*."

Photo 1: Indicative habitat of *Hibbertia fumana* at Bankstown Airport, regularly slashed.

At the Moorebank site the species is found growing in the transition zone between Castlereagh Ironbark Forest and Castlereagh Scribbly Gum woodland in open forest of *Eucalyptus sideroxylon, E. fibrosa, E. parramattensis, E. sclerophylla* and *Melaleuca decora* with a diverse understorey of shrubs including *Hakea sericea, Callistemon linearis, Bursaria spinosa, Grevillea parviflora* subsp. *parviflora, Acacia brownii, Acacia bynoeana, Pultenaea retusa, Pultenaea villosa, Hibbertia puberula* subsp. *puberula* and *H. aspera* subsp. *aspera*. The herb/grass layer is dominated by *Goodenia hederacea, Dianella revoluta, Thysanotus, Gonocarpus, Poa, Stylidium graminifolium, Patersonia, Themeda, Diuris* and *Microtis* (Telopea 2017).

Prior to the recent fire, the density of the understorey was variable across the site and ranged from sparse to extremely dense especially within the long-unburnt sections of the Castlereagh Scribbly Gum woodland. The variation in density is presumed to be due to the fire history, localised clearance events including recent remediation works, as well as minor changes in topography and drainage especially in swales.

In general, the topography of the land is described as flat although this is disrupted by the passage of Anzac Creek and by numerous minor depressions or swales likely to be remnants of past creek alignments and/or overflow channels that support Castlereagh Swamp Woodland. These swales and minor excavations / scrapings form small ephemeral pondages.

From limited brief inspections *Hibbertia fumana* was observed to be of sporadic occurrence across the site and appeared to be absent from ephemeral pondage locales preferring open slightly higher ground. Soils are described as fine sandy clay loam, grey brown in colour.

2.5 ANTHROPOGENIC THREATS TO THE HABITAT

Threats to the habitat of *Hibbertia fumana* that are relevant to sites within or adjacent to urban development include:

- Loss of existing habitats across the growth areas may occur for as-yet-missed unrecorded populations of the species.
- Development of the adjacent lands at Moorebank for a major transport hub may affect the plants, and there is a rarely-used railway line bisecting the site. At Bankstown airport infrastructure development could impact the population.
- Fire either too frequently (limiting recruitment) or too rarely (allowing midstorey thickening) are likely to impact the species.
- Clearing for fire protection zones and infrastructure works could remove habitat.
- Damage to habitat by trail biking, 4WDs, mountain bikes and rubbish dumping.
- High densities of weeds and invasive grasses occur at the top of ridgelines; there is significant potential for encroachment into areas of potential habitat.
- A number of weeds are likely to impact on the plant, with particular concern for low shrubs, dense shrubs and smothering grasses.
- Changes to hydrological processes can impact habitat by reducing subsoil infiltration, drying out seepages, or concentrating flow paths through habitat.
- Nutrification can increase weed potential.
- Road maintenance and slashing works can destroy habitat.

Field inspection of bushland remnants in the heavily urbanised sectors of GPEC growth area provide irrefutable proof of severe degradation caused by anthropogenic impacts and urbanisation (refer photos 2 through 6). Many of the remnants were heavily weed infested arising from a range of factors not limited to nutrification, stormwater discharge, garden refuse and fill dumping and exotic seed dispersal by various vectors.

Damage to zones adjacent urban development are often caused by clearing for fire hazard reduction, frequent control burning, and recreation activities.

Hibbertia fumana is a small shrub that would not survive in bushland that is heavily weed infested, or that is severely burnt on a regular basis. Fencing and on-going maintenance of the fencing around bushland remnants might reduce the severity of some of these impacts.

Photo 2: Indiscriminate access and rubbish dumping threatens the biological integrity of the former Air Services Australia Site.

3. Description of the study area

3.1 LAND USE HISTORY

The Cumberland Plain was first occupied by the Aboriginal peoples, who enjoyed a plentiful supply of fresh water and foods including fruit, tubers, fish, animals, birds and honey (Hills District Council website).

With the arrival of Europeans, land-use changed to timber gathering and agriculture, permanently altering the landscape. Particularly since the end of the Second World War urban settlement and industry have expanded west from Sydney into the Cumberland subregion. Over the last 40 years many rural properties have been subdivided as lifestyle and hobby farm properties.

Currently there is great pressure for further residential development to the west of Sydney in the Cumberland subregion.

3.2 LANDSCAPE CONTEXT

The changes in land use have caused the clearing of a large proportion of the natural bushland of the Cumberland subregion. In 2011 the Cumberland Plain Recovery Plan stated "Only 13% of the pre-1750 extent of the region's vegetation remains as intact bushland, with an additional 12% occurring as scattered trees in disturbed areas (NPWS 2002). Consequently, much of the region's biodiversity is listed as threatened under State and/or Commonwealth legislation."

Widespread clearing of the remaining habitat has continued with much of the extant vegetation now being assessed as Critically Endangered. Previously recorded from South Head and Western Sydney, *Hibbertia fumana* appears to have suffered a reduction in range caused by urbanisation.

3.3 NATIVE VEGETATION

Since 2011 there has been further clearing, there are now 15 vegetation communities that are listed as Critically Endangered, Endangered or Vulnerable in the Cumberland Plain.

The Cumberland Plain Recovery Plan states that "there are seven threatened species, four endangered populations and nine threatened ecological communities listed on the NSW *Threatened Species Conservation Act* 1995 that are found only on the Cumberland Plain. Seven of these are also listed as threatened under the Commonwealth *Environment Protection and Biodiversity Conservation Act* 1999." The remaining bushland is highly fragmented and much of it occurs on private lands.

Within the GPEC and the WSA nineteen Plant Community Types (PCTs) are mapped (mapping provided by the NSW Department of Planning and Environment). These PCTs are:

- 724 - Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion

- 725 - Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion
- 774 – Coast Banksia scrub on sand in the Elderslie area, Sydney Basin Bioregion
- 781 - Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion
- 806 - Derived grasslands on shale hills of the Cumberland Plain (50-300m asl)
- 807 – Derived grasslands on shale plains of the Cumberland Plain (<100m asl)
- 808 – Derived shrubland on Tertiary Gravels of the Cumberland Plain
- 830 - Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion
- 835 - Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion
- 849 - Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion
- 850 - Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion
- 877 - Grey Myrtle dry rainforest of the Sydney Basin Bioregion and South East Corner Bioregion
- 883 - Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion
- 1067 - Parramatta Red Gum woodland on moist alluvium of the Cumberland Plain, Sydney Basin Bioregion
- 1081 - Red Bloodwood – Grey Gum woodland of the Cumberland Plain, Sydney Basin Bioregion
- 1105 – River oak open forest of major streams, Sydney Basin Bioregion and SE Corner Bioregion
- 1181 - Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion
- 1253 – Sydney Peppermint – White Stringybark – Smooth Barked Apple Forest on shale outcrops, Sydney Basin Bioregion
- 1292 – Water Gum – Coachwood Riparian Scrub along sandstone streams, Sydney Basin Bioregion
- 1395 - Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion
- 1800 - Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley

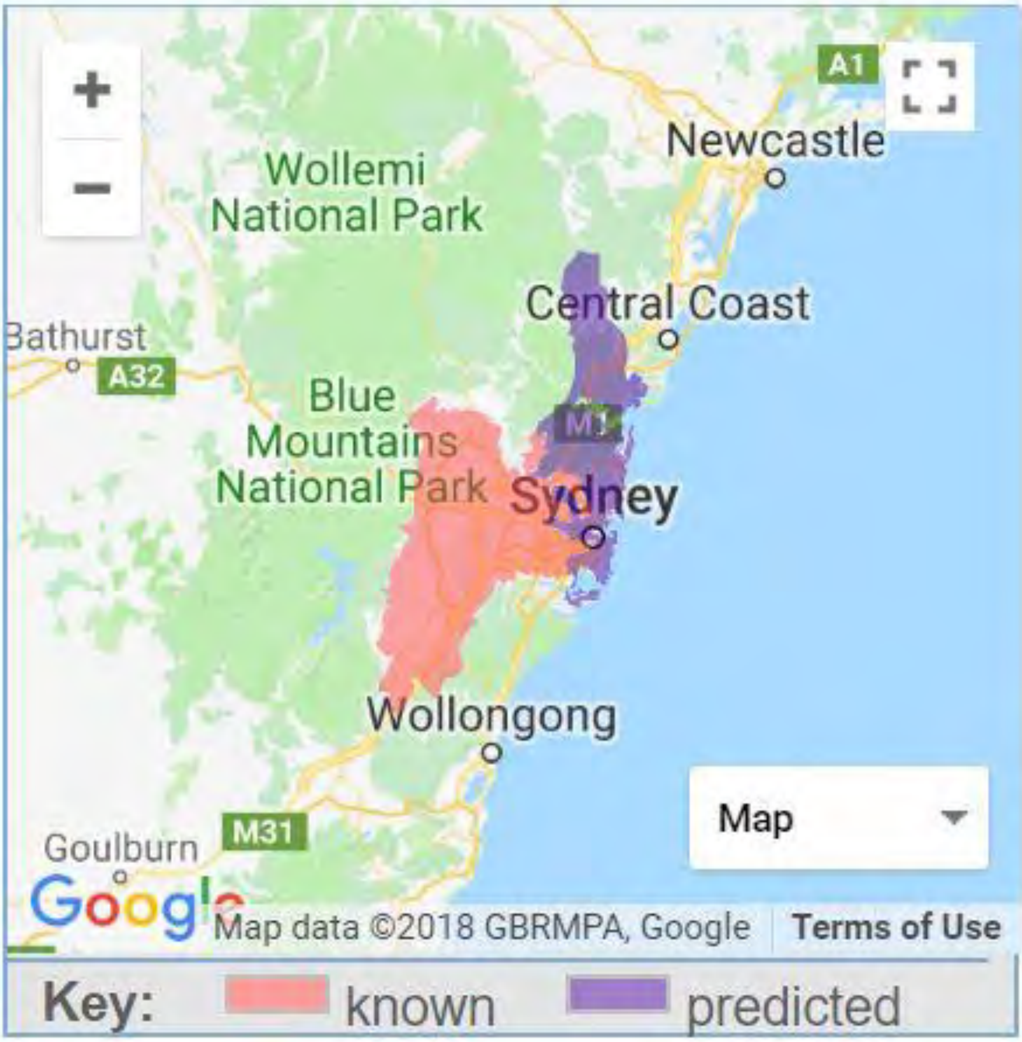
3.4 POTENTIAL HABITAT

Within the Sydney Basin Bioregion *Hibbertia fumana* is known from the IBRA subregion of Cumberland and is predicted to occur in the Pittwater IBRA sub-region (OEH website 2018). No geographic constraints are currently listed for the species. The subregions of known and predicted occurrence are shown in Map 3. The areas shown in pink and purple are the sub-regions where the species or community is known or predicted to occur. They may not occur throughout the sub-region but may be restricted to certain areas.

The OEH species profile sheet states: "found in the transition zone between Castlereagh Ironbark Forest and Castlereagh Scribbly Gum woodland in open forest of *Eucalyptus sideroxylon, E. fibrosa, E. parramattensis, E. sclerophylla*". The species has the potential to occur in similar intergrade alluvial habitats rich in sands and laterite in other parts of western Sydney.

Hibbertia fumana is currently known only from two locations in western Sydney. A single population at Moorebank and a single population in Bankstown (AVH record) but has the potential to occur elsewhere in greater Sydney.

At Moorebank it is found in areas of open woodland in a long intergrade between Castlereagh Scribbly Gum Woodland and Castlereagh Ironbark Forest. The AVH record for *Hibbertia fumana* at Bankstown records "Site is heavily managed and is routinely slashed to a height of about 10cm. Soils are grey heavy clay with ironstone fragments present at surface. Other native species observed indicate a derived form of Cooks River / Castlereagh Ironbark forest community."



Map 3: Known and predicted distribution of *Hibbertia fumana*.

Source OEH website 2018.

The habitat of an 1802 Caley collection 'near South Head' is uncertain, with potential communities in that area including coastal shale sandstone communities and open forest or forest communities on lateritised shale lenses. No similar alluvial sand deposits are identified in that area.

Hibbertia fumana has the potential to occur within the Greater Penrith to Eastern Creek and Western Sydney Aerotropolis Growth Areas in the following PCTs and in transition zones between these PCTs:

- PCT 724 - Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion
- PCT 725 Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion
- PCT 808 – Derived shrubland on Tertiary Gravels of the Cumberland Plain
- PCT 883 Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain
- PCT 1067 - Parramatta Red Gum woodland on moist alluvium of the Cumberland Plain, Sydney Basin Bioregion

Biosis has mapped PCTs 883, 725, and 724 as occurring within the Wianamatta Regional Park/ Ropes Crossing areas and PCTs 725, 724 and 1067 as occurring within the Kemps Creek area.

4. Assessment of species presence and suitable habitat

4.1 EXISTING RECORDS AND SURVEYS

Hibbertia fumana is assessed as site managed. There is limited data on the life history and ecology of the species. There are no records of the species within or adjoining the proposed growth areas. Only two known extant populations exist, at Moorebank approximately 14 km to the south-east of the southern boundary of WSA, and Bankstown Airport 17 km from the southern boundary of WSA.

Private land holdings comprise much of the area within the GPEC and WSA, restricting access opportunities for botanical surveys and incidental sightings. This is a likely contributing reason for the lack of prior records of threatened *Hibbertia* species, possibly including *Hibbertia fumana,* within the proposed growth areas.

There has been just a short period in which the species would have been formally considered in the assessment process as the species was thought to be extinct when described in 2012 and was only recently rediscovered in late 2016.

Even now, it would be likely that the species would not be adequately considered within many assessments as such species are frequently dismissed with statements of “unlikely, no suitable habit present” or “only known from one population” and therefore no targeted searches would be undertaken. As *Hibbertia fumana* was originally misidentified and therefore dismissed at

Moorebank as a common species it is possible this may have occurred at other locales. It was therefore deemed appropriate to consider the possibility of *Hibbertia fumana* being recorded in the data records as another entity. Species of *Hibbertia* with which it might have been confused are discussed in detail in Section 4.3.2.

<u>Potentially misidentified *Hibbertia* within database records</u>

Searches of databases revealed records of *Hibbertia riparia* at a number of locales within and adjacent to the growth areas. The name *Hibbertia riparia* is considered by Toelken to be misapplied to NSW taxa. Prior to the updated taxonomy a number of undescribed species were included within the name *Hibbertia riparia* then considered to be "a variable species complex".

As *Hibbertia fumana* has its stamens on one side of the ovaries it is possible that it may have been captured within the then *H*. *riparia* variable concept. To illustrate this point, Miller has observed that *Hibbertia puberula* is frequently still misidentified as *Hibbertia riparia*.

Reviewing the data set it also became apparent that there were a number of records for *Hibbertia serpyllifolia* in the general Western Sydney area. Recent taxonomic work (Toelken 2013) investigating "The eastern Australian *H. vestita* group, including *H. pedunculata* and *H. serpyllifolia*", has identified that the name *Hibbertia serpyllifolia* is misapplied to NSW. The species concept is now considered to be confined to coastal forests of mid-northern Queensland. All records from other states are now recognised as new taxa e.g. *Hibbertia ericifolia* group or misidentifications of existing taxa.

As *Hibbertia* are notoriously difficult to identify, and more so if not in flower, it is not surprising to find records of *Hibbertia* sp. within the data set.

The Western Sydney Urban Bushland Biodiversity Survey 1997 undertook the first comprehensive survey of the biota across the region including bushland remnants within the GPEC and WSA area. Although the taxonomy of *Hibbertia* has changed significantly since that time, the records of *Hibbertia* contained within provide additional insight into the potential occurrences of threatened *Hibbertia* species.

The Straede T.M. 1990 "Vegetation of the proposed Londonderry Waste Disposal Site" report for Waste Management Authority, Sydney found *Hibbertia cistiflora* in the Castlereagh – Londonderry Crown Lands. It is unknown if this species occurs in the area or is a misidentification. Like *Hibbertia fumana, H*. *cistiflora* also has its anthers to one side of the ovaries.

The current survey was limited in extent and did not visit the area of the Straede survey which is outside the growth area. The surveys conducted by CFFIS did not locate any specimens of *Hibbertia cistiflora*. There are no other records in the district and most vouchered records in the Sydney Metropolitan area occur north of the Harbour and are associated with sandstone ridges often in proximity to shale caps and Sandstone Shale Transition Forest associations.

It is noted in Toelken & Miller 2012 that subsp. *quadristaminea* is "often wrongly identified in herbaria as *H. serpyllifolia*, but subsp. *quadristaminea* has few stamens only in one dorsal cluster" c.f. *Hibbertia ericifolia* (*H. serpyllifolia* misapplied) possessing usually 8-16 but up to 30 stamens, dependant on the subspecies surrounding and obscuring the ovaries. This highlights that even herbaria have mis-assigned *Hibbertia* specimens. The fact that *H. cistiflora* has its anthers on one side of the ovaries opens the slight possibility that the Straede record could be what is now *Hibbertia fumana*, however it is most likely to be *H. puberula*. It is possible that Straede had another taxon from within the then *H. riparia* variable species complex previously identified, thereby determining it to be *H. cistiflora*. There is also a *Hibbertia riparia* record from the adjacent Castlereagh Nature Reserve which we have determined to be most likely *Hibbertia puberula* as the current CFFIS survey recorded *Hibbertia puberula* within the Nature Reserve.

It is unknown if the *Hibbertia serpyllifolia* UBBS Site (P1) Londonderry – Castlereagh Crown survey by R.S. Lembit & T.A. James - woodland south of Devlin Road & NW end of Nutt Road record was based on field identification of fertile or infertile material. If it was based on fertile material it is most likely to be an unverified record of *Hibbertia ericifolia* group. If it was based on infertile material it is most likely to be *Hibbertia puberula* or possibly *H. fumana.* CFFIS has recorded *Hibbertia puberula* in this vicinity.

Hibbertia pedunculata recorded at Mulgoa (Blue Mountains NP Sydney Sandstone complex) Coveny, R. 1976 – 95 Species lists for Mulgoa (off Fairlight Road – Nepean River) Blue Mountains NP is likely to be that species, however there is a possibility that it could also be potentially be *H. fumana* or *H. puberula* if the Coveny observation was based on field identification of infertile material.

4.2 SURVEYS COMPLETED FOR THE BIOCERTIFICATION

From the information provided, no prior targeted searches have been undertaken for this species as part of the biodiversity certification assessment process.

Surveys undertaken by Ecoplanning and Biosis consultancies since 2017 have largely been confined to the deemed "development footprint" and appear to have been undertaken predominantly to comply with the BAM protocols for vegetation sampling for assessment purposes with little survey for threatened species. As such, no new occurrences of threatened *Hibbertia* species including *Hibbertia fumana* were recorded by Biosis or Ecoplanning through their survey efforts.

Access to a spatial viewer was provided by DPE to assist in the expert assessment. Whilst this tool has been useful in gaining a general overview, the information presented is limited and is acknowledged to "have been acquired and developed from numerous sources of differing dates, accuracy and completeness and may include errors in extent and content". CFFIS are not aware of any surveys performed specifically for *Hibbertia fumana* by DPE, Ecoplanning or Biosis Consultancies. The broadscale vegetation mapping of PCTs that was provided to assist with this assessment cannot identify the habitat niches that may be present on a localised scale.

The level of data available is insufficient to base an assessment of presence/absence for a Critically Endangered species purely as a desktop study.

4.3 SURVEYS COMPLETED FOR THIS ASSESSMENT

Surveys for the biodiversity assessment informing the development of the biodiversity certification were constrained by private lands access issues, time and the overall size of the biodiversity certification area.

4.3.1 SURVEY METHODS

The surveys undertaken by Miller as part of this expert report relied on assessment of known habitat traits of extant sites and, although highly speculative, inferred habitat traits from historic records. PCT mapping and aerial digitised photography were used to select potential habitat areas for targeted surveys. Priority was given to finding the same habitat as occurs at the Moorebank and Bankstown Airport sites, although a variety of vegetation associations that are known habitat of other *Hibbertia* species such as *H. puberula* were surveyed to include inferred habitat from historic records. *Hibbertia puberula* co-occurs with *H. fumana* at the Moorebank site and grows nearby to *H. fumana* site at Bankstown Airport.

Biological data sets were searched for records of *Hibbertia fumana* within the study area. The BioNet and ALA searches failed to find any records of the species in the growth areas. Searches included Urban Bushland Biodiversity Survey of Western Sydney (UBBS) NPWS 1997. *Hibbertia* species are notoriously mis-identified, and as the species was described in 2012 any records prior to that time would be under a different name. Searches were made of all *Hibbertia* records within and adjacent to the growth areas to ascertain if any misidentifications might be included in the data set.

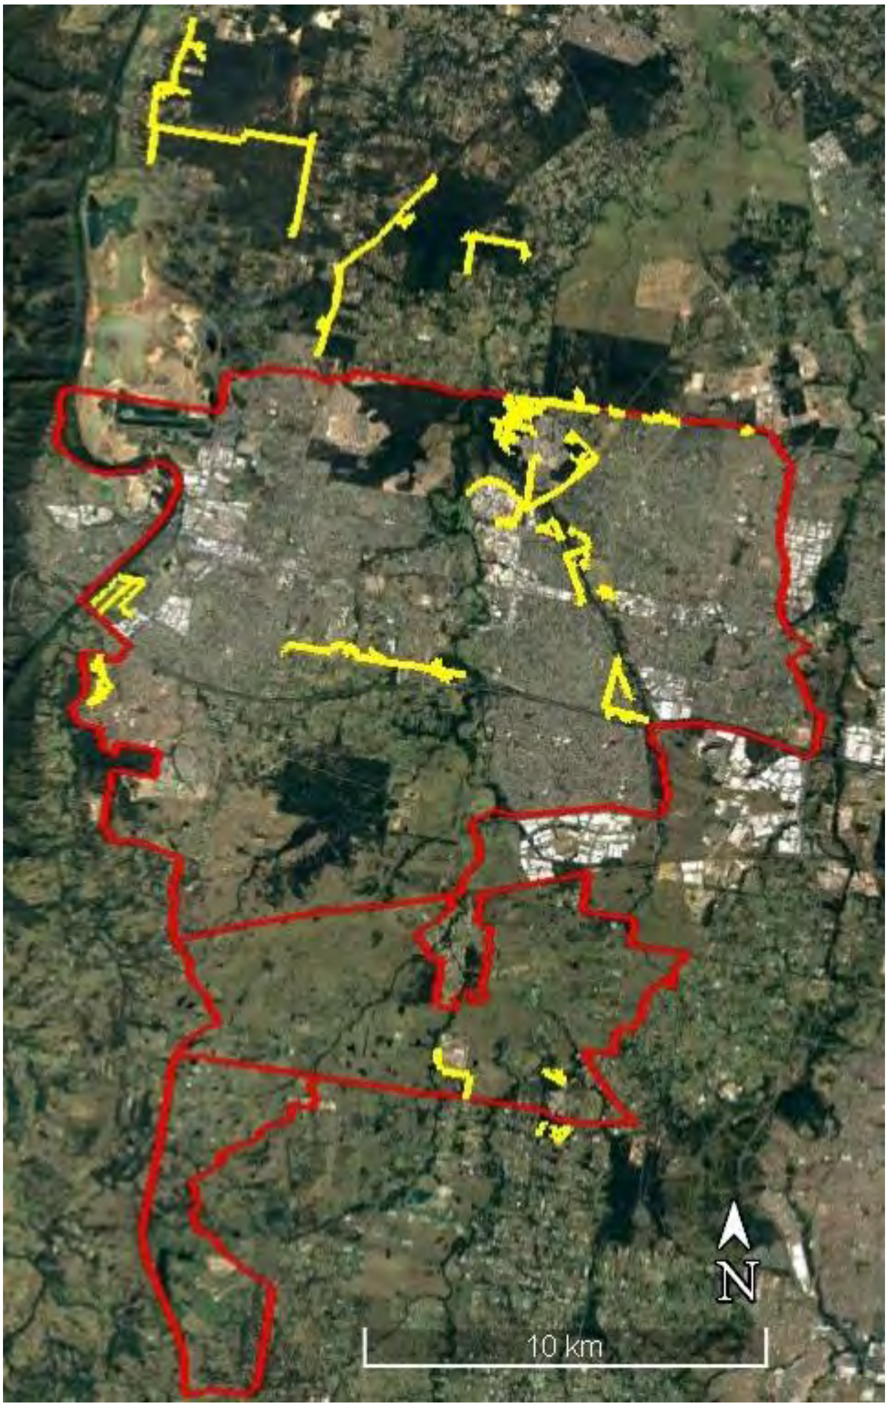
Records of *Hibbertia pedunculata*, *Hibbertia* sp., *Hibbertia* sp. A, *Hibbertia serpyllifolia* and *Hibbertia riparia* were included within the target survey effort where practical and where access had been granted. The large number of entries for *Hibbertia aspera* precluded visiting all known sites.

Searches were also made for indicative co-occurring species other than *Hibbertia* such as *Grevillea parviflora* subsp. *parviflora* to further refine the survey effort.

The prolonged rainfall deficient / drought period prior the survey effort posed significant challenges to the survey. Areas were targeted such as powerline easements where competition for moisture from large trees and shrubs was reduced and the targeted flora may have had greater chance of persisting through the dry period. This strategy was significant in locating one threatened *Hibbertia* adjoining Wianamatta Regional Park, namely *H. puberula*.

The greatest impediment to locating *Hibbertia* species during the survey was early petal drop of some species, thought to be increased due to the dry period and unusually high temperatures. This was most evident on 2nd November where petal drop of *Hibbertia puberula* had commenced before 8.30am (temperature of 30) and was complete by 9.30 am (temperature 32). As such, survey needed to start early in the day. There is no data available for the daily length of flowering times for *Hibbertia fumana*. Casual observations are not possible as access to known sites is restricted.

Map 4 shows the sites that were surveyed for this assessment, using targeted survey, random meander and in some locations of very low probability, drive past.



Map 4: Google Earth image of GPEC and WSA Growth Areas showing the tracks of CFFIS survey.

Key: Growth area approximate boundary shown in red, survey tracks shown in yellow.

4.3.2 SPECIES IDENTIFICATION

If a small-leaved *Hibbertia* was located that had macro morphological features resembling that of *Hibbertia fumana* then a specimen would be retained for later microscopic examination. CFFIS has also assessed the likelihood of *Hibbertia puberula* to occur in the GPEC and the WSA. *Hibbertia puberula* co-occurs with *H. fumana* at Moorebank and as both species are small-leaved, diminutive plants it is possible to misidentify *H. fumana* as *H. puberula* or other small-leaved species without careful examination (refer Photo 7). Selected specimens taken as part of the *Hibbertia puberula* assessment were microscopically examined to ensure that *Hibbertia fumana* was not inadvertently collected and dismissed as *Hibbertia puberula* or another small-leaved species. Due to the prevailing drought conditions plants were depauperate, such that any specimens removed consisted of very small fragments (eco-scraps) most only a few cm in length.

Figure 3 drawing depicts *Hibbertia fumana* in bud where those buds appear +/- sessile. During the Moorebank surveys it was purported by a consultant that pedunculate flowers are a key field identification tool even in bud. This is clearly erroneous and should not be used as the sole identifying feature (refer also to photo on the front cover, R.T. Miller and photo of the Isotype in Figure 2).

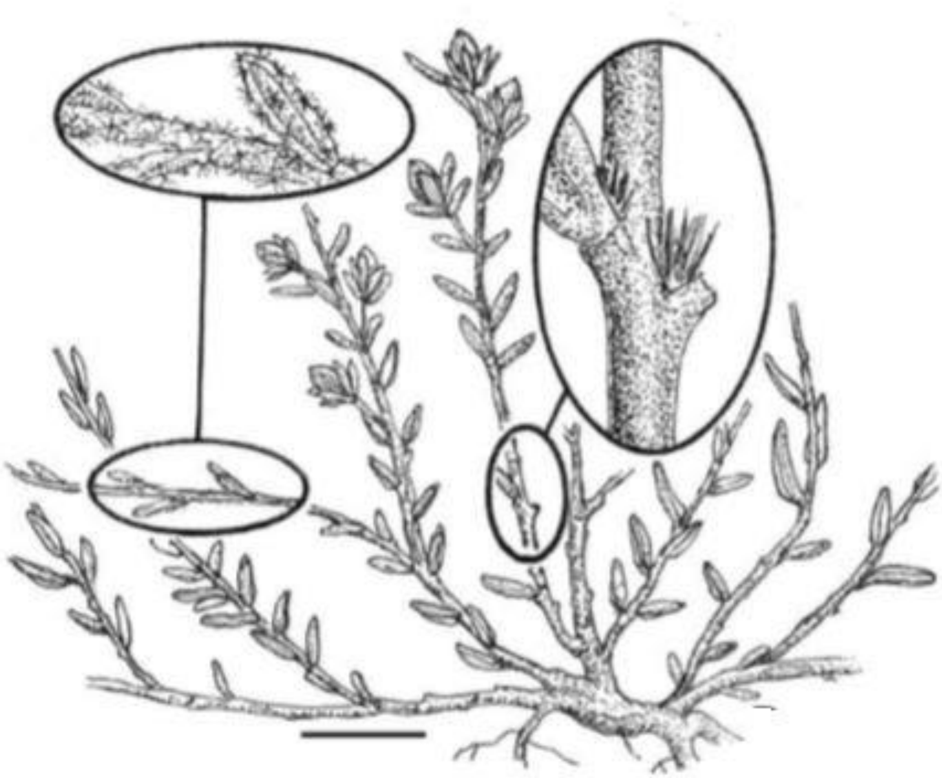


Figure 3: Stem and leaf characteristics of a flowering *Hibbertia fumana* specimen.

F.W. Sieber 147 (MEL 3111616) (Toelken and Miller 2012)

Peduncle elongation is clearly related to and is proportional to the developmental progression from buds to seed formation. Anecdotal observation by Miller suggests peduncle development is also related to environmental conditions such as moisture content of the soil and degree of exposure, for example, extended periods of low soil moisture and /or in combination with exposure appears to reduce peduncle length.

The species profile for *Hibbertia fumana* identifies some of the *Hibbertia* species with which it might be confused: "species with which it may be confused include *Hibbertia aspera* (peduncle of *H. fumana* is shorter, especially in flower, the foliage is more persistently hairy, and there are fewer stamens), *H. empetrifolia* (*H. fumana* is much more prominently stellate-hairy) and *H. riparia* (*H. fumana* has much shorter leaves). *Hibbertia superans* is another possible species for confusion, though *H. fumana* has smaller leaves" (OEH 2018).

It is unlikely that an expert would misidentify large / mature flowering plants of the above species with *Hibbertia fumana*. Confusion / unreliability is likely to arise if a population census is undertaken outside of optimal flowering time and/or the survey site is recovering from fire when a high proportion of the plants will be small and immature, or if depauperate in drought conditions.

There are several other small leaved diminutive Hibbertias that could be confused including *Hibbertia dispar*, *H. pedunculata*, *H. calycina* s.str. and other undescribed taxa.

Relying solely on stem and leaf characteristics in field survey can lead to mis-identification. *Hibbertia fumana*, *H*. *aspera* and *H*. *empetrifolia* have discolorous leaves and using this character alone on non-flowering specimens without a high-resolution microscopic examination could result in dismissing or mis-identifying a plant to be *H*. *fumana*. The discoloration of the under surface of the leaves in both *Hibbertia fumana* and *H*. *aspera* is due to the presence of a usually dense white/silvery tomentum whilst the leaf under surface of *H*. *empetrifolia* lacks dense tomentum but it is of a similar whitish coloration.

Apparent tomentum density and type on the stems and leaves will vary according to the section of branchlet examined and the prior climatic conditions. New growth is likely to have a higher density and a fuller range of hair types present whereas on older growth much of this tomentum will have "worn off" (Toelken), especially the longer simple hairs. Drought condition will see a marked reduction in new growth. *Hibbertia aspera*, like *H. empetrifolia*, shows much variation in different local populations as well as sometimes on the same plant (Toelken).

Hibbertia pedunculata was commonly encountered within suitable habitat. This floriferous species is readily identified in the field provided its flowers are open. It has normally (14-) 18-35 (-43) stamens surrounding the carpels c.f. *H. fumana* which has 5 or 6 (7), subequal stamens, clustered on one side of the ovaries. *Hibbertia fumana* could readily be overlooked as impoverished plants of *H. pedunculata* after petal drop or if surveyed outside the flowering season.

Hibbertia aspera was observed occasionally within potentially suitable habitat for *Hibbertia fumana* during the CFFIS survey but was noted in greater frequency within areas deemed unsuitable habitat such as Shale Plains Woodland.

Microscope photographs of *Hibbertia fumana* characteristic features used for identification during this survey by CFFIS are provided in Appendix 2, and Appendix 3 shows comparison photos of characteristics of *Hibbertia aspera*, *H. dispar, H*. *empetrifolia* and *H*. *pedunculata*.

Photo 7: Five species of Hibbertia, photo taken 30cm above specimens, but which one is which?

Key - A: *Hibbertia fumana* (Moorebank), B: *H. pedunculata* (Wianamatta Regional Park), C: *H*. *empetrifolia* D: *H. puberula* (Powerline easement), and E: *H*. *aspera* (Wianamatta Regional Park).

4.3.3 SURVEY ASSUMPTIONS

It was not possible to access and survey all the many bushland remnants within the Greater Penrith and Western Sydney Aerotropolis growth areas. As such, the first assumption was:

Assumption 1. *Hibbertia fumana* would not be found growing in bushland that is unlikely to be suitable habitat.

The author is familiar with the species type of habitat at the Moorebank Intermodal and Bankstown sites. Using this knowledge of geology, soil and vegetation type that is the known habitat of the species, areas of bushland that would not be suitable habitat were ruled out of the assessment.

Using this knowledge of habitat requirement, the second assumption was:

Assumption 2. *Hibbertia fumana* is likely to be present in areas that are known to be suitable habitat. While surveys in suitable PCTs since the species was described in 2012 have failed to find *H. fumana*, this is a cryptic plant and the precautionary principal should be applied to the potential for the species to occur in suitable habitat.

The survey was carried out following several years of drought in western Sydney, and many shrubs forbs and grasses were dead. This led to the third assumption:

Assumption 3. In areas of suitable habitat, where *Hibbertia fumana* specimens have not been found, the species could be present in the soil seed bank.

4.3.4 *HIBBERTIA* RECORDED BY THIS SURVEY

Six species of Hibbertia were observed whilst undertaking surveys for this report. They are:

Hibbertia puberula: This species is the subject of a separate report (Strategic assessment for Cumberland Plain Conservation Plan, Aerotropolis and Greater Penrith, *Hibbertia puberula* species group, R. Miller 2018).

Hibbertia pedunculata: Very significant populations of this species were observed in the GPEC within and outside the biodiversity certification areas in the Wianamatta Regional Park, also to the north in the former Air Services Australia Site adjoining the north of the GPEC.

Hibbertia diffusa: Widespread, sometimes locally common inside and outside growth areas. Most commonly observed on shale derived or influenced substrates including river-flat forests.

Hibbertia aspera: Widespread, sometimes locally common inside and outside growth areas. Most commonly observed on shale derived or influenced substrates.

Hibbertia acicularis: Noted in two areas outside the growth areas, at Agnes Banks Nature Reserve and Gulguer Nature Reserve.

Hibbertia fasciculata: Noted in one area outside the growth areas in Agnes Banks Nature Reserve, in Scribbly Gum Woodland.

It is a recommendation of this study that *Hibbertia pedunculata* be listed as a Threatened species or an Endangered Population, and taken into consideration as part of this biodiversity certification process.

Toelken (2013) in his revision of the *Hibbertia vestita* group, including *H. pedunculata* and *H. serpyllifolia*, considers *H. pedunculata* to be confined to NSW. Analysis of the cited specimens reveals that the species has two main areas of distribution the Greater Sydney Metro Area and the lower Hunter.

In the Greater Sydney Metropolitan area, the species has suffered a significant reduction in numbers and extant distribution due to urbanisation. Two cited locales occur within the growth area at St Mary's. The Greater St Mary's – Shane Park vicinity is now the only general vicinity that has long term viable habitat remaining for the species, that is, Wianamatta Regional Park including areas within the former ADI site not gazetted and the Former Air Services Australia site.

Of the twenty specimens cited in the Greater Sydney area six only are known to have extant populations, however all are under severe threat due to small population size and anthropogenic impacts. Nine populations are known or highly likely to be extinct.

4.3.5 INCIDENTAL SIGHTINGS OF SIGNIFICANT FLORA DURING THIS SURVEY

The bushland remnants surveyed were observed to support numerous threatened species including but not limited to *Hibbertia puberula*, *Persoonia nutans*, *Pultenaea parviflora*, *Dillwynia tenuifolia*, *Micromyrtus minutiflora* and *Grevillea juniperina*.

Photo 8: Habitat of threatened species recorded by this survey at Kemps Creek.

4.4 ASSESSMENT OF SPECIES PRESENCE

The previous survey data provided by Biosis and Ecoplanning Consultants was insufficient to assess the probability of occurrence of *Hibbertia fumana* from a desk top study. The species has demonstrated an ability to persist within suitable derived habitat, it was therefore appropriate to undertake specific targeted surveys.

A selection of areas mapped as suitable PCTs for *Hibbertia fumana* habitat were surveyed by CFFIS for the assessment. Areas of potential habitat identified as occurring within or adjacent to the biodiversity certification footprint were prioritised. We also surveyed for habitat appropriate to the species in small areas of potential tertiary sediments across the growth areas and adjacent lands, based on geology, soils and landform maps where access was provided.

4.4.1 LIKELIHOOD OF SPECIES PRESENCE

No specimens of *Hibbertia fumana* were observed whilst undertaking surveys for this report.

Non-detection should not be interpreted as the species not being present, but simply as not seen.

The population numbers of ground layer species at many locales were observed to be depauperate in areas of +/- intact canopy cover. A thick layer of detritus was noted to be suppressing the understorey in many places and particularly so if the site had a long fire interval. This was especially apparent within Wianamatta Regional Park and surrounds, including most of the area under the proposed urban footprint.

Similarly, the bushland remnant to the south of Elizabeth Drive, bounded by Western Avenue, and Cross Street, outside the growth area but used as a surrogate site, had significantly suppressed understorey. This included areas where known threatened species had been observed by Miller previously. Species such as *Grevillea parviflora* and *Dillwynia tenuifolia* had a significant retraction in apparent population numbers at that site.

Hibbertia fumana is known only from very few extant and historic records, this data suggests that *H. fumana* may have a very restricted distribution. The species is known only from a narrow band stretching from South Head, Connell's Point, Condell Park to Moorebank.

It is unknown, however, whether factors such as:

- the species only recently being described,
- being extremely cryptic,
- being easily misidentified and/or overlooked as a depauperate version of other species

may have resulted in populations being overlooked by past surveys.

The presence of this species cannot be dismissed on disturbance factors as the Bankstown Airport population survives in a highly modified environment. Bannerman and Hazelton (1990) in *Soil Landscapes of the Penrith 1:100,000 Sheet* map the entire site as disturbed terrain, although field observation by Miller and others have identified areas to retain the original soil profile. Areas of derived habitat have therefore the same probability of occurrence provided the soil profile is intact and anthropogenic factors have not irreversible change the soil chemistry and soil biota.

Hibbertia fumana is currently assessed as being Critically Endangered. There is limited ecological data available for this species. In this context, a precautionary approach is recommended. Locating and protecting new populations, no matter how small, is significant to the survival of this species.

Potential for *Hibbertia fumana* within the GPEC

The possibility of *Hibbertia fumana* occurring within the GPEC is assessed as low because potential habitat sites found within the biodiversity certification area do not have the same complexity of attributes to known extant sites. It is possible however that the species may exist in small habitat niches found within PCTs of the study area.

There is a moderate potential for *Hibbertia fumana* to occur to the north of the biodiversity certification area, not limited to areas such as the former Air Services Australia site, and the tertiary vegetation stretching from Agnes Banks, Berkshire Park, Castlereagh, Llandilo and Cranebrook vicinities. Many of the remnants in these areas are relatively large and support a complex mosaic of transitional vegetation between the various PCTs.

Photo 9: A complex mosaic of vegetation types occurs in this section of Agnes Banks NR.

The habitat depicted in Photo 9 shows PCT 958 Narrow-leaved Apple - Hard-leaved Scribbly Gum heathy woodland interface as it grades into PCT 1067 Parramatta Red Gum woodland on moist alluvium of the Cumberland Plain (occurring in the background). PCT 725 Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain occurs in close proximity. Such areas have a moderate probability of occurrence for *Hibbertia fumana*. No such areas with this complexity were observed within the GPEC growth area.

Of the sites investigated within the growth areas, no significant occurrences of typical PCT 883 were observed where Scribbly Gum grows on a +/- sandy substrate. Some sites adjoining and on the very northern extremity of the biodiversity certification area were recorded to support stands of *Eucalyptus sclerophylla* though the areas observed were on lateritised clays.

The most likely proximate potential habitat site to the GPEC is within the former Air Services Australia site which is immediately adjacent to the northern boundary of the GPEC (Photo 10). The area is mapped to support PCTs 725,724, 883 and 1067, and in combination provide a moderate likelihood of occurrence.

Photo 10: *Eucalyptus sclerophylla* growing on lateritised clay at the northern extremity of the GPEC.

Eucalyptus sclerophylla was noted to occur sporadically within PCTs 725 and 724 in the Wianamatta Regional Park. As PCTs 725 and 724 exist within the biodiversity certification area of the GPEC and Scribbly Gum is found within these communities, the presence of *H. fumana* cannot be dismissed entirely despite no pre-existing records or non-detection during this current survey. If present, *H. fumana* would be confined to very specific habitat niches.

The Bankstown Airport habitat data records “Soils are grey heavy clay with ironstone fragments present at surface. Other native species observed indicate a derived form of Cooks River / Castlereagh Ironbark forest community.”

Lateritised gravel soil and Cooks River / Castlereagh Ironbark forest are common in the northern GPEC, especially within the Wianamatta Regional Park. *Hibbertia puberula* subsp. *puberula* is a co-occurring species at Moorebank and *Hibbertia puberula* subsp. *glabrescens* is proximal (c. 450 m) to the *H. fumana* site at Bankstown. *H. puberula* was located adjacent to the Regional Park by this survey.

It is unknown if Scribbly Gum once occurred as part of the canopy layer at the Bankstown Airport *Hibbertia fumana* site. Remnant Scribbly Gum occurs nearby at the Georges River Golf Course on tertiary sands and a small Scribbly Gum Woodland remnant still exists C. 2.51 km to the south east adjacent Deverall Park.

Photo 11: Lateritised gravel soil substrate within the area of occurrence of *Hibbertia puberula*, east of Ropes Crossing.

No large occurrences of PCT 883 were observed by our survey effort within the Wianamatta Regional Park. The likelihood of the same complexity of habitat found at the Moorebank site to occur within the Regional Park is assessed as negligible. As such a long intergrade between PCT 725 and PCT883 was observed not to exist, however isolated small occurrences of Scribbly Gum were noted. This raises the possibility that localised potential habitat may exist in the area. The discovery of a localised occurrence of *Hibbertia puberula* adjacent to the Regional Park supports this assumption.

Derived habitat areas included in this assessment include the Ropes Creek environs between Ropes Crossing and Oxley Park. Relatively recent BioNet data for the area include records for *Grevillea parviflora* which suggests that potential habitat may exist here despite weed invasion being chronic along the immediate riparian zone and the invasive species *Eragrostis curvula* dominating large swathes of the derived grassland and remnant vegetation.

Large diversity of uncommon and common herbaceous species to the Sydney Metropolitan area including the rarely recorded forb *Murdannia graminea* were noted to be locally common in recently burnt and mown derived grassland under the powerlines. This suggest that other diminutive species such as *Hibbertia fumana* could still persist in the area.

Potential for *Hibbertia fumana* within the WSA

Within the Kemps Creek area of the WSA the likelihood of *H. fumana* occurrence was assessed to range from moderate to low potential adjacent the footprint. Two areas that were adjacent to the footprint and had moderate potential for the species had been mostly cleared in recent times.

The Kemps Creek area is 14 km from known occurrences of *H. fumana* and the complexity of habitat is more appropriate for the species (refer Photo 9). Similarly, a number of co-occurring threatened species have been recorded from the Kemps Creek area including a previously undocumented occurrence of *Hibbertia puberula*. *Grevillea parviflora* subsp. *parviflora* and *Persoonia nutans* are known to be proximate co-occurring species and were recorded by this survey at Kemps Creek.

Only a few remaining areas of remnant bushland exist in the Kemps Creek area. Those that remain are fragmented by development and variously modified and impacted by past and present land use practices. The exact extent of PCT assemblages that occurred in the area is uncertain, however it appears to have been a complex mosaic of various forest types with a diverse assemblage of minor habitat niches within the broader PCT community including heath and open woodland.

Site inspections supports this view with small areas of temporarily wet swales supporting heath/open woodland being observed. These have similarities to the Moorebank site of occurrence.

The Kemps Creek environs is therefore assessed to have potential habitat with a likely occurrence rating ranging from moderately high to low.

4.4.2 JUSTIFICATION FOR DETERMINATION

The following maps show an overview of areas containing potential habitat of *Hibbertia fumana*, based on vegetation mapping and BioNet records, within the GPEC and WSA. These areas were surveyed by CFFIS for this assessment. Vegetation mapping was provided by DPE.

Key to the maps is:

- development footprint – light orange
- CFFIS survey tracks - yellow
- vegetation type PCT 724 – dark blue
- vegetation type PCT 725 - dark green
- vegetation type PCT 835 – light blue
- vegetation type PCT 849 – olive green
- vegetation type PCT 883 – red
- vegetation type PCT 1800 – light green

4.5 ASSESSMENT OF SUITABLE HABITAT

4.5.1 SUITABLE HABITAT WITHIN THE GROWTH AREAS

This section provides detail of areas of suitable habitat within the growth areas that have been surveyed by CFFIS, and the outcomes of that survey.

Wianamatta Regional Park area and Outer Sydney Orbital corridor

Within the Regional Park and the Outer Sydney Orbital (OSO) corridor are areas mapped as having PCTs appropriate for *H. fumana* habitat. The potential for the species to occur in these areas is considered to be low.

Survey of the area did not locate the species. Non-detection was not viewed as meaning not present, but rather not observed. The bushland was very dry and had not been burnt for years. It is likely that if the species did occur in the vicinity it's occurrence would be confined to small localised patches that could be easily overlooked. The species is cryptic even in favourable times. Due to the preceding drought conditions the species may have contracted to the soil seed bank.

Hibbertia pedunculata and to a lesser degree *Dillwynia tenuifolia* and *Pultenaea parviflora* were used as surrogate indicator species in determining the likely impact of drought and fire regime on the population densities, within and outside of canopy cover in the assessment of likely occurrence of *Hibbertia fumana*. *Hibbertia pedunculata*, *Dillwynia tenuifolia* and *Pultenaea parviflora* were observed to be locally frequent species within some modified habitat areas.

Photo 12: *Hibbertia pedunculata* within derived habitat away from trees and shrubs.

In areas where these species were noted away from the influence of large trees and shrubs, they were easily discernible, flowering and vigorous. Under the canopy or within the rooting zone of trees and shrubs, flowering was significantly reduced but mostly absent and the apparent population densities low. Visible plants were typically in a late stage of senescence. This was particularly apparent with *Hibbertia pedunculata*.

Other shrub and ground layer species were also noted to be particularly sparse within the areas mapped as PCT 725 and PCT 724 within the Wianamatta Regional Park.

BioNet records the following species for the Regional Park that may indicate localised suitable habitat niches for *Hibbertia fumana*. Species include *Banksia spinulosus*, *Callistemon pinifolius*, *Baeckea diosmifolia*, *Hakea dactyloides*, *Isopogon anemonifolius*, *Leptospermum parvifolium*, *Melaleuca thymifolia*, *Pultenaea tuberculata* and *Xanthorrhoea minor*. The trees *Angophora bakeri*, *Corymbia gummifera*, *E. eugenioides*, *E. parramattensis* and *Eucalyptus sclerophylla* are also listed.

Photo 13: Typical condition of *Hibbertia pedunculata* within “intact” vegetation of the Regional Park.

Note: The *Hibbertia pedunculata* plant is exhibiting extreme water stress and lack of flowers. Detectability of *Hibbertia* in this state is very low.

Many areas were observed to have a particularly high percentage coverage of thick detritus further suppressing the groundcover. BAM plot data for the area records EP GPEC 18 litter cover as 83%, EP GPEC 01 as 93%, EP GPEC 03 as 83%, EP GPEC 12 as 100% and EP GPEC 08 as 72%.

These observations support the conclusion that non-detection of *Hibbertia fumana* within or adjacent to the development footprint (OSO corridor) within the Wianamatta Regional Park is likely to be attributable to a retraction to the soil seed bank rather than non-occurrence.

Photo 14: Typical high levels of detritus under the canopy Wianamatta Regional Park

Photo 15: Many hardy understorey species still show the symptoms of severe drought stress even following recent rains.

Ropes Creek Vicinity

A number of areas were targeted for survey along the Ropes Creek corridor, these were

- Whalan Reserve
- Tregear Reserve
- South of Whalan Reserve
- East of and to the south of St Marys Rugby League Club, Boronia Road North St Marys,
- Electricity Substation vicinity Kurrajong Road and Boronia Road, North St Marys.

The potential habitat sites in the Ropes Creek vicinity were selected based on the PCT mapping, aerial imagery and the following BioNet records:

Grevillea parviflora: 28/01/2015, Ropes Creek, Mt Druitt includes Whalan Reserve and Tregear Reserves, -33.77797 150.80575.

Dillwynia tenuifolia: near corner Roper Rd & Carlisle Ave, Colyton, -33.78435, 150.80540, Ropes Creek, Mt Druitt includes Whalan Reserve and Tregear Reserves -33.78544, 150.80727

Eucalyptus parramattensis subsp. *parramattensis*: Roper Road, St. Marys, -33.78435, 150.80540

Hibbertia pedunculata: Between power station and railway line near Boronia Park, St Marys

Grevillea juniperina: M4 Motorway, Ropes Creek includes Whalan Reserve and Tregear Reserves and near corner Roper Rd & Carlisle Ave, Colyton.

Grevillea parviflora and *Eucalyptus parramattensis* subsp. *parramattensis* are known co-occurring species at Moorebank and at Voyager Point. *Dillwynia tenuifolia* is a known co-occurring species at Kemps Creek and at Ropes Crossing. These species indicate the possibility of potential suitable habitat present in the Ropes Creek vicinity.

The condition of the vegetation and population status of some of the BioNet records remain unknown.

Both *Grevillea parviflora* and *Eucalyptus parramattensis* subsp. *parramattensis* were not located by this survey effort and the GPS points do not align with the descriptors.

The Ropes Creek vicinity was found to be severely impacted by weed invasion displacing most native species in many of the likely potential habitat areas. The majority of the Ropes Creek environs is therefore assessed as unsuitable habitat for *Hibbertia fumana* as no indicative co-occurring habitat species were located within the areas surveyed and these potential habitat areas were acutely degraded.

Further details of the habitat at these sites follows.

Whalan Reserve

Whalan Reserve is primarily developed as a recreational facility including sporting fields, BMX bike jumps, Whalan Model Car Club track, walkway / cycleway and exercise equipment. West of the pathway remnant river-flat forest and supplementary plantings were observed.

In the area surveyed the canopy / subcanopy was variously comprised of *Eucalyptus tereticornis*, *Angophora floribunda*, *Casuarina glauca, Acacia decurrens, A. parramattensis* and *Melaleuca decora*. A stand of Blue Box was noted west of the access road.

Photo 16: Whalan Reserve bushland west of the pathway.

The ground layer was impacted by weeds and dominated by *Eragrostis curvula* in many places. Despite this, numerous areas were observed to support a diverse array of indigenous species including: *Acacia falcata*, *A. elongata*, *Bursaria spinosa*, *Indigofera australis, Ozothamnus diosmifolius*, *Daviesia ulicifolia* var. *stenophylla*, *Tricoryne elatior*, *Phyllanthus virgatus*, *Opercularia diphylla*, *Cyanthillium cinereum*, *Cheilanthes sieberi*, *Glossogyne tannensis*, *Goodenia hederacea*, *G. bellidifolia*, *G. paniculata*, *Brunoniella australis*, *Chorizema parviflora*, *Chrysocephalum apiculatum*, *Centella asiatica*, *Glycine tabacina*, *Desmodium varians*, *Polymeria calycina*, *Zornia dyctiocarpa*, *Dianella longifolia*, *Lomandra longifolia*, *Microlaena stipoides*, *Themeda australis* and *Aristida* *vagans*. *Eucalyptus crebra*, *Melaleuca armillaris*, *Callistemon viminalis*, and *C. salignus* were noted in the plantings.

The river-flat community is atypical of *Hibbertia fumana* habitat as the higher nutrient status of the soils supporting typically a dense grassy /herbaceous layer is unsuitable habitat. However, the presence of minor alluvial terraces in combination with lateritised soil areas with relatively open ground layer provides a low potential for species presence.

Photo 17: Weedy understorey and habitat plantings at Whalan Reserve.

Photo 18: Remnant vegetation at Whalan Reserve severely impacted by *Eragrostis curvula*.

Photo 19: Minor alluvial terrace, potential habitat for *Hibbertia fumana* in Whalan Reserve.

Tregear Reserve

Tregear Reserve is primarily a developed recreational reserve with sporting fields, walkways/ cycleway, exercise facilities and an off-leash dog compound.

Undeveloped portions remain west of the pathway and include riverine remnant vegetation and large areas of unmown exotic grassland / herbland that has predominantly displaced the indigenous vegetation. Habitat enhancement plantings were noted along the bushland verge.

Habitat for *Hibbertia fumana* may have once existed at the interface between the alluvial floodplain and the lateritised rise. The potential habitat is too degraded to now support this species.

In the area surveyed the riparian vegetation was dominated by *Eucalyptus baueriana* with *Casuarina glauca*, *Acacia parramattensis*, *Melaleuca styphelioides*, *Bursaria spinosa* and the native grass *Microlaena stipoides* being relatively common.

Other indicative indigenous species noted included *Carex appressa*, *Scaevola albida*, *Dichondra repens*, *Centella asiatica* and *Alternanthera denticulata*.

The understorey in many locales is heavily weed impacted with species such as: *Eragrostis curvula*, *Chloris gayana*, *Setaria sphacelata*, *Verbena bonariensis*, *Rumex* sp. and *Tradescantia fluminensis*.

Enhancement plantings include: *Eucalyptus crebra*, *Casuarina glauca*, *Melaleuca styphelioides*, *M. decora*, *M. linariifolia* and *Bursaria spinosa*.

Photo 20: Looking across Tregear Reserve to the riparian zone of Ropes Creek

Photo 21: Treagar Reserve chronic weed infestation eliminating potential habitat for the species.

Although very limited in extent, a number of indigenous ground layer species were noted under the canopy of the enhancement plantings and to a lesser degree within the adjoining predominantly exotic weed meadow. Indigenous species noted include: *Wahlenbergia gracilis, W. communis, Centella asiatica, Tricoryne elatior, Microlaena stipoides, Phyllanthus virgatus*, *Rubus parviflorus*, *Glycine tabacina*, *Haloragis heterophylla, Cynodon dactylon* and *Glossogyne tannensis*.

The weed meadow adjoining the plantings was dominated by *Eragrostis curvula, Hypochaeris radicata*, *Plantago lanceolata*, *Melilotus albus* and *Paspalum dilatatum*.

The majority of the potential habitat was blanketed by dense weeds, primarily comprised of: *Eragrostis curvula*, *Cirsium vulgare*, *Verbena bonariensis*, *Melilotus albus*, *Foeniculum vulgare*, *Solanum sisymbriifolium*, *Bidens pilosa*, *Lactuca serriola*, *Plantago lanceolata*, *Chloris gayana*, *Nothoscordum gracile*, *Chenopodium album* and *Sorghum halepense*. No indigenous species were noted in this area.

Treagar Reserve vicinity is assessed as having no potential habitat remaining for *Hibbertia fumana*.

South of Whalan Reserve

The generalised geomorphology of the site is summarised by the intersection of the alluvial floodplain deposits of Ropes Creek with low lateritised rises. It is possible that such conditions once provided localised suitable habitat for *Hibbertia fumana*.

The potential habitat in this section of Ropes Creek is severely impacted by weed invasion and the potential for threatened species to now exist is negligible. A large area is being infilled with road ballast.

A small area of a few square metres was observed to support *Themeda australis* and *Wahlenbergia communis* and colonised by invasive species including *Briza subaristata*, *Eragrostis curvula*, *Hypericum perforatum*, *Lactuca serriola*, *Senecio madagascariensis*, *Verbena bonariensis* and *Hypochaeris radicata*. The site is surrounded by dense exotic vegetation now typical of the area.

No suitable habitat exists for *Hibbertia fumana* in this locale.

Photo 22: Eastern side of Ropes Creek south of Whalan Reserve.

Photo 23: *Eragrostis curvula* smothers potential habitat area of lateritised clay.

Photo 24: Only one small area of supporting *Themeda* was noted to remain.

Photo 25: The density of the grass and herbaceous layer precludes the possibility for the area to now support a viable population of *Hibbertia fumana*.

Boronia Road, North St Marys

A diverse herbaceous layer was observed in recently burnt sections of the powerline easement at North St Marys. Most locales including the adjacent wooded areas and containing PCT 724 were heavily infested with dense *Eragrostis curvula* tussocks, and this was smothering the ground layer.

Flowering species noted in one burnt area included *Murdannia graminea*, *Tricoryne elatior*, *Hypoxis hygrometrica* var. *hygrometrica*, *Isotoma fluviatilis*, *Ophioglossum lusitanicum* and *Hibbertia diffusa*. All of these plants were non-discernible under the adjoining tree cover and within the dense *Eragrostis* tussocks.

In the area inspected no indicative co-occurring species or habitat niches were noted that indicate likely potential habitat for *Hibbertia fumana*. Although the survey was very limited in its extent and duration, this area was assessed as unsuitable habitat for *Hibbertia fumana*.

Photo 26: East of and to the south of Boronia Road North St Marys.

Photo 27: North St Marys electricity easement environs.

Electricity Substation vicinity Kurrajong Road and Boronia Road, North St Marys

The selection of the electricity substation in the vicinity of Kurrajong Road and Boronia Road North St Marys is based on the BioNet records previously mentioned in addition to a BioNet record for *Hibbertia pedunculata* and PCT mapping on the Spatial Viewer. The fact that *Hibbertia pedunculata* was noted at the time of the BioNet entry indicates that the ground layer in that area was sufficiently intact to support diminutive species.

Many of the potential habitat zones along Ropes Creek have been significantly modified leaving a narrow band of vegetation along the immediate riparian zone. The modified areas are managed for various uses including in the Boronia Park vicinity sports fields and at the southern end the North St Marys Off leash Dog Park. These areas can no longer be considered potential habitat.

The riparian zone of Ropes Creek was noted to be particularly impacted by stormwater runoff with the understorey seriously degraded in many of the locales inspected. Where not degraded the PCTs were assessed as unsuitable for *Hibbertia fumana* based on current known ecological requirements.

The invasive *Eragrostis curvula* also dominated extensive areas. The potential for *H. fumana* to occur in Ropes Creek area is therefore considered to be low.

Photo 28: Open areas of lateritised clay soil to the east of the substation and north of railway line west of Ropes Creek support *Hibbertia pedunculata* and provide potential habitat for *H*. *fumana*.

Photo 29: Slashed native vegetation within the powerline easement, a potential habitat area for *Hibbertia fumana*.

Photo 30: An indigenous regrowth area between the substation and western railway line is potential habitat for *Hibbertia fumana*.

Kemps Creek area

The vegetation in the immediate vicinity of Lots 1, 2 and 3 DP812284 has been variously described as PCT 883 by Eco Logical Australia (2013), Ecoplanning (2015) and the Vegetation 100km consolidated layer in the Spatial Viewer, and Shale Gravel Transition Forest by Envirotech (2013). It is currently identified on the spatial viewer as PCT 725 on Lots 1, 2 and 3 DP812284 and PCT 724 as occurring to the east and west.

The vegetation in the Kemps Creek area has been dramatically altered with clearing for agriculture and removal of trees for various uses such as fence posts and firewood. The precise abundance of the various *Eucalyptus* species through the area is difficult to ascertain. *Eucalyptus sclerophylla* is obviously a major component within limited areas with stands still occurring south of Elizabeth Drive adjacent to Bill Anderson Park and the adjacent school. Scribbly Gum also appears to have been a major component of the canopy within Lot 3 DP812284 prior to clearance as documented within the Eco Logical 2013 report, refer Photo 31.

Photo 31: Scribbly Gum was an obvious common component of the site (photo Eco Logical 2013).

The presence of both temporary moist swale habitat niches and a transitional vegetation type comprised of Scribbly Gums, Broad-leaved Ironbark, Thin-leaved Stringybark and Woollybutt in combination with lateritised soil provides moderate to high potential of occurrence of *Hibbertia fumana*.

A periodic moist depression occurring on Lot 3 DP812284 provides habitat for species such as *Xanthorrhoea minor* indicating that before disturbance the area was likely to have supported a relative open small moist heath patch within the broader plant community. Such areas are potential habitat for *Hibbertia fumana*.

Lot 1 & 2 DP812284 Clifton Avenue, Kemps Creek in the Penrith local government area

The remnant vegetation is located at the rear portion of Lot 2 and the adjoining Lot 1. No access was granted therefore site assessment was limited to "through the fence" observation made from the adjoining property, Spatial viewer information and literature review of the Envirotech 2013 assessment.

An assessment by Envirotech 2013 noted a relatively intact flora community and that there was a healthy seed bank evidenced by the regeneration of native vegetation in disturbed portions of the property.

Photo 32: *Xanthorrhoea minor* growing in a periodically moist depression (photo S. Douglas).

Envirotech considered the site to have high species diversity including “well-represented herbaceous, understory and canopy layers that were clearly identifiable”. Weeds were confined to the perimeter of the property.

The “through the fence” inspection noted moderate to high potential habitat for *Hibbertia fumana* as species requiring periodic moist soil were easily detected and minor swales were noted. The habitat is +/- contiguous with the remnant remaining on the adjacent block (Lot 3) being separated only by perimeter trails.

Several undocumented threatened species were observed within the site including *Hibbertia puberula*, *Dillwynia tenuifolia* and *Pultenaea parviflora*. It was considered likely that *Grevillea parviflora* would also exist in the area.

Photo 33: Remnant bushland on Lot 2 DP812284, photo taken through fence.

Note: Subtle variation in elevation and possible substrate consistency providing periodic damp conditions supporting range of species e.g. *Xanthorrhoea minor* and potential habitat for threatened plants such as *Grevillea parviflora* and *Hibbertia fumana*.

Lot 22 DP 60122, 1541A Elizabeth Drive Kemps Creek and Lot 2 DP 587135, 146B Clifton Avenue Kemps Creek

Two blocks in the Kemps Creek area (Lot 22 DP60122 and Lot 2 DP 587135) are assessed as having a low to moderate probability of occurrence for *Hibbertia fumana*.

The majority of the understorey on Lot 2 DP 587135 could not be observed. It is included as potential habitat based on its continuity and close proximity to observed potential habitat areas. The area is mapped as PCT 724 thinned on the spatial viewer. Lot 22 DP60122 was assessed by ''through the fence'' inspection. The area is mapped as PCT 724 thinned on the spatial viewer. Much of the observable portions of the site are disturbed with weeds and fill dumping. Small areas were noted to contain an intact ground layer.

Photo 34: Lot 22 DP 60122, photo through fence taken from the adjoining block.

Note: small areas of regenerating native vegetation and intact ground layer occur within Lot 22 DP 60122. These provide potential habitat for threatened taxa.

Photo 35: View from south western corner of Lot 3 DP812284 into Lot 22 DP 60122.

Note: degradation of habitat by fill dumping and invasion of weeds, notably dense swathes of *Eragrostis curvula.*

Photo 36: Evidence of clearing, fill dumping and weed invasion degrading the habitat potential for threatened species Lot 22 DP 60122.

Lot 47 DP 734584 Kemps Creek

This block of land on Clifton Avenue is cleared and under investigation. It is most likely that similar moist habitat niches also occurred on this block. If so, they may have supported populations of *H. fumana* prior to clearing. From the most recent 31/10/2018 Google Earth imagery no habitat now remains on Lot 47. A narrow strip of very low potential habitat remains roadside.

Photo 37: Street view Google earth November 2016 of block to the north of Lot 3 DP812284.

Photo 38: Street view Google earth November 2016 of block to the north of Lot 3 DP812284.

Photo 39: Location of Lot 47 DP 734584, Lot 3 DP812284, Lot 2 DP587135 and Lot 22 DP601022.

Bushland Remnants Lot 4 DP812284 373 381 Clifton Road and Lot 6 DP812284, 316 Clifton Road, Kemps Creek

There are two blocks on the east side of Clifton Road that both have suitable habitat type although they are disturbed. These blocks have low to moderate probability for the species to occur.

The assessment was made from data shown in the Spatial Viewer from two BAM plots located on Lot 6. Species recorded include:

BIO WSAN 13: *Eucalyptus fibrosa* 15% coverage, *Eucalyptus globoidea* 1%, *Melaleuca decora* 2% and *Melaleuca nodosa* with a 15% coverage. Other species recorded each with a 1% coverage include: *Ozothamnus diosmifolius*, *Dillwynia sieberi*, *Dodonaea viscosa*, *Bursaria spinosa*, *Exocarpos cupressiformis*, *Aristida vagans*, *Lomandra gracilis*, *Daviesia ulicifolia*, *Dillwynia parvifolia*, *Pultenaea microphylla*, *Einadia hastata*, *Phyllanthus hirtellus*, *Pratia purpurascens*, *Eragrostis leptostachya*, *Entolasia stricta*, *Lepidosperma gunnii*, *Lepidosperma laterale*, *Cyathochaeta diandra*, *Lomandra longifolia*, and *L. multiflora*.

The only weed recorded in the BAM data is *Eragrostis curvula* with a 2% coverage.

BIO WSAN 14: *Eucalyptus globoidea* 30%, *Melaleuca decora* 2%, *Bursaria spinosa* 1% and *Cassinia uncata* 1% coverage. Ground layer species recorded cover 45% of the ground layer. They include: *Einadia hastata*, *Lomandra multiflora*, *Entolasia stricta*, *Eragrostis brownii*, *Cynodon dactylon*, *Dichelachne micrantha* and with *Microlaena stipoides* a 40% coverage.

Weeds in total had an 8% coverage, species recorded are: *Axonopus affinis*, *Sporobolus creber*, *Hypochaeris radicata*, *Sida rhombifolia*, *Eragrostis curvula* 1%, *Senecio madagascariensis*, and *Setaria parviflora*.

Photo 40: Google Earth image of Lot 6 DP812284 viewed from Clifton Road.

Remnant Vegetation North of Elizabeth Drive, Kemps Creek

The following Lots contain potential habitat for *Hibbertia fumana*: Lot 1 DP747285 1521 – 1539 Elizabeth Drive, Lot 1 DP1212980 1503 Elizabeth Drive, Lot 10 DP 1087346 1495 Elizabeth Drive Lot 16 DP2566 1491 Elizabeth Drive and Lot 1 DP 1o90754 1481-1489 Elizabeth Drive.

The two vegetation remnants north of Elizabeth Drive and south of Lot 2 DP812284 of land were assessed by ''over the fence'' and ''drive-by'' observation as access was not granted at the time of survey. Both sites were noted to have potential habitat from information contained within the spatial viewer, field observation revealed the small observable areas to be in poor condition and with low habitat suitability. Most of the vegetation was not able to be seen from the roadside.

The majority of the largest remnant Lot 1 DP747285 was not visible from the road. It is a large block extending northward from the road and adjoining the intact remnant on Lot 2 DP812284. Google Earth imagery provides evidence of potential moist swales to be present on the site. There is no BAM Plot data available for this site. The spatial viewer maps two vegetation types PCT 1067 thinned and PCT 725 thinned on the site providing potential likely habitat for the species. The remnant is bordered by a wholesale nursery in the west and a quarry to the east. Numerous site disturbances such as large areas of fill emplacement are observable on Google Earth Imagery providing evidence of degradation of habitat across much of the site.

The smaller remnant is bordered by the quarry on two sides and rural residential properties on Elizabeth Drive, consequently the impact of edge effects is likely to be high. Two BAM plots are located in this remnant and the Spatial viewer maps the site as PCT 725. The information provides some insight into the habitat.

BIO WSAN 10: *Angophora subvelutina* 15%, *Eucalyptus tereticornis* 5%, *Allocasuarina littoralis*, *Acacia decurrens*, *Ozothamnus diosmifolius*, *Acacia elongata*, *Cryptandra spinescens*, *Eragrostis brownii*, *Themeda australis*, *Glycine clandestina*, *Solanum prinophyllum*, *Hibbertia aspera*, *Microlaena stipoides* 50%, *Panicum simile*, *Eragrostis brownii*, *Cynodon dactylon, Lomandra multiflora*, *Juncus usitatus*, *Dichondra repens* and *Lepidosperma laterale*.

Weeds recorded in the BAM Plot include: *Ligustrum lucidum*, *Verbena bonariensis*, *Setaria parviflora*, *Bidens pilosa*, *Sonchus oleraceus*, *Eragrostis curvula*, *Senecio madagascariensis*, *Cyperus eragrostis*, *Ehrharta erecta*, *Anagallis arvensis*, *Araujia sericifera*, *Passiflora subpeltata*, *Chloris gayana*, *Axonopus compressus*, *Conyza* sp., *Sida rhombifolia*, and *Asparagus asparagoides*.

BIO WSAN 9: *Angophora floribunda*, *Eucalyptus tereticornis*, *Melaleuca decora, Acacia decurrens*, *Ozothamnus diosmifolius*, *Bursaria spinosa*, *Dillwynia sieberi*, *Themeda triandra*, *Glycine tabacina*, *Einadia trigonos*, *Opercularia diphylla*, *Brunoniella australis*, *Centella asiatica*, *Pratia puberula*, *Polymeria calycina*, *Microlaena stipoides*, *Aristida vagans*, *Entolasia marginata*, *E. stricta*, *Paspalidium distans*, *Dichelachne crinita*, *Echinopogon caespitosus*, *Cynodon dactylon*, *Lomandra multiflora*, *Carex inversa*, *Dichondra repens*, *Lepidosperma laterale*, *Lomandra filiformis* and *Cheilanthes sieberi*.

Weeds recorded in the BAM Plot include: *Senecio madagascariensis*, *Ehrharta erecta*, *Asparagus asparagoides*, *Cirsium vulgaris*, *Pennisetum clandestina*, *Cuscuta campestris*, *Sida rhombifolia*, *Opuntia stricta*, *Plantago lanceolata*, *Tradescantia fluminensis* and *Hypochaeris radicata*.

The representativeness of the habitat information contained within the BAM plot data is unknown. It is also unknown whether or not localised habitat niches prevail within the broader vegetation type as observed at other locales at Kemps Creek. Accordingly, the presence of *Hibbertia fumana* could not be ruled out though the likelihood of occurrence was assessed as low.

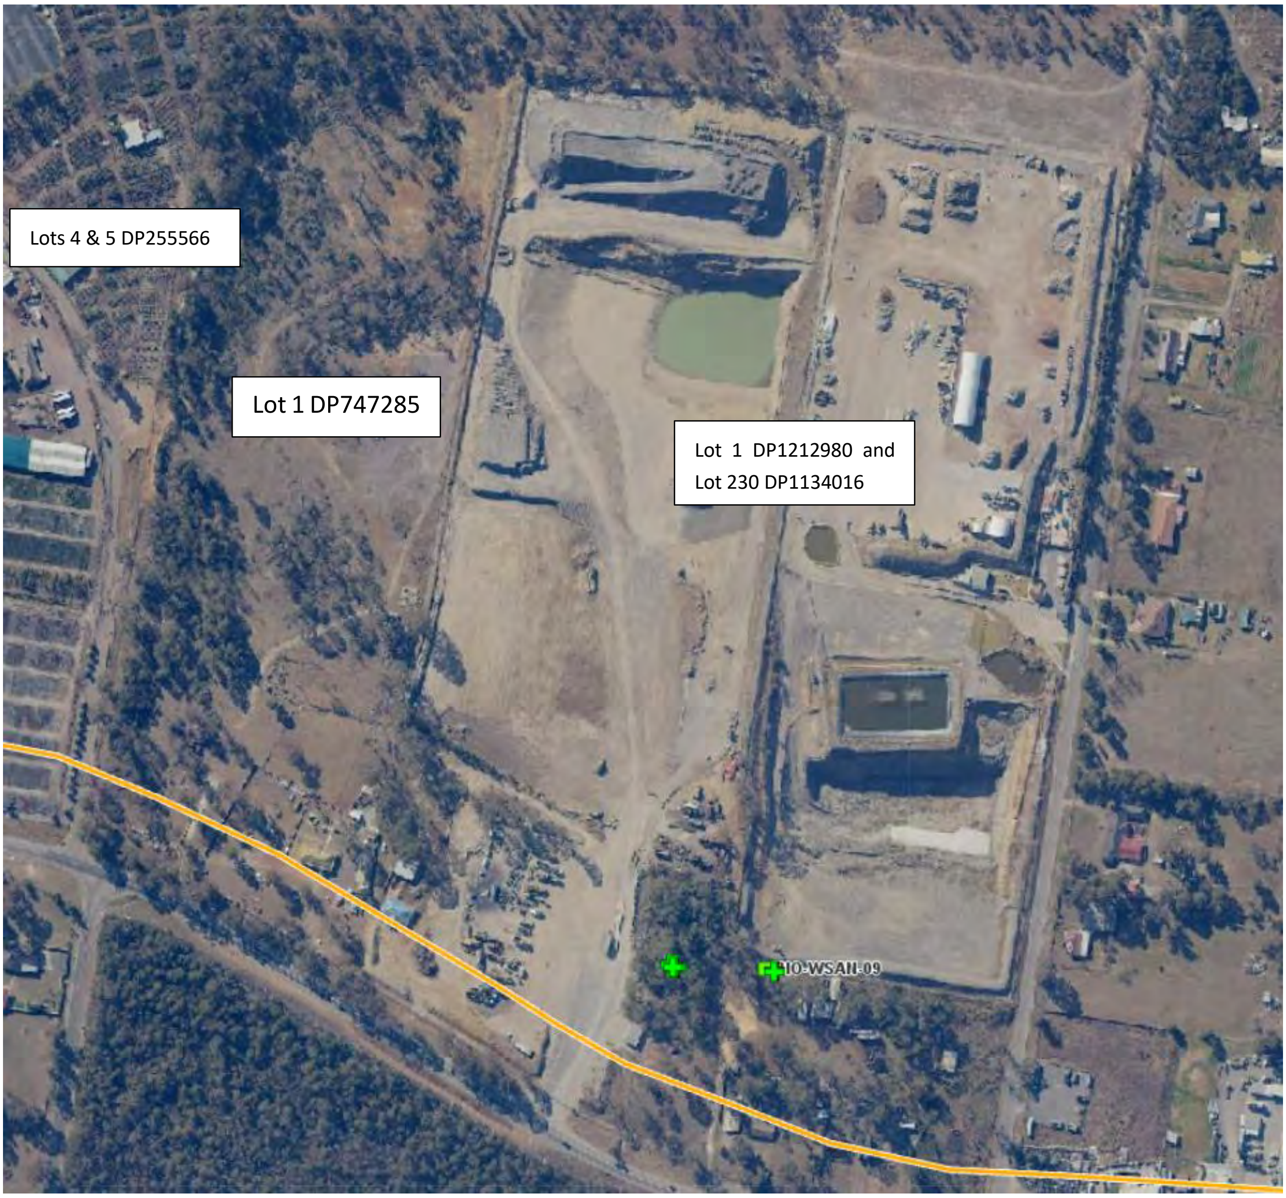

Photo 41: Location of BAM plots BIO WSAN 9 and BIOWSAN 10.

Note: Labels show the location of Lot 1 DP716403, Lots 4 and 5 DP255566, Lot 1 DP1212980 and Lot 230 DP1134016.

Photo 42: Land use practices have impacted upon the biological integrity of the site.

South of the SUEZ landfill site

Lot 4 DP860456, Elizabeth Drive, Kemps Creek.

Inspection of Lot 4 DP860456 was not granted. The area will not be certified due to pending investigation into clearing.

The determination of potential habitat occurring on Lot 4 DP860456 was therefore based on the information contained within the spatial viewer and google earth imagery. Drive by inspection was also constrained by the high volume of trucks entering and exiting the site and the adjoining Suez approved facility. There is a moderate probability that the species occurred in Lot 4 DP860456, as the spatial viewer identifies the area to have contained both PCT 725 and 724. The Google Earth imagery (Photo 43) shows a distinct change in vegetation and two farm dams (the larger on the adjoining property) indicating the presence of a moist depression. Periodically moist depressions in such habitats in the Kemps Creek area are known to support Threatened Species such as *Grevillea parviflora* e.g. at the bushland adjacent Bill Anderson Reserve. *Grevillea parviflora* is a co-occurring species with *Hibbertia fumana* at Moorebank.

Lot 4 is now mostly cleared and under investigation, with high volumes of fill emplacement being observe adjacent Elizabeth drive and the Suez facility 1. A linear band of vegetation remains in the central portion of the site.

Photo 43: Lot 4 DP860456 showing moist swale in the central portion of image prior to clearance and fill emplacement.

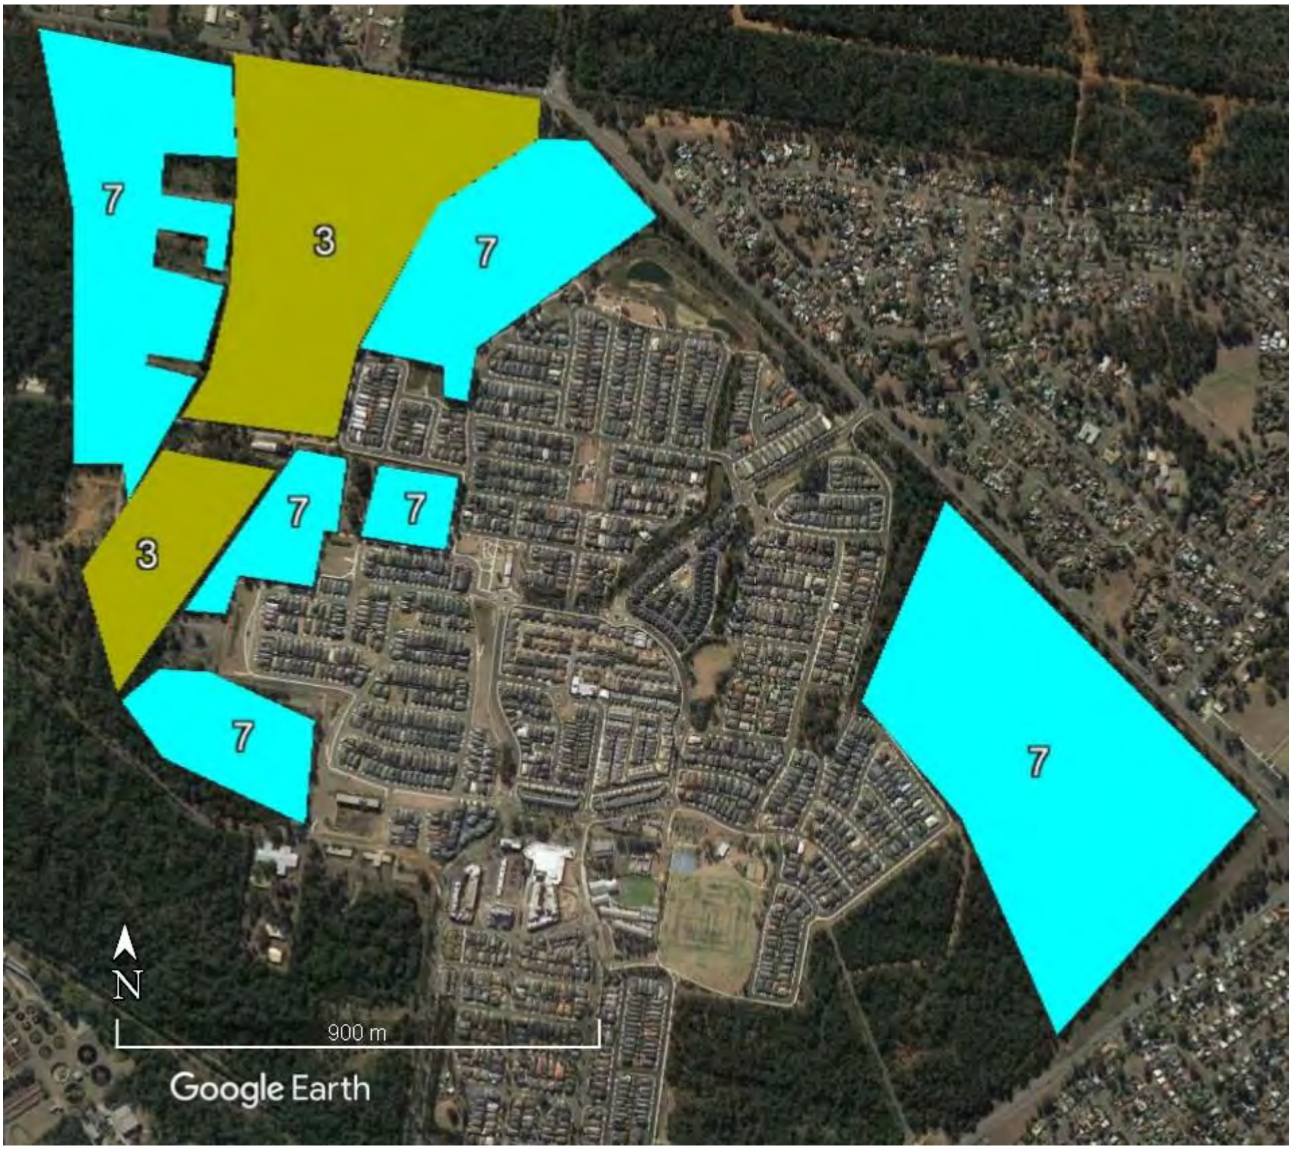
Photo 44: Google Earth Imagery 31/10/2018 Lot 4 DP860456 showing high volume of fill emplacement across most of the site. A small area remains providing some habitat potential.

Photo 45: Fill batter at northern end of Lot DP860456, South of SUEZ facility.

Note: This area is identified as not to be certified on the spatial viewer. Photo taken through fence from the adjoining SUEZ facility.

4.5.2 DETERMINATION OF SPECIES POLYGONS

Based on the available vegetation mapping, site survey and knowledge of the species habitat requirements, the following maps show the polygons of likely habitat and the estimated probability for the species to occur.



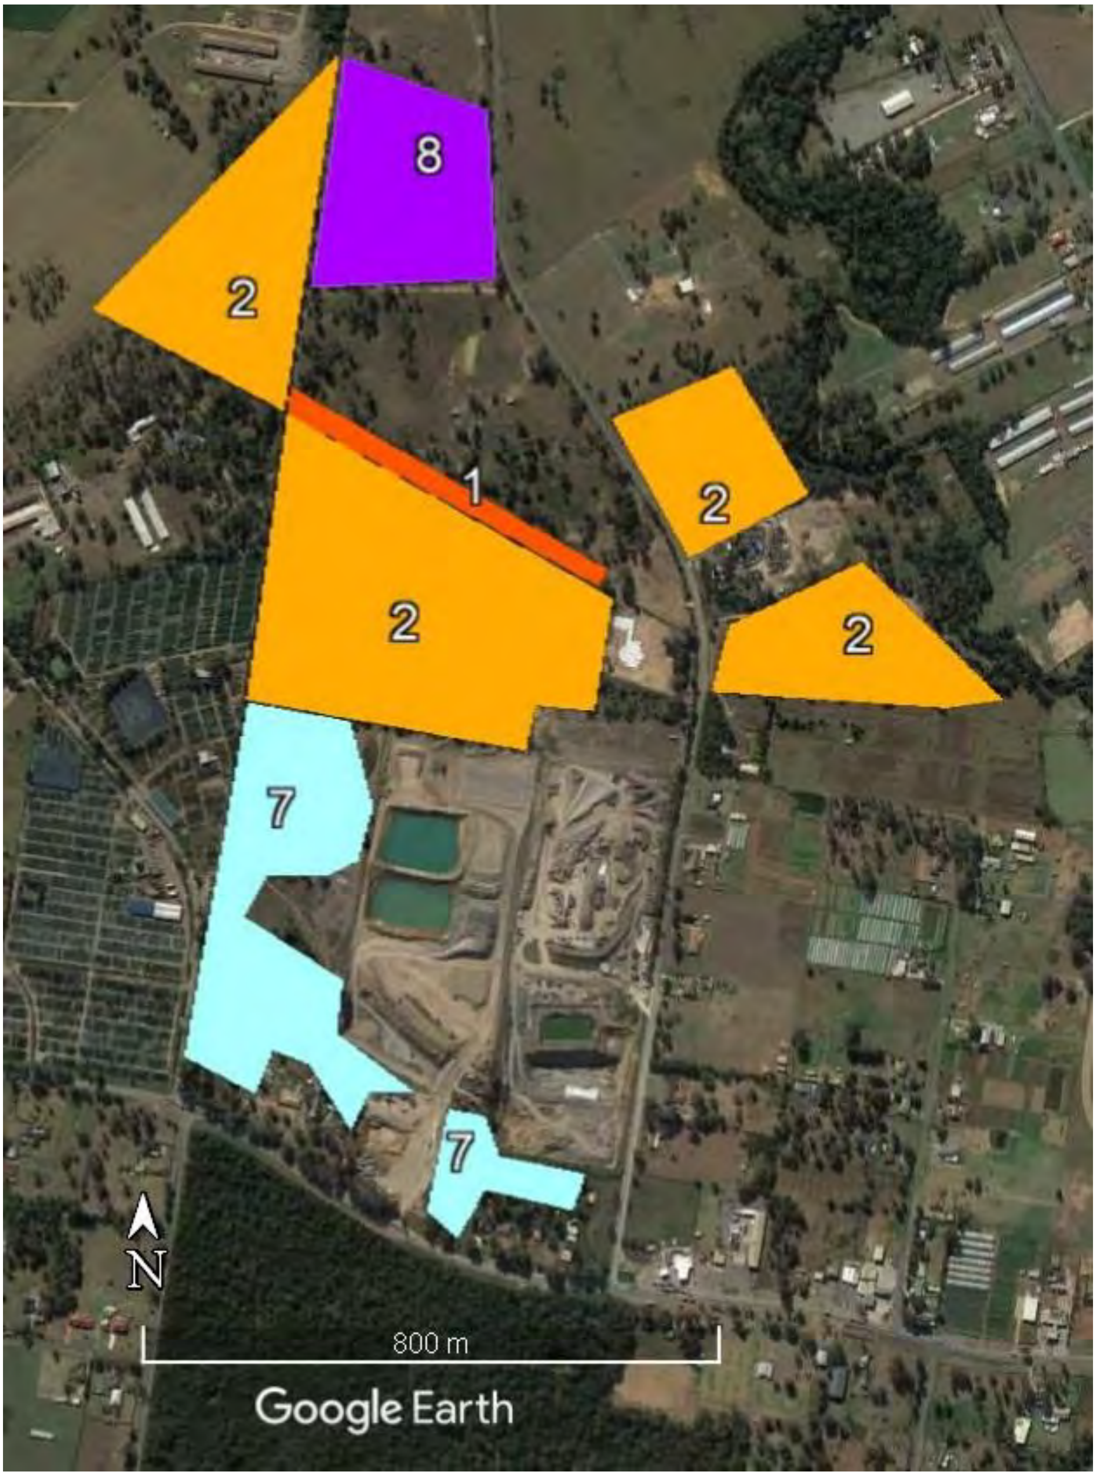
Map 11: Wianamatta Regional Park potential habitat sites.

Key: Within footprint, low probability, olive green - 3.

Proximate to footprint, low probability, light blue - 7

Map 12: Ropes Creek area potential habitat sites.

Key: Outside footprint, low probability, peach - 5



Map 13: Potential habitat sites in the Kemps Creek area

Key to map:

Removed from certification area, moderate probability for the species – dark orange - 1

Adjacent footprint, moderate probability for the species – pale orange - 2

Adjacent footprint, low probability for the species – pale blue - 7

Adjacent footprint, moderate probability for the species prior to clearing – purple - 8

Map 14: Former habitat site south of the SUEZ landfill site.

Key: Adjacent footprint, former moderate probability, purple - 8

4.5.3 ESTIMATE OF AREA OF HABITAT

The following are estimates of the potential habitat for the species. Note that the habitat could be small niches within these areas.

Greater Penrith to Eastern Creek Urban Release Investigation Area

Wianamatta Regional Park

In footprint, low probability, 32 ha.

Adjacent to the footprint, low probability, 77 ha

Ropes Creek vicinity

Adjacent footprint, low probability, 5 ha.

Western Sydney Aerotropolis Growth Area

Kemps Creek area

Removed from certification area, moderate probability, 1.47 ha

Adjacent footprint, moderate to high probability, 14.4 ha

Adjacent footprint, moderate to low probability, 15.6

Adjacent footprint, low probability, 10.25 ha

Adjacent footprint, moderate probability, cleared, 6.25 ha.

South of SUEZ landfill

Adjacent footprint, moderate probability, cleared, 4.4 ha.

In summary, 32ha of habitat with a low probability of the species occurring are within the development footprint, and more than 100 ha of habitat with moderate to low probability of species occurrence are outside the footprint but are likely to suffer from anthropogenic impacts caused by the development. More than 10 ha with moderate potential have recently been partly cleared.

5. Information used in the assessment

Information used in this assessment includes taxonomic papers, BioNet and ALA records of the target species, Critically Endangered Listing, online Threatened Species profile and associated documents, personal observations and site inspections, and the spatial viewer including the layers: survey access and coverage, (BAM plots, polygons and transects), PGA layer and geology and soils. Reference was made to Flora Appendix 2 & 3 of Western Sydney Biodiversity Survey NPWS 1997 for records of *Hibbertia species* observed in that study.

Employment Record

1993 – present

Cumberland Flora and Fauna Interpretive Services

Principal - flora surveys, plant identifications, vegetation assessment, project impact assessment, bush regeneration, rehabilitation, habitat enhancement, seed collection and propagation services.

1990 - 1997

Sylvan Grove Native Gardens

Curator of gardens and adjoining bushland - maintenance of and improvement to the plant collection, training and supervision of staff, liaison with other botanic gardens, guided tours, technical advice.

1982 - 1990

Sylvan Grove Native Gardens

Horticulturist Specialising in Australian Flora - collection, propagation, identification, and growing of native plants.

CUMBERLAND FLORA & FAUNA INTERPRETIVE SERVICES INFORMATION AND RELEVANT EXPERIENCE

Cumberland Flora and Fauna Interpretive Services have provided technical expertise since 1993 to numerous clients including Local Government, NSW Roads and Maritime, NSW Office Environment Heritage NPWS and community groups. Following is a list of some of our projects and clients:

REPORT	CLIENT
Expert advice for Conservation Assessment of *Solanum celatum* Eren Delgado 16/04/2018, Science Division, NSW Office of Environment and Heritage	OEH
Saving our Species (SoS) project for *Pomaderris adnata* a post fire population census Grid D 2018	OEH
Provision of expert advice to update the current ecological data for southern NSW threatened flora species, as part of the review of biodiversity assessments under the Biodiversity Conservation Act 2016.	OEH

REPORT	**CLIENT**
Expert witness in botany Residents Against Intermodal Development Moorebank Incorporated v NSW Minister for Planning and Anor – NSW Land & Environment Court Class 1 Proceedings No. 2017/81889. Review of project documentation, in particular the various biodiversity assessments including the BAM assessment for the project and Individual Expert Witness report of Dr David Robertson 15 October 2017; Site inspections to identify the location of and/or potential habitat for *Hibbertia fumana*, *Hibbertia puberula*, *Grevillea parviflora*, *Persoonia nutans*, *Acacia bynoeana*, provision of an expert report in accordance with Division 2 of Part 31 of the UCPR; confer with the other parties experts at a joint conference and produce a joint expert report; and f appear at the section 34 conciliation conference	EDO
Saving our Species (SoS) project for *Pomaderris adnata* a population census 2017	OEH
Central Coast Creek Monitoring Evaluating and Reporting 2016 – Vegetation Consultant	OEH
Great Lakes Creek Monitoring Evaluating and Reporting 2016 – Vegetation Consultant	OEH
Northern Beaches Creek Monitoring Evaluating and Reporting 2016 – Vegetation Consultant	OEH
Northern Beaches Creek Monitoring Evaluating and Reporting 2015 – Vegetation Consultant	OEH
Clarence Colliery Discharge Investigation April 2015	OEH
Vegetation Assessment as part of the Lachlan Wetlands Condition Assessment Project October 2013 – May 2014	Lachlan Catchment Management Authority
Field expertise and guidance in the Sydney basin to PhD candidate Karen Muscat studying the molecular phylogenetics and morphology of the genus Dianella with close scrutiny of the variation in the D. *caerulea* group of species in eastern Australia	Volunteer to University of Melbourne
Survey for *Pomaderris adnata* to determine population size, structure, occupancy and threats 2014	NPWS Illawarra Region
Survey of *Hibbertia stricta* subsp. *furcatula* (Hibbertia species ‘Menai’) to determine population size, structure, occupancy and threats. Collection of voucher herbarium material for taxonomic review June 2014	OEH
Survey of the southern populations of *Hibbertia stricta* subsp. *furcatula* (Hibbertia species ‘Menai’) to determine population size, structure, occupancy and threats May 2014	OEH
Investigation of works within the Sublime point precinct Illawarra Escarpment State Conservation Area February 2014.	NPWS Illawarra Region
Identification of Hibbertia species in proposed control burn sites Victoria Road precinct Dharawal National Park.	NPWS Illawarra Region
Assessment of impact of infrastructure upgrade Victoria Road, Dharawal National Park – location of threatened species.	NPWS Illawarra Region
APPEAL IN RESPECT OF PROPERTY AT Lot 1 and 2 DP 224431 Site 2 Sturdee Avenue, Bulli	Roy ‘Dootch’ Kennedy

REPORT	CLIENT
Expert Witness Report Relating to Some Environmental Issues Land & Environment Court of New South Wales PROCEEDINGS NO 10982 of 2012	Roy 'Dootch' Kennedy
Field surveys, collection, pressing, curation of botanical specimens and contributions of notes in association with the manuscript "Notes on Hibbertia subgen. Hemistemma (Dilleniaceae) 7. Eight new species, a new combination and four new subspecies from mainly central New South Wales H.R. Toelken & R.T. Miller 2006 - 10 July 2012	Volunteer to Adelaide Botanic Gardens
Vegetation Surveys and assessments & input into the preparation of REF for proposed car-park and amenities Victoria Road Precinct Dharawal National Park November 12.	NPWS Illawarra Region
Office of Environment and Heritage – Priority Action Statement Expert Consultant Interviews June 2012 – January 2013	OEH
Vegetation Surveys and assessments & input into the preparation of REF for proposed walking track re-alignment Maddens Falls in Dharawal National Park 2011 – 12.	NPWS Illawarra Region

Special Projects

- "Flora of Bankstown" a botanical inventory
- Founder & Convener Cookson's Landcare Group Bulli (2003 – 2007)
- President, Society for Growing Australian Plants, East Hills Region, 1987-1995.

- Vice President, Society for Growing Australian Plants, East Hills Region, 1996.
- Plant Steward, Society for Growing Australian Plants, East Hills Region, 1987-1996.
- Leader of the Prostanthera Study Group Australian Plant Society, 1992 - 2010.
- Editor and publisher of Prostanthera & Westringia Study Group's Newsletter *The National Mint* and the Study Groups' Journal – *Lasianthos*.
- Vice President and Founding Member, Bankstown Bushland Society.
- Coordinator Grants Application, Bankstown Bushland Society.
- Bushland Regeneration Grants Project Manager, Bankstown Bushland Society:
  - Deverall Park Restoration and Rehabilitation Swamp Woodland ($17,880).
  - The Crest of Bankstown Restoration and Rehabilitation ($27,850).
  - Airport and Ashford Reserves Restoration and Rehabilitation Swamp Woodland ($45,000).
- Co-recipient of Save the Bush grant for Flora of Bankstown by Hon. Ross Kelly, Minister for Arts, Sports and Environment, 1992-93 ($11,050).
- Founding Member of Illawarra Grevillea Park, Bulli.
- Curator, Lamiaceae collection, Illawarra Grevillea Park, Bulli.
- Former Bankstown City Council's Bushfire Taskforce Community Representative.
- Former presenter of an adult education course in gardening at Bankstown Evening College.
- Development and curation of a private regional herbarium.
- Expert Witness for NSW Police murder trial
- Former appointee as Trustee of the Georges River State Recreational Trust by the Minister for the Environment (the Hon. Tim Moore).

Expert report – *Hibbertia puberula*

Hibbertia puberula species group – Wilton and GMAC, Robert Miller, August 2018

Hibbertia puberula species group – WSA and GPEC, Robert Miller, December 2018

Strategic assessment for Cumberland Plain Conservation Plan

Hibbertia puberula species group

Hibbertia puberula subsp. *glabrescens* at Bankstown Airport

Report prepared for Department of Planning and Environment

By

Cumberland Flora & Fauna Interpretive Services

Robert Miller - August 2018

Executive Summary

Hibbertia puberula subsp. *extensa* and subsp. *puberula* are listed as an Endangered Species under the *Biodiversity Conservation Act 2016*. *Hibbertia puberula* subsp. *glabrescens* is listed as a Critically Endangered Species, being known from only one population at Bankstown. The species group is assessed as data-poor.

Survey for this report was limited by time constraints, lack of access to private property, survey outside the species' flowering season and years of preceding drought conditions. Assessment of potential habitat area relied on the expected presence of likely habitat, based on habitat of extant populations.

Specific habitat niches of potential occurrence include upper drainage lines, seepages especially those associated with exposed sandstone bedrock or slabs, margins of hanging swamps / wet heath, exposed sandstone rock plates, and large and small occurrences of colluvial or alluvial deposits.

Positive identification to species and subspecies requires flowers, which were not available, so *Hibbertia* that had leaf and stem characteristics consistent with *H. puberula* were considered to be that species. Despite the limitations, survey located three new populations of *Hibbertia* that had leaf and stem characteristics consistent with *H. puberula* within the growth areas and adjacent to the footprint.

H. puberula is a small shrub that could be severely affected by anthropogenic impacts resulting from development edge effects, particularly in areas downhill of development.

The assessment identified:

- Likely habitat for *Hibbertia puberula* subsp. *extensa* occurs within the footprint in the southern part of the WGA, habitat would be small seepages or wet heath within an area of 23ha.
- A further 278ha of land that could contain habitat niches for *H. puberula* subsp. *extensa* is adjacent to the footprint in the southern section of the WGA and the eastern side of the GMGA between Appin and Wedderburn.
- Likely habitat for *Hibbertia puberula* subsp. *glabrescens* occurs at Menangle Park. An area of approximately 92ha could contain likely habitat niches within the growth area footprint, and a further 31 ha of land containing likely habitat niches adjacent to the footprint.
- Likely habitat for *Hibbertia puberula* subsp. *puberula* occurs outside the development footprint at Milton Park, Kayess Park and in the vicinity of Bunbury Curran Creek reserve.
- Likely habitat for subspecies *puberula* within the development footprint occurs at Menangle Park (92ha), Gilead and Appin areas (8ha) and WGA (65ha).
- Likely and known habitat for subspecies *puberula* adjacent to the development footprint occurs at Menangle Park (31ha), Gilead and Appin areas (380ha) and WGA (680ha).

Survey during the flowering period is recommended, to identify the subspecies of *H. puberula* and to locate further populations within and adjacent the growth areas.

1. Introduction

1.1 PURPOSE

The purpose of this expert report is to determine the potential for future urban development in identified growth areas of Western Sydney to impact on *Hibbertia puberula*, the subspecies of which are listed as an Endangered or Critically Endangered Species under the *Biodiversity Conservation Act 2016*. This report forms part of the Cumberland Plain Conservation Plan, which will be assessed under the:

- Biodiversity certification under the *Biodiversity Conservation Act 2016* (BC Act)
- Strategic assessment and approval under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act).

The Biodiversity Assessment Method (BAM) sets out the framework and methods to be used for assessment of impacts to biodiversity to provide preferred conservation outcomes while also supporting the development approval process. Under the BAM an expert report can be used when adequate survey is not possible. An expert report can only be used for species to which species credits apply.

The expert report must document the information that was considered, and/or rejected as unsuitable for consideration, to reach the determination made in the expert report. The report must set out whether the subject species is likely to be present at the development site, and if present then the report must estimate, in the case of a species such as *Hibbertia puberula*, the area of habitat where the species is likely to be impacted, as well as areas from which it is known to occur in which it will be impacted.

1.2 PROJECT CONTEXT

The NSW Government is planning for future urban development in Western Sydney. Four growth areas have been identified, these are Wilton, Greater Macarthur (Campbelltown and Appin), Western Sydney Airport, and Greater Penrith to Eastern Creek. These growth areas are all located within the Cumberland Subregion in version 7 of the Interim Biogeographic Regionalisation for Australia (IBRA) (2016).

As part of the planning for this future development, the Department of Planning and Environment (DPE) is preparing the Cumberland Plain Conservation Plan. This is a strategic regional assessment that will lead to the identification of preferred conservation outcomes for the Cumberland subregion.

1.3 STUDY AREA

Map 1 shows the Cumberland Plain Conservation Plan Study Area and the two growth areas of Greater Macarthur (GMGA) and Wilton (WGA).

1.4 SPECIES SURVEYS

<u>Survey timing</u>

Survey for species such as *Hibbertia puberula* are usually carried out during the flowering period of October to December because the plant is a small shrub which can be quite cryptic. The bright yellow flowers, although small c. 10 – 20mm are readily discernible in bushland environs. Surveying in the flowering period makes species counts more reliable and relatively easy. Without flowers the tiny green leaves can hide amongst leaf litter, grasses and other ground covers making species counts near impossible and extremely unreliable.

The survey for this expert report was initially required to be completed within the month of June, when the species is not in flower. Further, the survey follows several very dry years which has caused high levels of leaf fall from trees and retraction of many shrubs to ground level. The following two photos show a close-up view of a *Hibbertia puberula* and the same plant from 2m away. These photos demonstrate the difficult task of finding *Hibbertia puberula* in the field when it is not in flower.

Photo 1: *Hibbertia puberula* plant at Smith's Creek Reserve at Campbelltown.

Photo on the left shows a *Hibbertia puberula* plant, the photo on the right shows the same plant from 2m distance. Scale: individual *Hibbertia* leaves are c.5mm. The photo depicts the largest and most obvious plant found.

<u>Survey methods</u>

To compensate for some of these difficulties the survey for this report followed the following steps:

- Visit known localities of the species, locate some *Hibbertia puberula* plants, and take particular note of the habitat characteristics, plant habit, co-occurring species and population density in the context of the protracted rainfall deficit and;
- Examine the Plant Community Type maps provided by the Department of Planning and Environment;
- Locate potential habitat sites based on the mapping and expert knowledge of the plant habitat requirements;
- Visit as many of these potential habitat sites as possible, considering time and access constraints; and
- Survey these potential habitat sites for the species.

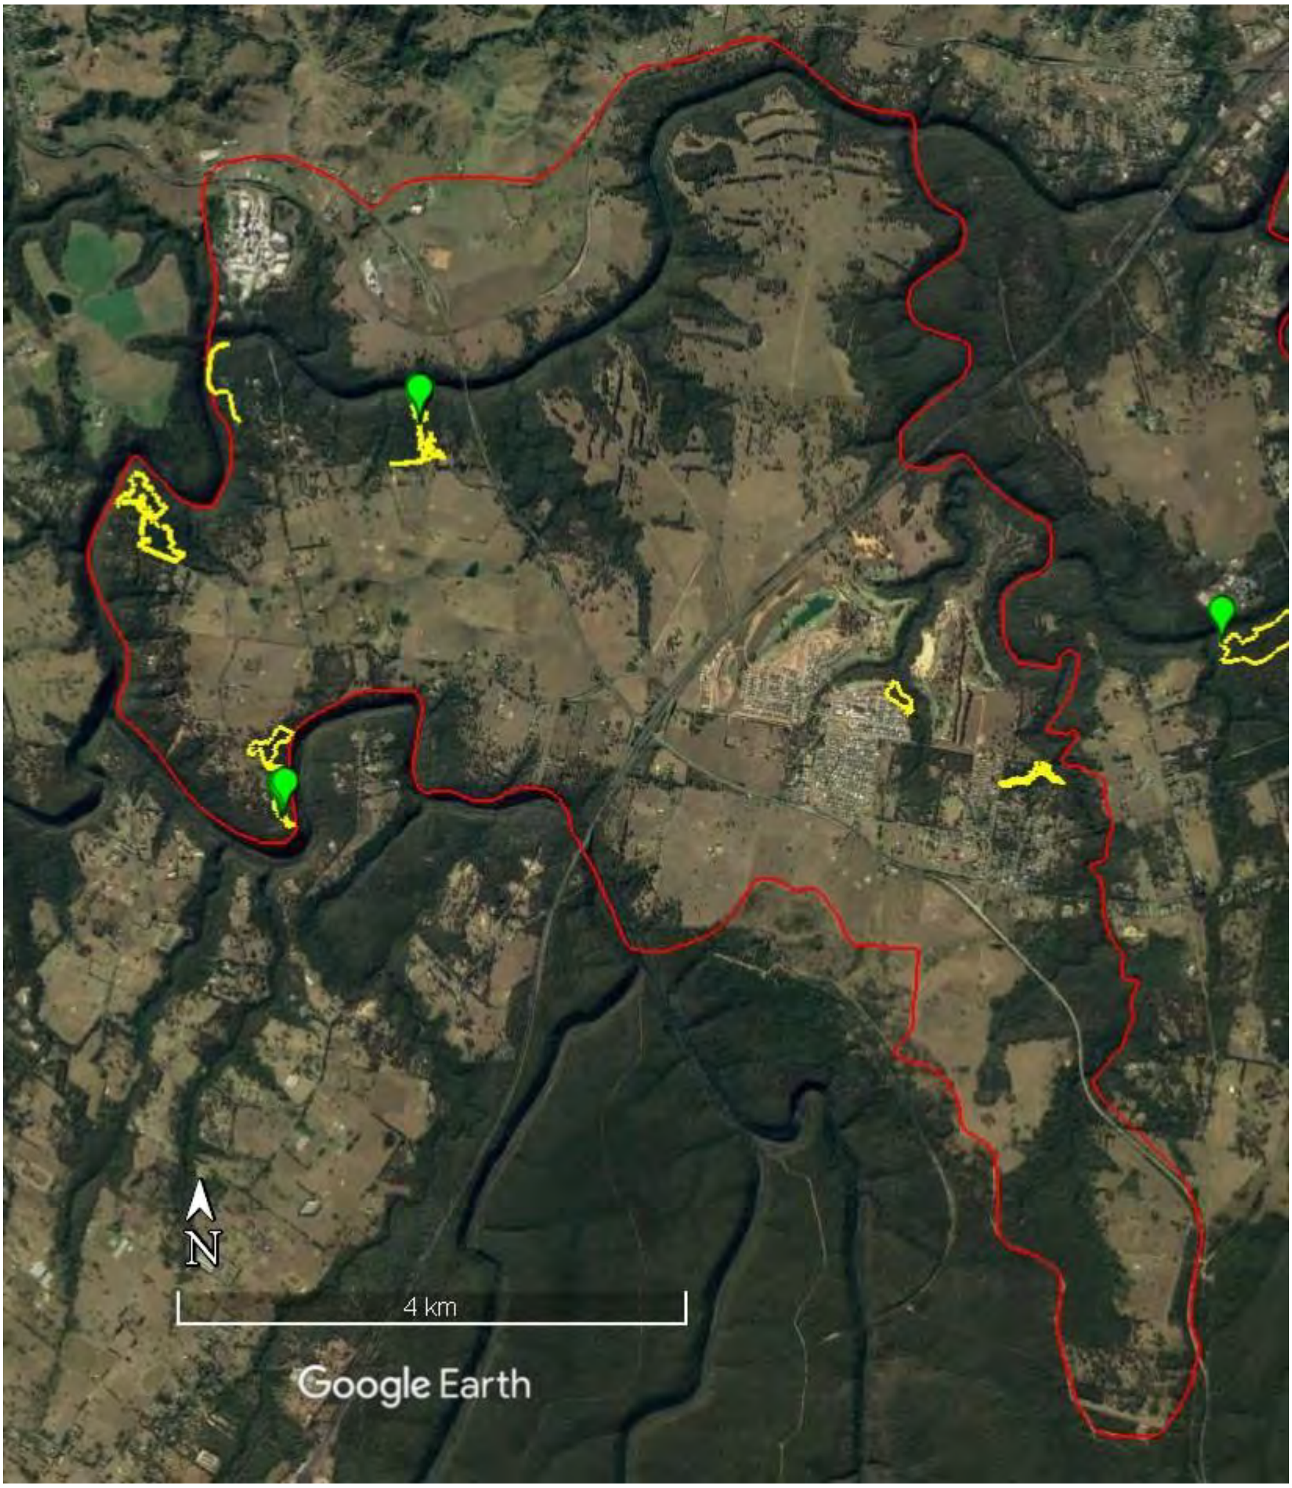
Surveys for the biodiversity assessment informing the development of the biocertification were constrained by private lands access issues, time and the overall size of the biocertification area.

Surveys undertaken by Ecoplanning and Biosis consultancies since 2017 have largely been confined to the deemed “development footprint” and have been undertaken predominantly to comply with the BAM protocols for vegetation sampling for assessment purposes with little survey for threatened species. As such, no new occurrences of threatened *Hibbertia* species including *Hibbertia puberula* were recorded by Biosis or Ecoplanning through their survey efforts.

Access to a spatial viewer was provided by DPE to assist in the expert assessment. Whilst this tool has been useful in gaining a general overview, the information presented is limited and is acknowledged to “have been acquired and developed from numerous sources of differing dates, accuracy and completeness and may include errors in extent and content”. CFFIS are not aware of any surveys performed specifically for *Hibbertia puberula* by DPE, Ecoplanning or Biosis Consultancies in the context of this project. The broadscale mapping of plant community types (PCTs) that was provided to assist with this assessment cannot identify the habitat niches that may be present on a localised scale.

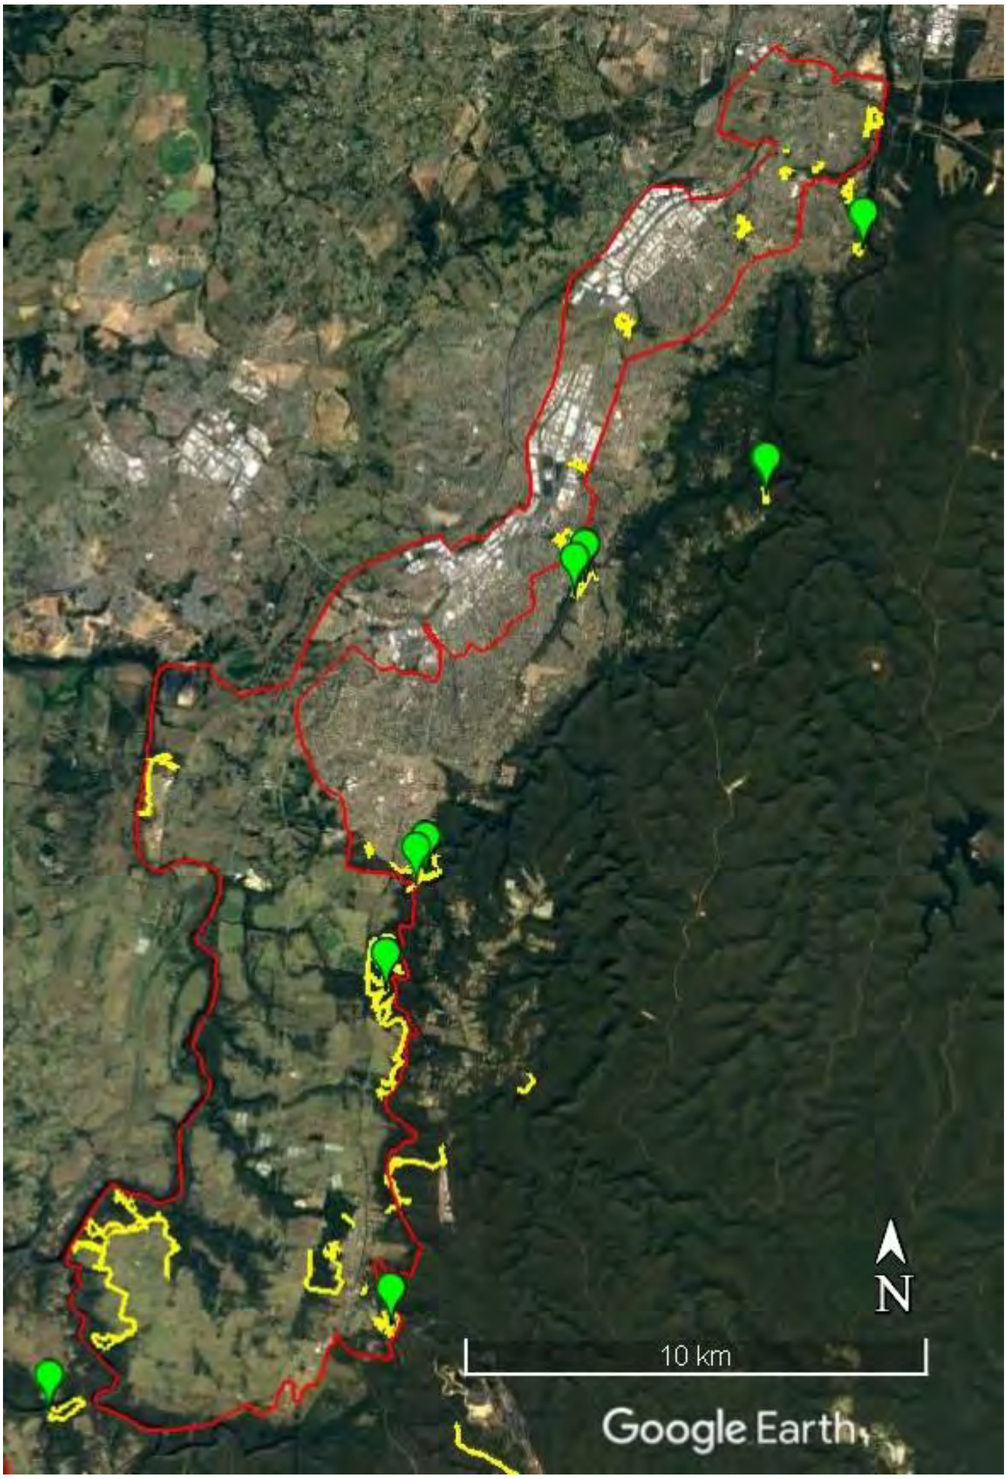
The surveys undertaken by CFFIS as part of this expert report relied on assessment of known habitat traits of extant sites. PCT mapping and aerial digitised photography were used to select potential habitat areas for targeted surveys.

Map 2 and Map 3 show the sites that were surveyed for this assessment.



Map 2: Google Earth map of Wilton Growth Area showing the tracks of CFFIS survey.

Key: Growth area approximate boundary shown in red, survey tracks shown in yellow, location of small leaved *Hibbertia* sp. with vegetative morphology +/- consistent with *H*. *puberula* marked in green.



Map 3: Google Earth map showing Greater Macarthur Growth Area and CFFIS survey tracks.

Key: Growth area approximate boundary shown in red, survey tracks shown in yellow, location of a small leaved *Hibbertia* sp. with vegetative features consistent with *H. puberula* marked in green.

NOTE: The absence of green dots along the survey route does not equate to the species not being present in that locale, only to the fact that it was not observed.

Species identification

When we located a small-leaved *Hibbertia* specimen that had macro morphological features resembling that of *Hibbertia puberula,* a specimen was retained for later microscopic examination. Selected specimens were taken according to protocols. Due to the time of the year and prevailing drought conditions plants were not in flower and depauperate, such that any specimens removed consisted of very small fragments (eco-scraps) most only a few cm in length.

This is far from ideal, the challenge was to then identify the eco-scraps to species using only stem and leaf characteristics, as shown in the drawing below (Toelken 2000). The small branchlets of each specimen was compared to voucher material of *Hibbertia puberula* under a dissecting microscope. Note that positive identification of the species requires flowering parts, however, some species of *Hibbertia* can be ruled out based on stem and leaf characteristics.

Microscope photographs of *H. puberula* characteristic features used during this survey by CFFIS are provided in Appendix 3.

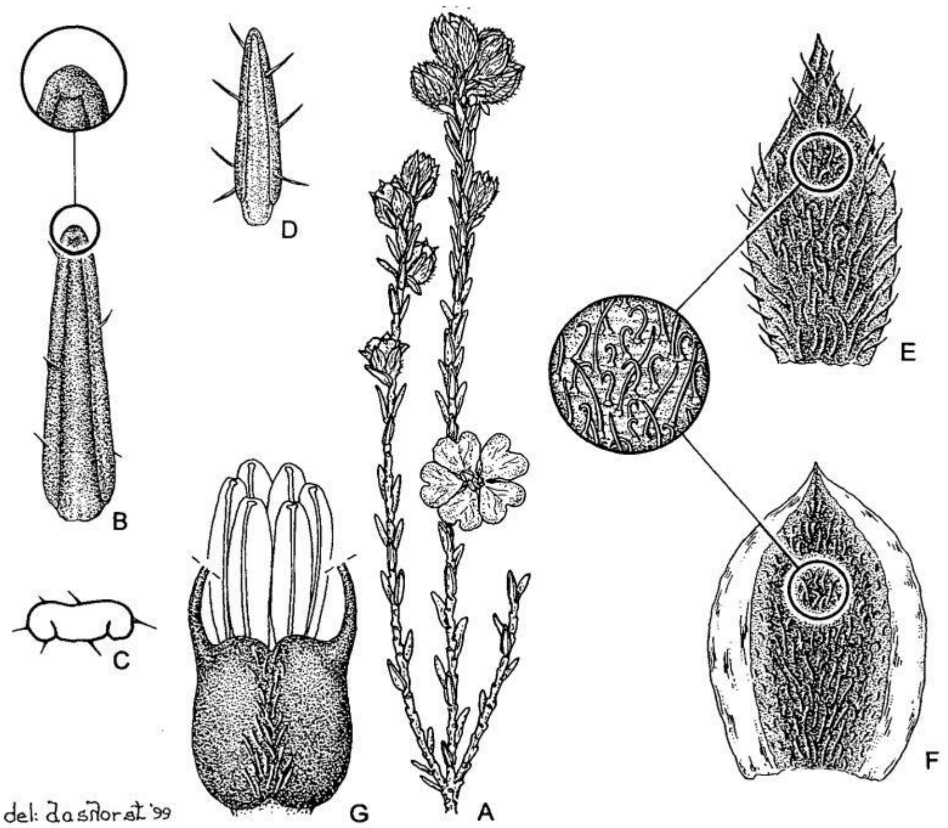


Fig. 7. ***H. puberula***. **A**, Flowering branch; **B**, cauline leaf; **C**, tranverse section; **D**. bract; **E**, outer calyx lobe; **F**, inner calyx lobe; **G**, two glabrescent ovaries. (**A–G**, *J.M.Lindale NSW 101952*; **A** ×1; **B**, **D** ×10; **C** ×15; **E**, **F** ×6; **G** ×20).

Figure 1: Line drawing of *Hibbertia puberula* distinguishing characteristics.

All small narrow leaved *Hibbertia* specimens found during the survey were examined under the microscope to determine if the stem and leaf characteristics matched those of *Hibbertia puberula.* Essential characters considered include leaf dimensions and shape, the leaf undersurface having revolute margins and recessed to bulging broader central vein obscuring the leaf undersurface, and branchlets having interpetiolar tuffs of hairs. Some of these characters are shown on Figure 1Figure 2. Where the majority of characters were a match, the species could not be ruled out of consideration and so was assumed to be the subject species. It should be noted that these characters vary slightly between sub-species, as shown in Figure 2 below, and confident identification to sub-species requires flower characteristics.

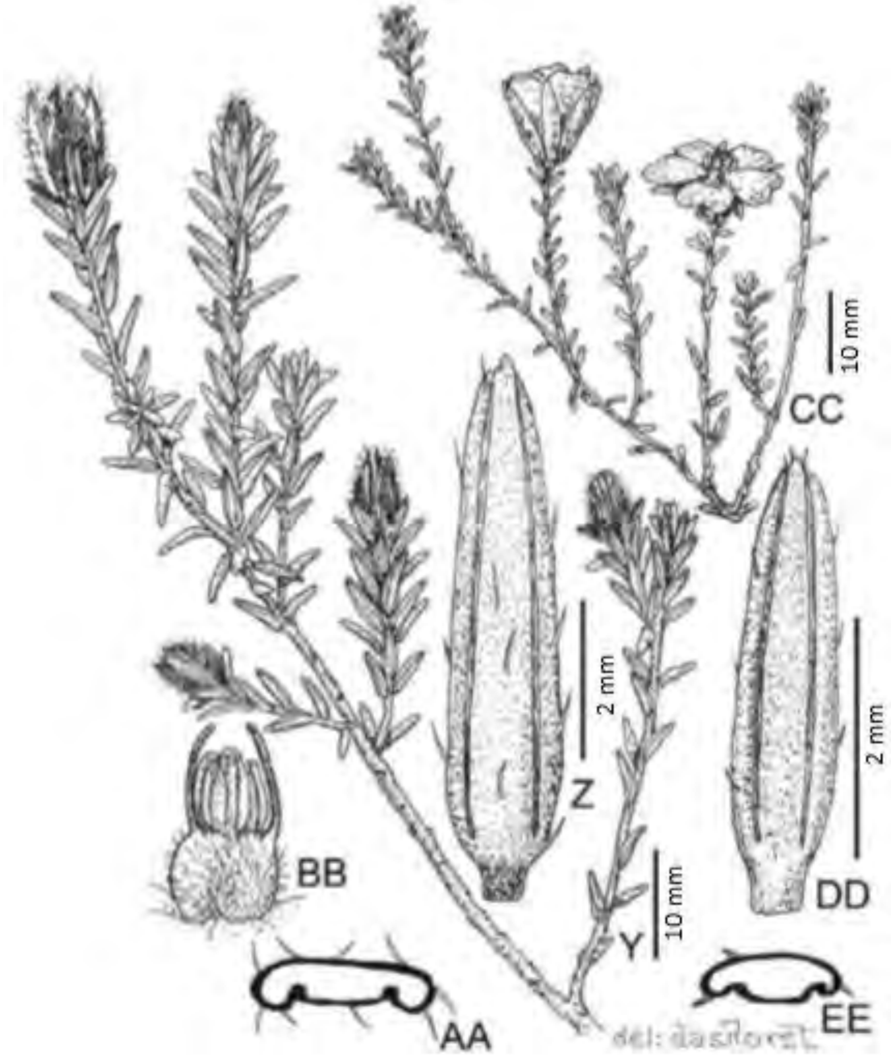

Figure 2: Line drawing of *H. puberula* subs. *extensa* and subsp. *glabrescens*.

Key: *H. puberula* subs. *extensa* Y flowering branch; Z leaf from below; AA transverse section through mid-leaf; BB flowers with petals and calyx removed. *H. puberula* subs. *glabrescens*: CC flowering branch; DD leaf from below; EE transverse section through mid-leaf.

A requisite taxonomic feature is hair types and the specific arrangement on leaf and branchlets. The persistence of the hairs on various parts of *Hibbertia* is variable according to the species. In many species such as *Hibbertia puberula,* hairs on the leaves and stem are notoriously non-persistent and “soon wear off” (Toelken pers. comm.). The full range hair expression is best observed on new and recent growth (Miller pers. obs.). The lack of new or recent growth is a significant limiting factor in the determination of the specimens as at all sites the vegetation was in severe drought stress.

Photo 2: A selection of *Hibbertia* voucher specimens, photo from c. 30cm away.

Key - A: *H. puberula* subsp. *puberula* Moorebank; B: *H. puberula* subsp. *puberula* Smiths Creek Reserve; C: *H.* sp. *puberula?* Round Hill Road, Wilton; D: *H.* sp. *puberula?* Shingle Hill, Wilton; E: *H. puberula*? FT SH1.4 Gilead; F: *H. puberula* subsp. *extensa* juvenile growth, south of Appin Road; G: *H. empetrifolia* Appin; H: *H. puberula* subsp. *extensa* Bonnum Pic vicinity; I: *H. puberula* subsp. *puberula* Lucas Heights and J: *Hibbertia puberula* subsp. *glabrescens*. (Photo by R.T. Miller August 2018). Morphological features are difficult to ascertain without microscopic examination.

Hibbertia sp. *puberula?* is a small leaved *Hibbertia* sp. with vegetative morphology +/- consistent with *H. puberula*.

<u>Survey assumptions</u>

The survey was carried out in June to August, during the non-flowering period, and it was not feasible to survey all the many bushland remnants within the Wilton and Greater Macarthur growth areas. As such, the first assumption was:

Assumption 1. *Hibbertia puberula* would not be found growing in bushland that is not its known habitat.

The author is familiar with the species' types of habitat at Bankstown Airport, the Moorebank Intermodal site, and locations such as Smiths Creek Reserve and Simmo's Beach Reserve. Using this knowledge of geology, soil and vegetation type that is the known habitat of the species, areas of bushland that would not be suitable habitat were ruled out of the assessment.

Using this knowledge of habitat requirement, the second assumption was:

Assumption 2. *Hibbertia puberula* is likely to be present in areas that are known to be suitable habitat.

Although there are occasions where the plant occurs in higher densities, the most common occurrences are rare and scattered throughout suitable habitat or low populations numbers localised to a small habitat niche. Areas of suitable habitat were surveyed using the random meander method. When only one or no individual specimens were located using this method, it was deemed likely that the species would occur scattered throughout these areas of suitable habitat.

The survey was carried out following several years of drought in western Sydney, and many shrubs forbs and grasses were dead. This led to the third assumption:

Assumption 3. In areas of suitable habitat, where *Hibbertia puberula* specimens have not been found, the species could be present in the soil seed bank.

There was a high amount of leaf fall in most locations and most locations have not recently been burnt. In these areas the species is likely to be present in the soil seed bank. An example is the Basin Reserve (outside the growth areas), where the species was previously scattered throughout suitable habitat within the reserve. Since the drought and control burning, the species appears to be very rare at this site but is likely to be still present in the soil seed bank in some of the unburnt habitat.

Identification to species of the *Hibbertia* relies on characters of the flowers. The survey was carried out in the non-flowering period which led to the fourth assumption:

Assumption 4. That specimens matching the stem and leaf characteristics of *Hibbertia puberula* could most likely be that species.

1.5 JUSTIFICATION FOR USE OF EXPERT REPORT

The BAM allows for situations where an expert report will be required to replace or complement survey effort at a development site. While there has been some field survey for the Strategic Biocertification assessment, the area covered by the proposed GMGA and WGA are extensive and there have been issues with gaining access to some of the private properties.

An expert report is required to assess potential impact to *Hibbertia puberula* for the following reasons:

Insufficient survey

A large extent of the identified growth areas could not be surveyed because it was on private property and could not be accessed within the project timeframe. Expertise was required to identify and survey potential species habitat and propose additional habitat based on extant populations and prior knowledge of the species.

Survey out of flowering season

Survey during June and July is at the non-flowering period for the species, so finding cryptic species of *Hibbertia* in the field is difficult even for an expert and more so for someone who is not an expert (refer Photo 13).

Survey during drought

The Western Sydney region has been experiencing dry conditions for several years, which means that the *Hibbertia puberula* plants are likely to be under severe drought stress and partially defoliated making this small and cryptic species more difficult to locate. It requires an expert in the species to locate and identify rare *Hibbertia* under these conditions.

Found in bushland at the end of Roundhill Road, Wilton, this plant shown on the left has vegetative morphological characters +/- consistent with *H*. *puberula*.

Scale reference: leaves are approximately 5mm in length.

Photo 3: A severely drought stressed plant of *Hibbertia* species.

Photo 3 shows the largest specimen of *Hibbertia* species with vegetative features consistent with *H*. *puberula* that was found within the Wilton growth area.

The plant is severely drought stressed, and it is likely that other plants in the area have succumbed to drought. The area had not been burnt for some years, so it is likely that the species apparent population has retracted and survives in numbers in the soil seed bank.

<u>Reliable species identification</u>

Identification of the genus *Hibbertia* to species level requires examination of flower parts in combination with stem and leaf characters, especially tomentum type and density. It is not practical nor reliable to identify small leaved species in the field as many of these morphological features require microscopic examination and comparison to known voucher specimens. This needs to be carried out by an expert in *Hibbertia*.

The use of an expert report to complement survey of the growth areas avoids the problems associated with *Hibbertia* misidentifications. *Hibbertia* species can be misidentified in vegetation assessments, frequently being dismissed as "common" species.

The misidentification of both *Hibbertia puberula* and presumably *Hibbertia fumana as Hibbertia riparia* during past surveys raises the possibility that other records of *Hibbertia riparia* may in fact be *Hibbertia puberula*. Searches of the databases revealed prior surveys undertaken for various projects have recorded *Hibbertia riparia* to occur at a number of locales within and adjacent to the GMGA and WGA (refer Appendix 5).

The *Hibbertia riparia / H. calycina / H. hirsuta* groups are currently under further detailed evaluation (Toelken pers. com.). *Hibbertia riparia* R.Br. s. str. occurs in Tasmania (Toelken) and is unlikely to occur in NSW, the name being misapplied (pers. com. Toelken). It was therefore anticipated that the identifications of *Hibbertia riparia* would be found to be incorrect.

Two recorded *H. riparia* sites were inspected for this assessment, one at Douglas Park (12 June 2018) and one at Wilton (17 August 2018). A third Site at Appin was not surveyed due to access constraints.

The *Hibbertia* sp. observed off Douglas Park Drive was found to have vegetative features consistent with *H. puberula*. The Wilton locale was inspected in August and it was found that the severity of impact to the bushland from drought had markedly increased. The site was extremely dry following the years of drought, the ground was covered with a thick layer of leaf litter, and many plants were dead including large numbers of *Hibbertia aspera*. No plants resembling *H. riparia* were found at the location, so the correct identification of the species could not be ascertained.

It is considered likely that this species is the same taxon as the proximate occurrence off Douglas Park Drive which has vegetative features consistent with *H. puberula*.

1.6 CREDENTIALS OF EXPERT

Robert Miller has over 30 years' experience in field botany. Over this time Robert has identified many rare and endangered plant species and has contributed to the scientific knowledge of native flora distribution and habitat in NSW.

Robert has worked with Hellmut Toelken of the State Herbarium of South Australian, locating, collecting and identifying undescribed or rare species of *Hibbertia*. Some of these taxa were known only from historic records with non-precise locality details and depauperate or non-existent habitat information. Many of the specimens have been used for the taxonomic revision of the genus and are cited in various taxonomic publications including "Notes on *Hibbertia* subg. *Hemistemma* (Dilleniaceae) 9. The eastern Australian *H. vestita* group, including *H. pedunculata* and *H. serpyllifolia*" published in the Journal of the Adelaide Botanic Gardens 26 (2013). Examples of the cited specimens include: *Hibbertia ericifolia* subsp. *acutifolia* Toelken, subsp. nov. Type: New South Wales, Sarahs Knob, R. & J. Miller s.n., 21.x.2006 (holo.: AD; iso.: BRI, CANB, NSW, PERTH) and *Hibbertia dispar* R.T. Miller s.n., 0.5 km S of Penrose Rest area, along western boundary track, Penrose State Forest, 12.x.2010 (AD, NSW).

Robert and Hellmut's paper "Notes on *Hibbertia* (Dilleniaceae) 8. Seven new species, a new combination and four new subspecies from subgen. *Hemistemma*, mainly from the central coast of New South Wales", was published in the Journal of the Adelaide Botanic Gardens in 2012. The paper describes 13 new taxa including *Hibbertia fumana* Toelken and *Hibbertia puberula* subsp. *puberula,* – subsp. extensa *R.T.Mill.* and – subsp. *glabrescens Toelken.*

In 2017 Robert was called as an expert to identify the species of *Hibbertia* on the Moorebank bushland site that is the subject of the Intermodal development proposal.

Robert is also a recognised expert for other threatened taxa including *Pomaderris adnata*, *Solanum celatum*, *Epacris purpurascens* var. *purpurascens*, and the genus *Prostanthera* including the threatened taxa *Prostanthera discolor*, *P. stricta*, *P. densa*, *P. junonis* and has provided expertise to the OEH Saving our Species programs.

2. Species information

2.1 SPECIES DESCRIPTION

There are 3 sub-species of *Hibbertia puberula*. The following descriptions are taken directly from the Toelken and Miller 2012 paper "Notes on Hibbertia (Dilleniaceae) 8. Seven new species, a new combination and four new subspecies from subgen. Hemistemma, mainly from the central coast of New South Wales".

***Hibbertia puberula* Toelken**

Typus: New South Wales, Yowie Bay, A.A.Hamilton s.n., 14.xi.1908

Description: Shrublets up to 0.25 m tall, decumbent or rarely suberect, much to sparsely branched or spreading; branches wiry to stiff from a woody stem or base, with decurrent leaf bases more or less flanged, pubescent to hirsute mainly between flanges, rarely glabrescent or glabrous. Vestiture often not persistent, with spreading longer over shorter simple hairs on all parts of the plant; on branches with few to many (rarely glabrous) mainly longer hairs (but varying very much in actual length) over much shorter ones, often predominantly in the grooves between flanges of the leaf bases, becoming appressed and wearing off soon; on leaves above with scattered spreading antrorse simple hairs becoming longer towards the margins, often wearing off; on leaves below with few scattered hairs as above on the revolute margins but not on the central vein, wearing off; on bracts with finer but similar hairs to leaves; on outer calyx lobes outside moderate to dense, with erect short hooked hairs overtopped by longer tubercled straight hairs up to 1.3 mm long, often becoming bristle-like particularly on the margins and the base and receptacle, persisting, inside dense, with fine, often silky appressed antrorse hairs; on inner calyx lobes outside and inside usually similar to the outer lobes, but hairs finer and decreasing in number and size towards the glabrous, membranous margins. Leaves usually with dense intrapetiolar tuft spilling over into grooves between flanges; petiole 0–0.6 mm long, ± flattened; lamina linear-lanceolate to oblong-lanceolate or oblong-elliptic, (1.2–) 2.8–5 (–7.6) × (0.5–) 0.7–1 (–1.2) mm, ± abruptly constricted into petiole, acute and usually with a terminal tuft of hairs wearing off soon, often becoming obtuse, above ± flat and sparsely pilose to glabrescent, below revolute margins and recessed to bulging broader central vein obscuring the undersurface, sparsely pilose to glabrous on the margins. Flowers single and terminal, rarely in clusters of up to three from subtending axils; pedicel 0–3 mm long; bracts linear-elliptic to elliptic-lanceolate, (2.9–) 3.2–3.8 (–4.2) × (0.4–) 0.6–0.8 (–0.9) mm, leaf-like but flatted with central vein ± visible, short pilose, rarely glabrous. Calyx distinctly accrescent; outer calyx lobes lanceolate to ovate, (5.3–) 6–8 (–11.7) × (1.6–) 2–3 (–4.2) mm, frequently longer than inner lobes, acute to beaked, usually with raised ridge and recurved distal margins, hirsute, strigose, rarely pubescent to glabrescent; inner calyx lobes oblong-ovate to oblong-elliptic, (4.6–) 5–8 (–11.6) × (2.1–) 2.5–3.5 (–3.7) mm, acute to cuspidate and with lateral membranous margins rarely up to the apex when obtuse and mucronate, hirsute to finely pilose, decreasing towards the margins. Petals broadly obovate to oblanceolate, or rarely oblong-oblanceolate, 5.5–10.6 mm long, ± bilobed. Stamens (4–) 10–14 (–18); filaments (0.6–) 1.4–1.7 (–1.9) mm long, up to one-third connate basally;

anthers obloid, (0.8–) 1.4–1.8 (–2.1) mm long, subequal, rarely unequal, abruptly constricted above and below. Pistils 2; ovaries erect-obloid and usually horizontally truncate, (4–) 6 (–8) ovules, puberulous, rarely shortly pubescent, with style attached apically, rarely laterally, then curved back- and upwards on either side of the anthers with style well above or rarely at the apex of anthers. Fruit puberulous to glabrescent with simple hairs. Seeds oblong-obovoid to almost obloid, 1.6–1.8 × (1.2–) 1.3–1.4 mm, brown; aril with fleshy base surmounted by one-sided membranous cup covering one-third to half of seed.

Notes: The extra specimens now available introduced a much wider range of variation in the *H. puberula* complex. Specimens from the Central Coast can frequently be recognized by almost sessile leaves, broadly ovoid to ellipsoidal buds with apices of the calyx erect to incurved, and often more than one flower is born terminally on branches, while plants from more inland localities have usually petiolate leaves, slender ovoid to ellipsoidal buds with more or less recurved apices of the calyx and a single terminal flower on branches. None of these characters can be decisively used to distinguish these forms. The terminal flower clusters are formed by axillary growth from one or two leaves below the bract of the terminal flower and, in keeping with other species of the H. sericea group with fascicled hairs, immediately develop a terminal flower after usually two nodes with distinct internodes between, so that it becomes a more or less corymbiform cluster. (This is also a distinction from *H. stricta* s.l., which has usually spikiform (pyramidal) terminal clusters). Similar, but loosely branched cymbiform terminal inflorescences have been observed on only one collection (Turpentine Road, Flat Rock Creek, R.T. & J.Miller 22/30.x.2010). The most southern population of *H. puberula*, as represented by this and other mass collections, as well as R.D.Hoogland 11702 and E.Gauba NBG4784, is a particularly interesting extension of the species, as most of the flowers, though large, show a distinct reduction of hairs on the calyx and, more significantly, the styles tend to be laterally attached to the ovaries, similar to those of *H. cistiflora* in the *H. stricta* group. However, this phenomenon, indicative of a convergent development, can be observed in different stages on different plants, varying from an apically attached style curving down- and backwards to being attached laterally. The calyx lobes of most of the specimens identified as belonging to the *H. puberula* complex are hirsute to strigose on the outer surface, but in a few specimens both the shorter hooked hairs as well as the straight overtopping longer ones are very short or absent on plants from a few different localities (cf. variation under subsp. *glabrescens*). Among these, the plants from Bankstown Airport are smaller with thread-like branches and have consistently smaller calyx lobes, which are up to 2.7 mm broad, so that they are here described as subsp. *glabrescens*. The calyx of some flowers of subsp. *puberula* from Voyager Point (R.T.Miller & C.P.Gibson 52/20.x.2006) are of similar size, but hirsute and with a distinct terminal ridge on the outer calyx lobes. Furthermore, the flowering calyx of one plant must always be compared with other specimens at a similar stage, as the calyx (accrescent) elongates after flowering. Specimens from Lucas Heights are an extreme example, as the outer calyx lobes of a flower are 7.2 mm long and those of a fruit on the same specimen (R.T.Miller 3/16.x.2007) are 11.6 mm long. Of all the variation observed, *H. puberula* subsp. *extensa* is very unusual, as its androecium of commonly six stamens was previously unknown in *H. puberula*, which has ten or more stamens. There is a distinct gap between the two types of stamen numbers, as, unlike specimens of the typical subspecies from Simmos Beach Recreation Reserve (R.T.Miller 24–32/2.xi.2007), which has a range of stamens from 15–18, no specimen has as yet been recorded to complete the range from (4–) 6 or 7 stamens of the subsp. *extensa*. However, the wide variation recorded for the typical subspecies suggests this new form should be recognized at subspecific level. The anthers of subsp. *extensa* also tend to be smaller like those of the subsp. *glabrescens*, and their cuneate base into the filaments is rarely observed in the other subspecies.

Key to subspecies of the *H. puberula* complex

1. Stamens (4–) 6 or 7; lateral branches usually spreading up to about right angles to the main axis …………………………………………………………………………………….. *H. puberula* subsp. *extensa*

1: Stamens (9) 10–14 (–18); irregularly and commonly untidily branched

2. Anthers (1.3–) 1.4–2.1 mm long; outer calyx lobes distinctly ridged toward the apex, strigose to hirsute or if pubescent to glabrescent then (2.5–) 2.6–3.0 (–3.8) mm broad when flowering .... ……………………………………………………………… *H. puberula* subsp. *puberula*

2: Anthers 0.9–1.3 mm long; outer calyx lobes 1.6–2.1 mm broad when flowering, scarcely ridged towards the apex, puberulous to glabrescent

……………………………………………………………………….................................. *H. puberula* subsp. *glabrescens*

Hibbertia *puberula* subsp. *puberula*

Description: Branches wiry to stiff-woody from woody stems. Leaf lamina mainly lanceolate. Outer calyx lobes lanceolate to ovate, (7.3–) 7.8–9.3 (–11.6) × (2.5–) 2.6– 3.0 (–3.8) mm, acute to beaked with strongly recurved margins and distinctly raised central ridge towards the apex, strigose or hirsute to rarely puberulous; inner calyx lobes broadly elliptic to oblong-ovate, (6.9–) 7.3– 7.8 (–10.1) × (2.8–) 3.15–3.3 (–3.7) mm, with innermost two acute to ± cuspidate above broad membranous margins, hirsute to strigose, rarely pubescent along the central ridge becoming smaller to glabrous towards the margins. Stamens (9–) 10–14 (–18); anthers (1.3–) 1.4– 2.1 mm long. Flowering: October–December (January).

Variation: The few previous collections available have been disconcertingly variable, but mass collections from a few localities revealed that individual populations are often very variable in the size and number of hairs on various organs. Buds vary from almost spherical to narrow-ellipsoidal to -ovoid with lanceolate to ovate outer calyx lobes, each with an incurved, erect or recurved apex and more or less densely covered with spreading, straight and smaller hooked hairs of varying length. Flowers have usually 12–14 stamens in this subspecies, but the number varies locally from 9 or 10 at Wollemi National Park to 18 in one specimen from Yeramba Lagoon (C.P.Gibson & R.T.Miller 50/14.x.1993). Specimens from Simmos Beach Recreation Reserve show a few flowers with 15 to 17 stamens, while other flowers of similar plants of the same population have 12 to 14 (R.T.Miller 24–32/2. xi.2007). The filaments are up to one-third basally connate. Usually the anthers are described as subequal and forming a range from the slightly smaller to larger ones, but occasionally one or two distinctly larger ones were observed. The typical obloid ovaries are surmounted by a horizontal style base and, while the style is usually attached at the apex, it is sometimes more or less dipping to a lateral position in a number of populations, mainly from Morton National Park. This must not be confused with fruiting specimens, where the bulging developing seeds often displace the position of the style attachment. While the ovaries are usually puberulous, they may vary from pubescent (R.T.Miller 111–113/20.xi.2007) to almost glabrous (R.T.Miller 33–43/12.x.2007).

Hibbertia *puberula* subsp. *extensa* R.T.Mill., subsp. nov.

Typus: New South Wales, south of Appin Road, upper George River catchment, R.T.Miller 102 & A.Henderson, 8.x.2007 (holo.: AD; iso.: NSW).

Description: Branches stiff-woody and lateral ones spreading up to about right angles. Leaf lamina mainly lanceolate. Outer calyx lobes ovate, (6.1–) 66–72 (–7.9) × 3.1–3.5 (–3.8) mm, acute to beaked with ± strongly recurved margins and distinctly raised ridge towards the apex, strigose to hirsute; inner calyx lobes elliptic rarely oblong-ovate, (4.2–) 4.5–4.8 (–5) × 2.9–3.2 (–3.4) mm, with innermost two abruptly constricted into minute terminal point continuous with broad membranous margins, hirsute to strigose with hairs becoming smaller towards the margins. Stamens (4–) 6 (7); anthers 0.8–1.2 mm long. Flowering: October, November (March, April). Fig. 2Y–BB.

Variation: In spite of their often isolated occurrence very little variation was observed in the material examined. The specimens from south of Appin had usually 6 stamens, whereas several flowers from the Wanganderry Tableland had 7. The subspecies has generally very long straight hairs on the calyx and some of them are up to 1.3 mm long. Not only are the stamens shorter in this subspecies, but also the styles are short and robust and often just reach the apex of the anthers. These robust specimens are easily distinguished from superficially very similar plants with spreading branches of the typical subspecies from Lucas Heights (R.T.Miller 111– 113/20.xi.2007) by the number and size of the anthers. While most of the specimens of this subspecies occur in a restricted area from Appin to Wedderburn, a collection from Sackville Road (R.T.Miller 81/23.x.2008) seems to indicate that the taxon has a much wider geographic range. This preceding specimen exhibits in addition to six stamens also the robust spreading branching of the plants from the southern localities in spite of records of more slender forms of the typical subspecies nearby. Etymology. The epithet ‘extensa’, Latin, ‘stretched out, extended’ refers to the impression created by the lateral branches spreading at about right angles to the main branches.

Hibbertia puberula* subsp. *glabrescens Toelken, subsp. nov.

Typus: New South Wales, Bankstown Airport, G.M. Cunningham s.n., 13.xii.2006 (holo.: AD200524; iso.: CANB, K, MEL, NSW). Hibbertia sp. Bankstown (R.T. Miller & C.P. Gibson s.n. 18.x.2006) N.S.W. Herbarium in Australian Plant Census database (2011). Hibbertia sp. nov. (Bankstown Airport) C.P. Gibson, Bushland Bulletin 59: 4, 6 (2009).

Description: Branches thread-like wiry from short stiff-woody stems. Leaf lamina mainly elliptic-oblong. Outer calyx lobes linear-lanceolate, (5.3–) 5.5–6.1 (–6.3) × 1.6–2.1 mm, not beaked and with scarcely recurved margins and faint central ridge towards the apex, glabrescent or sparsely pubescent; inner calyx lobes narrowly oblongovate, (4.6–) 4.8–5.2 (–5.6) × 2.1–2.3 (–2.7) mm, innermost two abruptly constricted into minute terminal mucro continuous with broad membranous margins, glabrous or glabrescent along central ridge. Stamens 12–14; anthers 0.9–1.3 mm long. Flowering: October, November (December).

Variation: The plants at Bankstown Airport are comparatively uniform, as one would expect for such a small and extremely localized population. However, the plants and especially also the calyx lobes are rarely entirely glabrous. Although specimens of some plants of the typical subspecies, especially from nearby Simmos Beach Reserve (R.T. Miller 24–32/2.xi.2007), as well as those from the much further south population along Turpentine Road near Sassafras (e.g. R.T. & J. Miller AD15A–M), show a variation from a hirsute or strigose through to glabrescent tomentum of the calyx lobes, they are always more robust plants and in particular, the calyx lobes are larger and especially broader. Some specimens of the mass collection R.T. Miller 1622/12.x.2007 are very similar to subsp. glabrescens, but can be distinguished by the shape of the calyx or by their strigose to hirsute calyx (C.P. Gibson & R.T. Miller 27/23.x.1990). Furthermore specimens from Bankstown Airport collected in subsequent years (since 2006) have not shown any significant change in morphology. Thus we must assume that a taxon has established itself here that is suited to the unusual ecological conditions artificially maintained by the Bankstown Airport management since about 1940. Etymology. Since all organs of this subspecies have very few small and delicate hairs which usually wear off soon, the epithet ‘glabrescens’, Latin, ‘glabrescent’ seemed appropriate.

2.2 LIFE CYCLE

Peak flowering time is October to December and sometimes into January, and seed is set during this period. Anecdotal evidence (Miller pers. obs.) suggests time of flowering and time to petal dehiscence is variable across subspecies and appears also to be influenced by prevailing climatic conditions. Very limited observations of the flowering times of *Hibbertia puberula* subsp. *extensa* suggest this subspecies has a very short period of flowering each day. Total petal dehiscence has been noted to occur before 1 pm on two occasions in the largest population south of Appin Road. It is not known at what time petal expansion commenced. The subspecies is virtually invisible when not in flower.

Hibbertia puberula and *H. diffusa* at Moorebank were noted to have a window of daily peak flowering (albeit in September, outside its normal recognised peak flower period) being not apparent in early mid-morning and petal senescing by early afternoon. This phenomenon has been observed with several *Hibbertia* species, whilst others appear to have protracted flowering across the day e.g. *Hibbertia dentata*.

Photo 4: *Hibbertia puberula* subsp. *puberula* at Moorebank.

The plants in photos 4 and 5 were not flowering at 8.40 am, the pictures show near total petal dehiscence by early afternoon. (Miller Friday, 29 September 2017 12:05 PM).

Further research is needed to ascertain daily flowering ranges particularly for threatened taxa as this has significant implications for threatened species assessments regarding the reliability of detection.

Flowering time of day may explain, in part, the non-detection of the significant and widespread population of *Hibbertia puberula* at West Menai in the environmental assessment (refer Appendix 4 Indicative distribution of *Hibbertia puberula* at West Menai).

Photo 5: *Hibbertia diffusa* plant at Moorebank.

Plant was not in flower on the way into the site c. 8.40 am, flowered and shed petals by 12.14 pm.

No systematic fire response studies have been undertaken on *Hibbertia puberula*. Anecdotal observations and inferred information from similar species suggest *H. puberula* subsp. *puberula* is killed by fire. In certain circumstances the species may be capable of re-sprouting from near or just below the soil surface as noted at the Keith Longhurst Reserve (formerly the Basin Reserve) in 2007 (R. Miller pers. obs.). At the same site Miller noted in June 2018 the species appears to have mostly been killed by a recent control burn, with limited recruitment from the soil seed bank observed. It is unknown to what degree the protracted dry period has impacted apparent recruitment, but it is thought that the combined impact of fire and drought has been significant.

Since its discovery there has not been a fire in the habitat of *Hibbertia puberula* subsp. *glabrescens*.

The impact of fire upon *Hibbertia puberula* subsp. *extensa* is also poorly known, with only observation by Miller providing a limited insight. The two occurrences south of Appin Road have recently been control burnt. Price *et. al.* (2016) state that "The first fire was 52 ha, lit at 09:45 on 22 August 2015, and targeted patches of forest within the scout camp. The second was 700 ha, lit at 10:15 on 9 October 2015 and burnt the area surrounding the camp in an arc from north through west to south". All pre-existing plants appear to have been killed. Only three tiny plants presumably seedlings were apparent at one site and no plants were detectable at the other.

2.3 DISTRIBUTION AND ABUNDANCE

Limited systematic population surveys have been undertaken for *Hibbertia puberula* s. lat.. The most comprehensive population survey undertaken is for *Hibbertia puberula* subsp. *glabrescens* at Bankstown Airport environs (refer to that subsp.). The population of *Hibbertia puberula* subsp. *puberula* occurring at the Moorebank Intermodal Terminal was, in part, assessed in the environmental assessment for the project.

Hibbertia puberula* subsp. *puberula

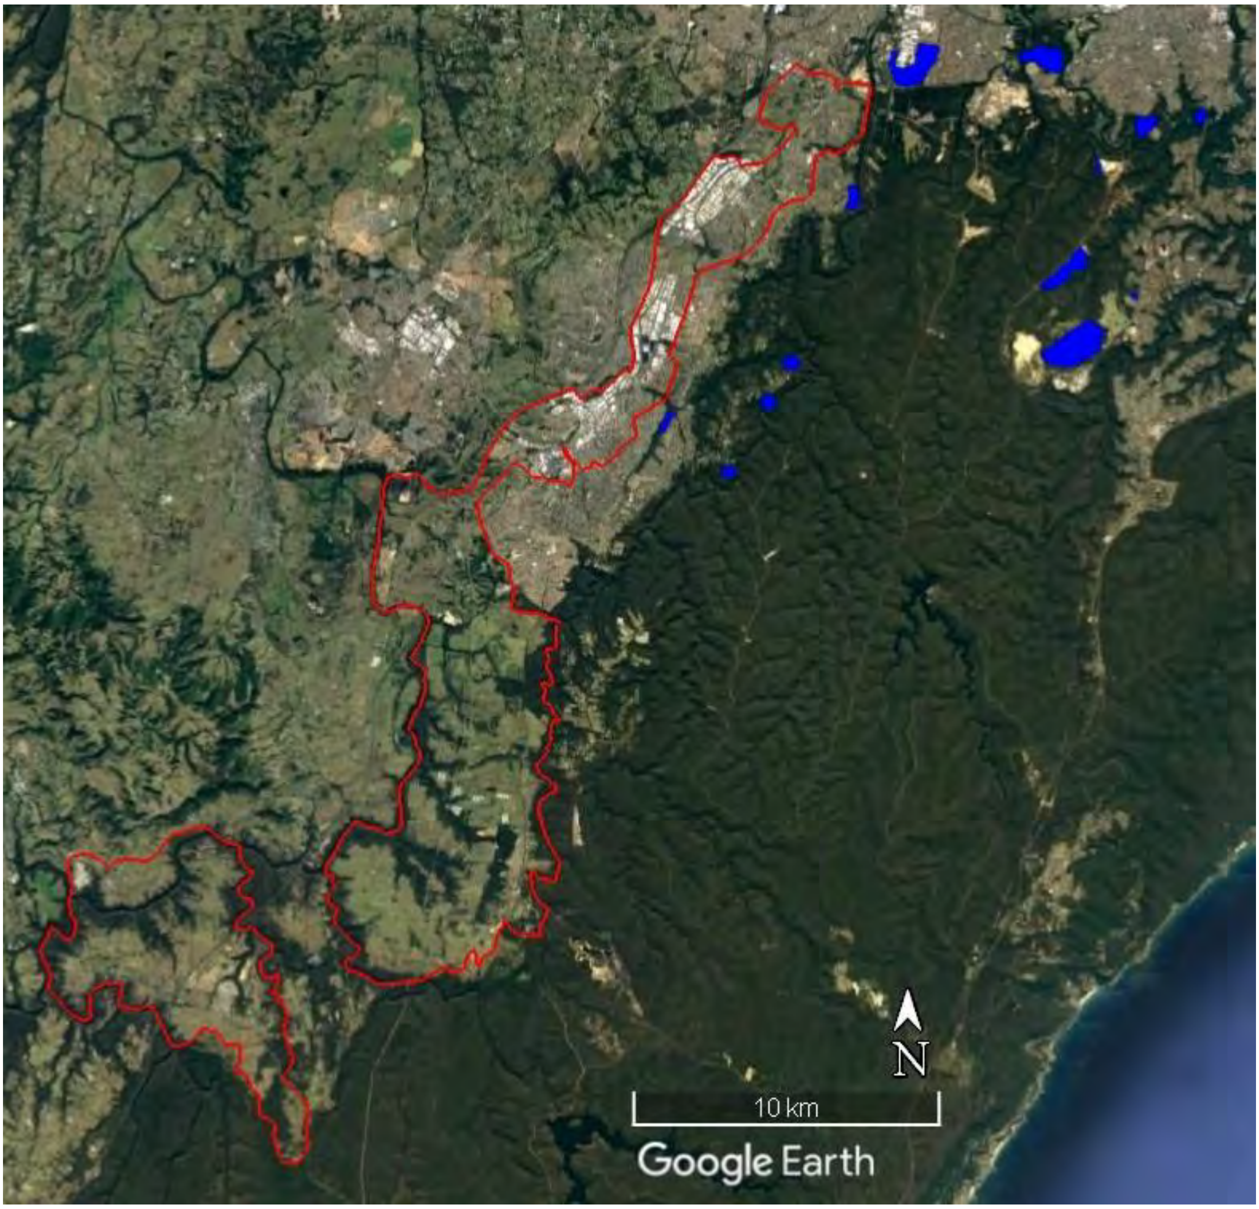
This sub species is known in New South Wales mainly from near Sydney (CC), but also from Wollemi National Park and near Morton National Park (SC, ST).

Of relevance to this study are those sites close to the Wilton and Greater Macarthur growth areas. The sub species has been collected from Smiths Creek Reserve, Moorebank Intermodal site, Simmos Beach Recreation Reserve, Peter Meadows Reserve, the Keith Longhurst Reserve (formerly the Basin Reserve), Kentlyn, Freres Crossing Reserve, Kentlyn, Old Kent Road, Kentlyn, and Lucas Heights. Map 4 shows the areas from which the sub species had been collected prior to this study.

Environmental assessment surveys for the Moorebank Intermodal Terminal have provided some population data on *Hibbertia puberula* subsp. *puberula*. The population data derived cannot be inferred to reflect population density at all recorded sites of its distribution and specifically not within the GMGA or the WGA. The predominant vegetation communities found at the Moorebank Intermodal Terminal where surveys were undertaken are Castlereagh Scribbly Gum Woodland and Cooks River/Castlereagh Ironbark Forest with Shale-Gravel Transition Forest and Castlereagh

Swamp Woodland being recorded in close proximity. Extant examples of these communities in combination are not known to occur in the GMGA or WGA.

The majority of records in proximity to GMGA and WGA occur as small populations in a variety of habitats at the edge of sandstone shale transition or in transition with or in the lower elements of the Mittagong formation. Appendix 4 shows the indicative distribution of *H. puberula* at West Menai, where the species was found to occur as small subpopulations in suitable micro-habitats.



Map 4: Generalised location of *Hibbertia puberula* subsp. *puberula* collections.

Key – Areas of *H. puberula* subsp. *puberula* collections (blue) in relation to the growth areas (red) from surveys prior to this BAM assessment.

A selection of habitat and occurrence notes compiled by Miller in 2007 as herbarium specimen notes are provided below:

- At Lucas Heights the population at a site in Open Woodland / heath – Canopy: *Eucalyptus haemastoma*? and Stringybark species is described as: “Abundance: extremely localised, rare < 12 plants noted”.
- At Lucas Heights Little Forest the population is described as Localised in narrow zone in upper drainage line.
- At Simmos Beach Reserve in Open Woodland of *Eucalyptus sclerophylla*?, *E. punctata, Angophora bakeri* one sub-population is described as “Very localised but locally common c. 20 plants noted”
- At Barden Ridge one population is described as scattered through sedges - relatively rare at edge of wet heath/swamp.

Further details of herbarium specimen collections from Western Sydney in 2007 are provided in Appendix 2.

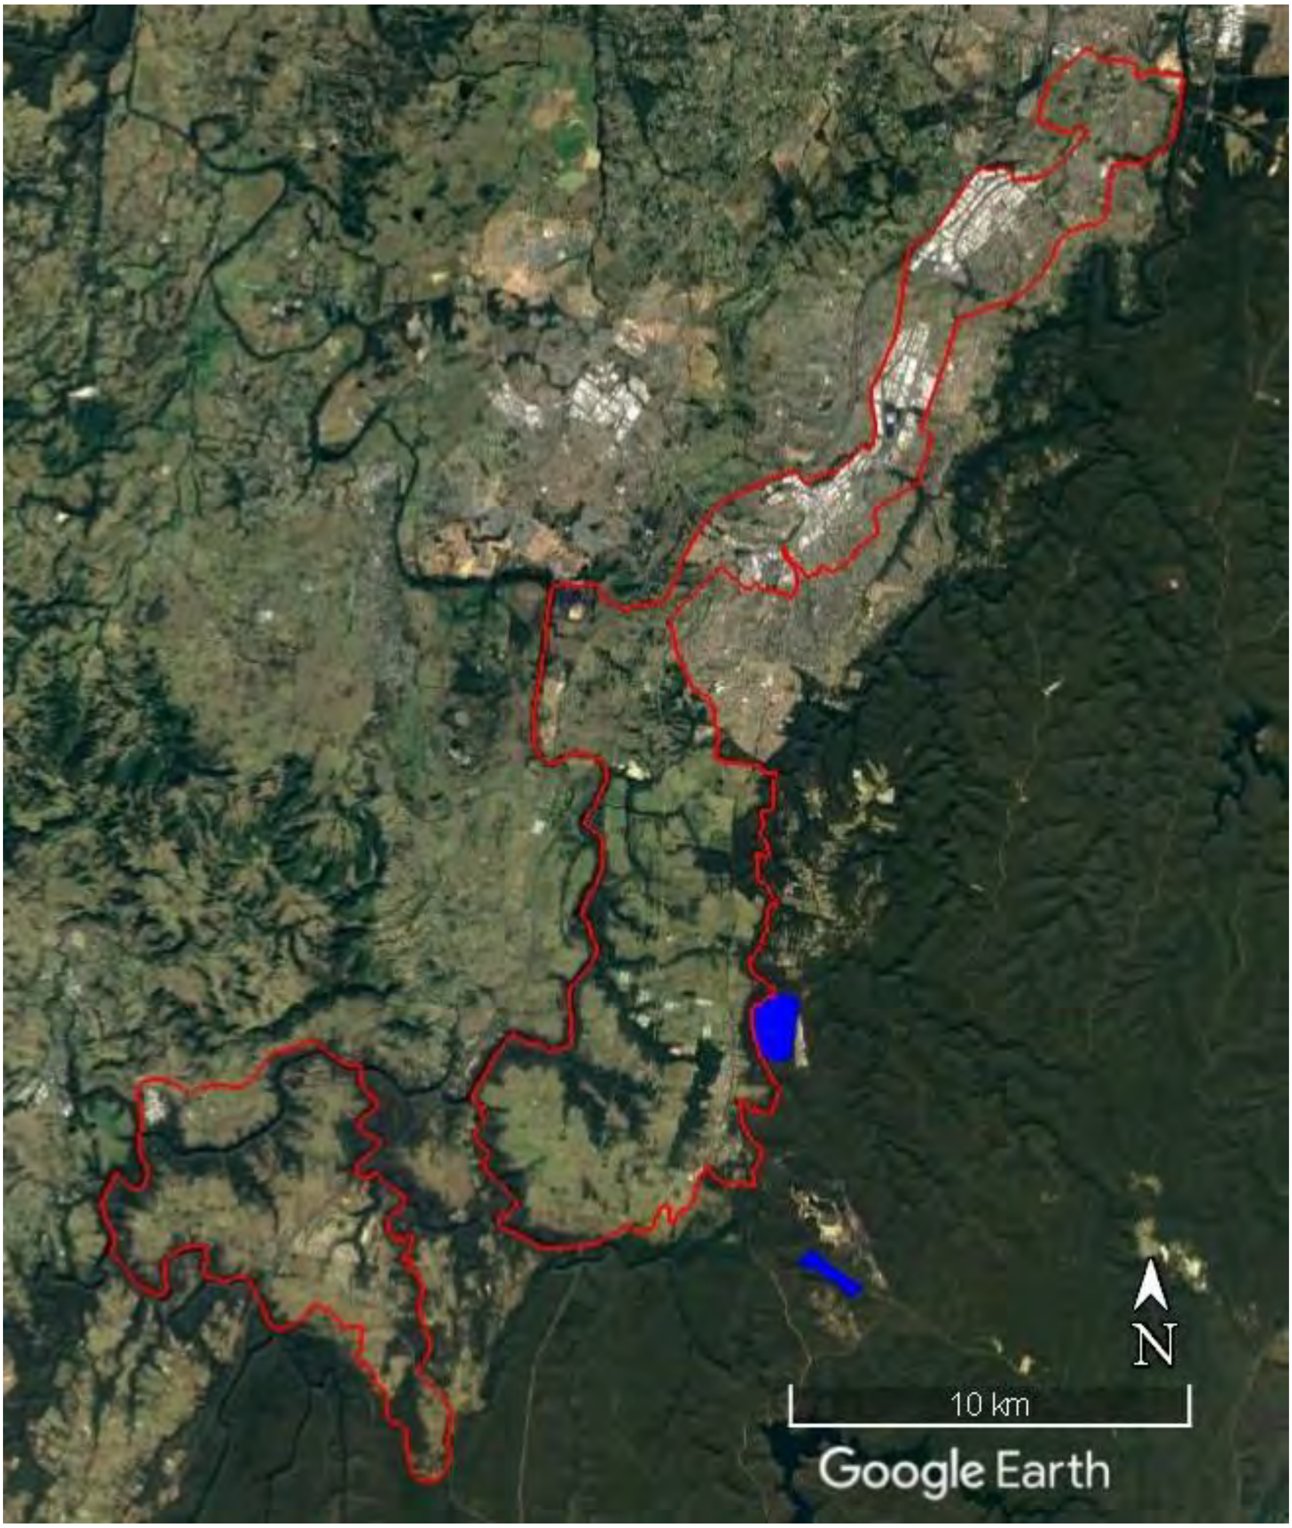
Hibbertia puberula subsp. *extensa*

This subspecies grows with heath on upper headwaters of the Georges River and in rock plate heath on the Wanganderry Tableland, New South Wales (CC).

Collection sites located in the vicinity of the Wilton and Greater Macarthur growth areas are c. 3.5–4 km SE of Appin township, South of Appin Road and Wedderburn, NSW Sports & Aircraft Club, walking tracks, Lysaghts Road vicinity. Map 5 shows the locations of collection sites.

No systematic population surveys have been undertaken for this subspecies. All known populations are thought to be small with most observations noting only a few individuals. One location south of Appin Road was the only population noted as having more than 10 plants. The sightings at Woronora Dam vicinity, Sackville North, the two recorded Wedderburn locations and the Bonnum Pic vicinity all recorded a few individuals only. The known Sackville North occurrence has subsequently been severely impacted by hazard reduction measures and is possibly now extinct at the known site. Similarly, the known occurrence west of Wedderburn Aerodrome has been impacted by grading and fill emplacement and only one specimen could be relocated (Miller pers. obs. July 2018).

A small population of a *Hibbertia* species with vegetative features consistent with *H. puberula* subsp. *extensa* was observed to occur on the verge of a fire trail within the Dharawal National Park at Wedderburn. Only six plants were noted. Positive determination can only be ascertained in combination with floral characters.



Map 5: Generalised location of *Hibbertia puberula* subsp. *extensa* collections.

Key – Areas of past *H. puberula* subsp. *extensa* collections (blue) in relation to the growth areas (red).

Hibbertia puberula* subsp. *glabrescens

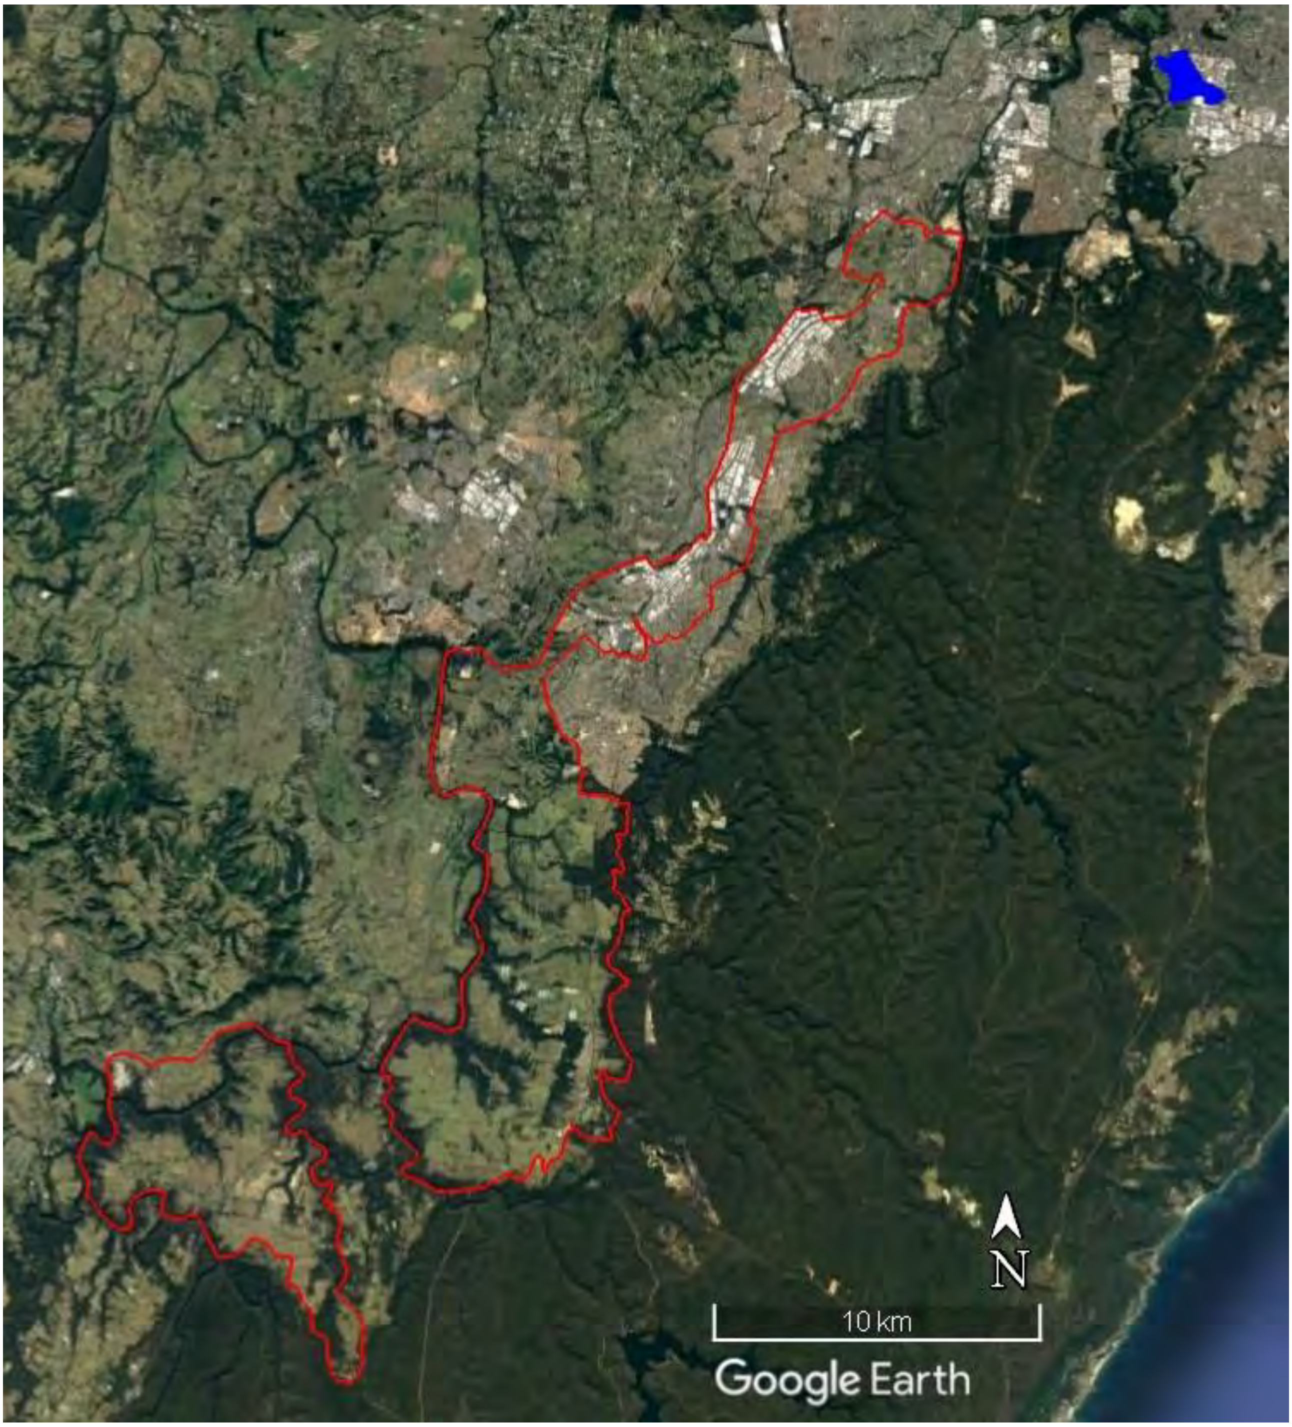
Subspecies *glabrescens* is known only from Bankstown Airport. Map 6 shows the general area where this species has been collected. The population contains between 50 and 100 individuals. Survey by Eco Logical in 2015 could not differentiate individual plants and recorded area of plants only.

The species has a limited area of occupancy. Most of the extant plants are known from one small area to the north of a modified drainage line colloquially referred to as Airport Creek. It was previously recorded by Gibson and Gibson & Miller to occur to the south of Airport Creek. Development and maintenance measures have negatively impacted upon those known occurrences and it had not been observed there again until October 2017 when one plant was observed (Gibson pers. obs.).

Photo 6: *Hibbertia puberula* subsp. *glabrescens* growing in a slashed area of Bankstown Airport.

Top: measure of slashing height, bottom: Airport Area 5. Photos taken by R. Miller 8 October 2014.

Both photographs clearly show the bright yellow flowers of *Hibbertia puberula* subsp. *glabrescens* while vegetative features such as leaves and stems are not discernible. These photographs illustrate the importance of undertaking surveys for small Hibbertia species within the flowering period.



Map 6: Generalised location of past *Hibbertia puberula* subsp. *glabrescens* collections.

Key – Area of *H. puberula* subsp. *glabrescens* collections (blue) and the growth areas (red).

2.4 HABITAT REQUIREMENTS

Hibbertia puberula* subsp. *puberula

Occurs in a wide range of habitats, but usually low heath, on sandy soil or rarely in clay, with or without rocks underneath (Toelken 2000). Proximate populations have been recorded from habitats associated with the Mittagong formation, shale sandstone transitional vegetation and tertiary alluvial deposits. Associated canopy species may include, but not limited to, in combination or isolation: Scribbly Gum spp., Grey Gum (*Eucalyptus punctata*), Scaly Bark (*Eucalyptus squamosa*), Ironbark spp., Narrow-leaved Apple (*Angophora bakeri*), Dwarf Apple (*A. hispida*), and Stringybark spp.

Hibbertia puberula* subsp. *extensa

The habitat requirements of *Hibbertia puberula* subsp. *extensa* are poorly known. The subspecies has only been recorded from five localities: south of Appin Road, Wedderburn vicinity, Woronora Dam vicinity, Sackville North vicinity and Bonnum Pic vicinity Wanganderry Tablelands.

This subspecies appears to have highly specific micro-habitat requirements. The largest known population occurs south of Appin Road, where less than 30 plants of *Hibbertia puberula* subsp. *extensa* have been recorded. Its area of occupancy is small, being noted to occur in a narrow band within a small upland swamp amongst wet heath vegetation. In a larger nearby wet heath site a few specimens of the subspecies were recorded to occur on skeletal soil, in the downslope seepage zone, where the underlying sandstone substrate outcrops. The subspecies has not yet been observed in superficially similar nearby wet heath habitats but as it is very cryptic it may be present. The Woronora, Sackville North and one of the two Wedderburn populations grow in seepage zones of sandstone outcropping in skeletal soil downslope of heathland. In the Bonnum Pic vicinity a few plants were noted growing on rock plate heath.

Hibbertia puberula* subsp. *glabrescens

Subspecies *glabrescens* is known only from Tertiary alluvial soil along Airport Creek on Bankstown Airport and not from areas where subsequent fill has been deposited in between (pers. com. Gibson). The plant assemblage is attributable to “Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion”.

The airport site is very heavily modified from the natural state, lacks canopy species and is currently a low grass/shrub association with many pasture grasses and other introduced herbaceous weeds.

Soil at the site is a sandy (Tertiary) alluvium with a high silt content.

The remnant at the site and soil type are consistent with an inferred pre-settlement cover of Castlereagh Ironbark Forest although some remnant vegetation at and near the site (along the channel in particular) suggests Castlereagh Scribbly Gum Woodland is equally valid.

Hibbertia sp. Bankstown has been observed to flower from October to December, with seed setting from October to January. Most Hibbertia species are primarily pollinated by bees, but many have specialised mechanisms requiring particular bee species, beetles or syrphid flies (OEH Threatened Species Profile).

2.5 ANTHROPOGENIC THREATS TO THE HABITAT

Threats to the habitat of *Hibbertia puberula* that are relevant to sites within or adjacent to urban development include:

- Loss of habitat.
- Damage to habitat by trailbikes, 4WDs and mountain bikes.
- High densities of weeds and invasive grasses occur at the top of ridgelines; there is significant potential for encroachment into areas where the species occurs.
- Altered fire regime, either too frequent or too seldom.
- Potential for widening of major roads to affect populations of the species.
- Road maintenance and slashing works.
- Clearing for fire protection zones.
- One of the subspecies (subsp. *extensa*) occurs in areas subject to underground mining and is known from rock shelves and upland swamps. One site has been destroyed the rock outcropping utilised as a turning circle for hazard reduction purposes and another the habitat has been impacted by fire trail widening and spoil placement.

Photo 7: Smith’s Creek Reserve, clearing and weed invasion adjacent housing.

Field inspection of bushland remnants in the heavily urbanised sectors of GMGA provide irrefutable proof of severe degradation arising from a range of anthropogenic impacts and urbanisation. Without exception, all creeks and many of the remnants were heavily weed infested caused by a range of factors not limited to altered hydrology as well as nutrification and stormwater discharge, garden refuse and fill dumping and exotic seed dispersal by various vectors.

Photo 8: Bunbury Curran Park adjacent Harrow Road Canterbury Road intersection.

The photo shows garden refuse dumping and fire trail maintenance impacting upon the small remnant of potential habitat.

Damage to zones adjacent urban development can also be caused by clearing for fire hazard reduction, control burning frequently, and recreation activities such as 4WD vehicle access, mountain bikes and kids' cubby house building. Changes to hydrology, nutrification, stormwater discharge are of particular concern to this species group as many habitat niches are associated with seepages.

Photo 9: Severe weed infestation at Bunbury Curran Creek vicinity south of Harrow Road.

Photo 10: Severe impact of fire on bushland adjacent Bunbury Curran Creek, potential habitat.

Photo 11: Severe weed degradation of habitat, Pembroke Park, Minto.

Photo 12: Recreational impacts upon habitat, Pembroke Park, Minto.

3. Description of the study area

3.1 LAND USE HISTORY

The Cumberland subregion was first occupied by the Aboriginal peoples, who enjoyed a plentiful supply of fresh water and foods including fruit, tubers, fish, animals, birds and honey (Hills District Council website).

With the arrival of Europeans land use changed to timber gathering and agriculture, permanently altering the landscape. Particularly since the end of the second world war urban settlement and industry have expanded west from Sydney into the Cumberland subregion. Over the last 40 years many rural properties have been subdivided as lifestyle and hobby farm properties.

Currently there is great pressure for further residential development to the west of Sydney in the Cumberland subregion.

3.2 LANDSCAPE CONTEXT

The changes in land use have caused the clearing of a large proportion of the natural bushland of the Cumberland subregion. In 2011 the Cumberland Plain Recovery Plan stated "Only 13% of the pre-1750 extent of the region's vegetation remains as intact bushland, with an additional 12% occurring as scattered trees in disturbed areas (NPWS 2002 in DECCW 2011). Consequently, much of the region's biodiversity is listed as threatened under State and/or Commonwealth legislation."

Widespread clearing of the remaining habitat has continued with much of the extant vegetation now being assessed as Critically Endangered. This widespread clearing has resulted in loss of habitat for endangered species such as *Hibbertia puberula*.

3.3 NATIVE VEGETATION

Since 2011 there has been further clearing, there are now 15 Plant Community Types that are listed as Critically Endangered, Endangered or Vulnerable in the Cumberland subregion.

The Cumberland Plain Recovery Plan states that "there are seven threatened species, four endangered populations and nine threatened ecological communities listed on the NSW *Threatened Species Conservation Act* 1995 that are found only on the Cumberland Plain. Seven of these are also listed as threatened under the Commonwealth *Environment Protection and Biodiversity Conservation Act* 1999." The remaining bushland is highly fragmented and much of it occurs on private lands.

Within the GMGA and the WGA eleven Plant Community Types (PCTs) are mapped (mapping provided by the NSW Department of Planning and Environment). The PCTs are:

- Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion, PCT 830

- Forest Red Gum – Rough Barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion, PCT 835
- Grey – Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion. PCT 849
- Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion. PCT 850
- Grey Myrtle dry rainforest of the Sydney Basin Bioregion and South East Corner Bioregion. PCT 877
- Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion. PCT 883
- Red Bloodwood – Grey Gum woodland of the Cumberland Plain, Sydney Basin Bioregion. PCT 1081
- Red Bloodwood – Scribbly Gum heathy woodland on sandstone plateau of the Sydney Basin Bioregion. PCT 1083
- Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion. PCT 1181
- Water Gum- Coachwood riparian scrub along sandstone streams, Sydney Basin Bioregion. PCT 1292
- Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion. PCT 1395

3.4 POTENTIAL HABITAT

Hibbertia puberula has the potential to occur within five Plant Community Types (PCTs) mapped as occurring within the GMGA and the WGA. These community types are:

- Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion. PCT 883
- Red Bloodwood – Grey Gum woodland of the Cumberland Plain, Sydney Basin Bioregion. PCT 1081
- Red Bloodwood – Scribbly Gum heathy woodland on sandstone plateau of the Sydney Basin Bioregion. PCT 1083
- Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion. PCT 1181
- Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion. PCT 1395

With the exception of PCT 883 at Moorebank, *Hibbertia puberula* has not been recorded to occur uniformly or in substantive numbers across any of the above listed communities. In general, it is usually confined to a variety of specific habitat niches within these regional mapping units. The area of occupancy within and/or the area of the specific habitat niches at any locale may be as small as a few square metres.

Specific habitat niches of potential occurrence may include upper drainage lines, seepages especially those associated with exposed sandstone bedrock or slabs, margins of hanging swamps / wet heath, exposed sandstone rock plates, and large and small occurrences of colluvial or alluvial deposits.

At most locales presence or absence can only be positively determined by intensive targeted surveys that investigate such habitat niches thoroughly within the peak flowering period. Refer to Photo 6 of *Hibbertia puberula* subsp. *glabrescens* that clearly shows the importance of surveying in the flowering period.

Photo 13: *Hibbertia puberula* habitat at Smiths Creek Reserve.

Note that the *Hibbertia* is not discernible. Refer also to the conspicuousness of flowering *Hibbertia puberula* subsp. *glabrescens* in Photo 6.

4. Assessment of species presence and suitable habitat

4.1 SPECIES RECORDS AND HABITAT ASSESSMENTS

Hibbertia puberula including its subspecies are poorly known and assessed as data poor. Apart from Miller (June – August 2018), there have been no other specific targeted surveys for *Hibbertia puberula* within the study area. General vegetation assessments undertaken for various purposes appear also not to have found *Hibbertia puberula* as there are no prior database records of the species within the proposed growth areas.

<u>Prior Records of *Hibbertia puberula*</u>

The nearest known populations of *Hibbertia puberula* subsp. *puberula* to the GMGA boundary are 850m away in West Moorebank and 990m away in Smiths Creek Reserve.

The nearest known population of *Hibbertia puberula* subsp. *puberula* to the northern boundary of WGA is approximately 22km away at Old Kent Road, Kentlyn.

The closest known population of *Hibbertia puberula* subsp. *extensa* occurs just 30 m from the GMGA boundary east of the Georges River Appin. The closest known population to the WGA boundary is c. 7.5km away south of Appin Road.

Hibbertia puberula subsp. *glabrescens* is only known from Bankstown Airport which is situated 9km from the northern boundary of GMGA and approximately 41km from WGA.

Searches of the databases revealed records of *Hibbertia riparia* at a number of locales including a Biobanking site at Douglas Park, just to the north of WGA (refer Appendix 5 *Hibbertia riparia* records in or adjacent GMGA and WGA). The name *Hibbertia riparia* is consider by Toelken to be misapplied to NSW taxa. Miller has observed that *Hibbertia puberula* is sometimes misidentified as *Hibbertia riparia*.

4.2 PRIOR SPECIES SURVEYS

From the information provided, no prior dedicated targeted searches have been undertaken for this species as part of the biocertification process.

4.3 ASSESSMENT OF SPECIES PRESENCE

The previous survey data provided by Biosis and Ecoplanning Consultants was insufficient to assess the probability of occurrence of *Hibbertia puberula* from a desk top study. CFFIS undertook targeted survey of suitable habitat where access was granted.

4.3.1 LIKELIHOOD OF SPECIES PRESENCE

Hibbertia puberula subsp. *extensa*

It is unlikely that suitable habitat for the subspecies occurs within the footprint of the growth areas, with the exception of the area at the southern extent of the WGA where the landscape may contain areas of wet heath or small localised seepages.

It is highly probable that this subspecies occurs within the GMGA and WGA boundaries adjacent to the footprints. Any occurrences would be confined to small populations restricted to very localised habitat niches. Potential habitat areas adjacent to the footprint would be highly susceptible to significant indirect impacts from a range of anthropogenic influences arising from the increase in urbanisation.

Hibbertia puberula subsp. *glabrescens*

Within the GMGA footprint the only location that supports potential habitat for the subspecies is the Menangle Park area. The subspecies may have once existed at Milton Park and Kayess Park vicinities, however, it is now unlikely to occur at those parks. Targeted surveys are recommended within the flowering period at these locales.

The likelihood of occurrence within or adjacent to the WGA is assessed as negligible. From known occurrence data the subspecies does not have the capacity to exist in habitats that occur within the proposed WGA development footprint. No further, specific targeted surveys are warranted for this subspecies in the WGA.

In the unlikely event that this subspecies was to occur it would be picked up in the targeted surveys for the other subspecies.

Hibbertia puberula subsp. *puberula*

Within the development footprint the subspecies is likely to occur at Menangle Park area, Milton Park and Kayess Parks, as well as in areas fringing and adjacent to the footprints (see maps 7 to 9).

From CFFIS limited field surveys, a small-leaved *Hibbertia* sp. has been observed to occur at three sites within the GMGA and WGA boundaries adjacent to the development footprint. Plants were also observed outside but proximate to the GMGA and WGA boundaries. These plants have vegetative morphological features +/- consistent with *Hibbertia puberula*.

It is highly probable that this subspecies occurs at many other locales within the GMGA and WGA boundaries. Any occurrences are likely to be confined to small populations restricted to very localised habitat niches. Potential habitat areas adjacent to the footprint would be highly susceptible to significant indirect impacts from a range of anthropogenic influences arising from the increase in urbanisation.

4.3.2 JUSTIFICATION FOR DETERMINATION

Hibbertia puberula subsp. *extensa*

Occurs in very close proximity to GMGA eastern boundary approximately 30m upslope from the Georges River in seepage zones associated with sandstone outcroppings. Similar outcropping formations were observed within GMGA and WGA that have the potential to support the subspecies. Within the development footprint the only area that may have suitable habitat is at the southern section of the WGA.

No extensive areas of wet heath/swamp areas were noted to occur in the limited sites inspected. Small localised areas supporting species associated with periodically damp soil were observed. There is potential for small localised areas of heath/swamp to occur within WGA in a number of areas where access was not granted.

Hibbertia puberula subsp. *glabrescens*

Sand deposits are noted in the Nepean River floodplain at Menangle Park as evidenced by past and present sand extraction. The alluvial sand deposits may provide suitable habitat.

Hibbertia puberula subsp. *puberula*

Shale – Sandstone geology is widespread around the periphery of both the GMGA and WGA, within this it has been demonstrated from limited field validation that habitat and potential habitat exist. Within the development footprint this habitat occurs at Menangle Park, Kayess Park and Milton Park. Sand deposits are noted in the Nepean River floodplain at Menangle Park as evidenced by past and present sand extraction. The alluvial sand deposits may provide suitable habitat.

4.4 ASSESSMENT OF SUITABLE HABITAT

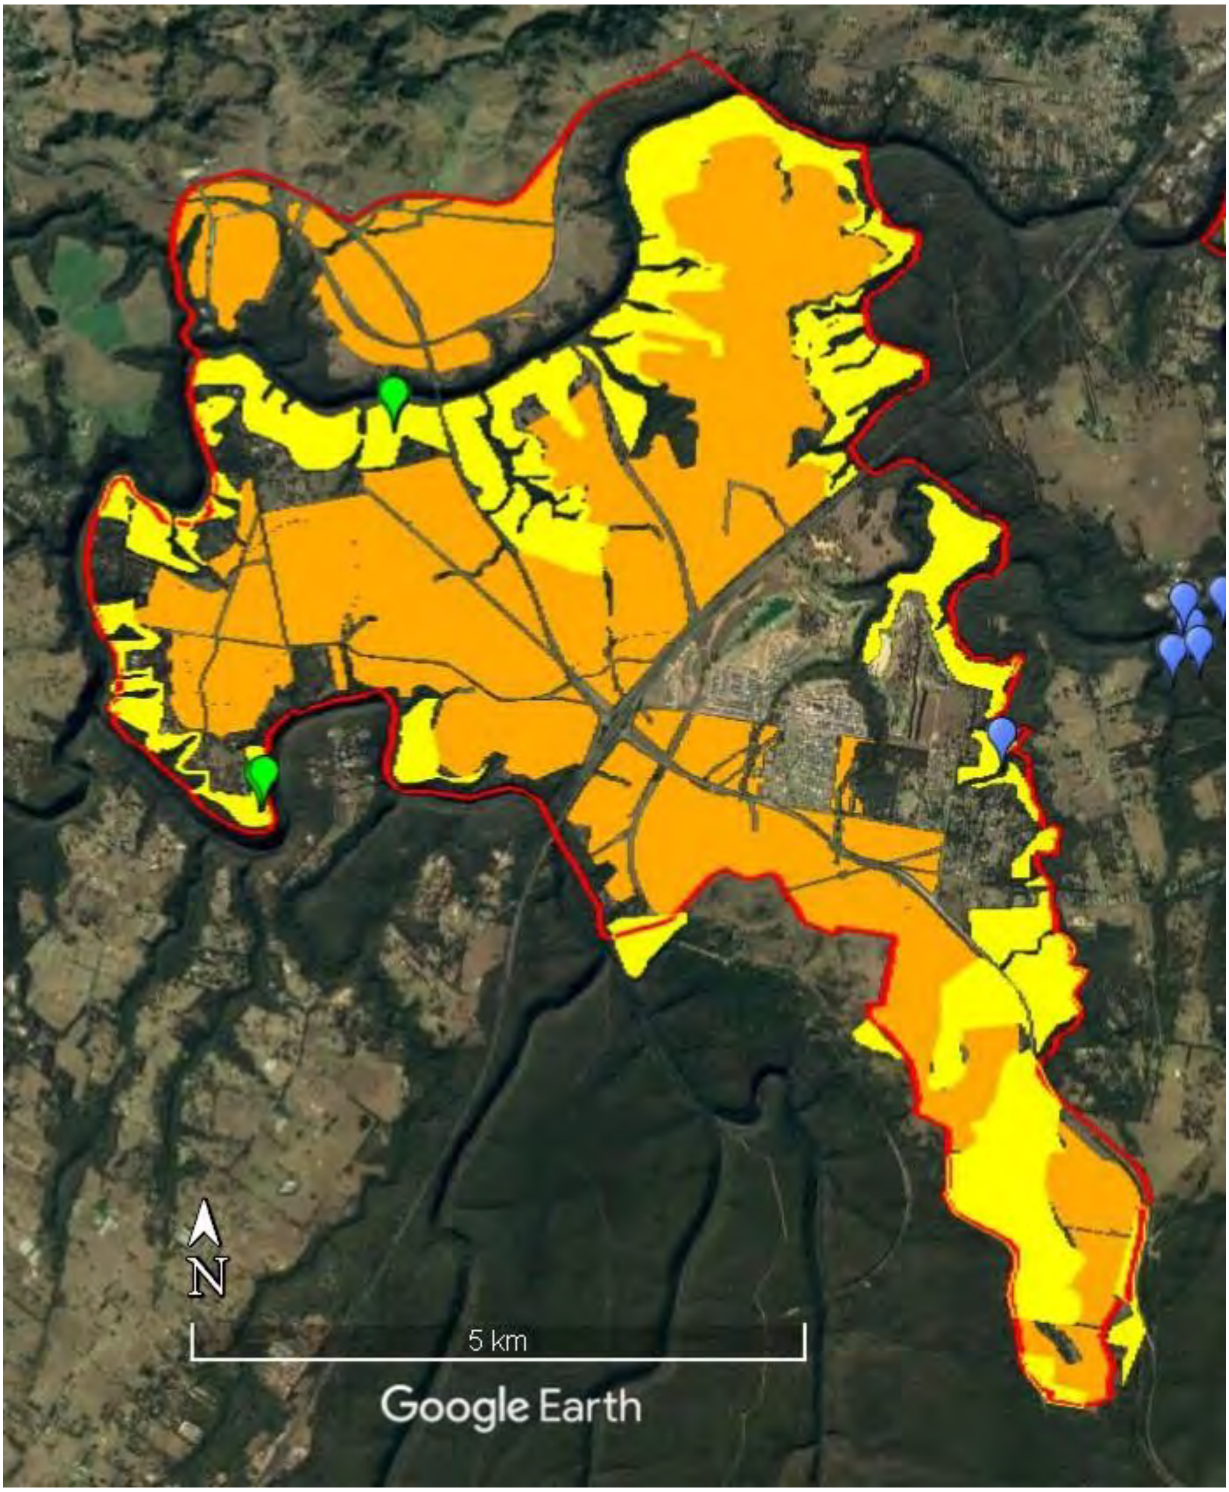
The assessment of suitable habitat has been described in section 4.3, assessment of species presence, because the survey during the non-flowering period required the presumption that if suitable habitat were present then the species could also be present.

The species group could be present in areas of alluvial / colluvial deposition especially adjacent shale and shale / sandstone transition. Within the WGA and GMGA occurrences within and shale / sandstone transition communities are most likely to occur in microhabitats such as seepage zones below or above sandstone outcrops or minor sandy colluvial deposits. Broad scale vegetation survey and mapping do not identify habitats at this scale. Survey during the flowering season is recommended.

4.4.1 DETERMINATION OF SPECIES POLYGONS

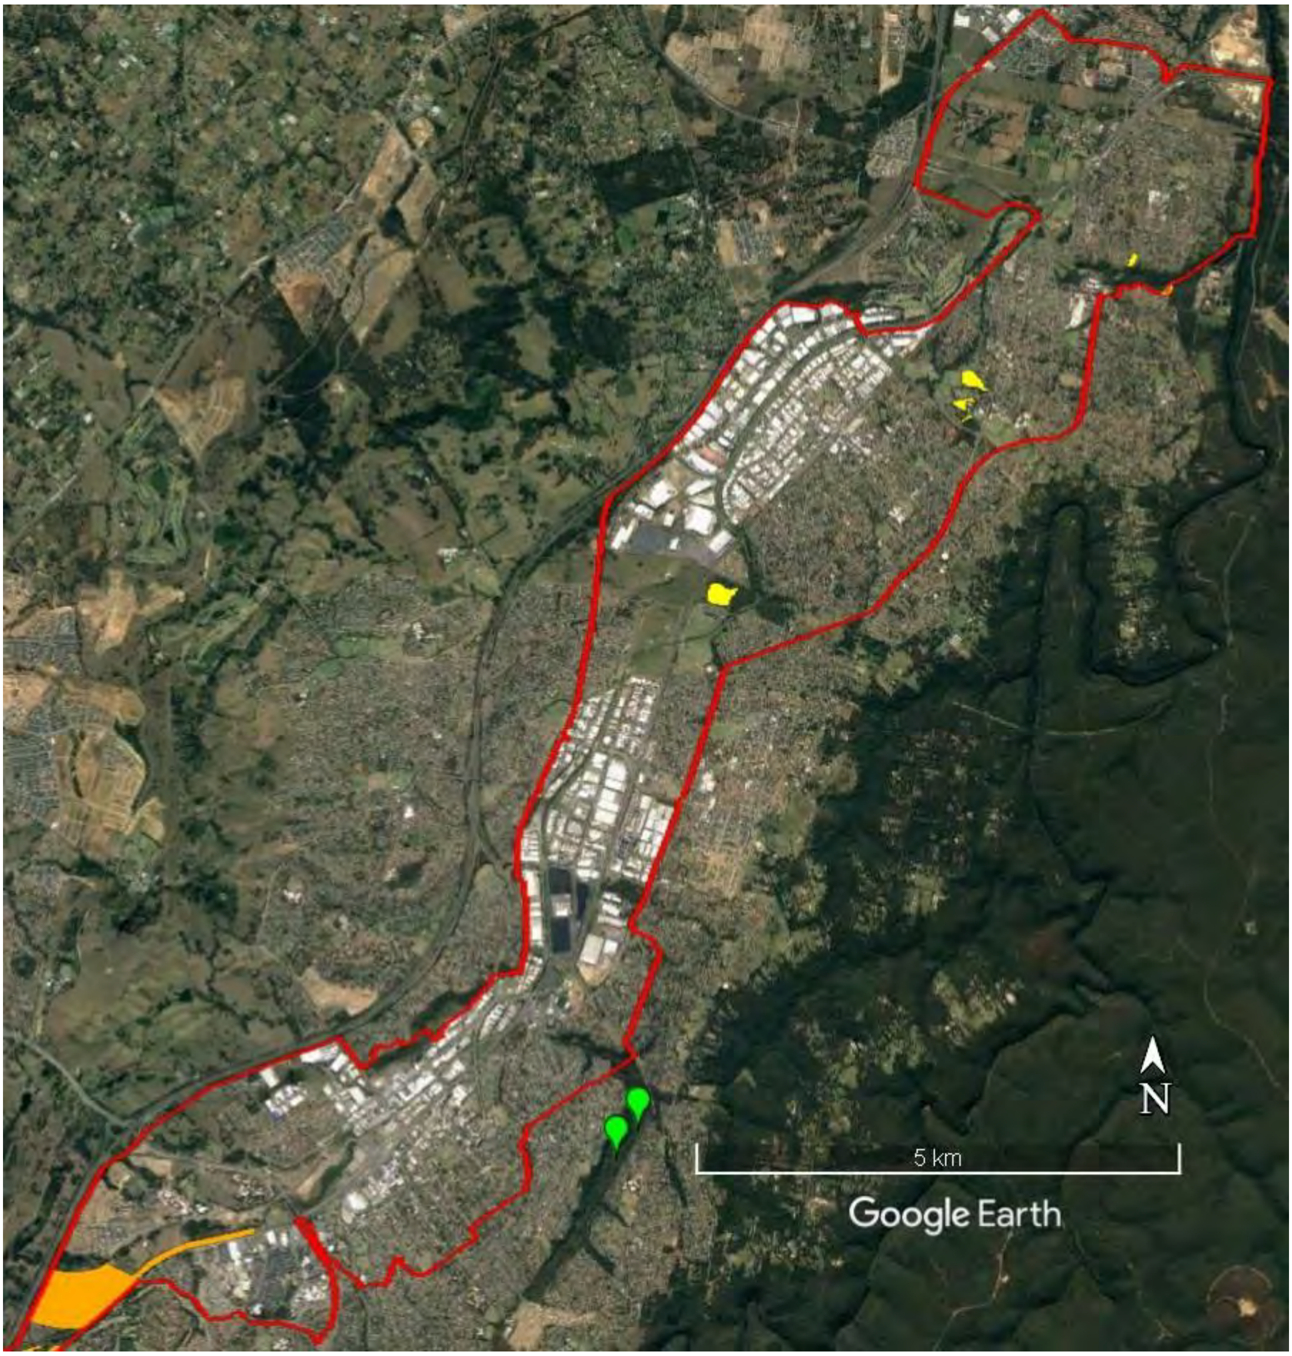
Determination of potential habitat for *Hibbertia puberula* includes areas identified outside the deemed biocertification area. Anthropogenic impacts are well documented to adversely affect vegetation well beyond the direct urban footprint.

The following maps show an overview of areas containing potential habitat of *Hibbertia puberula* group within the GMGA and WGA.



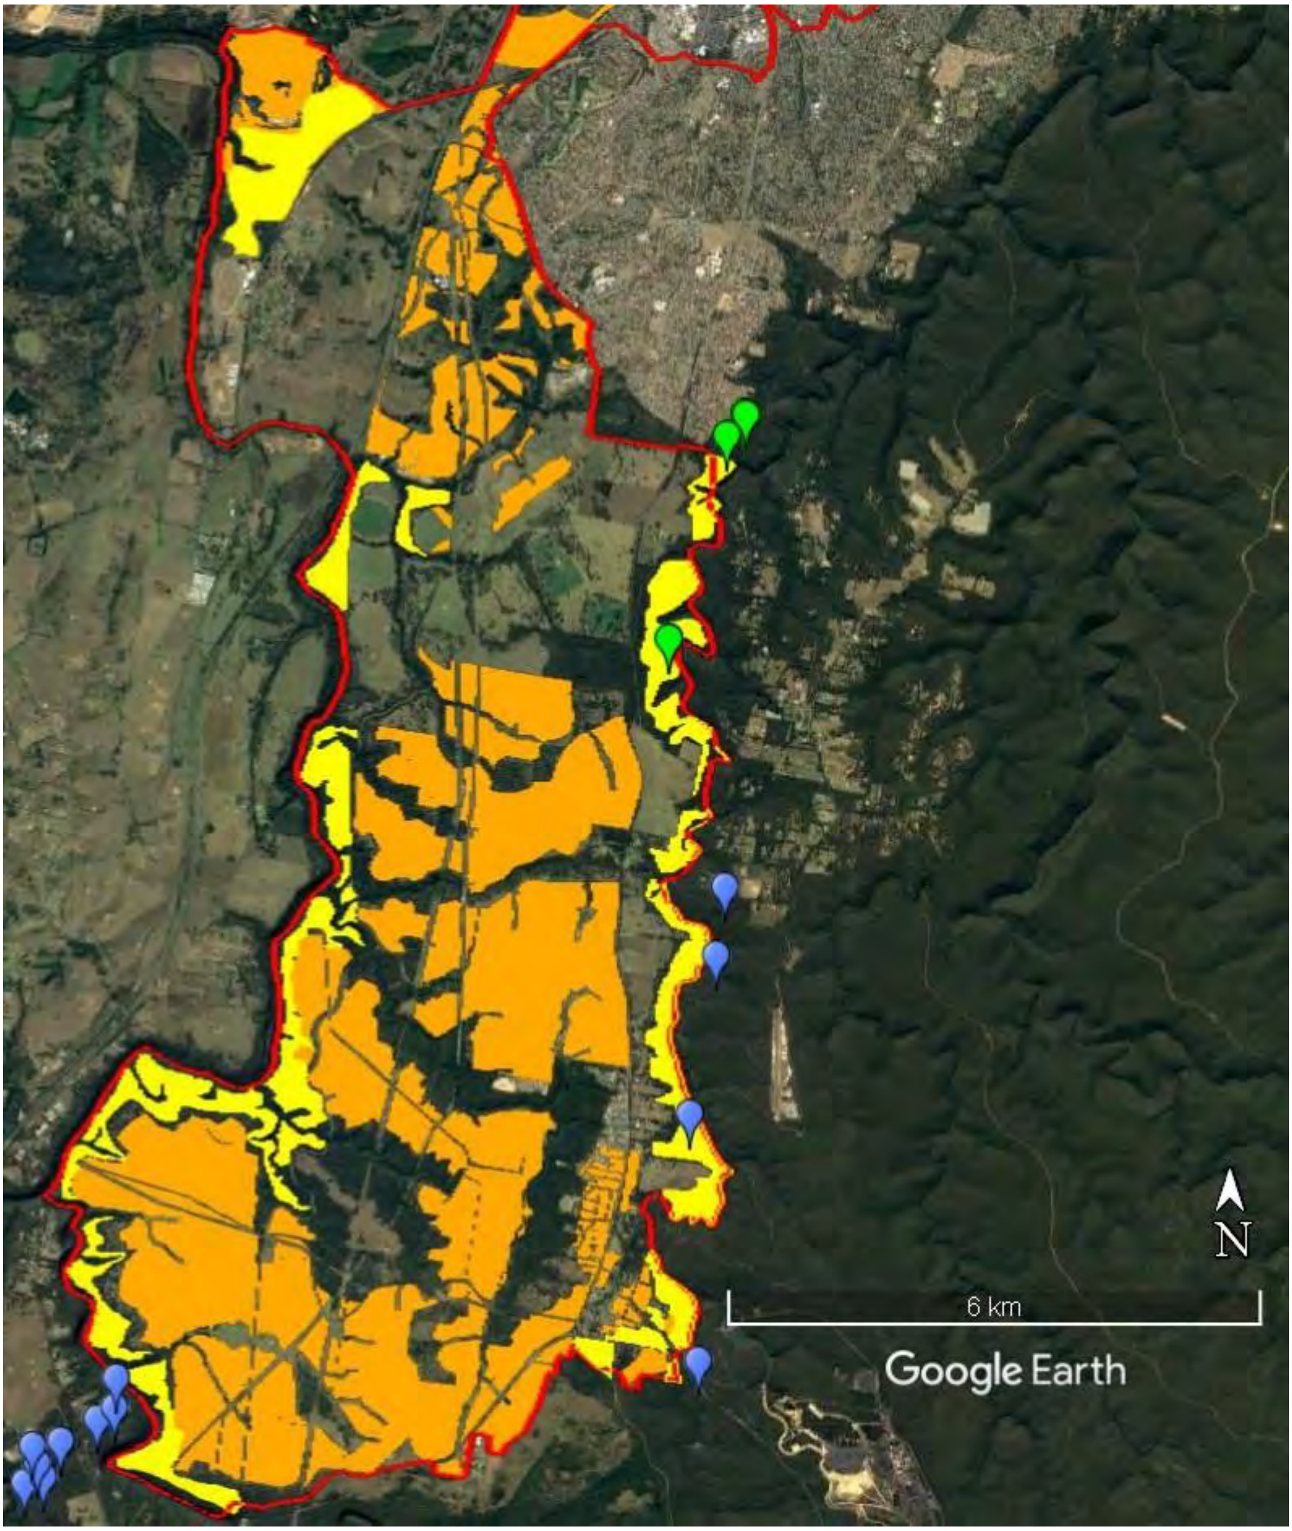
Map 7: Polygons of areas containing potential and known *H. puberula* habitat, WGA.

Key: Red - growth area boundary, orange – growth area footprints, yellow – areas containing known and likely habitat niches, green markers - location of a small leaved *Hibbertia* sp. with vegetative features consistent with *H. puberula*, purple markers – locations of *H. riparia* records.



Map 8: Polygons of areas containing potential *H. puberula* habitat, GMGA northern section.

Key: Red - growth area boundary, orange – growth area footprint, yellow - habitats assessed as having attributes similar to known extant populations, green markers - location of a small leaved *Hibbertia* sp. with vegetative features consistent with *H. puberula*.



Map 9: Polygons of areas containing potential *H. puberula* habitat, GMGA southern section.

Key: Red - growth area boundary, orange – growth area footprint, yellow - habitats assessed as having attributes similar to known populations, green markers - location of a small leaved *Hibbertia* sp. with vegetative features consistent with *H. puberula*, purple markers – location of *H. riparia* records.

4.4.2 JUSTIFICATION FOR DETERMINATION

The species potential habitat polygons for Milton Park, Kayess Park, Bunbury Curran Creek and Menangle Park in the GMGA are based on limited field inspections undertaken in adverse environmental conditions outside the flowering period. Therefore, the polygons are indicative only. The *Hibbertia puberula* group has been recorded from similar habitats.

The majority of potential habitat polygons for the WGA are based on regional mapping data provided by DPE as access issues limited field validation. Similar access issues arose with other potential habitat areas within the southern and central portions of the GMGA. Unless indicated potential habitat polygons for the southern and central portions of the GMGA are also based on regional mapping data.

The *Hibbertia puberula* group has been frequently recorded from Shale /Sandstone transition environs. The polygons are also an extrapolation of habitat characteristics where a small leaved *Hibbertia* sp. was located within or adjacent to the growth areas during survey for this assessment.

4.5 ESTIMATE OF AREA OF HABITAT OR NUMBER OF INDIVIDUALS

4.5.1 ESTIMATES

The assessment provides the following estimates:

- Likely habitat for *Hibbertia puberula* subsp. *extensa* occurs within the footprint in the southern part of the WGA, habitat would be small seepages within an area of 23ha.
- A further 278ha of land that could contain habitat niches for *H. puberula* subsp. *extensa* is adjacent to the footprint in the southern section of the WGA and the eastern side of the GMGA between Appin and Wedderburn.
- Likely habitat for *Hibbertia puberula* subsp. *glabrescens* occurs at Menangle Park. An area of approximately 92ha could contain likely habitat niches within the growth area footprint, and a further 31 ha of land containing likely habitat niches adjacent to the footprint.
- Likely habitat for *Hibbertia puberula* subsp. *puberula* occurs outside the development footprint at Milton Park, Kayess Park and in the vicinity of Bunbury Curran Creek reserve.
- Likely habitat for subspecies *puberula* within the development footprint occurs at Menangle Park (92ha), Gilead and Appin areas (8ha) and WGA (65ha).
- Likely and known habitat for subspecies *puberula* adjacent to the development footprint occurs at Menangle Park (31ha), Gilead and Appin areas (380ha) and WGA (680ha).

4.5.2 JUSTIFICATION FOR ESTIMATES

Assessment relied on personal knowledge of the species habitat for known populations, combined with vegetation mapping and soil and landscape features, to determine likely habitat locations within and adjacent the growth areas footprints.

It was not possible to provide accurate habitat areas or counts due to the following:

- Access was not granted to the majority of development footprint.
- Positive determination of the small leaved Hibbertias found as part of this expert report is not possible even though the vegetative morphological features are assessed to be +/- consistent with *Hibbertia puberula*. Floral characters in combination with vegetative features are essential to confirm identification of many *Hibbertia* species.
- The region has undergone a period of protracted drought and small diminutive species, forbs and even many of the larger resilient shrubs were observed to be in severe drought stress or dead. At all locations only a few *Hibbertia* sp. attributable to *H. puberula* were found, most almost dead. It is well documented that the above ground populations of many genera including *Hibbertia* species fluctuate widely in response to various conditions such as rainfall and time since last fire.
- Most sites inspected within the WGA and many within GMGA were noted to have senescing or dead shrubs, high levels of leaf, bark and branch fall and dead understorey, an indication of both a long fire interval and severe drought. Apparent diversity and population numbers of many species significantly decline, retreating to the soil seedbank under such conditions. It is inconclusive to undertake population census or estimates of occupied area under such circumstances.
- The cryptic nature of small-leaved *Hibbertia* when not in flower also make their detection extremely difficult and population count or area calculation unreliable.
- The use of a surrogate site(s), with the possible exception of *Hibbertia puberula* subsp. *glabrescens*, as a base for the estimation, in this case, is also deemed not credible. *Hibbertia puberula* is a data-poor species group. Insufficient or no reliable data exists with regard to population density across its range of habitat niches and fluctuation in population density over time at any given site.

5. Information used in the assessment

Information used in this assessment includes taxonomic papers, BioNet and ALA records of the target species, Critically Endangered Listing, online Threatened Species profile and associated documents, personal observations and site inspections, and the spatial viewer including the layers: survey access and coverage, (BAM plots, polygons and transects), PGA layer and geology and soils.

Current Position:

Principal of Cumberland Flora & Fauna Interpretive Services

Qualifications:

Associate Diploma Horticulture from the University of Western Sydney (formerly Hawkesbury Agricultural College), conferred on 17 April 1982

Journal Articles

H.R. Toelken & R.T. Miller **2012** Notes on *Hibbertia* (Dilleniaceae) 8. Seven new species, a new combination and four new subspecies from subgen. *Hemistemma*, mainly from the central coast of New South Wales, in Journal of the Adelaide Botanic Gardens, Vol. 25.

Miller J and Miller R **2005** Aquatic macroinvertebrates of headwater streams in the south east forests – diversity and conservation management issues, Wetlands (Australia) 23 (1).

Employment Record

1993 - present

Cumberland Flora and Fauna Interpretive Services

Principal - flora surveys, plant identifications, vegetation assessment, project impact assessment, bush regeneration, rehabilitation, habitat enhancement, seed collection and propagation services.

1990 - 1997 **Sylvan Grove**
Native Gardens

Curator of gardens and adjoining bushland - maintenance of and improvement to the plant collection, training and supervision of staff, liaison with other botanic gardens, guided tours, technical advice.

1982 - 1990 **Sylvan Grove**
Native Gardens

Horticulturist Specialising in Australian Flora - collection, propagation, identification, and growing of native plants.

CUMBERLAND FLORA & FAUNA INTERPRETIVE SERVICES INFORMATION AND RELEVANT EXPERIENCE

Cumberland Flora and Fauna Interpretive Services have provided technical expertise since 1993 to numerous clients including Local Government, NSW Roads and Maritime, NSW Office Environment Heritage NPWS and community groups. Following is a list of some of our projects and clients:

REPORT	CLIENT
Expert advice for Conservation Assessment of *Solanum celatum* Eren Delgado1 16/04/2018, Science Division, NSW Office of Environment and Heritage	OEH
Saving our Species (SoS) project for *Pomaderris adnata* a post fire population census Grid D 2018	OEH
Provision of expert advice to update the current ecological data for southern NSW threatened flora species, as part of the review of biodiversity assessments under the Biodiversity Conservation Act 2016.	OEH

REPORT	CLIENT
Expert witness in botany Residents Against Intermodal Development Moorebank Incorporated v NSW Minister for Planning and Anor – NSW Land & Environment Court Class 1 Proceedings No. 2017/81889. Review of project documentation, in particular the various biodiversity assessments including the BAM assessment for the project and Individual Expert Witness report of Dr David Robertson 15 October 2017; Site inspections to identify the location of and/or potential habitat for *Hibbertia fumana*, *Hibbertia puberula*, *Grevillea parviflora*, *Persoonia nutans*, *Acacia bynoeana*, provision of an expert report in accordance with Division 2 of Part 31 of the UCPR; confer with the other parties experts at a joint conference and produce a joint expert report; and f appear at the section 34 conciliation conference	EDO
Saving our Species (SoS) project for *Pomaderris adnata* a population census 2017	OEH
Central Coast Creek Monitoring Evaluating and Reporting 2016 – Vegetation Consultant	OEH
Great Lakes Creek Monitoring Evaluating and Reporting 2016 – Vegetation Consultant	OEH
Northern Beaches Creek Monitoring Evaluating and Reporting 2016 – Vegetation Consultant	OEH
Northern Beaches Creek Monitoring Evaluating and Reporting 2015 – Vegetation Consultant	OEH
Clarence Colliery Discharge Investigation April 2015	OEH
Vegetation Assessment as part of the Lachlan Wetlands Condition Assessment Project October 2013 – May 2014	Lachlan Catchment Management Authority
Field expertise and guidance in the Sydney basin to PhD candidate Karen Muscat studying the molecular phylogenetics and morphology of the genus Dianella with close scrutiny of the variation in the D. *caerulea* group of species in eastern Australia	Volunteer to University of Melbourne
Survey for *Pomaderris adnata* to determine population size, structure, occupancy and threats 2014	NPWS Illawarra Region
Survey of *Hibbertia stricta* subsp. *furcatula* (Hibbertia species 'Menai') to determine population size, structure, occupancy and threats. Collection of voucher herbarium material for taxonomic review June 2014	OEH
Survey of the southern populations of *Hibbertia stricta* subsp. *furcatula* (Hibbertia species 'Menai') to determine population size, structure, occupancy and threats May 2014	OEH
Investigation of works within the Sublime point precinct Illawarra Escarpment State Conservation Area February 2014.	NPWS Illawarra Region
Identification of Hibbertia species in proposed control burn sites Victoria Road precinct Dharawal National Park.	NPWS Illawarra Region
Assessment of impact of infrastructure upgrade Victoria Road, Dharawal National Park – location of threatened species.	NPWS Illawarra Region
APPEAL IN RESPECT OF PROPERTY AT Lot 1 and 2 DP 224431 Site 2 Sturdee Avenue, Bulli	Roy 'Dootch' Kennedy

REPORT	CLIENT
Expert Witness Report Relating to Some Environmental Issues Land & Environment Court of New South Wales PROCEEDINGS NO 10982 of 2012	Roy 'Dootch' Kennedy
Field surveys, collection, pressing, curation of botanical specimens and contributions of notes in association with the manuscript "Notes on Hibbertia subgen. Hemistemma (Dilleniaceae) 7. Eight new species, a new combination and four new subspecies from mainly central New South Wales H.R. Toelken & R.T. Miller 2006 - 10 July 2012	Volunteer to Adelaide Botanic Gardens
Vegetation Surveys and assessments & input into the preparation of REF for proposed car-park and amenities Victoria Road Precinct Dharawal National Park November 12.	NPWS Illawarra Region
Office of Environment and Heritage – Priority Action Statement Expert Consultant Interviews June 2012 – January 2013	OEH
Vegetation Surveys and assessments & input into the preparation of REF for proposed walking track re-alignment Maddens Falls in Dharawal National Park 2011 – 12.	NPWS Illawarra Region
Vegetation Surveys and assessments for proposed walking track re-alignment Maddens Falls in Dharawal National Park 2011 – 12.	NPWS Illawarra Region
Vegetation Surveys and assessments for proposed walking tracks in Dharawal National Park input into conservation risk assessments 2011 – 12.	NPWS Illawarra Region
Nomination to list Prostanthera saxicola R. Br. S. Str. as an Endangered Species under the NSW TSC Act September 2011	
Field surveys, collection, pressing and curation of botanical specimens of undescribed Kunzea to assist in the taxonomic circumscription of previously presumed extinct, rare and/or poorly known taxa for Dr. H.R. Toelken Honorary Research Associate State Herbarium Science Resource Centre Department of Environment and Natural Resources SA 2011	Volunteer to Adelaide Botanic Gardens
Significant Plant Survey – Maddens Plains Forest Path to Mount Mitchell Precinct IIllawarra Escarpment State Conservation Area Cumberland Flora & Fauna Interpretive Services June 2011	NPWS Illawarra Region
Significant Plant Survey – Significant Plant Survey – Wongawillii Precinct Illawarra Escarpment State Conservation Area Cumberland Flora & Fauna Interpretive Services June 2011	NPWS Illawarra Region
Significant Plant Survey – Kembla State Forest Precinct Illawarra Escarpment State Conservation Area Cumberland Flora & Fauna Interpretive Services June 2011	NPWS Illawarra Region
Site Inspections and Vegetation Survey of Proposed Minor Track Re-Alignments: Forest Path to Woodward Track & Sublime Point to Austinmer Track Maddens Plains To Sublime Point Precinct Illawarra Escarpment State Conservation Area August 2010	NPWS Illawarra Region

REPORT	**CLIENT**
Sandon Point Aboriginal Place and Kuradji Lands Vegetation Management Plan April 2010	Illawarra Aboriginal Land Council, Wollongong Council, Southern Rivers Catchment Management Authority.
Forest Path to Woodward Track Precinct Track-head Realignment Maddens Plains IESCA Vegetation Survey April 2010.	NPWS Illawarra Region
Bushland Conservation Project 95 Glendiver Road, The Oaks 2008	A & S Fitzsimmons / Hawkesbury Nepean Catchment Management Authority
Significant Plant Survey – Maddens Plains Forest Path to Woodward Track Precinct Illawarra Escarpment State Conservation Area June 2007	NPWS Illawarra Region
Nomination of Hibbertia "Bankstown Airport" (R.T. Miller & C.P. Gibson s.n. 18/10/2006) as Critically Endangered under the Environment Protection and Biodiversity Conservation Act	Bankstown Bushland Society
Proposal to Demolish A Derelict Amenities Block at Deepwater Park Webster Street Milperra Environmental Assessment of Impacts	Bankstown City Council
Significant Plant Survey – Sublime Point to Panorama House Precinct Illawarra Escarpment Conservation Area August – September 2006	NPWS Illawarra Region
A Consultant for Priority Action Statement Workshop July 2005	NPWS
PHD research assistance – 'The Benefits of Riparian Vegetation in Maintaining Water Quality as Assessed Using Biological Indicators".	UNSW
Plan of Management for Part Lot 11 Dp 1049307 Kurrajong Road Prestons January 2005	Sule College
Preliminary Investigation & Vegetation Survey of Lands At Prestons Bounded By Maxwells Creek, Kurrajong Road, Ash Road & The Western Sydney Orbital December 2003	Sule College
Supply and collection of seed for a research project entitled: Factors Affecting Seed Germination and Mycorrhizal Development of the Epacrid: *Woolsia pungens* (2001-2003)	UNSW
Compensatory Habitat Assessment Western Sydney Orbital March 2004	RTA
Compensatory Habitat Assessment Western Sydney Orbital July 2002	RTA
Compensatory Habitat Assessment of Flora at Rouse Hill, Doonside, Cecil Hills & Kemps Creek for The Western Sydney Orbital March 2002	RTA
Compensatory Habitat Assessment Western Sydney Orbital November 2001	RTA
Preliminary Vegetation Survey Between Lawson Rd & Alfords Point Rd, Menai as Part of The Proposed Bangor Bypass 2001	RTA
8-Part Tests for The Proposed Bangor Bypass 2000	RTA
Preliminary Vegetation Survey for The Proposed Bangor Bypass 2000	RTA
Species Impact Statement for the Western Sydney Orbital 2000	Sinclair Knight Mertz

REPORT	**CLIENT**

Ongoing research projects:

Private taxonomic research into the Australian plant genera Prostanthera, Westringia, Dianella, Thelionema, Viola and Hibbertia.

Private research into the invertebrate fauna of the Illawarra with particular emphasis on the Mayfly genus Atalophlebia

Flora of Bankstown" a botanical inventory

Botanical inventories of the Sublime Point and Maddens Plains precincts in the Illawarra Escarpment State Conservation Area

Other Publications & Reports

Miller, R.T. (1984 to 2006) numerous papers for the Prostanthera and Westringia Study Group Newsletters.

Miller, R.T. (1991) Vegetation Consultant on Eloura Nature Reserve Vegetation Survey: Report to Liverpool City Council, Greening Australia.

Miller, R.T. Vegetation Consultant on Salt Pan Creek Stage 1 Vegetation Survey: Report to Bankstown City Council, Ian Olsen.

Gibson, C.P. & Miller, R.T. Plant Species List for Bankstown's Natural Heritage: McLaughlin, L., BCC.

Gibson, C.P. & Miller, R.T. Flora of Bankstown Scientific Inventory of Botanical Heritage: Report to Australian National Parks and Wildlife Service, Gibson, C.P. and Miller, R.T. (in preparation).

Nomination of Prostanthera saxicola R. Br. s. str. As an Endangered Species under the NSW TSC Act November 2011

Special Projects

- "Flora of Bankstown" a botanical inventory
- Founder & Convener Cookson's Landcare Group Bulli (2003 – 2007)
- President, Society for Growing Australian Plants, East Hills Region, 1987-1995.
- Vice President, Society for Growing Australian Plants, East Hills Region, 1996.

- Plant Steward, Society for Growing Australian Plants, East Hills Region, 1987-1996.
- Leader of the Prostanthera Study Group Australian Plant Society, 1992 - 2010.
- Editor and publisher of Prostanthera & Westringia Study Group's Newsletter *The National Mint* and the Study Groups' Journal – *Lasianthos*.
- Vice President and Founding Member, Bankstown Bushland Society.
- Coordinator Grants Application, Bankstown Bushland Society.
- Bushland Regeneration Grants Project Manager, Bankstown Bushland Society:

- Deverall Park Restoration and Rehabilitation Swamp Woodland ($17,880).
- The Crest of Bankstown Restoration and Rehabilitation ($27,850).
- Airport and Ashford Reserves Restoration and Rehabilitation Swamp Woodland ($45,000).

- Co-recipient of Save the Bush grant for Flora of Bankstown by Hon. Ross Kelly, Minister for Arts, Sports and Environment, 1992-93 ($11,050).
- Founding Member of Illawarra Grevillea Park, Bulli.
- Curator, Lamiaceae collection, Illawarra Grevillea Park, Bulli.
- Former Bankstown City Council's Bushfire Taskforce Community Representative.
- Former presenter of an adult education course in gardening at Bankstown Evening College.
- Development and curation of a private regional herbarium.
- Expert Witness for NSW Police murder trial
- Former appointee as Trustee of the Georges River State Recreational Trust by the Minister for the Environment (the Hon. Tim Moore).

Appendix 2. *Hibbertia puberula* subs. *puberula* COLLECTION RECORDS

Field notes compiled by Miller and Miller & Gibson

Site: Lucas Heights Site 1 16/10/07

Abundance: extremely localised, rare < 12 plants noted.

Field notes: Lucas Heights Soil Landscape, Gentle plateau slope, skeletal soil above first sandstone outcropping +/- intermittent seepage zone. Vegetation sparse and stunted probably from the impact of drought and fire episode > 2 years. All *Hibbertia* appeared to be seedlings at this locale. Open Woodland / heath – Canopy: *Eucalyptus haemastoma*? and Stringybark species. Associated understorey: *Banksia ericifolia, B. oblongifolia, Leptospermum arachnoides, Grevillea sericea, Xanthorrhoea* sp., *Cyathochaeta diandra, Burchardia umbellata, Hypoxis hygrometrica*.

Site: Simmos Beach Recreation Reserve Macquarie Fields, Habitat 1 Ridgetop Laterite

Field notes: Very disturbed site (past trailbike/FWD and possible laterite extraction but now protected and regenerating. Open Woodland/Laterite Heath: *Eucalyptus punctata.* Associated understorey species: *Exocarpos cupressiformis, Goodenia hederacea, Pomax umbellata, Brachyloma daphnoides, Patersonia sericea, Gompholobium minus, Leptospermum parvifolium, Kunzea ambigua, Persoonia laurina, Micrantheum ericoides.*

Site: Simmos Beach Recreation Reserve Macquarie Fields, Habitat 2 Easterly Plateau slope above Georges River

Abundance: Very localised but locally common c. 20 plants noted.

Field notes: Soil: fine sand with clay component, undisturbed habitat, walking track only. Habit: compact wiry shrub 30-60cm wide with many lax stems arising from a rootstock. In Open Woodland. *Eucalyptus sclerophylla?, E. punctata, Angophora bakeri*. Associated understorey: *Melaleuca nodosa, Lambertia formosa, Leptospermum trinervium, Callistemon linearis, Kunzea ambigua, Kunzea capitata, Helichrysum collinum, Xanthorrhoea sp., Stipa pubescens, Themeda australis*.

Site: Simmos Beach Recreation Reserve Macquarie Fields, Habitat 3 Upperslope/headwaters of upper drainage line.

Field notes: Undisturbed. *Eucalyptus punctata, E. sclerophylla*? and *Angophora bakeri*. Associated understorey: *Kunzea ambigua, Melaleuca nodosa, Gompholobium minus, Isopogon anemonifolius, Leucopogon, Kunzea capitata, Xanthorrhoea* sp. Dominated by *Kunzea* and *Melaleuca nodosa*.

Site: Simmos Beach Recreation Reserve Macquarie Fields, Habitat 4 Laterite Ridgetop.

Field notes: *Angophora bakeri. Leptospermum parvifolium* (dominates), *Kunzea ambigua, Petrophile sessilis, Micrantheum ericoides, Kunzea capitata, Lambertia formosa, Pimelea linifolia, Stipa pubescens*.

Site: Keith Longhurst Reserve (formerly The Basin Reserve) Georges River Road Kentlyn Habitat 1: Lateritic Heath

Field notes: *Eucalyptus* sp. (Stringybark), *E. squamosa, Allocasuarina littoralis, Angophora hispida*. Associated understorey*: Leptospermum trinervium* (narrow-leaved form), *Petrophile sessilis, Persoonia lanceolata, Isopogon anemonifolius, Hakea laevipes, H. sericea, Grevillea diffusa, Actinotus minor, Cyathochaeta diandra, Entolasia stricta, Caustis flexuous*.

Site: Keith Longhurst Reserve (formerly The Basin Reserve) Georges River Road Kentlyn Habitat 2: Lateritic Heath

Field notes: Soil very fine sandy loam. Habit: low +/- prostrate shrub sprawling through sedges. *Angophora hispida, Corymbia gummifera, Allocasuarina littoralis*. Associated understorey: *Leptospermum trinervium* (narrow-leaved form), *Petrophile sessilis, Persoonia lanceolata, Pultenaea elliptica, Isopogon anemonifolius, Banksia spinulosa, Grevillea diffusa, Actinotus minor, Cyathochaeta diandra, Entolasia stricta*.

Site: Keith Longhurst Reserve (formerly The Basin Reserve) Georges River Road Kentlyn Habitat 3

Field notes: Soil sandy loam with small sandstone outcroppings. Open Forest *Eucalyptus punctata*, E. sp. (Stringybark), and *Corymbia gummifera.* Associated understorey: *Hakea laevipes, Leptospermum parvifolium, Isopogon anemonifolius, Lissanthe strigosa, Grevillea diffusa, Hakea sericea, Acacia linifolia, Themeda australis, Lomandra obliqua, Lomandra cylindrica, Cyathochaeta diandra*.

Site: Keith Longhurst Reserve (formerly The Basin Reserve) Georges River Road Kentlyn Habitat 4

Field notes: Soil: fine sandy loam scattered lateritic fragments. Open Forest with grassy and herbaceous understorey comprised of *Eucalyptus punctata*, E. sp. (Stringybark), and *Corymbia gummifera.* Associated understorey: *Leptospermum parvifolium, Isopogon anemonifolius, Lissanthe strigosa, Grevillea diffusa, Goodenia hederacea, Stipa pubescens, Themeda australis, Entolasia stricta, Hypoxis hygrometrica, Hovea linearis, Cryptandra* sp., *Lobelia dentata, Patersonia sericea, Cyathochaeta diandra* and *Xanthorrhoea* sp.

Site: Peter Meadows Reserve Old Kent Road Kentlyn

Field notes: Soil: sandy, lateritic. Lateritic Ridgetop Heath *Eucalyptus sclerophylla, E. squamosa, Angophora hispida* heath. Lateritic Ridgetop Heath /Woodland interface: *Eucalyptus sclerophylla, E. punctata, Angophora hispida*. Associated understorey species: *Petrophile sessilis, Lambertia formosa, Kunzea capitata, Leptospermum arachnoides, Brachyloma daphnoides, Hakea laevipes, Xanthorrhoea sp., Actinotus minor, Pultenaea elliptica, Hakea sericea, Gompholobium minus, Goodenia hederacea* and *Entolasia stricta*.

Site: Freres Crossing Reserve, Freres Road Kentlyn 2/11/07, Ridgetop slopes

Field notes: *Eucalyptus punctata, Syncarpia glomulifera* Associated understorey: *Hakea laevipes, Persoonia linearis, Leptospermum trinervium, Isopogon anemonifolius, Gompholobium minus,* *Acacia terminalis, Gonocarpus tetragynus, Brachyloma daphnoides, Eriostemon australis, Grevillea diffusa, Hibbertia diffusa, Hypoxis hygrometrica, Xanthorrhoea* sp*., Themeda australis, Lomandra obliqua, Entolasia stricta.*

Site: Freres Crossing Reserve, Freres Road Kentlyn 2/11/07, Ridgetop

Field notes: *Eucalyptus punctata, Angophora costata*, Stringybark sp. Associated understorey*: Allocasuarina littoralis, Kunzea ambigua, Acacia terminalis, Brachyloma daphnoides, Hypoxis hygrometrica, Themeda australis* and *Stipa pubescens*.

Site: Ella Avenue Barden Ridge (formerly Lucas Heights) 20/11/07 Below Detention Basin

Field notes: Localised in drainage line. Site impacted by housing development – weed invasion occurring due to urban runoff and sedimentation. *Eucalyptus punctata*, E. sp. (Stringybark), *E. haemastoma, Corymbia gummifera, Angophora hispida*. Associated understorey: *Hakea sericea, Banksia oblongifolia, Leptospermum polygalifolia, L. arachnoides, Lambertia formosa, Kunzea ambigua, Grevillea sericea, Epacris pulchella, Banksia spinulosus, B. marginata, Isopogon anemonifolius, Hakea laevipes, Phyllota phylicoides, Actinotus minor, Patersonia sericea, Xanthorrhoea resinosa, Stipa pubescens, Xanthosia tridentata, Lomandra obliqua, Cyathochaeta diandra, Lepyrodia scariosa, Schoenus brevifolius, Lindsaea linearis*.

Site: Ella Avenue Barden Ridge (formerly Lucas Heights) 20/11/07 Downslope of Detention Basin

Field notes: Scattered through sedges - relatively rare at edge of wet heath/swamp. *Eucalyptus haemastoma*, E. sp. (stringybark), *E. punctata*. Associated understorey: Sedges dominate understorey: *Leptocarpus tenax, Schoenus brevifolius, Xanthorrhoea resinosa, Leptospermum polygalifolia, Banksia oblongifolia, Actinotus minor, Dampiera stricta, Epacris pulchella, Entolasia stricta, Deyeuxia decipiens.*

Site: Little Forest Lucas Heights 20/11/07

Field notes: Soil: fine sandy loam with clay content, +/- impeded drainage, Lucas Heights Soil Landscape, Localised in narrow zone in upper drainage line. *Eucalyptus oblonga, E. haemastoma, Corymbia gummifera, Angophora hispida.* Associated understorey: *Callistemon citrinus, Banksia oblongifolia, Leptospermum polygalifolia, L. arachnoides, Lambertia formosa, Kunzea ambigua, Grevillea diffusa, G. sericea, Melaleuca thymifolia, Callistemon linearis, Hakea sericea, H. teretifolia, Acacia linifolia, Mirbelia rubiifolia, Actinotus minor, Patersonia sericea, Xanthorrhoea resinosa, Stipa pubescens, Xanthosia tridentata, Lomandra obliqua, Cyathochaeta diandra, Schoenus brevifolius*.

Site: Voyager Point Adjacent Old Single Mens Quarters

Field notes: Soil: Fine sand atop of lateritic gravels – Surface layer -Well drained, Aspect: easterly Slope: 0-2. Open Woodland: *Eucalyptus sclerophylla, E. parramattensis, Angophora bakeri*. Understorey diverse open to moderately dense with well-developed ground layer. Dominant Associated Shrub Species: *Melaleuca nodosa, Petrophile sessilis, Leptospermum parvifolium, L.*

trinervium, Banksia spinulosa, Hakea laevipes, Kunzea ambigua, Persoonia lanceolata, Callistemon linearis, Hakea sericea, Acacia brownii, Daviesia acicularis. Dominant Associated Ground Layer Species: *Platysace ericoides, Hovea linearis, Lomandra obliqua, Lepyrodia scariosa, Austrostipa pubescens, Austrodanthonia tenuior, Cyathochaeta diandra*.

Site: Voyager Point adjacent Sirius Drive

Field notes: Soil: Fine sand and laterite – Surface layer -Well drained. Aspect northerly slope 0-2. Open Woodland: *Eucalyptus sclerophylla, Angophora bakeri* and *Eucalyptus oblonga*. Understorey diverse, open to moderately dense with well-developed ground layer. Dominant Associated Shrub Species: *Petrophile sessilis, Leptospermum trinervium, Banksia spinulosa, Babingtonia densiflora, Brachyloma daphnoides, Kunzea ambigua, Persoonia levis, Grevillea sericea, Hakea sericea, Isopogon anemonifolius, Melaleuca nodosa, Lambertia formosa, Philotheca scaber, Styphelia laeta.* Dominant Associated Ground Layer Species: *Platysace ericoides, Dianella revoluta, Lomandra obliqua, Lepyrodia scariosa, Austrostipa pubescens, Cyathochaeta diandra*.

Site: Yeramba Lagoon 2/1/07 Ridge slopes 1

Field notes: Shelving sandstone terraces. Soil: Sandy loam. Surface layer: Well drained but drainage impeded by sandstone bedrock. Aspect: westerly slope: 5. Open Woodland: *Eucalyptus racemosa, Corymbia gummifera, Eucalyptus oblonga & Angophora bakeri.* Understorey diverse, open grassy site. Dominant Associated Shrub Species: *Petrophile sessilis, Leptospermum polygalifolium, Banksia oblongifolia, B. spinulosa, B. marginata, Kunzea ambigua, Persoonia levis, Grevillea sericea, Hakea sericea, Grevillea sericea, Hakea laevipes, Leptospermum arachnoides, Epacris microphylla, Hibbertia stricta.* Dominant Associated Ground Layer Species: *Actinotus minor, Schoenus moorei, Austrostipa pubescens, Themeda australis, Entolasia stricta, Lomandra multiflora.*

Site: Yeramba Lagoon 2/1/07 Ridge slopes 2

Field notes: Ridge slopes – shelving sandstone terraces. Soil: Sandy loam. Surface layer: Well drained. Aspect: northwest. Slope: 5. Interface between Woodland*: Eucalyptus oblonga, Corymbia gummifera, Eucalyptus punctata* Open Woodland: *Eucalyptus racemosa, Corymbia gummifera, Eucalyptus oblonga & Angophora bakeri.* Understorey diverse and well developed moderately dense. Dominant Associated Shrub Species: *Petrophile sessilis, Leptospermum trinervium, B. marginata, Hibbertia stricta*, *Leucopogon microphyllus, Lambertia formosa, Callistemon linearis, Melaleuca thymifolia, Gompholobium grandiflora, Epacris microphylla, Lasiopetalum ferrugineum.*

Dominant Associated Ground Layer Species: *Themeda australis, Entolasia stricta, Burchardia umbellata*, *Actinotus minor, Lomandra obliqua, Schoenus moorei, Austrostipa pubescens.*

Site: Blackwall 2/1/07 Ridgetop / Plateau

Field notes: Soil: relatively deep sand. Aspect: Northerly Slope: < 2. Open Woodland: *Corymbia gummifera, Eucalyptus racemosa, E. punctata, and E. oblonga.* Understorey diverse. Dominant Associated Shrub Species: *Brachyloma daphnoides, Banksia spinulosa, Petrophile sessilis, Leptospermum trinervium, L. parvifolium, Isopogon anemonifolius, Babingtonia densifolia, Dillwynia* *retorta, Philotheca scabra, Grevillea sericea, Gompholobium glabratum, Xanthorrhoea media, Kunzea ambigua, Bossiaea heterophylla, Acacia myrtifolia.* Dominant Associated Ground Layer Species: *Phyllanthus hirtellus, Pomax umbellata, Austrostipa pubescens, Themeda australis* and*Cyathochaeta diandra.*

Site: Mickeys Point 2/1/07 Ridgetop / Plateau

Field notes: Soil: lateritic. Aspect: North east Slope: < 2. Open Woodland / Heath: *Eucalyptus racemosa, Angophora hispida,* and *Allocasuarina littoralis.* Understorey diverse. Dominant Associated Shrub Species: *Petrophile sessilis, Leptospermum trinervium, Hakea sericea, Persoonia levis, Kunzea ambigua, Styphelia triflora, Isopogon anemonifolius, Brachyloma daphnoides, Babingtonia densifolia, Hemigenia purpurea, Hibbertia stricta*. Dominant Associated Ground Layer Species: *Actinotus minor, Baeckea ramosissima, Poranthera ericoides, Lomandra obliqua, Austrostipa pubescens, Entolasia stricta.*

Appendix 3. *Hibbertia puberula* IDENTIFICATION CHARACTERS

All microscopic photos by Miller 2018.

Photo 14: *Hibbertia puberula* subsp. *puberula* Canoelands.

Photo shows that the hairs are “worn off” on the older growth.

Photo 15: *Hibbertia puberula* subsp. *puberula* Canoelands

Photo shows tomentum characteristics of new shoots, revolute margins and recessed to bulging broader central vein that obscures the leaf undersurface.

Photo 16: *Hibbertia puberula* subsp. *puberula* from Lucas Heights.

Photo 17: *Hibbertia puberula* subsp. *puberula* (Lucas Heights)

Photo shows leaf and stem tomentum, revolute margins and bulging broader central vein obscuring the leaf undersurface of new shoot.

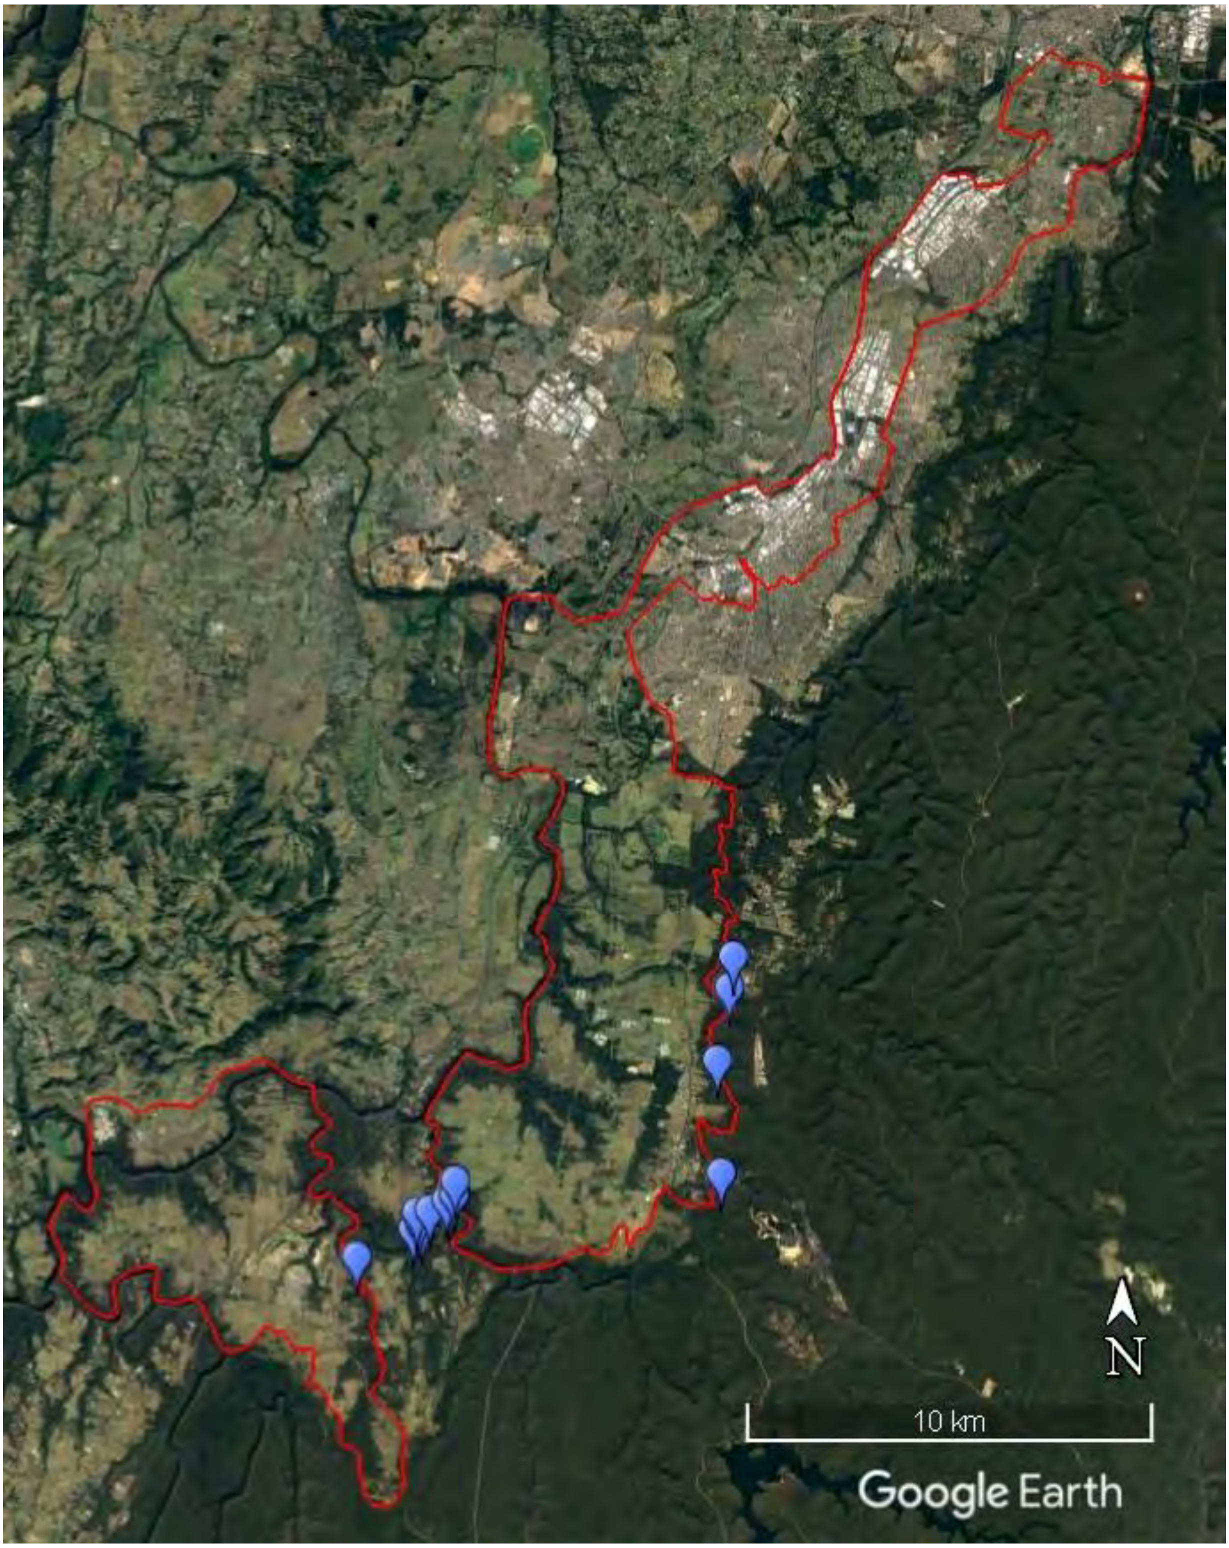
Appendix 5. DISTRIBUTION OF *Hibbertia riparia* IN / CLOSE TO THE GROWTH AREAS.



Map 10: Records of *Hibbertia riparia* in or close to the Growth Areas.

Note that *H. riparia* is unlikely to occur in NSW and these records could be *H. puberula.*

Strategic assessment for Cumberland Plain Conservation Plan Aerotropolis and Greater Penrith,

Hibbertia puberula species group

Hibbertia puberula subsp. *glabrescens* at Bankstown Airport

Report prepared for Department of Planning and Environment

By

Cumberland Flora & Fauna Interpretive Services

Robert Miller - December 2018

Executive Summary

Hibbertia puberula subsp. *extensa* and subsp. *puberula* are listed as Endangered Species under the *Biodiversity Conservation Act 2016*. *Hibbertia puberula* subsp. *glabrescens* is listed as a Critically Endangered Species, being known from only one population at Bankstown. There is limited data on the life history and ecology of the species.

Survey for this report was limited by time constraints, lack of access to private property, and years of preceding drought conditions. Survey targeted areas of suitable habitat identified from the habitat of extant populations and DPE vegetation mapping.

Areas adjacent to the development footprint were included in the survey because *H. puberula* is a small shrub that could be severely affected by anthropogenic impacts, particularly in areas downhill of development. The proposed road corridors will fragment habitat exposing the species to greater edge effects.

Outcomes of the assessment:

<u>*Hibbertia puberula* subsp. *extensa*</u>: It is extremely unlikely that this subspecies exists within the WPEC and WSA growth areas. No suitable habitat is known to occur or is likely to occur within the proposed urban footprint or the growth areas. The likelihood of occurrence is assessed as negligible.

<u>*Hibbertia puberula* subsp. *glabrescens*</u>: The likelihood of occurrence within or adjacent to the GPEC is considered to be low to moderate, and the likelihood of occurrence within or adjacent to the WSA is assessed as low. From known occurrence data the subspecies does not have the capacity to exist in habitats that occur within the proposed WSA development footprint.

<u>*Hibbertia puberula* subsp. *puberula*</u>: Within the development footprint the subspecies is likely to occur within the Wianamatta Regional Park, as well as in areas adjacent to the footprints at Ropes Crossing and Kemps Creek. This study provided 7 new records for *H. puberula* subsp. *puberula*, two within the growth areas and 5 to the north. The species was unknown to occur within or adjacent to the growth areas prior to this survey.

Outcomes of this assessment are that 34 ha of habitat with a high to moderate probability of the species occurring are within the development footprint, and that more than 100 ha of habitat with high to moderate probability of species occurrence are outside the footprint but are likely to suffer from anthropogenic impacts caused by the development.

<u>Recommendations:</u> It is a recommendation of this study to list *Hibbertia pedunculata* as a Threatened species or an Endangered Population, and to take it into consideration as part of this biodiversity certification process as the known populations are likely to be severely impacted by development. It is also a recommendation that all bushland remnants adjacent to development be fenced and maintained to minimise anthropogenic impacts.

1. Introduction

1.1 PURPOSE

The purpose of this expert report is to determine the potential for future urban development in identified growth areas of Western Sydney to impact on *Hibbertia puberula*, the subspecies of which are listed as an Endangered or Critically Endangered Species under the *Biodiversity Conservation Act 2016*. This report forms part of the Cumberland Plain Conservation Plan, which will be assessed for:

- Biodiversity certification under the *Biodiversity Conservation Act 2016* (BC Act)
- Strategic assessment and approval under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act).

The Biodiversity Assessment Method (BAM) sets out the framework and methods to be used for assessment of impacts to biodiversity to provide preferred conservation outcomes while also supporting the development approval process. Under the BAM an expert report can be used when adequate survey is not possible. An expert report can only be used for species to which species credits apply.

The expert report must document the information that was considered, and/or rejected as unsuitable for consideration, to reach the determination made in the expert report. The report must set out whether the subject species is likely to be present at the development site, and if present then the report must estimate, in the case of a species such as *Hibbertia puberula*, the area of habitat where the species is likely to be impacted, as well as areas from which it is known to occur in which it will be impacted.

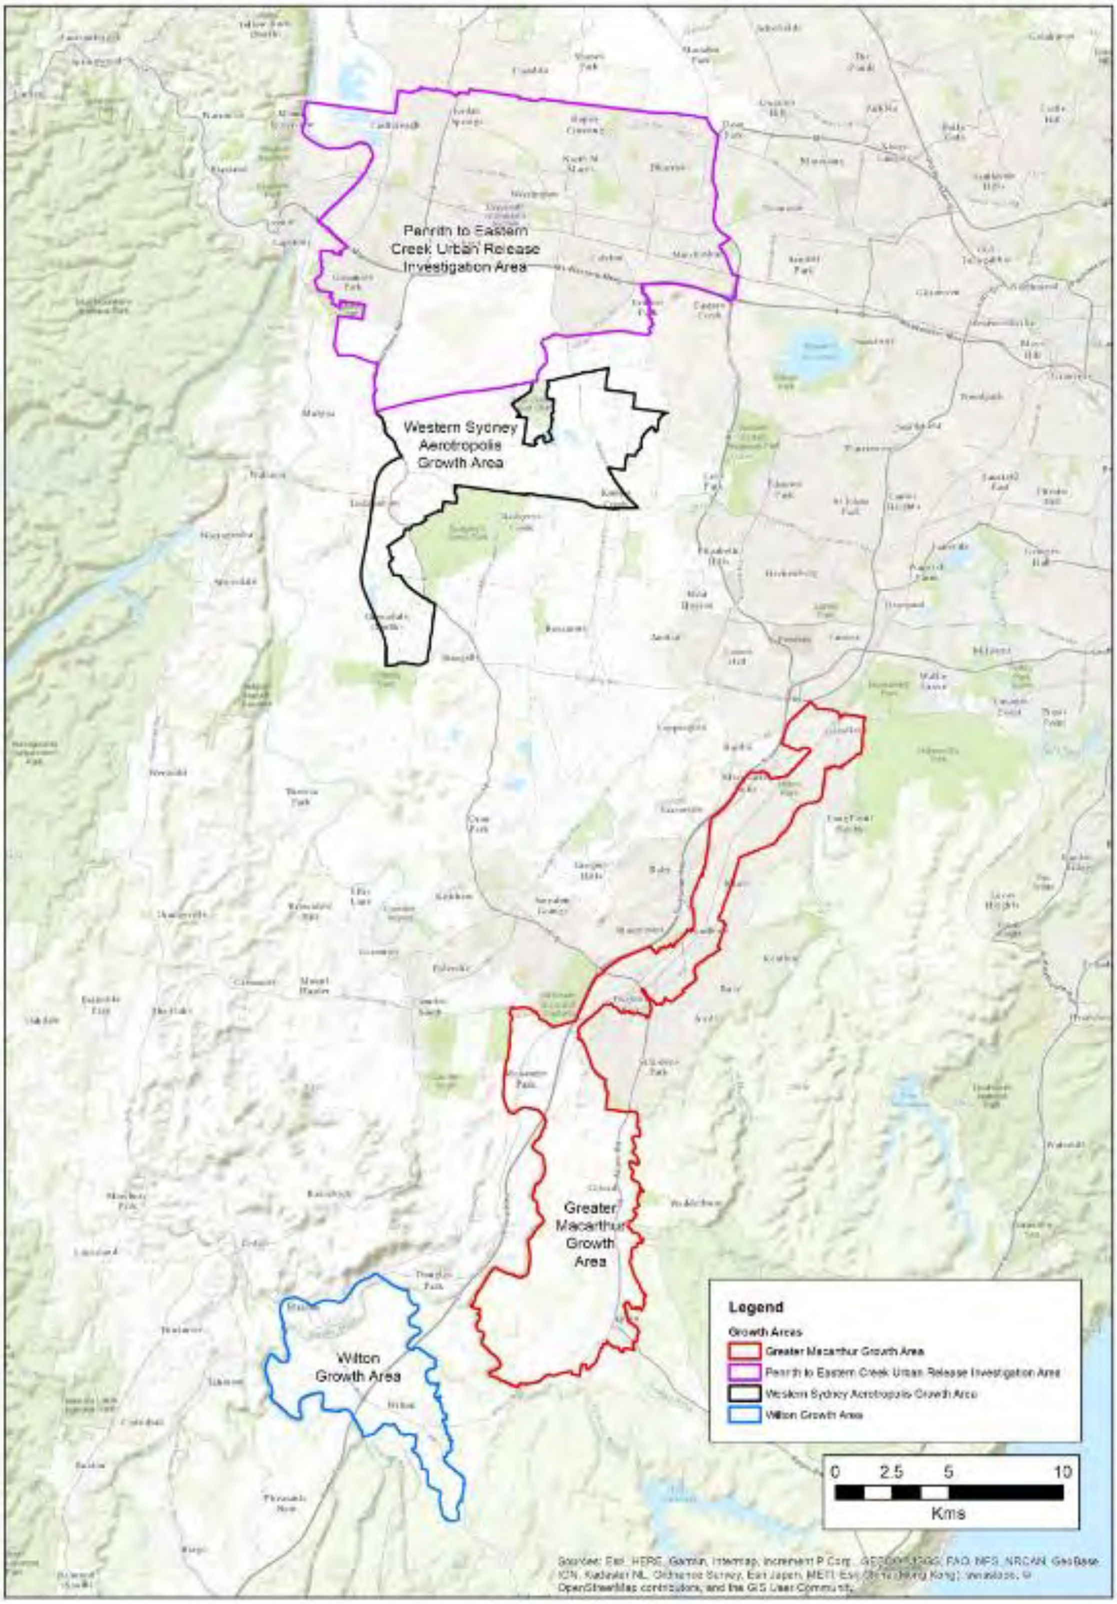
1.2 PROJECT CONTEXT

The NSW Government is planning for future urban development in Western Sydney. Four growth areas have been identified, these are Wilton, Greater Macarthur (Campbelltown and Appin), Western Sydney Aerotropolis (WSA), and Greater Penrith to Eastern Creek (GPEC). These growth areas are all located within the Cumberland Subregion in version 7 of the Interim Biogeographic Regionalisation for Australia (IBRA) (2016).

As part of the planning for this future development, the Department of Planning and Environment (DPE) is preparing the Cumberland Plain Conservation Plan. This is a strategic regional assessment that will lead to the identification of preferred conservation outcomes for the Cumberland subregion.

1.3 STUDY AREA

Map 1 shows the growth areas of Greater Penrith to Eastern Creek (GPEC) and Western Sydney Aerotropolis (WSA) which are the subject of this report, and the Greater Macarthur and Wilton growth areas which are the subject of a separate report.



Map 1: The four Western Sydney Growth Areas

Map source: NSW Department of Planning and Environment.

1.4 JUSTIFICATION FOR USE OF EXPERT REPORT

The BAM allows for situations where an expert report will be required to replace or complement survey effort at a development site. While there has been some field survey for the Strategic Biodiversity Certification assessment, the area covered by the proposed GPEC and WSA are extensive and there have been issues with gaining access to some of the private properties.

An expert report is required to assess potential impact to *Hibbertia puberula* for the following reasons:

Insufficient survey: A large extent of the identified growth areas could not be surveyed because it was on private property and could not be accessed within the project timeframe. Expertise was required to identify and survey potential species habitat and propose additional habitat based on extant populations and prior knowledge of the species.

Survey following prolonged rainfall deficiency / drought: The Western Sydney region has been experiencing extremely dry conditions for several years, resulting in the *Hibbertia puberula* plants being subject to severe drought stress causing partial and/or full defoliation. In many instances the majority of the population at a particular site may have retracted to the soil seed bank.

Compounding the effect of reduced soil moisture, following drought many areas have a significant increase in leaf, twig and branch drop making this small and cryptic species more difficult to locate or possibly covering them completely.

Herbivory of a wide range of native species can severely impact small plants during dry conditions.

The discernible population was therefore likely to be significantly reduced from these causes.

Rainfall events in months prior to this assessment allowed many *Hibbertia* species to produce new growth and therefore flowers. However, the rainfall was insufficient to replenish subsoil moisture. A dry period and unusually hot conditions prior to, and during, this assessment resulted in moisture stress for many plants. In the case of some *Hibbertia* species this is noticeable by unusually early petal dehiscence making their detection difficult.

It requires an expert in the species to locate and identify rare *Hibbertia* under these conditions.

Reliable species identification: Identification of the genus *Hibbertia* to species level requires examination of flower parts in combination with stem and leaf characters, especially tomentum type and density. It is not practical nor reliable to identify small leaved species in the field as many of these morphological features require microscopic examination and comparison to known voucher specimens. This needs to be carried out by an expert in *Hibbertia*.

The use of an expert report to complement survey of the growth areas avoids the problems associated with *Hibbertia* misidentifications.

1.5 CREDENTIALS OF EXPERT

Robert Miller has over 30 years' experience in field botany. Over this time Robert has identified many rare and endangered plant species and has contributed to the scientific knowledge of native flora distribution and habitat in NSW.

Robert has been certified as an expert for *Hibbertia fumana* and *H. puberula* under the Biodiversity Assessment Methodology.

Robert has worked with Hellmut Toelken of the State Herbarium of South Australian, locating, collecting and identifying undescribed or rare species of *Hibbertia*. Some of these taxa were known only from historic records with non-precise locality details and depauperate or non-existent habitat information. Many of the specimens have been used for the taxonomic revision of the genus and are cited in various taxonomic publications including "Notes on *Hibbertia* subg. *Hemistemma* (Dilleniaceae) 9. The eastern Australian *H. vestita* group, including *H. pedunculata* and *H. serpyllifolia*" published in the Journal of the Adelaide Botanic Gardens 26 (2013). Examples of the cited specimens include: *Hibbertia ericifolia* subsp. *acutifolia* Toelken, subsp. nov. Type: New South Wales, Sarahs Knob, R. & J. Miller s.n., 21.x.2006 (holo.: AD; iso.: BRI, CANB, NSW, PERTH) and *Hibbertia dispar* R.T. Miller s.n., 0.5 km S of Penrose Rest area, along western boundary track, Penrose State Forest, 12.x.2010 (AD, NSW).

Robert and Hellmut's paper "Notes on *Hibbertia* (Dilleniaceae) 8. Seven new species, a new combination and four new subspecies from subgen. *Hemistemma*, mainly from the central coast of New South Wales", was published in the Journal of the Adelaide Botanic Gardens in 2012. The paper describes 13 new taxa including *Hibbertia fumana* Toelken and *Hibbertia puberula* subsp. *puberula,* – subsp. *extensa R.T.Mill.* and – subsp. *glabrescens Toelken.*

In 2017 Robert was called as an expert to identify the species of *Hibbertia* on the Moorebank bushland site that is the subject of the Intermodal development proposal.

Robert has recognised expertise for other threatened taxa including *Pomaderris adnata*, *Solanum celatum*, *Epacris purpurascens* var. *purpurascens*, and the genus *Prostanthera* including the threatened taxa *Prostanthera discolor*, *P. stricta*, *P*. *densa*, *P*. *junonis* and has provided expertise to the OEH Saving our Species programs.

2. Species information

2.1 SPECIES DESCRIPTION

There are 3 sub-species of *Hibbertia puberula*. The following descriptions are taken directly from the Toelken and Miller 2012 paper "Notes on Hibbertia (Dilleniaceae) 8. Seven new species, a new combination and four new subspecies from subgen. Hemistemma, mainly from the central coast of New South Wales".

***Hibbertia puberula* Toelken**

Typus: New South Wales, Yowie Bay, A.A.Hamilton s.n., 14.xi.1908

Description: Shrublets up to 0.25 m tall, decumbent or rarely suberect, much to sparsely branched or spreading; branches wiry to stiff from a woody stem or base, with decurrent leaf bases more or less flanged, pubescent to hirsute mainly between flanges, rarely glabrescent or glabrous. Vestiture often not persistent, with spreading longer over shorter simple hairs on all parts of the plant; on branches with few to many (rarely glabrous) mainly longer hairs (but varying very much in actual length) over much shorter ones, often predominantly in the grooves between flanges of the leaf bases, becoming appressed and wearing off soon; on leaves above with scattered spreading antrorse simple hairs becoming longer towards the margins, often wearing off; on leaves below with few scattered hairs as above on the revolute margins but not on the central vein, wearing off; on bracts with finer but similar hairs to leaves; on outer calyx lobes outside moderate to dense, with erect short hooked hairs overtopped by longer tubercled straight hairs up to 1.3 mm long, often becoming bristle-like particularly on the margins and the base and receptacle, persisting, inside dense, with fine, often silky appressed antrorse hairs; on inner calyx lobes outside and inside usually similar to the outer lobes, but hairs finer and decreasing in number and size towards the glabrous, membranous margins. Leaves usually with dense intrapetiolar tuft spilling over into grooves between flanges; petiole 0–0.6 mm long, ± flattened; lamina linear-lanceolate to oblong-lanceolate or oblong-elliptic, (1.2–) 2.8–5 (–7.6) × (0.5–) 0.7–1 (–1.2) mm, ± abruptly constricted into petiole, acute and usually with a terminal tuft of hairs wearing off soon, often becoming obtuse, above ± flat and sparsely pilose to glabrescent, below revolute margins and recessed to bulging broader central vein obscuring the undersurface, sparsely pilose to glabrous on the margins. Flowers single and terminal, rarely in clusters of up to three from subtending axils; pedicel 0–3 mm long; bracts linear-elliptic to elliptic-lanceolate, (2.9–) 3.2–3.8 (–4.2) × (0.4–) 0.6–0.8 (–0.9) mm, leaf-like but flatted with central vein ± visible, short pilose, rarely glabrous. Calyx distinctly accrescent; outer calyx lobes lanceolate to ovate, (5.3–) 6–8 (–11.7) × (1.6–) 2–3 (–4.2) mm, frequently longer than inner lobes, acute to beaked, usually with raised ridge and recurved distal margins, hirsute, strigose, rarely pubescent to glabrescent; inner calyx lobes oblong-ovate to oblong-elliptic, (4.6–) 5–8 (–11.6) × (2.1–) 2.5–3.5 (–3.7) mm, acute to cuspidate and with lateral membranous margins rarely up to the apex when obtuse and mucronate, hirsute to finely pilose, decreasing towards the margins. Petals broadly obovate to oblanceolate, or rarely oblong-oblanceolate, 5.5–10.6 mm long, ± bilobed. Stamens (4–) 10–14 (–18); filaments (0.6–) 1.4–1.7 (–1.9) mm long, up to one-third connate basally;

anthers obloid, (0.8–) 1.4–1.8 (–2.1) mm long, subequal, rarely unequal, abruptly constricted above and below. Pistils 2; ovaries erect-obloid and usually horizontally truncate, (4–) 6 (–8) ovules, puberulous, rarely shortly pubescent, with style attached apically, rarely laterally, then curved back- and upwards on either side of the anthers with style well above or rarely at the apex of anthers. Fruit puberulous to glabrescent with simple hairs. Seeds oblong-obovoid to almost obloid, 1.6–1.8 × (1.2–) 1.3–1.4 mm, brown; aril with fleshy base surmounted by one-sided membranous cup covering one-third to half of seed.

Notes: The extra specimens now available introduced a much wider range of variation in the *H. puberula* complex. Specimens from the Central Coast can frequently be recognized by almost sessile leaves, broadly ovoid to ellipsoidal buds with apices of the calyx erect to incurved, and often more than one flower is borne terminally on branches, while plants from more inland localities have usually petiolate leaves, slender ovoid to ellipsoidal buds with more or less recurved apices of the calyx and a single terminal flower on branches. None of these characters can be decisively used to distinguish these forms. The terminal flower clusters are formed by axillary growth from one or two leaves below the bract of the terminal flower and, in keeping with other species of the *H. sericea* group with fascicled hairs, immediately develop a terminal flower after usually two nodes with distinct internodes between, so that it becomes a more or less corymbiform cluster. (This is also a distinction from *H. stricta* s.l., which has usually spikiform (pyramidal) terminal clusters). Similar, but loosely branched cymbiform terminal inflorescences have been observed on only one collection (Turpentine Road, Flat Rock Creek, R.T. & J.Miller 22/30.x.2010). The most southern population of *H. puberula*, as represented by this and other mass collections, as well as R.D.Hoogland 11702 and E.Gauba NBG4784, is a particularly interesting extension of the species, as most of the flowers, though large, show a distinct reduction of hairs on the calyx and, more significantly, the styles tend to be laterally attached to the ovaries, similar to those of *H. cistiflora* in the *H. stricta* group. However, this phenomenon, indicative of a convergent development, can be observed in different stages on different plants, varying from an apically attached style curving down- and backwards to being attached laterally. The calyx lobes of most of the specimens identified as belonging to the *H. puberula* complex are hirsute to strigose on the outer surface, but in a few specimens both the shorter hooked hairs as well as the straight overtopping longer ones are very short or absent on plants from a few different localities (*cf*. variation under subsp. *glabrescens*). Among these, the plants from Bankstown Airport are smaller with thread-like branches and have consistently smaller calyx lobes, which are up to 2.7 mm broad, so that they are here described as subsp. *glabrescens*. The calyx of some flowers of subsp. *puberula* from Voyager Point (R.T.Miller & C.P.Gibson 52/20.x.2006) are of similar size, but hirsute and with a distinct terminal ridge on the outer calyx lobes. Furthermore, the flowering calyx of one plant must always be compared with other specimens at a similar stage, as the calyx (accrescent) elongates after flowering. Specimens from Lucas Heights are an extreme example, as the outer calyx lobes of a flower are 7.2 mm long and those of a fruit on the same specimen (R.T.Miller 3/16.x.2007) are 11.6 mm long. Of all the variation observed, *H. puberula* subsp. *extensa* is very unusual, as its androecium of commonly six stamens was previously unknown in *H. puberula*, which has ten or more stamens. There is a distinct gap between the two types of stamen numbers, as, unlike specimens of the typical subspecies from Simmos Beach Recreation Reserve (R.T.Miller 24–32/2.xi.2007), which has a range of stamens from 15–18, no specimen has as yet been recorded to complete the range from (4–) 6 or 7 stamens of the subsp. *extensa*. However, the wide variation recorded for the typical subspecies suggests this new form should be recognized at subspecific level. The anthers of subsp. *extensa* also tend to be smaller like those of the subsp. *glabrescens*, and their cuneate base into the filaments is rarely observed in the other subspecies.

Key to subspecies of the *H. puberula* complex

1. Stamens (4–) 6 or 7; lateral branches usually spreading up to about right angles to the main axis ……………………………………………………………………………………………………. *H. puberula* subsp. *extensa*

1: Stamens (9) 10–14 (–18); irregularly and commonly untidily branched

2. Anthers (1.3–) 1.4–2.1 mm long; outer calyx lobes distinctly ridged toward the apex, strigose to hirsute or if pubescent to glabrescent then (2.5–) 2.6–3.0 (–3.8) mm broad when flowering .... ……………………………………………………………… *H. puberula* subsp. *puberula*

2: Anthers 0.9–1.3 mm long; outer calyx lobes 1.6–2.1 mm broad when flowering, scarcely ridged towards the apex, puberulous to glabrescent

…………………………………………………………………………………………………… *H. puberula* subsp. *glabrescens*

Hibbertia *puberula* subsp. *puberula*

Description: Branches wiry to stiff-woody from woody stems. Leaf lamina mainly lanceolate. Outer calyx lobes lanceolate to ovate, (7.3–) 7.8–9.3 (–11.6) × (2.5–) 2.6– 3.0 (–3.8) mm, acute to beaked with strongly recurved margins and distinctly raised central ridge towards the apex, strigose or hirsute to rarely puberulous; inner calyx lobes broadly elliptic to oblong-ovate, (6.9–) 7.3– 7.8 (–10.1) × (2.8–) 3.15–3.3 (–3.7) mm, with innermost two acute to ± cuspidate above broad membranous margins, hirsute to strigose, rarely pubescent along the central ridge becoming smaller to glabrous towards the margins. Stamens (9–) 10–14 (–18); anthers (1.3–) 1.4– 2.1 mm long. Flowering: October–December (January).

Variation: The few previous collections available have been disconcertingly variable, but mass collections from a few localities revealed that individual populations are often very variable in the size and number of hairs on various organs. Buds vary from almost spherical to narrow-ellipsoidal to -ovoid with lanceolate to ovate outer calyx lobes, each with an incurved, erect or recurved apex and more or less densely covered with spreading, straight and smaller hooked hairs of varying length. Flowers have usually 12–14 stamens in this subspecies, but the number varies locally from 9 or 10 at Wollemi National Park to 18 in one specimen from Yeramba Lagoon (C.P.Gibson & R.T.Miller 50/14.x.1993). Specimens from Simmos Beach Recreation Reserve show a few flowers with 15 to 17 stamens, while other flowers of similar plants of the same population have 12 to 14 (R.T.Miller 24–32/2. xi.2007). The filaments are up to one-third basally connate. Usually the anthers are described as subequal and forming a range from the slightly smaller to larger ones, but occasionally one or two distinctly larger ones were observed. The typical obloid ovaries are surmounted by a horizontal style base and, while the style is usually attached at the apex, it is sometimes more or less dipping to a lateral position in a number of populations, mainly from Morton National Park. This must not be confused with fruiting specimens, where the bulging developing seeds often displace the position of the style attachment. While the ovaries are usually puberulous, they may vary from pubescent (R.T.Miller 111–113/20.xi.2007) to almost glabrous (R.T.Miller 33–43/12.x.2007).

Hibbertia *puberula* subsp. *extensa* R.T.Mill., subsp. nov.

Typus: New South Wales, south of Appin Road, upper George River catchment, R.T.Miller 102 & A.Henderson, 8.x.2007 (holo.: AD; iso.: NSW).

Description: Branches stiff-woody and lateral ones spreading up to about right angles. Leaf lamina mainly lanceolate. Outer calyx lobes ovate, (6.1–) 66–72 (–7.9) × 3.1–3.5 (–3.8) mm, acute to beaked with ± strongly recurved margins and distinctly raised ridge towards the apex, strigose to hirsute; inner calyx lobes elliptic rarely oblong-ovate, (4.2–) 4.5–4.8 (–5) × 2.9–3.2 (–3.4) mm, with innermost two abruptly constricted into minute terminal point continuous with broad membranous margins, hirsute to strigose with hairs becoming smaller towards the margins. Stamens (4–) 6 (7); anthers 0.8–1.2 mm long. Flowering: October, November (March, April). Fig. 2Y–BB.

Variation: In spite of their often isolated occurrence very little variation was observed in the material examined. The specimens from south of Appin had usually 6 stamens, whereas several flowers from the Wanganderry Tableland had 7. The subspecies has generally very long straight hairs on the calyx and some of them are up to 1.3 mm long. Not only are the stamens shorter in this subspecies, but also the styles are short and robust and often just reach the apex of the anthers. These robust specimens are easily distinguished from superficially very similar plants with spreading branches of the typical subspecies from Lucas Heights (R.T.Miller 111– 113/20.xi.2007) by the number and size of the anthers. While most of the specimens of this subspecies occur in a restricted area from Appin to Wedderburn, a collection from Sackville Road (R.T.Miller 81/23.x.2008) seems to indicate that the taxon has a much wider geographic range. This preceding specimen exhibits in addition to six stamens also the robust spreading branching of the plants from the southern localities in spite of records of more slender forms of the typical subspecies nearby. Etymology. The epithet ‘extensa’, Latin, ‘stretched out, extended’ refers to the impression created by the lateral branches spreading at about right angles to the main branches.

Hibbertia puberula* subsp. *glabrescens Toelken, subsp. nov.

Typus: New South Wales, Bankstown Airport, G.M. Cunningham s.n., 13.xii.2006 (holo.: AD200524; iso.: CANB, K, MEL, NSW). Hibbertia sp. Bankstown (R.T. Miller & C.P. Gibson s.n. 18.x.2006) N.S.W. Herbarium in Australian Plant Census database (2011). Hibbertia sp. nov. (Bankstown Airport) C.P. Gibson, Bushland Bulletin 59: 4, 6 (2009).

Description: Branches thread-like wiry from short stiff-woody stems. Leaf lamina mainly elliptic-oblong. Outer calyx lobes linear-lanceolate, (5.3–) 5.5–6.1 (–6.3) × 1.6–2.1 mm, not beaked and with scarcely recurved margins and faint central ridge towards the apex, glabrescent or sparsely pubescent; inner calyx lobes narrowly oblongovate, (4.6–) 4.8–5.2 (–5.6) × 2.1–2.3 (–2.7) mm, innermost two abruptly constricted into minute terminal mucro continuous with broad membranous margins, glabrous or glabrescent along central ridge. Stamens 12–14; anthers 0.9–1.3 mm long. Flowering: October, November (December).

Variation: The plants at Bankstown Airport are comparatively uniform, as one would expect for such a small and extremely localized population. However, the plants and especially also the calyx lobes are rarely entirely glabrous. Although specimens of some plants of the typical subspecies, especially from nearby Simmos Beach Reserve (R.T. Miller 24–32/2.xi.2007), as well as those from the much further south population along Turpentine Road near Sassafras (e.g. R.T. & J. Miller AD15A–M), show a variation from a hirsute or strigose through to glabrescent tomentum of the calyx lobes, they are always more robust plants and in particular, the calyx lobes are larger and especially broader. Some specimens of the mass collection R.T. Miller 1622/12.x.2007 are very similar to subsp. *glabrescens*, but can be distinguished by the shape of the calyx or by their strigose to hirsute calyx (C.P. Gibson & R.T. Miller 27/23.x.1990). Furthermore, specimens from Bankstown Airport collected in subsequent years (since 2006) have not shown any significant change in morphology. Thus we must assume that a taxon has established itself here that is suited to the unusual ecological conditions artificially maintained by the Bankstown Airport management since about 1940. Etymology. Since all organs of this subspecies have very few small and delicate hairs which usually wear off soon, the epithet ‘glabrescens’, Latin, ‘glabrescent’ seemed appropriate.

2.2 LIFE CYCLE

Flowering time and duration

Peak flowering time is October to December and sometimes into January, and seed is set during this period. Anecdotal evidence (Miller pers. obs.) suggests time of flowering and time to petal dehiscence is variable across subspecies and appears also to be influenced by prevailing climatic conditions.

Very limited observations of the flowering times of *Hibbertia puberula* subsp. *extensa* suggest this subspecies has a very short period of flowering each day. Total petal dehiscence has been noted to occur before 1 pm on two occasions and before 11am on 30 November 2018 in the largest population south of Appin Road. It is not known at what time petal expansion commenced. The subspecies is virtually invisible when not in flower.

Hibbertia puberula and *H. diffusa* at Moorebank were noted to have a window of daily peak flowering (albeit in September, outside its normal recognised peak flower period) being not apparent in early mid-morning (8.40 am) and petal senescing by early afternoon (12:05 PM) on Friday, 29 September 2017.

This phenomenon has been observed with several *Hibbertia* species, whilst others appear to have protracted flowering across the day e.g. *Hibbertia dentata*.

Photo 1: *H. puberula* subsp. *puberula* at Berkshire Park dehiscing petals before our eyes.

Note: Photo 1 shows one of the few plants retaining petals on Friday, 2 November 2018 at 9:14 AM.

Additional information into flowering time and duration has been gained from this biodiversity assessment. On 29 October 2018 petal dehiscence had already commenced by 10 am and was finished before 11am at Ropes Crossing. On the 31 October 2018 total petal dehiscence was recorded to have occurred before 1.15pm but noting many plants of the co-occurring *Hibbertia pedunculata* still retained the majority of their petals though petal drop on those plants had begun.

Conversely, a site inspection of Bankstown Airport by Peter Ridgeway, Paul Bircher, Stephanie Clark, Colin Gibson, Damien Vella and Foster Walker – Environmental Manager Bankstown Airport Limited (BAL) revealed that *Hibbertia puberula* subsp. *glabrescens* was in full flower at 2.50pm and petals were still evident at approximately 4.30pm. It is unknown if the subspecies has a longer flowering duration than the other subspecies or whether the cool overcast conditions with a light shower earlier in the day prolonged flowering.

Photo 2: *H. puberula* subsp. *glabrescens* at Bankstown Airport.

Photo 2 taken on Friday, 16 November 2018 2:54 PM by Stephanie Clark.

Further research is needed to ascertain daily flowering ranges of *Hibbertia,* particularly for threatened taxa, as this has significant implications for reliable detection of threatened species during biodiversity assessments.

<u>Fire response</u>

No systematic fire response studies have been undertaken on *Hibbertia puberula*. Anecdotal observations and inferred information from similar species suggest *H. puberula* subsp. *puberula* is killed by fire in many instances. In certain circumstances the species is capable of re-sprouting from near or just below the soil surface as noted at the Keith Longhurst Reserve (formerly the Basin Reserve) in 2007 (R. Miller pers. obs.). At the same site Miller noted in June 2018 the species appeared to have mostly been killed by a recent control burn, with limited recruitment from the soil seed bank observed. It is unknown to what degree the protracted dry period has impacted apparent recruitment, but it is thought that the combined impact of fire and drought has been significant.

This current survey has noted that the “form” observed at Berkshire Park during this study is capable of resprouting from a thickened rootstock. This form is consistent with J.M. Lindale NSW 101952 shown in Figure 1 Toelken (2000) and reproduced as Figure 2 of this report.

Since its discovery there has not been a fire in the habitat of *Hibbertia puberula* subsp. *glabrescens*.

The impact of fire upon *Hibbertia puberula* subsp. *extensa* is also poorly known, with only observation by Miller providing a limited insight. The two occurrences south of Appin Road have recently been control burnt. Price *et al.* (2016) state that “The first fire was 52 ha, lit at 09:45 on 22 August 2015, and targeted patches of forest within the scout camp. The second was 700 ha, lit at 10:15 on 9 October 2015 and burnt the area surrounding the camp in an arc from north through west to south”. All pre-existing plants appear to have been killed. Only three tiny plants presumably seedlings were apparent at one site and no plants were detectable at the other in a survey by Miller on 1 July 2018. A subsequent survey on 30 November 2018 confirmed the three plants had survived and flowered with 9, 8 and 8 plus 3 aborted and/or mature buds observed. Two plants were located at the second site both with 3 buds only.

Photo 3: *H. puberula* subsp. *extensa* with flower buds 30/11/2018 after the October 2015 fire.

2.3 DISTRIBUTION AND ABUNDANCE

Limited systematic population surveys have been undertaken for *Hibbertia puberula* s. lat.. The most comprehensive population survey undertaken is for *Hibbertia puberula* subsp. *glabrescens* at Bankstown Airport environs (refer to that subsp.). The population of *Hibbertia puberula* subsp. *puberula* occurring at the Moorebank Intermodal Terminal was, in part, surveyed in the environmental assessment for the project.

Hibbertia puberula* subsp. *puberula

This subspecies is known in New South Wales mainly from near Sydney (CC), but also from Wollemi National Park and near Morton National Park (SC, ST). The most significant sites are located at Moorebank and to lesser degree at Voyager Point.

Of most relevance to this study are those locations with similar attributes to those within the two growth areas. Few locations exhibit such habitat characteristics.

With the exception of the Moorebank and Liverpool records, known occurrences within the Sydney Metropolitan area occur in transitional soils adjoining sandstone areas, communities not found within the growth area boundaries. A selection of such sites includes the Georges River environs including The Georges River National Park, Lucas Heights to West Menai area, Simmos Beach Recreation Reserve, Peter Meadows Reserve, the Keith Longhurst Reserve (formerly the Basin Reserve), Kentlyn, Freres Crossing Reserve, Kentlyn, and Old Kent Road, Kentlyn.

Appendix 5 shows the indicative distribution of *H. puberula* at West Menai, where the species was found to occur as small subpopulations in suitable micro-habitats.

The species is also known from the lower Blue Mountains in the Warrimoo vicinity, and scattered occurrences within the Hawkesbury River Catchment including Sackville North, Canoelands, and the McCarrs Creek vicinity.

Historic collections localities include Yowie Bay 1908, Frenchs Forest 1946 and Coogee 1954.

Map 2 shows the areas proximate to the growth areas from which the subspecies had been collected prior to this study as well as new records provided by this biodiversity assessment.

Environmental assessment surveys for the Moorebank Intermodal Terminal have provided some population data on *Hibbertia puberula* subsp. *puberula*. At this site the species is relatively common and is significant in number. The population data derived cannot be inferred to reflect population density at other recorded sites of its distribution and specifically not within the GPEC or the WSA. The predominant vegetation communities found at the Moorebank Intermodal Terminal where surveys were undertaken are Castlereagh Scribbly Gum Woodland and Cooks River/Castlereagh Ironbark Forest with Shale-Gravel Transition Forest and Castlereagh Swamp Woodland being recorded proximally.

Extant examples of these communities are known to occur in and to the north of GPEC. Data obtained from field surveys for this assessment, though extremely limited, have found only small localised occurrences. Within the WSA, only the Kemps Creek area retains small remnants of the Castlereagh communities.

A selection of habitat and occurrence notes compiled by Miller in 2007 for herbarium specimens are:

- At Lucas Heights the population at a site in Open Woodland / heath – Canopy: *Eucalyptus haemastoma*? and Stringybark species is described as: "Abundance: extremely localised, rare < 12 plants noted".
- At Lucas Heights Little Forest the population is described as Localised in narrow zone in upper drainage line.
- At Simmos Beach Reserve in Open Woodland of *Eucalyptus sclerophylla*?, *E. punctata, Angophora bakeri* one sub-population is described as "Very localised but locally common c. 20 plants noted"
- At Barden Ridge one population is described as scattered through sedges - relatively rare at edge of wet heath/swamp.

Further details of herbarium specimen collections from Western Sydney in 2007 are provided in Appendix 3.

<u>Details of prior collections proximate to growth areas</u>

The closest known prior collections to the growth areas are an McBarron, E.J. 1964-11-08 record stating "Glenbrook township", "In open heathland" and Constable, E.F. 1949-10-28 Blaxland with no other collecting information presented on the data base. It is unknown if the species survives in these localities.

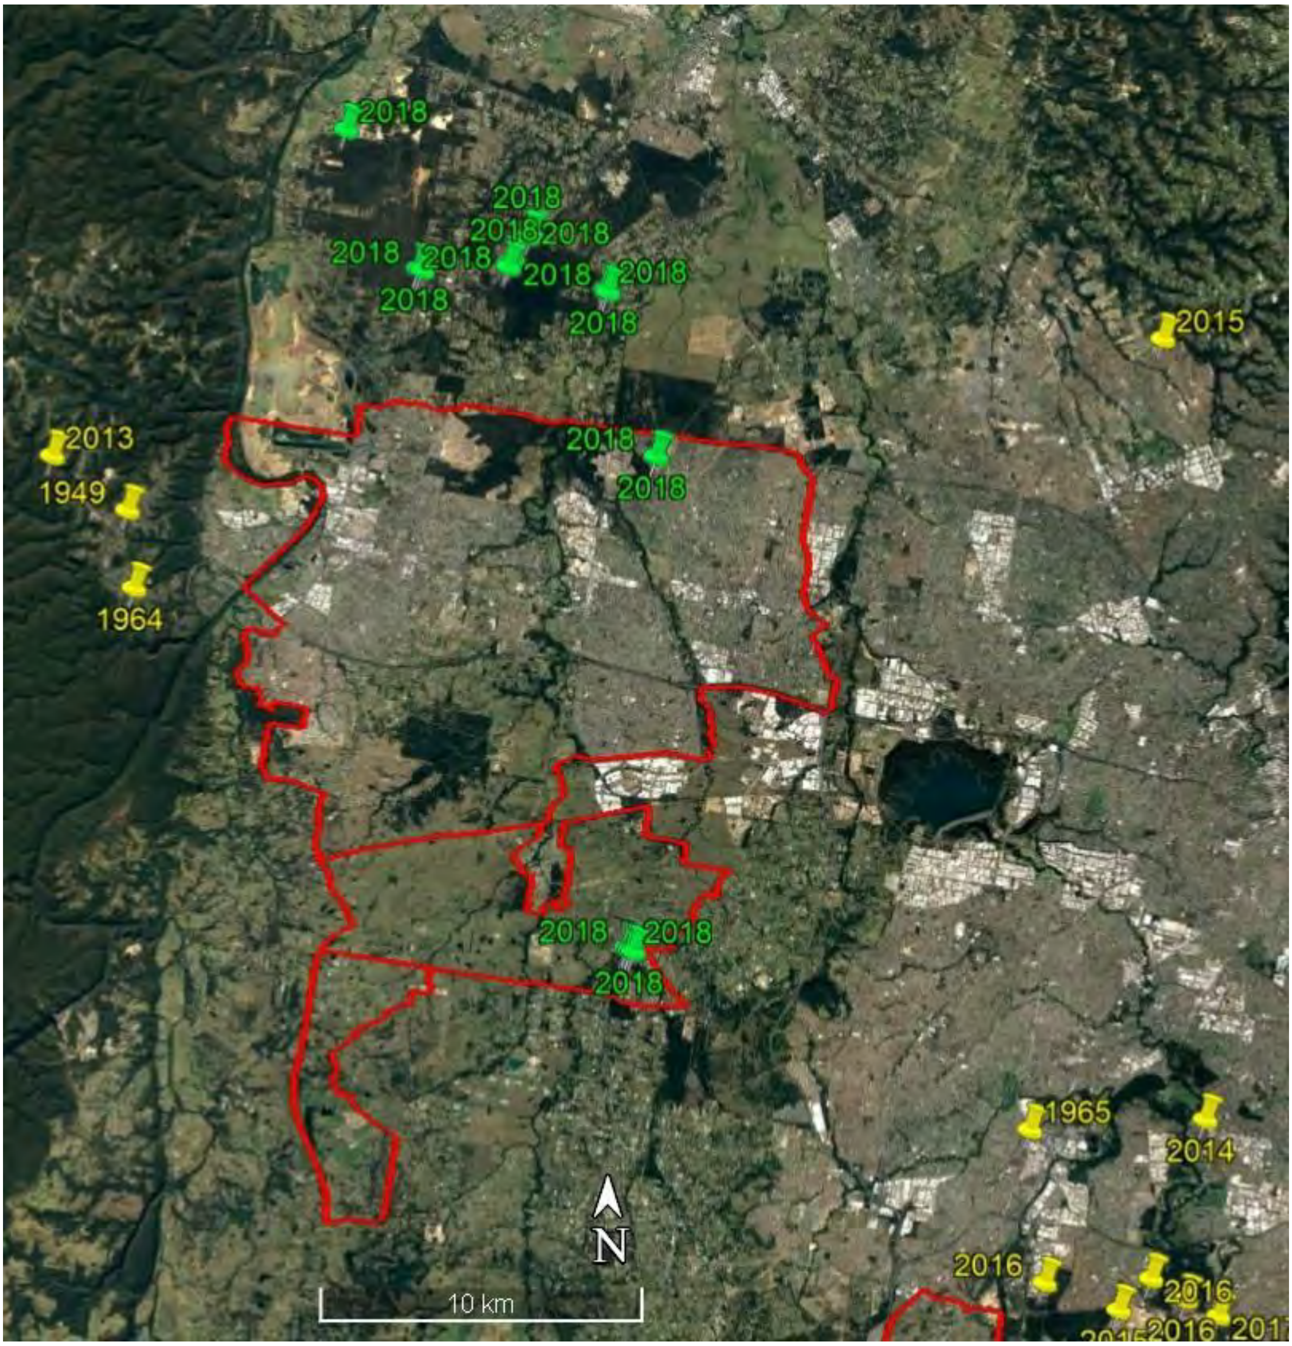
The closest extant population to the growth areas is 5.5 km from the NW corner of the GPEC at Warrimoo (observed and photographed by Greg Steenbeeke in 2018). The original Andrew Orme 2009-11-07 collection records this population as "5 plants noted over a 50m graded fire trail verge". With habitat details "Low open forest of *Eucalyptus notabilis*, *E. consideniana*, *E. sparsifolia*, *Corymbia gummifera*, and *Angophora costata*, with dense understorey of *Leptospermum trinervium*, *Acacia linifolia* co-dominant, also with *Hakea laevipes*, *H. sericea*, *Petrophile pulchella*, *Leptospermum arachnoides*, *Grevillea phylicoides*, *Banksia spinulosa*, *Bossiaea rhombifolia*, *Pultenaea scabra*, *Schoenus imberbis*, *Lepyrodia scariosa*, etc. Gentle easterly slope on sandstone ridge. Shallow yellow sandy soil with some surface laterite over sandstone rock platforms. Disturbed graded fire trail edge".

The closest record to the NE of the growth areas is a Mark Stables 2015-12-01 collection at Kellyville stating the habitat as: "Partially cleared area. Surrounding vegetation sandstone ridgetop woodland with laterite: *Eucalyptus sclerophylla*, *E. squamosa*, *E. sparsifolia*, *Angophora hispida*, *Banksia ericifolia*, *Leptospermum trinervium*, *Grevillea speciosa*, *G. buxifolia* subsp. *buxifolia*, *Calytrix tetragona*, *Boronia ledifolia*, *Phyllota phylicoides*, *Pultenaea tuberculata*, *Cyathochaeta diandra*, *Lepyrodia scariosa*, *Caustis flexuosa*, *Entolasia stricta* & *Austrostipa pubescens*".

The closest record to the south east of the growth areas is a historic record McBarron, E.J. 1965-11-23, Liverpool Cemetery. The species is presumed extinct at this locality.

The closest extent record to the south east occurs at Moorebank 14 km from the WSA.

With the exception of the Moorebank and Liverpool records all other recorded localities occur in close proximity to Sandstone.



Map 2: Location of *Hibbertia puberula* subsp. *puberula* records and year of record.

Key – Historic *H. puberula* subsp. *puberula* records (yellow markers), CFFIS records (green markers) growth areas outlines (red line).

Hibbertia puberula* subsp. *extensa

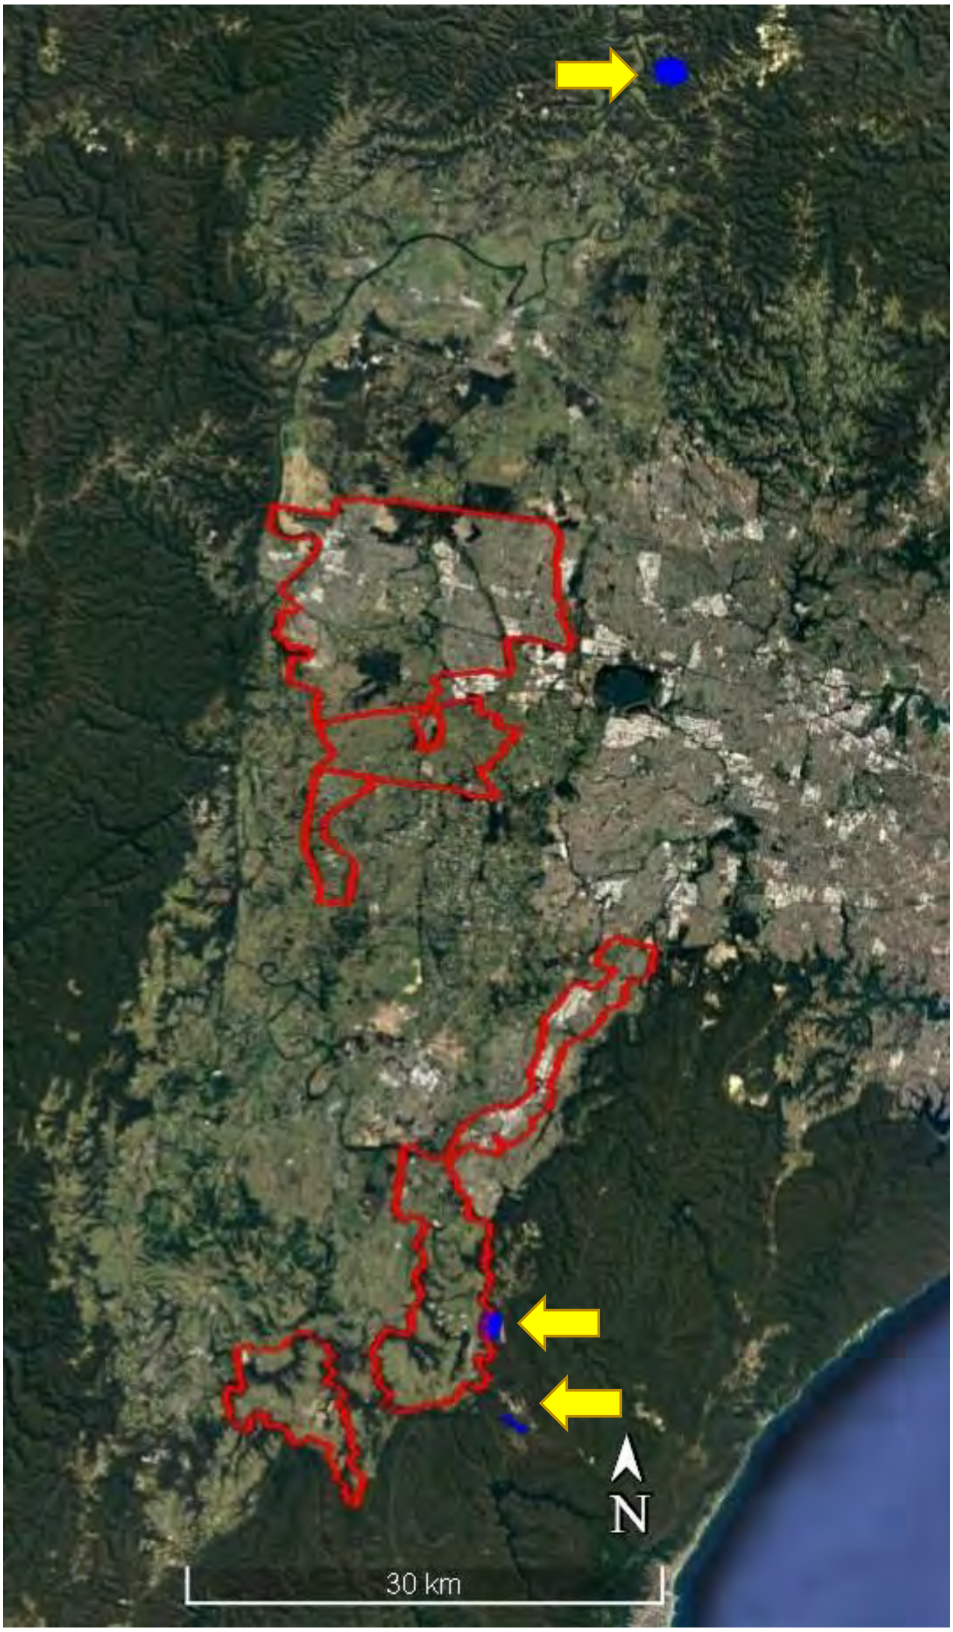
This subspecies grows with heath on upper headwaters of the Georges River and in rock plate heath on the Wanganderry Tableland, New South Wales (CC). Few collections are known of this subspecies.

The closest known extant sites are in the Wedderburn vicinity 27.5 km from the southern border of the WSA. A record cited in Toelken & Miller (2012) in the North Sackville vicinity is 29.5 km from the northern boundary. Map 3 shows the locations of collection sites.

No systematic population surveys have been undertaken for this subspecies. All known populations are thought to be small with most observations noting only a few individuals. One location south of Appin Road was the only population noted as having more than 10 plants. The sightings at Woronora Dam vicinity, Sackville North, the two recorded Wedderburn locations and the Bonnum Pic vicinity all recorded a few individuals only. The known Sackville North occurrence has subsequently been severely impacted by hazard reduction measures and is possibly now extinct at the known site. Similarly, the known occurrence west of Wedderburn Aerodrome has been impacted by grading and fill emplacement and only one specimen could be relocated (Miller pers. obs. July 2018).

A small population of a *Hibbertia* species with vegetative features consistent with *H*. *puberula* subsp. *extensa* was observed to occur on the verge of a fire trail within the Dharawal National Park at Wedderburn. Only six plants were noted. Positive determination can only be ascertained in combination with floral characters. The subject plants were not in flower at the time of observation and their identity remains unconfirmed.

Photo 4: *Hibbertia puberula* subsp. *extensa* habitat south of Appin Road.



Map 3: Generalised location of *Hibbertia puberula* subsp. *extensa* collections.

Key – Areas of past *H. puberula* subsp. *extensa* collections (blue) in relation to the growth areas (red).

Hibbertia puberula **subsp.** ***glabrescens***

Subspecies *glabrescens* is known only from Bankstown Airport which is located approximately 16.5 km from the south eastern corner of WSA. Map 4 shows the general area where this species has been collected. The population contains between 50 and 100 individuals. Survey by Eco Logical in 2015 could not differentiate individual plants and recorded area of plants only.

The species has a limited area of occupancy. Most of the extant plants are known from one small area to the north of a modified drainage line colloquially referred to as Airport Creek. It was previously recorded by Gibson and Gibson & Miller to occur to the south of Airport Creek. Development and maintenance measures have negatively impacted upon those known occurrences and it had not been observed there again until October 2017 when one plant was observed (Gibson pers. obs.).

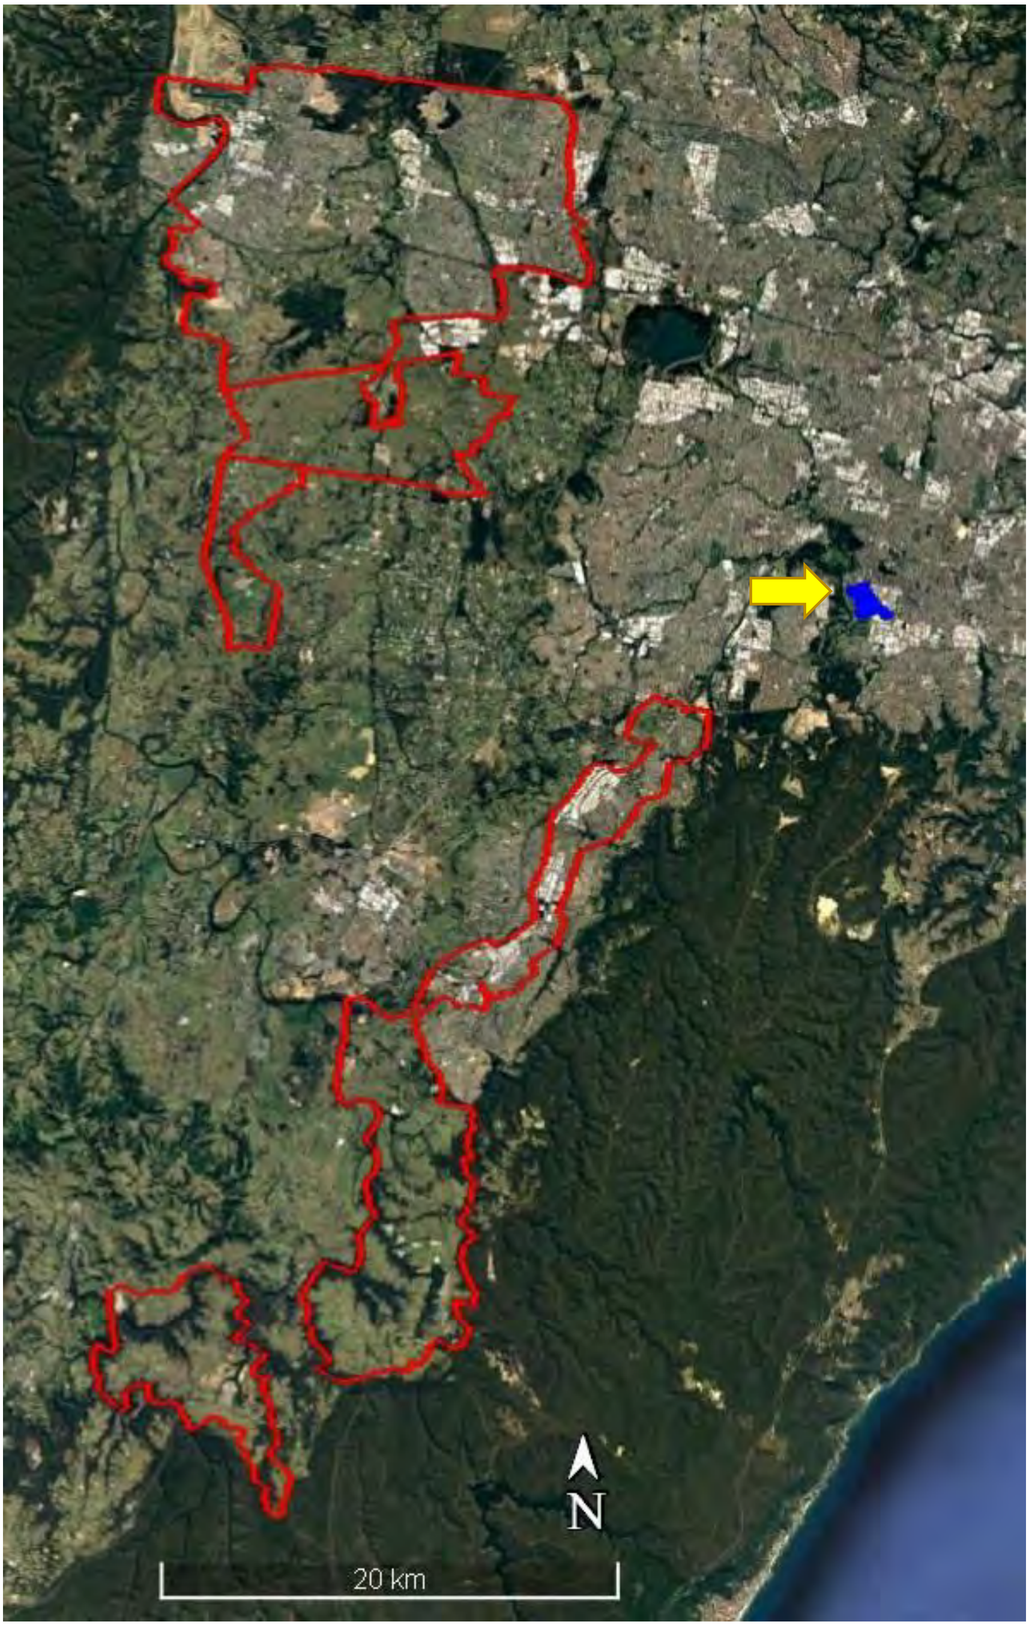
Photo 5: Measure of slashing height, *H. puberula* subsp. *glabrescens* at Bankstown Airport.

Note: See also photo of slashed area on front cover, photos taken by R. Miller 8 October 2014.

A site visit on 16 November 2018 found that creek stabilisation works had negatively impacted upon the site south of the creek, restricting mowing and resulting in dense swathes of *Eragrostis curvula* infesting the location (C.P. Gibson pers. obs.). No plants were detectible at this site despite the main colony being in heavy flower at the time of inspection (C.P. Gibson pers obs.) Site visit was 2.50pm – approximately 4.30 pm (Stephanie Clark pers. com.).

Photo 6: *Hibbertia puberula* subsp. *glabrescens* Bankstown Airport 16/11/2018.

Note: Photo by Stephanie Clark.



Map 4: Generalised location of past *Hibbertia puberula* subsp. *glabrescens* collections.

Key – Area of *H. puberula* subsp. *glabrescens* collections (blue) and the growth areas (red).

2.4 HABITAT REQUIREMENTS

Hibbertia puberula* subsp. *puberula

Occurs in a wide range of habitats, but usually low heath, on sandy soil or rarely in clay, with or without rocks underneath (Toelken 2000). Proximate populations have been recorded from habitats associated with the Mittagong formation, shale sandstone transitional vegetation and tertiary alluvial deposits. Associated canopy species may include, but not limited to, in combination or isolation: Scribbly Gum spp., Grey Gum (*Eucalyptus punctata*), Scaly Bark (*Eucalyptus squamosa*), Ironbark spp., Narrow-leaved Apple (*Angophora bakeri*), Dwarf Apple (*A. hispida*), and Stringybark spp.

Hibbertia puberula* subsp. *extensa

The habitat requirements of *Hibbertia puberula* subsp. *extensa* are poorly known. The subspecies has only been recorded from five localities: south of Appin Road, Wedderburn vicinity, Woronora Dam vicinity, Sackville North vicinity and Bonnum Pic vicinity Wanganderry Tablelands.

This subspecies appears to have highly specific micro-habitat requirements. The largest known population occurs south of Appin Road, where less than 30 plants of *Hibbertia puberula* subsp. *extensa* have been recorded. Its area of occupancy is small, being noted to occur in a narrow band within a small upland swamp amongst wet heath vegetation. In a larger nearby wet heath site a few specimens of the subspecies were recorded to occur on skeletal soil, in the downslope seepage zone, where the underlying sandstone substrate outcrops. The subspecies has not yet been observed in superficially similar nearby wet heath habitats but as it is very cryptic it may be present. The Woronora, Sackville North and one of the two Wedderburn populations grow in seepage zones of sandstone outcropping in skeletal soil downslope of heathland. In the Bonnum Pic vicinity a few plants were noted growing on rock plate heath.

Hibbertia puberula* subsp. *glabrescens

Subspecies *glabrescens* is known only from Tertiary alluvial soil along Airport Creek on Bankstown Airport and not from areas where subsequent fill has been deposited in between (pers. comm. Gibson). The plant assemblage is attributable to “Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion”.

The airport site is very heavily modified from the natural state, lacks canopy species and is currently a low grass/shrub association with many pasture grasses and other introduced herbaceous weeds.

Soil at the site is a sandy (Tertiary) alluvium with a high silt content.

The remnant at the site and soil type are consistent with an inferred pre-settlement cover of Castlereagh Ironbark Forest although some remnant vegetation at and near the site (along the channel in particular) suggests Castlereagh Scribbly Gum Woodland is equally valid.

Hibbertia sp. Bankstown has been observed to flower from October to December, with seed setting from October to January. Most *Hibbertia* species are primarily pollinated by bees, but many have specialised mechanisms requiring particular bee species, beetles or syrphid flies (OEH Threatened Species Profile).

2.5 ANTHROPOGENIC THREATS TO THE HABITAT

Threats to the habitat of *Hibbertia puberula* that are relevant to sites within or adjacent to urban development include:

- Direct loss of habitat through clearing.
- Reduction in size of habitats predisposing plants to edge effects.
- Fragmentation of habitat reducing the potential seed or gene dispersal across population or subpopulations.
- Damage to habitat by trailbikes, 4WDs and mountain bikes and other recreation activities.
- High densities of weeds and invasive grasses occur at the top of ridgelines; there is significant potential for encroachment into areas where the species occurs.
- Altered fire regime, either too frequent or too seldom.
- Potential for widening of major roads to affect populations of the species.
- Road maintenance and slashing works.
- Clearing for fire protection zones.
- Dumping of garden waste including invasive exotic species.

Field inspection of bushland remnants in the GPEC and WSA growth areas provided irrefutable proof of severe degradation arising from anthropogenic impacts and urbanisation (refer photos 6 through 9). Many of the remnants were heavily weed infested arising from a range of factors not limited to nutrification, stormwater discharge, garden refuse and fill dumping and exotic seed dispersal by various vectors. Environmental degradation was especially evident adjacent to creeks and drainage channels.

Hibbertia puberula is a small shrub that would not survive in bushland that is severely weed infested, or that is severely burnt on a regular basis.

The invasive grass species *Eragrostis curvula* is of significant threat to the species as it was observed to dominate extensive areas of the landscape.

Increased urbanisation is likely to see an upsurge in indiscriminate access into bushland that has not been cleared for development with increased illegal dumping, vehicular access including dumping and arson of stolen cars, and 4WD and trailbike causing serious long-term impacts.

Excluding EECs and Threatened Species habitats from the direct impacts of clearing will not ensure their long-term security without funding for fencing and active management. This funding and management could be a major outcome from the biodiversity certification process.

3. Description of the study area

3.1 LAND USE HISTORY

The Cumberland subregion was first occupied by the Aboriginal peoples, who enjoyed a plentiful supply of fresh water and foods including fruit, tubers, fish, animals, birds and honey (Hills District Council website).

With the arrival of Europeans land use changed to timber gathering and agriculture, permanently altering the landscape. Particularly since the end of the second world war urban settlement and industry have expanded west from Sydney into the Cumberland subregion. Over the last 40 years many rural properties have been subdivided as lifestyle and hobby farm properties.

Currently there is great pressure for further residential development to the west of Sydney in the Cumberland subregion.

3.2 LANDSCAPE CONTEXT

The changes in land use have caused the clearing of a large proportion of the natural bushland of the Cumberland subregion. In 2011 the Cumberland Plain Recovery Plan stated "Only 13% of the pre-1750 extent of the region's vegetation remains as intact bushland, with an additional 12% occurring as scattered trees in disturbed areas (NPWS 2002 in DECCW 2011). Consequently, much of the region's biodiversity is listed as threatened under State and/or Commonwealth legislation."

Widespread clearing of the remaining habitat has continued with much of the extant vegetation now being assessed as Critically Endangered. This widespread clearing has resulted in loss of habitat for endangered species such as *Hibbertia puberula*.

3.3 NATIVE VEGETATION

Since 2011 there has been further clearing, there are now 15 Plant Community Types that are listed as Critically Endangered, Endangered or Vulnerable in the Cumberland subregion.

The Cumberland Plain Recovery Plan states that "there are seven threatened species, four endangered populations and nine threatened ecological communities listed on the NSW *Threatened Species Conservation Act* 1995 that are found only on the Cumberland Plain. Seven of these are also listed as threatened under the Commonwealth *Environment Protection and Biodiversity Conservation Act* 1999." The remaining bushland is highly fragmented and much of it occurs on private lands.

Within the GPEC and the WSA nineteen Plant Community Types (PCTs) are mapped (mapping provided by the NSW Department of Planning and Environment). These PCTs are:

- 724 - Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion

- 725 - Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion
- 774 – Coast Banksia scrub on sand in the Elderslie area, Sydney Basin Bioregion
- 781 - Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion
- 806 - Derived grasslands on shale hills of the Cumberland Plain (50-300m asl)
- 807 – Derived grasslands on shale plains of the Cumberland Plain (<100m asl)
- 808 – Derived shrubland on Tertiary Gravels of the Cumberland Plain
- 830 - Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion
- 835 - Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion
- 849 - Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion
- 850 - Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion
- 877 - Grey Myrtle dry rainforest of the Sydney Basin Bioregion and South East Corner Bioregion
- 883 - Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion
- 1067 - Parramatta Red Gum woodland on moist alluvium of the Cumberland Plain, Sydney Basin Bioregion
- 1081 - Red Bloodwood – Grey Gum woodland of the Cumberland Plain, Sydney Basin Bioregion
- 1105 – River oak open forest of major streams, Sydney Basin Bioregion and SE Corner Bioregion
- 1181 - Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion
- 1253 – Sydney Peppermint – White Stringybark – Smooth Barked Apple Forest on shale outcrops, Sydney Basin Bioregion
- 1292 – Water Gum – Coachwood Riparian Scrub along sandstone streams, Sydney Basin Bioregion
- 1395 - Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion
- 1800 - Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley

3.4 POTENTIAL HABITAT

Hibbertia puberula has the potential to occur within seven Plant Community Types (PCTs) mapped as occurring within the GPEC and the WSA. These community types are:

- 724 - Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion
- 725 - Cooks River Castlereagh Ironbark Forest

- 808 – Derived shrubland on Tertiary Gravels of the Cumberland Plain
- 835 - Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion
- 883 - Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion
- 1067 - Parramatta Red Gum woodland on moist alluvium of the Cumberland Plain, Sydney Basin Bioregion
- 1395 - Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion

With the exception of PCT 883 at Moorebank, *Hibbertia puberula* has not been recorded to occur uniformly or in substantive numbers across any of the above listed communities. In general, it is usually confined to a variety of specific habitat niches within these regional mapping units. The area of occupancy within and/or the area of the specific habitat niches at any locale may be as small as a few square metres.

Specific habitat niches of potential occurrence may include upper drainage lines, seepages especially those associated with exposed sandstone bedrock or slabs, margins of hanging swamps / wet heath, exposed sandstone rock plates, and large and small occurrences of colluvial or alluvial deposits. At most locales presence or absence can only be positively determined by intensive targeted surveys that investigate such habitat niches thoroughly within the peak flowering period.

Photo 11: PCT 808 in power easement east of Ropes Crossing.

Note: Large numbers of threatened species survive in the derived habitat.

4. Assessment of species presence and suitable habitat

4.1 EXISTING RECORDS AND SURVEYS

Hibbertia puberula including its subspecies are poorly known and there is limited data on the life history and ecology of the species. Apart from Miller (November 2018), there have been no other specific targeted surveys for *Hibbertia puberula* within the study area. General vegetation assessments undertaken for various purposes appear also not to have found *Hibbertia puberula* as there are no prior database records of the species within the proposed growth areas.

In many instances the species group has not been considered within assessments or dismissed with statements of "unlikely no suitable habit present" and therefore no targeted searches were undertaken.

<u>Potentially misidentified *H. puberula* in the records</u>

Searches of databases revealed records of *Hibbertia riparia* at a number of locales within and adjacent to the growth areas. The name *Hibbertia riparia* is considered by Toelken to be misapplied to NSW taxa. Prior to the updated taxonomy a number of undescribed species were included within the name *Hibbertia riparia* then considered to be "a variable species complex".

Miller has observed that *Hibbertia puberula* is frequently still misidentified as *Hibbertia riparia*.

Reviewing the data set it became apparent that there were a number of records for *Hibbertia serpyllifolia* in the general Western Sydney area. Recent taxonomic work (Toelken 2013) investigating "The eastern Australian *H. vestita* group, including *H. pedunculata* and *H. serpyllifolia*", has identified that the name *Hibbertia serpyllifolia* is misapplied to NSW. The species concept is now considered to be confined to coastal forests of mid-northern Queensland. All records from other states are now recognised as new taxa e.g. *Hibbertia ericifolia* group or misidentifications of existing taxa.

As *Hibbertia* are notoriously difficult to identify, and more so if not in flower, it is not surprising to find records of *Hibbertia* sp. within the data set.

The Western Sydney Urban Bushland Biodiversity Survey 1997 undertook the first comprehensive survey of the biota across the region including bushland remnants within the GPEC and WSA area. Although the taxonomy of *Hibbertia* has changed significantly since that time, the records of *Hibbertia* contained within provide additional insight into the potential occurrences of threatened *Hibbertia* species.

The Straede T.M. 1990 "Vegetation of the proposed Londonderry Waste Disposal Site" report for Waste Management Authority, Sydney found *Hibbertia cistiflora* in the Castlereagh – Londonderry Crown Lands. It is unknown if this species occurs in the area or is a misidentification.

The current survey was limited in extent and did not visit the precise area of the Straede survey which is outside the growth area. The surveys conducted by CFFIS did not locate any specimens of *Hibbertia cistiflora*. There are no other records in the district and most vouchered records in the Sydney Metropolitan area occur north of the Harbour and are associated with sandstone ridges often in proximity to shale caps and Sandstone Shale Transition Forest associations.

It is noted in Toelken & Miller 2012 that subsp. *quadristaminea* is "often wrongly identified in herbaria as *H. serpyllifolia*, but subsp. *quadristaminea* has few stamens only in one dorsal cluster" c.f. *Hibbertia ericifolia* (*H. serpyllifolia* misapplied) possessing usually 8-16 but up to 30 stamens, dependant on the subspecies surrounding and obscuring the ovaries. This highlights that even herbaria have mis-assigned *Hibbertia* specimens. The fact that *H. cistiflora* has its anthers on one side of the ovaries opens the possibility that the Straede record could be what is now *Hibbertia puberula*. It is possible that Straede had another taxon from within the then *H. riparia* variable species complex previously identified. The current survey identified *Hibbertia puberula* to be present within the adjacent Castlereagh Nature Reserve.

It is unknown if the *Hibbertia serpyllifolia* UBBS Site (P1) Londonderry – Castlereagh Crown Lands survey by R.S. Lembit & T.A. James - woodland south of Devlin Road & NW end of Nutt Road record was based on field identification of fertile or infertile material. If it was based on fertile material it is most likely to be an unverified record of *Hibbertia ericifolia* group. If it was based on infertile material it is most likely to be *Hibbertia puberula.* CFFIS has recorded *Hibbertia puberula* in this vicinity.

Hibbertia pedunculata recorded at Mulgoa (Blue Mnts NP Sydney Sandstone complex) Coveny, R. 1976 – 95 Species lists for Mulgoa (off Fairlight Road – Nepean River) Blue Mtns National Park is likely to be that species, however there is a possibility that it could also be potentially be *H. fumana* or *H. puberula* if the Coveny observation was based on field identification of infertile material.

A *Hibbertia riparia* record from the Castlereagh Nature Reserve is most likely to be *Hibbertia puberula.* The current CFFIS survey recorded *Hibbertia puberula* within the Nature Reserve.

4.2 SURVEYS COMPLETED FOR THE BIOCERTIFICATION

From the information provided, no prior dedicated targeted searches have been undertaken for this species as part of the biodiversity certification process.

Surveys undertaken by Ecoplanning and Biosis consultancies since 2017 have largely been confined to the deemed "development footprint" and appear to have been undertaken predominantly to comply with the BAM protocols for vegetation sampling for assessment purposes with little survey for threatened species. As such, no new occurrences of threatened *Hibbertia* species including *Hibbertia puberula* were recorded by Biosis or Ecoplanning through their survey efforts.

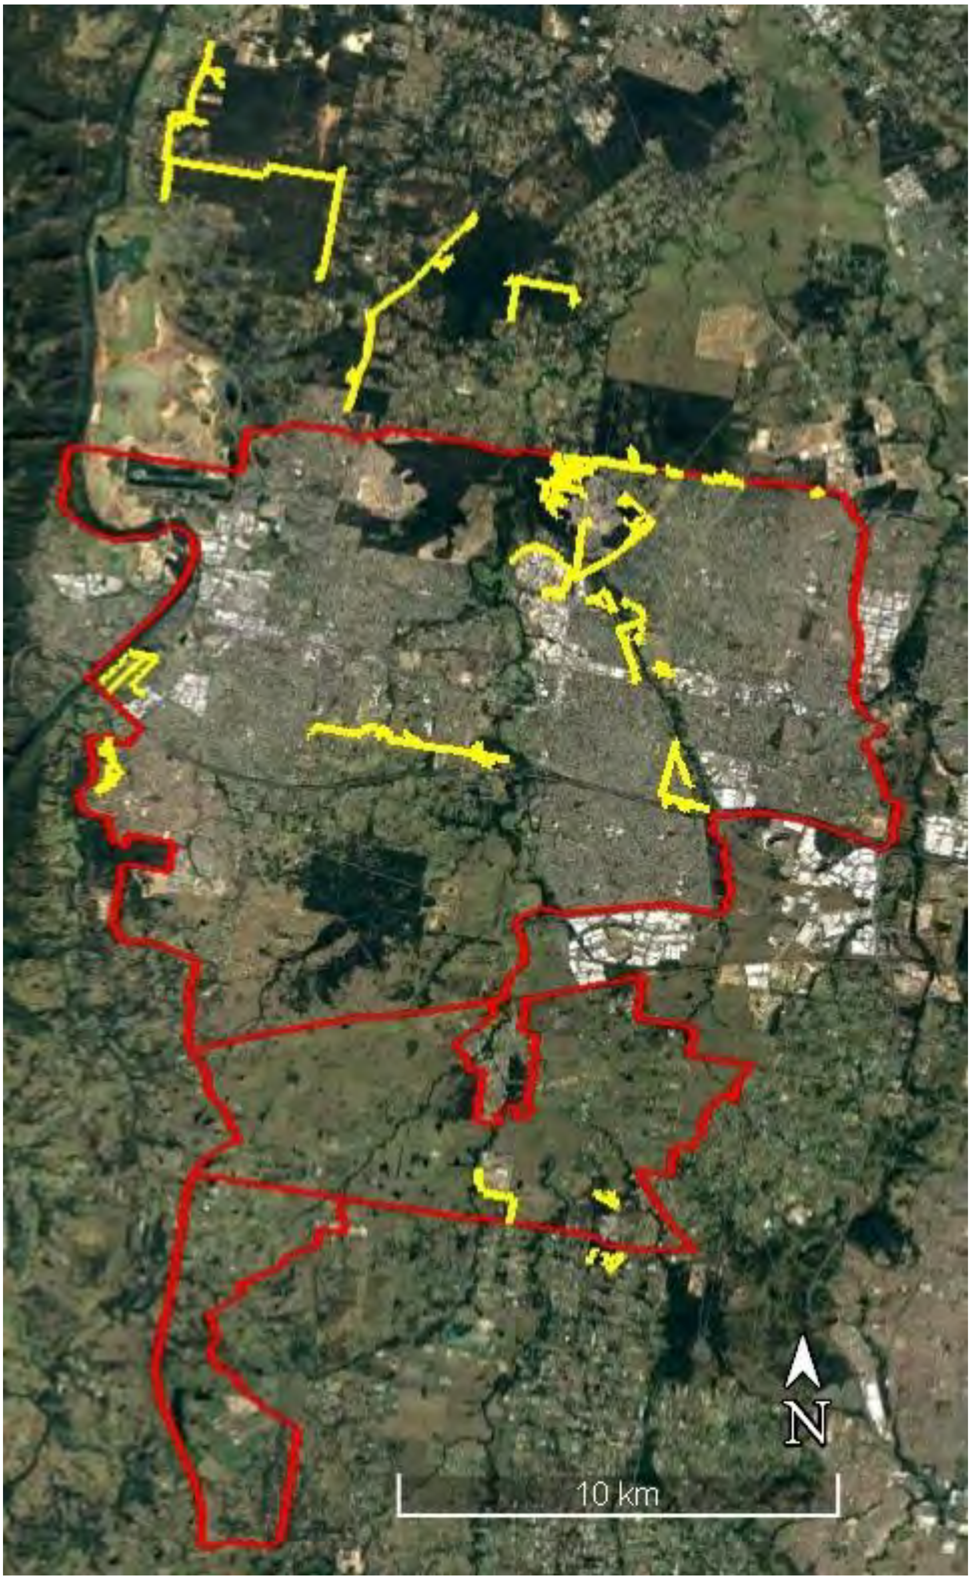
Access to a spatial viewer was provided by DPE to assist in the expert assessment. Whilst this tool has been useful in gaining a general overview, the information presented is limited and is acknowledged to "have been acquired and developed from numerous sources of differing dates, accuracy and completeness and may include errors in extent and content". CFFIS are not aware of any surveys performed specifically for *Hibbertia puberula* by DPE, Ecoplanning or Biosis Consultancies. The broadscale vegetation mapping of PCTs that was provided to assist with this assessment cannot identify the habitat niches that may be present on a localised scale.

The level of data available is insufficient to base an assessment of presence/absence for a Critically Endangered / Endangered species group purely as a desktop study.

4.3 SURVEYS COMPLETED FOR THIS ASSESSMENT

Surveys for the biodiversity assessment informing the development of the biodiversity certification were constrained by private lands access issues, time and the overall size of the biodiversity certification area. Map 4 shows the locations that were surveyed by CFFIS for this assessment.

Photo 12: *H. puberula* subsp. *puberula* located at Ropes Crossing by the CFFIS survey.



Map 5: Google Earth image of GPEC and WSA Growth Areas and tracks of CFFIS survey.

Key: Growth area approximate boundary shown in red, survey tracks shown in yellow.

4.3.1 SURVEY METHODS

Survey for this report followed the following steps:

- Visit a selection of known localities of the species, locate some *Hibbertia puberula* plants, and take particular note of the habitat characteristics, plant habit, co-occurring species and population density in the context of the protracted rainfall deficit.
- Search biological data sets for any records within the study area. The BioNet and ALA searches failed to find any records of the *Hibbertia puberula* group in the growth areas. *Hibbertia* species are notoriously mis-identified. Searches were then made of all *Hibbertia* recorded within and adjacent to the growth areas to ascertain if any misidentification may be included in the data set. Searches included UBBS NPWS 1997. Records stating *Hibbertia pedunculata*, *Hibbertia* sp., *Hibbertia* sp. A, *Hibbertia serpyllifolia*, *Hibbertia cistiflora* and *Hibbertia riparia* were included within the target survey effort where practical and survey access had been granted. The large amount of entries for *Hibbertia aspera* precluded visiting all known sites. An additional rationale for including these records apart from possible mis-identification is the presence of these species may indicate potential suitable habitat for the *Hibbertia puberula* group.
- Search for records of indicative co-occurring species other than *Hibbertia* such as *Grevillea parviflora* subsp. *parviflora* in order to further refine the survey effort.
- Examine the vegetation type maps provided by the Department of Planning and Environment.
- Locate potential habitat sites based on the mapping and expert knowledge of the plant habitat requirements.
- The prolonged rainfall deficient / drought period prior the survey effort posed significant challenges to the survey. Areas were targeted such as powerline easements where competition for moisture from large trees and shrubs may have been reduced and the targeted flora would have had a greater chance of persisting through the dry period. This strategy was significant in locating one new population *Hibbertia puberula* adjoining Wianamatta Regional Park.
- Survey in early to mid-morning. The greatest impediment to detecting *Hibbertia* species during the survey was early petal drop of some species thought to be increased due to the dry period and unusually high temperatures. Early petal dehiscence was most evident on 3 November 2018 where petal drop of *Hibbertia puberula* was noted to have commenced prior to reaching the site at 8.30am (temperature of 30) and was complete by 9 am (temperature 32).
- Visit as many of these potential habitat sites as possible, considering time and access constraints. Conduct drive-by and over-fence survey where habitat is clearly not suitable.
- Survey potential habitat sites for the species.

4.3.2 SPECIES IDENTIFICATION

As there were no prior records of the *Hibbertia puberula* group within or proximate to the growth areas it was deemed appropriate to prepare herbarium voucher specimens for later lodgement with the National Herbariums of NSW and Adelaide to substantiate the records. Selected specimens were taken according to protocols.

If we located a small-leaved *Hibbertia* specimen that was not in flower and it had macro morphological features resembling that of *Hibbertia puberula,* a specimen was retained for later microscopic examination. Due to the antecedent drought conditions many plants were depauperate, such that, in some cases specimens removed consisted of very small fragments (eco-scraps) some only a few cm in length. This is far from ideal, the challenge was to then identify the non-flowering eco-scraps to species using only stem and leaf characteristics, as shown in the drawing below (Toelken 2000).

The small branchlets of each specimen were compared to voucher material of *Hibbertia puberula* under a dissecting microscope. Note that positive identification of the species requires flowering parts, however, some species of *Hibbertia* can be ruled out based on stem and leaf characteristics. Microscope photographs of *H. puberula* characteristic features used during this survey by CFFIS are provided in Appendix 4.

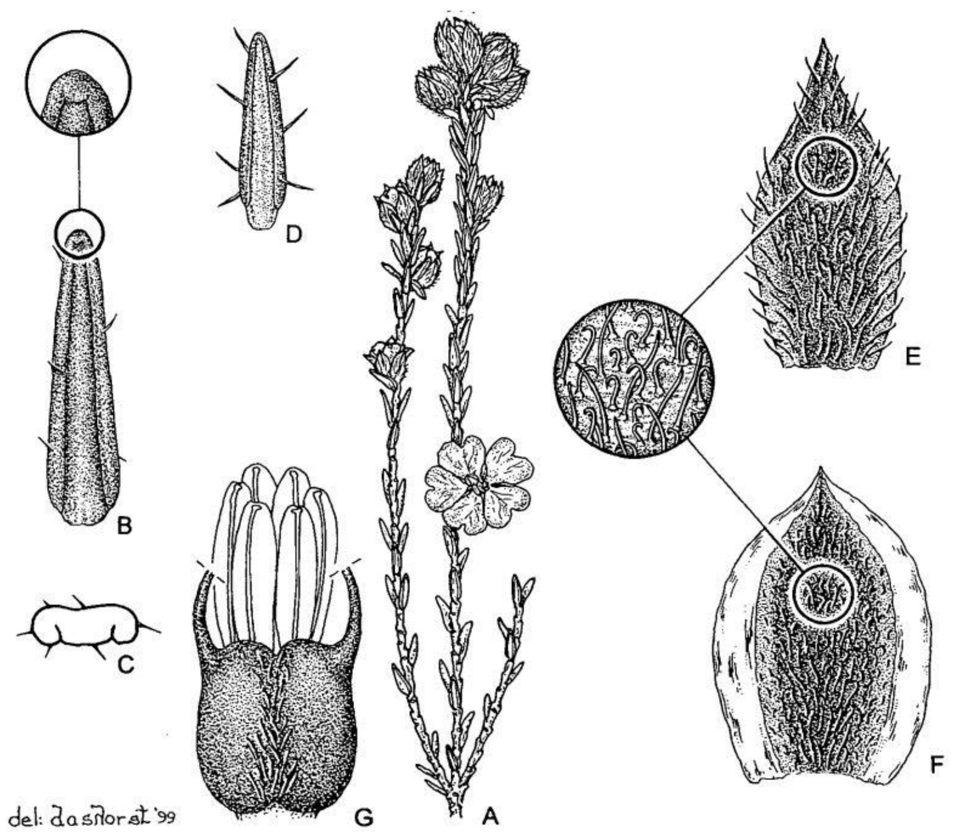


Fig. 7. ***H. puberula***. **A**, Flowering branch; **B**, cauline leaf; **C**, tranverse section; **D**. bract; **E**, outer calyx lobe; **F**, inner calyx lobe; **G**, two glabrescent ovaries. (**A–G**, *J.M.Lindale NSW 101952*; **A** ×1; **B, D** ×10; **C** ×15; **E, F** ×6; **G** ×20).

Figure 1: Line drawing of *Hibbertia puberula* distinguishing characteristics.

All non-flowering small narrow leaved *Hibbertia* specimens found during the survey were examined under the microscope to determine if the stem and leaf characteristics matched those of *Hibbertia puberula.* Essential characters considered include leaf dimensions and shape, the leaf undersurface having revolute margins and recessed to bulging broader central vein obscuring the leaf undersurface, and branchlets having interpetiolar tuffs of hairs. Some of these characters are shown on Figure 1Figure 2. Where the majority of characters were a match, the species could not be ruled out of consideration and so was assumed to be the subject species. It should be noted that these characters vary slightly between sub-species, as shown in Figure 2 below, and confident identification to sub-species requires flower characteristics.

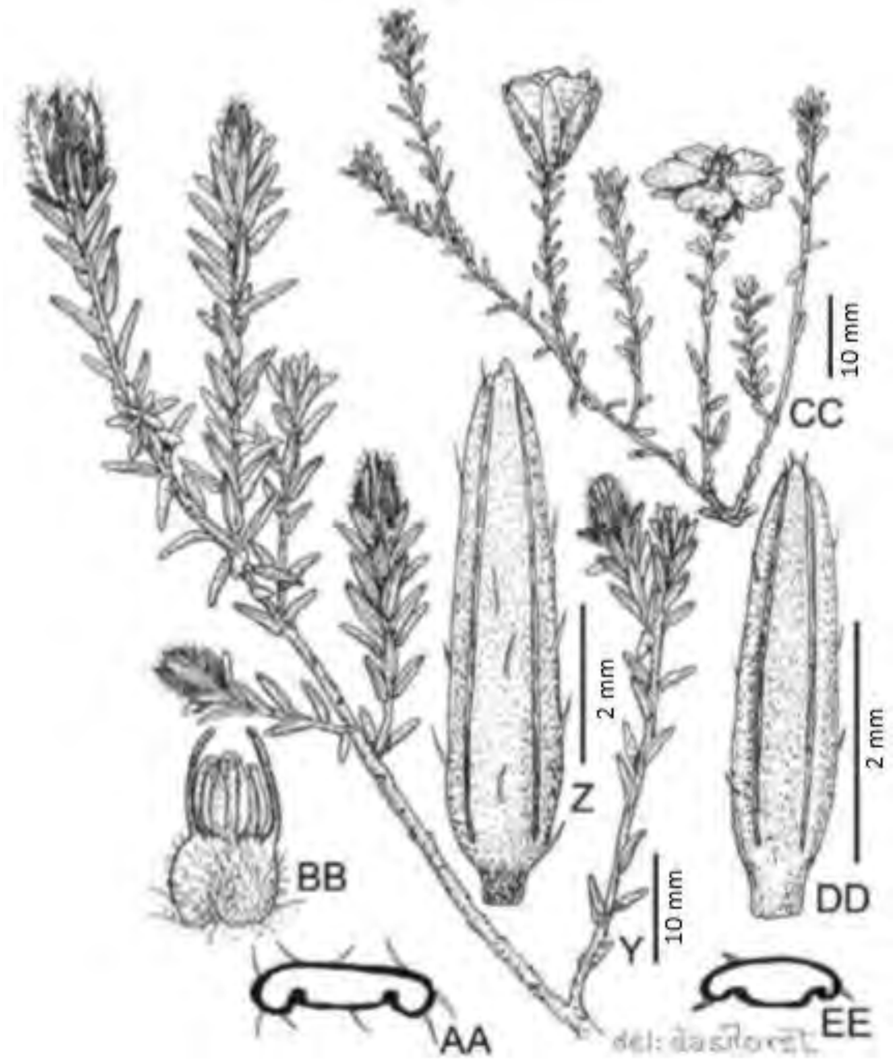

Figure 2: Line drawing of *H. puberula* subs. *extensa* and subsp. *glabrescens*.

Key: *H. puberula* subs. *extensa* Y flowering branch; Z leaf from below; AA transverse section through mid-leaf; BB flowers with petals and calyx removed. *H. puberula* subs. *glabrescens*: CC flowering branch; DD leaf from below; EE transverse section through mid-leaf.

A requisite taxonomic feature is hair types and the specific arrangement on leaf and branchlets. The persistence of the hairs on various parts of *Hibbertia* is variable according to the species. In many species such as *Hibbertia puberula,* hairs on the leaves and stem are notoriously non-persistent and "soon wear off" (Toelken). The full range hair expression is best observed on new and recent growth (Miller pers. obs.). The lack of new or recent growth is a significant limiting factor in the determination of the specimens as at all sites the vegetation was in severe drought stress.

Photo 13: A selection of *Hibbertia* voucher specimens, photo from c. 30cm away.

4.3.3 SURVEY ASSUMPTIONS

It was not feasible to survey all the many bushland remnants within the GPEC and WSA growth areas. As such, the first assumption was:

Assumption 1. *Hibbertia puberula* would not be found growing in bushland that is not its known habitat.

The author is familiar with the species' types of habitat across its entire known range. Using this knowledge of geology, soil and vegetation type that is the known habitat of the species, areas of bushland that would not be suitable habitat were ruled out of the assessment.

Using this knowledge of habitat requirement, the second assumption was:

Assumption 2. *Hibbertia puberula* is likely to be present in areas that are known to be suitable habitat.

Although there are occasions where the plant occurs in higher densities, the most common occurrences are rare and scattered throughout suitable habitat or low populations numbers localised to a small habitat niche. Areas of suitable habitat were surveyed using the random meander method. When only one or no individual specimens were located using this method, it was deemed likely that the species would occur scattered throughout these areas of suitable habitat.

The survey was carried out following several years of drought in western Sydney, and many shrubs forbs and grasses were dead. This led to the third assumption:

Assumption 3. In areas of suitable habitat, where *Hibbertia puberula* specimens have not been found, the species could be present in the soil seed bank.

There was a high amount of leaf fall in most locations and most locations have not recently been burnt. In these areas the species is likely to be present in the soil seed bank. An example is the Basin Reserve (outside the growth areas), where the species was previously scattered throughout suitable habitat within the reserve. Since the drought and control burning, the species appears to now be very rare at this site, however it is likely to be present in the soil seed bank.

4.3.4 *HIBBERTIA* RECORDED BY THIS SURVEY

Six species of Hibbertia were observed whilst undertaking surveys for this report. They are:

Hibbertia puberula: First records for the growth areas and to the north of the growth areas. See Appendix 2 for collection notes.

Hibbertia pedunculata: Very significant populations of this species were observed in the GPEC within and outside the biodiversity certification areas in the Wianamatta Regional Park, also to the north in the former Air Services Australia Site adjoining the north of the GPEC.

Hibbertia diffusa: Widespread, sometimes locally common inside and outside growth areas. Most commonly observed on shale derived or influenced substrates.

Hibbertia aspera: Widespread, sometimes locally common inside and outside growth areas. Most commonly observed on shale derived or influenced substrates.

Hibbertia acicularis: Noted in two areas outside the growth areas, at Agnes Banks Nature Reserve and Gulguer Nature Reserve.

Hibbertia fasciculata: Noted in one area outside the growth areas in Agnes Banks Nature Reserve, in Scribbly Gum Woodland only.

It is a recommendation of this study that *Hibbertia pedunculata* be listed as a Threatened species or an Endangered Population and taken into consideration as part of this biodiversity certification process.

Toelken (2013) in his revision of the *Hibbertia vestita* group, including *H. pedunculata* and *H. serpyllifolia*, considers *H. pedunculata* to be confined to NSW. Analysis of the cited specimens reveals that the species has two main areas of distribution the Greater Sydney Metro Area and the lower Hunter.

In the Greater Sydney Metropolitan area the species has suffered a significant reduction in numbers and extant distribution due to urbanisation. Two cited locales occur within the growth area at St Mary's. The Greater St Mary's – Shane Park vicinity is now the only general vicinity that has long term viable habitat remaining for the species, that is, Wianamatta Regional Park including areas within the former ADI site not gazetted and the Former Air Services Australia site.

Of the twenty specimens cited in the Greater Sydney area six only are known to have extant populations, however all are under severe threat due to small population size and anthropogenic impacts. Nine populations are known or highly likely to be extinct (refer to Appendix 6).

Prior to this survey *H. puberula* had not been recorded within or adjoining the growth areas, although potential habitat had been identified. Seven new locations of the *H. puberula* group were confirmed by this study, 2 within the Growth areas and 5 to the north west.

At the time of publishing (Toelken 2000) few collections were known of *H. puberula*. The J. M. Lindale collection was the only known specimen which displayed a predominance of hooked hairs on the calyxes and a reduced number and number of overtopping +/- straight simple hairs. It is a significant outcome of this survey that additional specimens of this "form" have been located. Although from limited sampling these new specimens may indicate a distinct localised form (Toelken pers. comm.) as all specimens of *Hibbertia puberula* identified for this survey appear to +/- consistent with the Lindale NSW 101952.

Further investigation is warranted to ascertain both the morphological trend observed and the abundance at each of the sites of occurrence.

4.3.5 INCIDENTAL SIGHTINGS OF SIGNIFICANT FLORA DURING THIS SURVEY

The bushland remnants surveyed were observed to support numerous threatened species including but not limited to *Hibbertia puberula*, *Persoonia nutans*, *Pultenaea parviflora*, *Dillwynia tenuifolia*, *Micromyrtus minutiflora* and *Grevillea juniperina*.

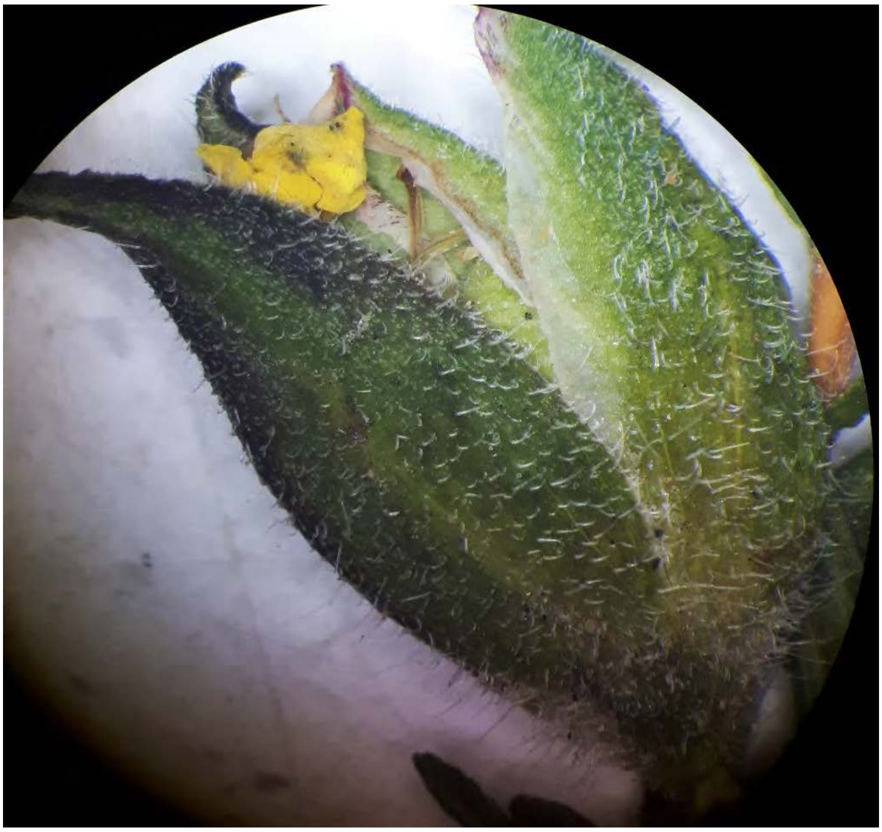

Photo 14: *H. puberula* Kemps Creek showing close similarities to the Lindale NSW 101952

Photo 15: *H. puberula* subsp. *extensa* showing long simple hairs.

4.4 ASSESSMENT OF SPECIES PRESENCE

Within the GPEC and WSA growth areas the species group could be present in the following PCTs:

> 724 - Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion,
>
> 725 - Cooks River Castlereagh Ironbark Forest,
>
> 808 – Derived shrubland on Tertiary Gravels of the Cumberland Plain,
>
> 835 - Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion, and
>
> 883 - Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion,
>
> 1067 - Parramatta Red Gum woodland on moist alluvium of the Cumberland Plain, Sydney Basin Bioregion,
>
> 1395 - Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion.

Occurrences within these broadscale mapping units are most likely to occur in microhabitats. Broad scale vegetation survey and mapping do not identify habitats at this scale. Potential habitat within these PCTs were targeted for survey where access was available.

Determination of potential habitat for *Hibbertia puberula* includes areas identified outside the deemed biodiversity certification area. Anthropogenic impacts are well documented to adversely affect vegetation well beyond the direct urban footprint.

Although there were no pre-existing records of the species within the growth areas, as previously discussed in section 4.1 there are records that could be misidentifications and that could be *H. puberula.* There have been no previous targeted surveys for the species in the growth areas.

4.4.1 LIKELIHOOD OF SPECIES PRESENCE

Hibbertia puberula* subsp. *extensa

It is extremely unlikely that *Hibbertia puberula* subsp. *extensa* exists within the WPEC and WSA growth areas. No suitable habitat for the subspecies is known to occur or is likely to occur within the proposed urban footprint or the growth areas. The likelihood of occurrence is assessed as negligible.

Hibbertia puberula* subsp. *glabrescens

The likelihood of occurrence within or adjacent to the GPEC is considered to be low to moderate, and the likelihood of occurrence within or adjacent to the WSA is assessed as low.

From known occurrence data the subspecies does not have the capacity to exist in habitats that occur within the proposed WSA development footprint. No further, specific targeted surveys are warranted for this subspecies in the WSA footprint. In the unlikely event that this subspecies was to occur it would be picked up in the targeted surveys for *H. puberula* subsp. *puberula*.

Hibbertia puberula* subsp. *puberula

Within the development footprint the subspecies is likely to occur within the Wianamatta Regional Park, as well as in areas adjacent to the footprint at Ropes Crossing and Kemps Creek (see maps 6 to 10).

<u>Within the GPEC</u>

From CFFIS limited field surveys, *Hibbertia puberula* subsp. *puberula* was found to occur at one site immediately adjacent to the Wianamatta Regional Park east of Ropes Crossing. The area of occurrence is a highly modified environment which prior to clearing would have been identified as PCT 725. Mostly now devoid of trees, the derived habitat consists of grassland/herbland/shrubland which is periodically slashed.

It is probable that this subspecies occurs at other locales within the Wianamatta Regional Park and nearby vicinity, especially in the former Air Services Australia Site at Shane Park, the southern border of which is within the biodiversity certification area boundaries. Any occurrences are likely to be confined to small populations restricted to very localised habitat niches. Potential habitat areas adjacent to the footprint would be highly susceptible to significant indirect impacts from a range of anthropogenic influences arising from the increase in urbanisation.

<u>Within the WSA</u>

Whilst undertaking field surveys for this report *Hibbertia puberula* subsp. *puberula* was found to occur at Kemps Creek. The Kemps Creek area is therefore now a known habitat for this species. The likelihood of occurrence within identified suitable habitat within the Kemps Creek vicinity ranges from high (known to be present) to moderate to low depending on location and condition of vegetation. Highly modified environments such as derived shrubland/grassland/herbland cannot be ruled out of consideration and remain assessed as moderate/high as evidenced by the presence of more than 20 *H. puberula* subsp. *puberula* plants observed on Lot 3 DP812284 at Kemps Creek.

A low rating is only justifiable where the soil profile has been significantly altered by fill emplacement or soil chemistry has been significantly altered by past agricultural practices or through urban runoff and where weed invasion is acute.

<u>North of the growth areas</u>

Whilst undertaking field surveys for this report new occurrence records of *Hibbertia puberula* subsp. *puberula* were located in the Agnes Banks, Castlereagh to Berkshire Park vicinities to the north of the GPEC growth area (see Map 2).

4.4.2 JUSTIFICATION FOR DETERMINATION

The following maps show an overview of areas containing potential habitat of *Hibbertia puberula* group, based on vegetation mapping and BioNet records, within the GPEC and WSA. These areas were surveyed by CFFIS for this assessment. Vegetation mapping provided by DPE.

Key to the maps is:

- development footprint – light orange
- CFFIS survey tracks - yellow
- vegetation type PCT 724 – dark blue
- vegetation type PCT 725 - dark green
- vegetation type PCT 835 – light blue
- vegetation type PCT 849 – olive green
- vegetation type PCT 883 – red
- vegetation type PCT 1800 – light green

4.5 ASSESSMENT OF SUITABLE HABITAT

4.5.1 SUITABLE HABITAT WITHIN THE GROWTH AREAS

This section provides detail of areas of suitable habitat within the growth areas that have been surveyed by CFFIS, and the outcomes of that survey.

Powerline Easement Adjacent Forrester Road, Ropes Crossing

Vegetation of the powerline easement has not been allocated a PCT despite the area containing high population numbers of threatened taxa.

The Powerline easement is periodically slashed, maintaining a grassland/herbland/shrubland derived habitat. Scattered remnant trees adjacent Forresters Road are mapped as PCT 725 and are mostly *Eucalyptus fibrosa* with a few Stringybarks noted. Along the western portion of the easement the vegetation grades into +/- intact remnants found within the Wianamatta Regional Park and mapped as PCT 725 and PCT 883 (refer Map 6).

The easement supports a high diversity of indigenous flora and has minor incursion of invasive exotic species which are mainly confined to areas adjacent to Forresters and Palmyra Roads. A small upper gullyline, however is weed impacted and a vector source into the regional park.

40 plants of *Hibbertia puberula* subsp. *puberula* were located within the easement and are presumably the same taxon as that assigned as *Hibbertia riparia* in UBBS. The species was only observed in 3 discrete but proximate patches in a limited area. On 29 October 2018 two large plants were noted with petals, approximately 8 other plants with no flowers were scattered amongst plants of *Hibbertia pedunculata.* On 31 October 2018 a further 15 plants were observed at two additional patches. The plants mostly aborted all their petals or were not in flower, so it is likely that more plants are present but were not observed.

Hibbertia pedunculata was observed to be abundant within the easement, the majority of the plants possessing many flowers and easily detectable. This is significant, as virtually no plants of *Hibbertia pedunculata* were noted within the more heavily vegetated western edge of the easement and within the immediate adjoining sector of the regional park.

Similarly, *Pultenaea parviflora* and *Dillwynia tenuifolia* were frequently encountered within the easement but were noticeably infrequently observed within the adjoining intact vegetation.

It is thought that this is attributable to the preceding drought conditions and fire regime. The absence of trees in the easement meant that there was less competition for water allowing smaller plants to thrive.

The power easement is within the GPEC growth area but is not within the development footprint.

Photo 16: Detail of flower structure, *H. puberula* subsp. p*uberula* from powerline easement.

Photo 17: From *H. puberula* site, lush shrub regrowth including large numbers of threatened species.

Photo 18: Photo of powerline easement edge adjacent to trees.

Note that within the sphere of influence of trees the ground layer is sparse and shrubs regrowth stunted.

Photo 19: A large plant of *H. puberula* subsp. *puberula* located in the powerline easement.

Photo 20: *H. pedunculata* within the powerline easement growing with *H. puberula*.

Note: The density of *H. pedunculata* flowers makes detection easy as compared to low-density occurrences under the long-unburnt Cooks River Castlereagh Ironbark Forest.

Photo 21: Lateritised gravel soil substrate within the area of occurrence of *Hibbertia puberula.*

Note: Lateritised gravel soil is common within the Wianamatta Regional Park and the former Air Services Australia site.

Photo 22: Western boundary of the powerline easement.

Note: Few threatened species were detectable, and none were in flower. The population of threatened species is presumed to be reduced to the soil seed bank.

Photo 23: Typical sparse understorey within Wianamatta Regional Park adjacent easement.

Note: no flowering threatened species.

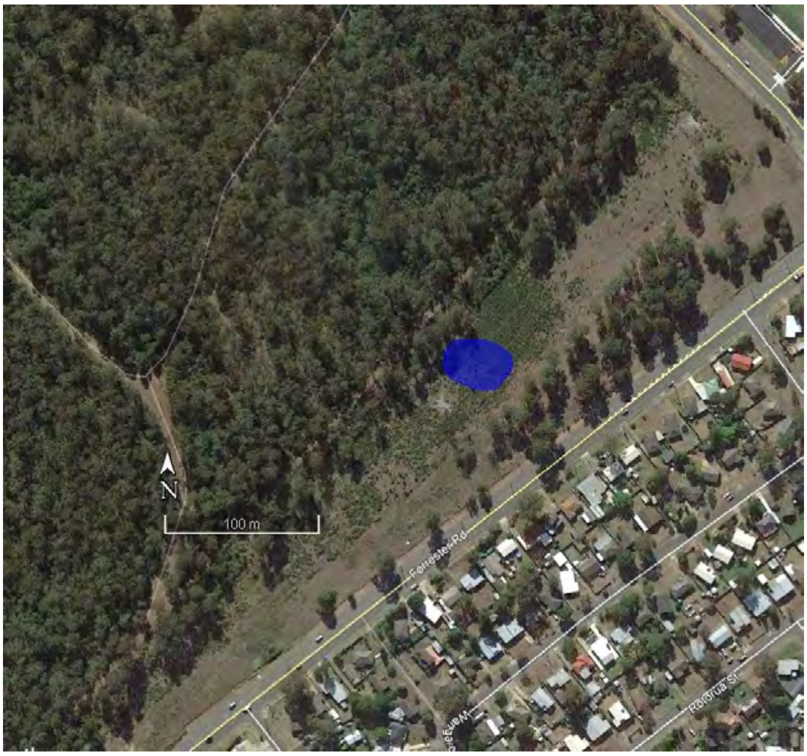

Photo 24: Google image of power easement, location of *H. puberula* subsp. *puberula* in blue.

Wianamatta Regional Park area and Outer Sydney Orbital corridor

Within the Regional Park and the Outer Sydney Orbital (OSO) corridor are areas mapped as having PCTs appropriate for *H. puberula* habitat. The potential for the species to occur in these areas is moderate. Survey of the area did not locate the species, however, the bushland was very dry, had not been burnt for years, and it is likely that the species could be surviving in localised patches in the soil seed bank.

This assessment is based on the proximate record of *Hibbertia puberula* within the electricity easement, the associate species observed there and the presence of lateritised clay soils at both locales.

Hibbertia pedunculata and to a lesser degree *Dillwynia tenuifolia* and *Pultenaea parviflora* were used as surrogate indicator species in determining the likely impact of drought and fire regime on the population densities, within and outside of canopy cover in the assessment of likely occurrence of *Hibbertia puberula*. *Hibbertia pedunculata*, *Dillwynia tenuifolia* and *Pultenaea parviflora* were observed to be locally frequent species within some modified habitat areas.

In areas where these species were noted away from the influence of large trees and shrubs they were easily discernible, flowering and vigorous. Under the canopy or within the sphere of influence of trees and shrubs, flowering was significantly reduced but mostly absent and the apparent population densities low. Visible plants were typically in a late stage of senescence. This was particularly apparent with *Hibbertia pedunculata*.

Photo 25: Typical sparse shrub and ground layer in the regional park.

Other shrub and ground layer species were also noted to be particularly sparse within the areas mapped as PCT 725 and PCT 724 within the Wianamatta Regional Park.

These observations support the conclusion that non-detection of *Hibbertia puberula* within or adjacent to the development footprint (OSO corridor) within the Wianamatta Region Park is likely to be attributable to a retraction to the soil seed bank rather than non-occurrence.

Photo 26: Typical thick detritus suppressing the ground layer in the regional park.

Photo 27: Photo of Wianamatta Regional Park showing depauperate understory.

Note that the extended dry conditions in the Regional Park means that understory species cannot compete with trees for available water. Most of the ground layer has retracted to the soil seedbank.

Photo 28: Sparse shrubs of *Grevillea juniperina*, *Dillwynia tenuifolia* and *Daviesia ulicifolia* subsp. *stenophylla*.

Photo 29: *H. pedunculata* within derived habitat away from trees and shrubs.

Photo 30: Typical condition of *H. pedunculata* within "intact" vegetation of the Regional Park.

Note: The plant is exhibiting extreme water stress and lack of flowers. Detectability of *Hibbertia* in this condition is very low.

The Bells Line of Road Castlereagh Connection Corridor (BLRCCC)

The vegetation within the road corridor can be generalised to consist of PCTs 725 and 724 interspersed with areas of Scribbly Gum Woodland on lateritised clays in the western portion and with PCT 849 more apparent in the eastern sector. Minor and major drainage lines interrupt the generalised vegetation pattern and were noted to be often degraded by urban runoff and weed invasion, at least within and immediately adjacent to the road corridor.

Areas of PCT 1800 - Swamp Oak were noted in the eastern sector. PCT 835 Forest Red Gum - Rough-barked Apple grassy woodland and PCT 1067 Parramatta Red Gum woodland are mapped on the Spatial viewer in the vegetation 100km consolidated layer as occurring adjoining and to the north of the corridor. However, presence or absence of these PCT was not confirmed, as inspection was confined to the road corridor in these locales due to time constraints.

Photo 31: Northern verge of the Bells Line of Road Castlereagh Connection corridor.

Note: A deep trench separates the predominantly intact high-quality remnants from the urban impacted vegetation existing south of the trench adjacent to the cleared sections of the road corridor. The photo foreground has moderate potential habitat and is within the footprint and background has high potential, adjacent to and outside of the growth area boundary. The adjacent highly significant vegetation will be very prone to indirect impacts.

The presence of PCTs 725 and 724 in conjunction with Scribbly Gum Woodland provide potential suitable habitat for *Hibbertia puberula*. Within the growth area boundary, the potential of occurrence is rated as moderate due to disturbance factors.

Adjacent to the northern boundary (the road corridor), being the former Air Services Australia Site, the likelihood of occurrence is rated as moderate to high.

Photo 32: The former Air Services Australia site adjacent to the north of the growth area contains significant populations of *H. pedunculata* and other threatened taxa.

Photo 33: Areas of Scribbly Gum Woodland in the former Air Services Australia site provide likely potential habitat.

Note: Illegal access to the Air Services Australia site by trail bikes and cars has caused impact to vegetation and facilitated rubbish dumping.

The northern edge of the road corridor consists of predominantly intact high-quality remnant vegetation including the edge of the Scribbly Gum Woodland.

A large part of the road corridor is cleared and weed impacted including most of the ground flora which is intermittently slashed. *Eragrostis curvula* dominates much of the disturbed corridor environs.

The following photos show examples of clearing, weed invasion and rubbish dumping along the length of the corridor behind the houses and within the former Air Services Australia site. The photos highlight the significant indirect impacts acting upon remnant vegetation in the region.

Hibbertia puberula is highly unlikely to survive within areas of nutrified mown exotic grasses, dense swathes of *Eragrostis curvula* and thick piles of garden refuse.

Photo 34: Stark contrast in vegetation condition.

Left is highly degraded. Right is intact high quality PCT 725 in part protected from urban runoff and unauthorised access and rubbish/garden refuse dumping by a trench acting as a physical barrier.

Photo 35: Significant species *H. pedunculata* still apparent within disturbance zones.

Photo 36: Anthropogenic impacts along the corridor.

Note: Top left rubbish dumping on verge of high-quality habitat, top right clearing for fire break, mid left acute weed invasion from garden refuse dumping: Mother of Millions, Wandering Jew and *Eragrostis curvula*, mid right commercial scale refuse dumping, bottom left garden refuse dumping facilitating the invasion of *Eragrostis curvula*, bottom right chronic weed invasion and clearing for fire break.

Photo 37: Unsuitable habitat for the *H. puberula* group.

Left, looking westward from the electricity easement to disturbed PCT 849. Right, looking eastward across a highly disturbed electricity easement chronically infested with exotic pasture.

Photo 38: Unsuitable habitat for the *H. puberula* group.

Left, highly disturbed PCT 849, the ground layer dominated by *Eragrostis curvula*. Right, farmland.

The electricity easement in the eastern sector of the road corridor is unlikely habitat, it is the wrong PCT for the species and is highly degraded due to past rural uses, urban runoff and subsequent weed invasion.

Ropes Creek Vicinity

A number of areas were targeted for survey along the Ropes Creek corridor, these were

- Whalan Reserve
- Tregear Reserve
- South of Whalan Reserve
- East of and to the south of St Marys Rugby League Club, Boronia Road North St Marys
- Electricity Substation vicinity Kurrajong Road and Boronia Road, North St Marys, and
- Shephard Street Vicinity, Colyton.

The potential habitat sites in the Ropes Creek vicinity were selected based on the PCT mapping, aerial imagery and the following BioNet records:

Grevillea parviflora: 28/01/2015, Ropes Creek, Mt Druitt includes Whalan Reserve and Tregear Reserves, -33.77797 150.80575.

Dillwynia tenuifolia: near corner Roper Rd & Carlisle Ave, Colyton, -33.78435, 150.80540, Ropes Creek, Mt Druitt includes Whalan Reserve and Tregear Reserves -33.78544, 150.80727

Eucalyptus parramattensis subsp. *parramattensis*: Roper Road, St. Marys, -33.78435, 150.80540

Hibbertia pedunculata: Between power station and railway line near Boronia Park, St Marys

Grevillea juniperina: M4 Motorway, Ropes Creek includes Whalan Reserve and Tregear Reserves and near corner Roper Rd & Carlisle Ave, Colyton.

Grevillea parviflora and *Eucalyptus parramattensis* subsp. *parramattensis* are known co-occurring species at Moorebank and at Voyager Point. *Dillwynia tenuifolia* is a known co-occurring species at Kemps Creek and at Ropes Crossing. These species indicate the possibility of potential suitable habitat present in the Ropes Creek vicinity.

The condition of the vegetation and population status of some of the BioNet records remain unknown.

Both *Grevillea parviflora* and *Eucalyptus parramattensis* subsp. *parramattensis* were not located by this survey effort and the GPS points do not align with the descriptors.

Much of the Ropes Creek vicinity was found to be severely impacted by weed invasion displacing most native species in many of the likely habitat areas.

Further details of the habitat at these sites follows.

Whalan Reserve

Whalan Reserve is primarily developed as a recreational facility including sporting fields, BMX bike jumps, Whalan Model Car Club track, walkway / cycleway and exercise equipment.

West of the path remnant river-flat forest and supplementary plantings were observed.

In the area surveyed the canopy / subcanopy was variously comprised of *Eucalyptus tereticornis*, *Angophora floribunda*, *Casuarina glauca, Acacia decurrens, A. parramattensis* and *Melaleuca decora*. A stand of Blue Box was noted west of the access road.

Photo 39: Whalan Reserve bushland west of the pathway.

The ground layer was impacted by weeds and dominated by *Eragrostis curvula* in many places. Despite this, numerous areas were observed to support a diverse array of indigenous species including: *Acacia falcata*, *A. elongata*, *Bursaria spinosa*, *Indigofera australis, Ozothamnus diosmifolius*, *Daviesia ulicifolia* var. *stenophylla*, *Tricoryne elatior*, *Phyllanthus virgatus*, *Opercularia diphylla*, *Cyanthillium cinereum*, *Cheilanthes sieberi*, *Glossogyne tannensis*, *Goodenia hederacea*, *G. bellidifolia*, *G. paniculata*, *Brunoniella australis*, *Chorizema parviflora*, *Chrysocephalum apiculatum*, *Centella asiatica*, *Glycine tabacina*, *Desmodium varians*, *Polymeria calycina*, *Zornia dyctiocarpa*, *Dianella longifolia*, *Lomandra longifolia*, *Microlaena stipoides*, *Themeda australis* and *Aristida* *vagans*. *Eucalyptus crebra*, *Melaleuca armillaris*, *Callistemon viminalis*, and *C. salignus* were noted in the plantings.

The riverflat community is atypical of *Hibbertia puberula* habitat as the higher nutrient status of the soils supporting typically a dense grassy /herbaceous layer is unsuitable habitat. However, the presence of minor alluvial terraces in combination with lateritised soil areas with relatively open ground layer provides habitat with low potential for the species to occur.

Photo 40: Weedy understorey and habitat plantings at Whalan Reserve.

Photo 41: Remnant vegetation at Whalan Reserve severely impacted by *Eragrostis curvula*.

Photo 42: Minor alluvial terrace, potential habitat for *H. puberula* in Whalan Reserve.

Tregear Reserve

Tregear Reserve is primarily a developed recreational reserve with sporting fields, walkways/ cycleway, exercise facilities and an off-leash dog compound.

Undeveloped portions remain west of the pathway and include riverine remnant vegetation and large areas of unmown exotic grassland / herbland that has predominantly displaced the indigenous vegetation. Habitat enhancement plantings were noted along the bushland verge.

Habitat for *Hibbertia puberula* may have once existed at the interface between the alluvial floodplain and the lateritised rise. The potential habitat is mostly too degraded to now support this species.

In the area surveyed the riparian vegetation was dominated by *Eucalyptus baueriana* with *Casuarina glauca*, *Acacia parramattensis*, *Melaleuca styphelioides*, *Bursaria spinosa* and the native grass *Microlaena stipoides* being relatively common.

Other indicative indigenous species noted included *Carex appressa*, *Scaevola albida*, *Dichondra repens*, *Centella asiatica* and *Alternanthera denticulata*.

The understorey in many locales is heavily weed impacted with species such as: *Eragrostis curvula*, *Chloris gayana*, *Setaria sphacelata*, *Verbena bonariensis*, *Rumex* sp. and *Tradescantia fluminensis*.

Enhancement plantings include: *Eucalyptus crebra*, *Casuarina glauca*, *Melaleuca styphelioides*, *M. decora*, *M. linariifolia* and *Bursaria spinosa*.

Photo 43: Looking across Tregear Reserve to the riparian zone of Ropes Creek

Photo 44: Treagar Reserve chronic weed infestation eliminating potential habitat for the species.

Although very limited in extent, a number of indigenous ground layer species were noted under the canopy of the enhancement plantings and to a lesser degree within the adjoining predominantly exotic weed meadow. Indigenous species noted include: *Wahlenbergia gracilis, W. communis, Centella asiatica, Tricoryne elatior, Microlaena stipoides, Cynodon dactylon, Phyllanthus virgatus*, *Rubus parviflorus*, *Glycine tabacina*, *Haloragis heterophylla* and *Glossogyne tannensis*.

Weed meadow adjoining plantings was dominated by *Eragrostis curvula, Hypochaeris radicata Plantago lanceolata*, *Melilotus albus* and *Paspalum dilatatum*.

The majority of the potential habitat was blanketed by dense weeds, primarily comprised of: *Eragrostis curvula*, *Cirsium vulgare*, *Verbena bonariensis*, *Melilotus albus*, *Foeniculum vulgare*, *Solanum sisymbriifolium*, *Bidens pilosa*, *Lactuca serriola*, *Plantago lanceolata*, *Chloris gayana*, *Nothoscordum gracile*, *Chenopodium album* and *Sorghum halepense*.

South of Whalan Reserve

The generalised geomorphology of the site is summarised by the intersection of the alluvial floodplain deposits of Ropes Creek with low lateritised rises. It is possible that such conditions once provided localised suitable habitat for *Hibbertia puberula*.

The potential habitat in this section of Ropes Creek is severely impacted by weed invasion and the potential for threatened species to now exist is negligible. A large area is being infilled with road ballast.

Photo 45: Eastern side of Ropes Creek south of Whalan Reserve.

Photo 46: *Eragrostis curvula* smothers potential habitat area of lateritised clay.

Photo 47: Only one small area of Themeda grassland was noted to remain.

Photo 48: Photos show dense growth of *Imperata cylindrica* (top left) and a variety of weeds eliminate potential habitat for the species.

Boronia Road, North St Marys

A diverse herbaceous layer was observed in recently burnt sections of the powerline easement at North St Mary's. Most locales including the adjacent wooded areas and including PCT 724 were heavily infested with dense *Eragrostis curvula* tussocks, and this was smothering the ground layer.

Flowering species noted in one burnt area included *Murdannia graminea*, *Tricoryne elatior*, *Hypoxis hygrometrica* var. *hygrometrica*, *Isotoma fluviatilis* and *Hibbertia diffusa*, as well as fertile *Ophioglossum lusitanicum.* All of these plants were non-discernible under the adjoining tree cover and within the dense *Eragrostis* tussocks.

No *Hibbertia puberula* or *H. pedunculata* plants were observed in this locale though the survey was very limited in its extent and duration.

Photo 49: North St Marys electricity easement environs.

Photo 50: East of and to the south of Boronia Road North St Marys.

Electricity Substation vicinity Kurrajong Road and Boronia Road, North St Marys

The potential habitat areas in the vicinity of Kurrajong and Boronia Road intersections occur on slightly higher ground outside the influence of nutrified stormwater discharges and overflows from Ropes Creek.

A small highly disturbed remnant exists between the substation and the western rail line supporting a population of *Hibbertia pedunculata* estimated +/- > 50 plants.

Planted/escaped *Eucalyptus maculata*, *E. sideroxylon*, *Melaleuca armillaris*, *Callistemon salignus*, *Leptospermum petersonii*, *Melaleuca hypericifolia* and *Casuarina glauca* were common in the tree and shrub layer adjoining the substation facility.

Indigenous species noted include *Eucalyptus moluccana*, *E. tereticornis*, *Daviesia ulicifolia* subsp. *stenophylla*, *Hibbertia pedunculata, Dillwynia tenuifolia*, *Acacia decurrens*, *A. elongata*, *Ozothamnus diosmifolius*, *Pimelea linifolia*, *Leptospermum trinervium*, *Goodenia hederacea*, *Cheilanthes sieberi*, *Lepidosperma laterale*, *Microlaena stipoides* and *Entolasia stricta*.

Eragrostis curvula formed extensive swathes throughout the surrounding area including the mown perimeter of the substation.

Photo 51: An indigenous regrowth area between the substation and western railway line is potential habitat for *H. puberula*.

Photo 52: Indigenous and non-indigenous "native" vegetation form the remnant between substation and railway line.

Photo 53: *H. pedunculata* in the remnant between the substation and the railway line.

Potential habitat also exists to the east of the substation adjacent to a small stand of *Eucalyptus fibrosa* and *Melaleuca decora* within an electricity easement and extending toward the rail line. Significant numbers of *Hibbertia pedunculata* were noted in open areas.

Photo 54: Foreground, *H. pedunculata* within open areas of native grassland/herbland.

Note: Background shows dense swathes of *Eragrostis curvula* adjacent electricity substation.

Photo 55: Slashed native vegetation in the powerline easement, potential habitat for *H. puberula*.

Photo 56: Open areas of lateritised clay soil east of the substation and north of railway line west of Ropes Creek support *H. pedunculata* and provide potential habitat for *H. puberula*.

Shephard Street Vicinity, Colyton

Bushland Remnant Roper Road / Shephard Street / Western Motorway interchange.

A linear bushland remnant between Shephard Street and the Western Motorway was targeted for survey due to BioNet records for *Hibbertia pedunculata* and *Grevillea juniperina* at the site and mapping on the spatial viewer indicating the presence of PCT 724.

In consideration of its size the remnant is in good condition with the exception of the eastern extremity which has recently been further degraded by roadworks.

The understorey was noted to be impacted by drought (refer photos 60 and 61). Specimens of both *Hibbertia pedunculata* and *Grevillea juniperina* were observed but were drought impacted. A number of specimens of the *Grevillea* had senesced adjacent to the roadworks.

No *Hibbertia puberula* plants were observed at the time of survey undertaken between 11-12 am, after likely petal dehiscence. Due to the site conditions, detectability was rated as extremely low and as such the species could have easily been overlooked as the plants, if present, would have existed as tiny sprigs with a few leaves only. It is also possible that the species has retreated to the soil seed bank in response to drought.

The indigenous species noted at the site include: *Eucalyptus fibrosa*, *Melaleuca decora*, *M. nodosa*, *Allocasuarina littoralis*, *Pimelea linifolia*, *Kunzea ambigua*, *Acacia elongata*, *A. falcata*, *Callistemon pinifolius*, *Grevillea juniperina*, *Dillwynia tenuifolia*, *Hibbertia pedunculata*, *Exocarpos cupressiformis*, *Bursaria spinosa*, *Daviesia ulicifolia* subsp. *stenophylla*, *Lissanthe strigosa*, *Xanthorrhoea* sp., *Boronia polygalifolia*, *Phyllanthus hirtellus*, *Billardiera scandens*, *Goodenia hederacea*, *Cheilanthes sieberi*, *Lobelia purpurascens*, *Wahlenbergia gracilis*, *Dianella laevis*, *D. revoluta*, *Opercularia diphylla*, *Centella asiatica*, *Lomandra multiflorus*, *L. filiformis*, *Lepidosperma laterale*, *Entolasia stricta*, *E. marginata* and *Microlaena stipoides*.

Photo 57: Bushland remnant south of Shephard Street, adjacent the Western Motorway

Photo 58: *Eucalyptus fibrosa*, *Allocasuarina littoralis*, *Melaleuca decora* and *M. nodosa*.

Photo 59: Drought impacted *H. pedunculata*, the largest and only plant noted in flower.

Photo 60: Severe drought impacted understorey in western sector of the site

Photo 61: Severe drought impacted understorey in middle section of the site

Shephard Street Park environs, Colyton

The spatial viewer identifies the Shephard Street Park vicinity as PCT 724 thinned remnant, urban.

Shephard Park itself is devoid of indigenous understorey and is dominated by an upper canopy of *Melaleuca decora* and widely scattered *Eucalyptus* trees. The ground layer consists mainly of mown exotic grasses with scattered small areas of mixed native/exotic grasses and herbs. It is extremely unlikely to support a viable population of *Hibbertia puberula* due to past and current management.

Photo 62: Left and right, Shephard Park.

At the rear of Shephard Park, a linear band of remnant vegetation extends along the Western Motorway. A fire break separates the bushland from residential properties. Edge effects have and will continue to have a deleterious impact upon the vegetation.

Photo 63: Linear band of remnant vegetation along the Western Motorway near Shephard Park.

Photo 64: A small core area of weed free vegetation exists above the Motorway cutting.

South of Dunheved Circuit and north of Christie Street, St Marys

The area was included as it is mapped as PCT 725 and PCT 724 on the spatial viewer and recent records exist for *Grevillea juniperina*, *Dillwynia tenuifolia* and *Pultenaea parviflora* suggesting that sufficient habitat remains that may support *Hibbertia puberula*.

Photo 65: Dunheved Estate Reserve bushland remnant adjacent Dunheved Circuit

Photo 66: Bushland remnant north of Christie Street

Site inspection of the Dunheved Estate Reserve and surrounds observed transitional vegetation grading from PCT 725 in the eastern end to PCT 724 westward. The soil was clay with laterite nodules. The remnant vegetation was confined to a narrow band on both sides of the disused railway cutting. Of the threatened species noted; *Grevillea juniperina* was observed to be widespread and common even colonising the former station platform. *Pultenaea parviflora* and *Dillwynia tenuifolia* were more localised but frequently observed.

Eucalyptus fibrosa was the dominant tree species eastward with *E. tereticornis, Angophora floribunda* and *E. moluccana* becoming more prevalent and dominating westward. A small stand of *E. baueriana* was noted within Dunheved Estate Reserve along with planted *Corymbia maculata* and *E. crebra* noted on the northern verge.

Indigenous species recorded include: *Allocasuarina littoralis, Melaleuca decora, M. nodosa, Acacia elongata, A. falcata, A. parramattensis, Daviesia ulicifolia* var. *stenophylla, Ozothamnus diosmifolius, Bursaria spinosa, Lissanthe strigosa, Astroloma humifusum, Phyllanthus hirtellus*, *Cyanthillium cinereum*, *Linum marginale*, *Caesia parviflora* var. *vittata*, *Goodenia hederacea*, *Phyllanthus virgatus*, *Dichondra repens*, *Glycine tabacina*, *Einadia nutans*, *E. polygonoides*, *Cheilanthes sieberi*, *Opercularia diphylla*, *Hibbertia diffusa*, *Brunoniella australis*, Vittadinia sp., *Dianella revoluta*, *D. longifolia*, *Themeda australis*, *Lepidosperma laterale*, *Lomandra multiflora*, *L. filiformis*, *Microlaena stipoides* and *Aristida vagans*.

Single specimens of both *Glochidion ferdinandi* and *Melia azedarach* were observed near the overpass. *Eragrostis curvula* is the dominant weed above the cutting. Sufficient site integrity remains to support diminutive species such as *Hibbertia puberula.*

Photo 67: Park at Dunheved Circuit, rail cutting on the right of picture.

Photo 68: Rail cutting with remnant bushland on steep banks.

Photo 69: Looking along rail cutting to footbridge, remnant bushland on banks.

Photo 70: *Grevillea juniperina*, *Pultenaea parviflora* and *Dillwynia tenuifolia* on the rail cutting embankment.

Photo 71: *Grevillea juniperina* colonising the abandoned railway platform.

Photo 72: Abandoned railway platform, remnant bushland both sides of cutting.

Claremont Meadows Bushland

The area was included for consideration as the Claremont Meadows bushland is identified on the spatial viewer as containing two vegetation communities, primarily as PCT 724 and with small areas of PCT 849 indicated.

Photo 73: Equestrian Circuit - Ridgetop Woodland *Eucalyptus moluccana*, *E. eugenioides*? and *E. fibrosa*

Photo 74: Equestrian Circuit - regrowth with understorey dominated by *Eragrostis curvula*.

Claremont Meadows bushland remnant contains small areas of ridgeline vegetation primarily in the Equestrian Circuit and Blackwood Street vicinities comprised of a varying combination of *Eucalyptus tereticornis*, *E. moluccana*, *E. eugenioides*? and *E. fibrosa*. The majority of the vegetation is found on the slopes and flats and is mainly comprised of *Eucalyptus tereticornis* and *E. moluccana* with a dense understorey of *Bursaria spinosa* present on the slopes.

All the ridgetop areas adjoin recent subdivisions and are impacted by past landuse practices with most of the understorey being cleared or significantly thinned. Some areas remain unvegetated, but most are now colonised by exotic grasses and herbaceous species.

Although PCT 724 may have potential as habitat for the *Hibbertia puberula* group in some circumstances, from current known habitat information it is thought that this is only the case where this community intergrades with PCT 725, and/or PCT 883 and/or PCT 1067.

Claremont Meadows bushland is assessed as unsuitable habitat for the *Hibbertia puberula* group.

Photo 75: Understorey is cleared or dense swathes of exotic grasses.

Photo 76: Much of the understorey in the Blackwood and Fowler Street vicinities is comprised of dense swathes of exotic grasses.

Apple Gum Reserve, Glenmore Park

Apple Gum Reserve in Glenmore Park is identified on the spatial viewer as containing two vegetation communities, PCT 1395 and PCT 849, with areas mapped as Urban native / exotic – noting planted native exotic.

Apple Gum Reserve is a highly modified urban park / linear bushland reserve. The majority of the indigenous flora is situated within and on the slopes of a +/- south – north gully line to the east of Lady Jamison Drive. PCT 1395 is mapped as occurring in the higher southern portion of the reserve and PCT 849 at the northern portion. Over 1/3 of the Reserve is mown exotic grassland with significant areas of mulched beds surrounding both remnant trees and plantings including all the vegetation mapped as PCT 1395.

Although PCT 1395 is known potential habitat for the *Hibbertia puberula* group no suitable habitat exists for *Hibbertia puberula* at this locale irrespective of the mapping accuracy.

Photo 77: Apple Gum Reserve at Glenmore Park from Lady Jamison Drive.

Note: photo taken from Lady Jamison Drive looking across to the intersection of Bursaria Drive and Honeysuckle Avenue from an area mapped as Urban exotic to PCT 1395 adjoining Bursaria Drive.

Photo 78: Google Earth image of area mapped as PCT 1395, mown and mulched at corner of Bursaria Crescent and Honeysuckle Avenue.

Photo 79: Google Earth image of area mapped as PCT 1395 mown and mulched at corner of Bursaria Crescent and Honeysuckle Avenue.

Photo 80: Google Earth image Corner of Bursaria and Acacia Avenues Mapped as PCT 1395 mown and mulched.

Photo 81: Google image looking across to linear bushland remnant bordering Lady Jamison Drive mapped as PCT 849.

Photo 82: Apple Gum Reserve at Glenmore Park remnant bushland.

Note: *Eucalyptus tereticornis*, *E. moluccana* and *Bursaria* dominated bushland remnant mapped as PCT 1395 is unsuitable habitat for the *Hibbertia puberula* group.

Photo 83: Photo of Apple Gum Reserve showing mown weeds of the bushland margin.

Photo 84: Photo of Apple Gum Reserve showing chronic weed infestation of the bushland margin.

Photo 85: Apple Gum Reerve at Glenmore Park bushland remnant.

Note: *Eucalyptus tereticornis*, *E. moluccana* and *Bursaria* dominated bushland remnant is unsuitable habitat for the *Hibbertia puberula* group. Mapped as PCT 1395.

Kemps Creek area, Lot 3 DP 812284, 90 Clifton Avenue Kemps Creek

Most of the block is cleared and is used for storage of materials and logged timber.

A narrow strip along the southern boundary supports native plants including 4 endangered species. More than 20 plants of *H. puberula* were found in this area during our survey on 9 November 2018. The majority of the *Hibbertia puberula* plants observed had shed their petals prior to start of the site inspection at 11am to 12.15pm. The species had not previously been recorded for the Kemps Creek vicinity.

The remaining species habitat has been excluded from the biodiversity certification footprint but remains threatened by vast mounds of mulch, fill and invasive weeds.

Photo 86: The remaining threatened species habitat at 90 Clifton Avenue Kemps Creek.

Note that the habitat exists only as a linear band adjacent to northern boundary of the adjoining block to the south.

The vegetation in the immediate vicinity has been variously described as PCT 883 by Eco Logical Australia (2013), Ecoplanning (2015) and the Vegetation 100km consolidated layer in the Spatial Viewer, and Shale Gravel Transition Forest by Envirotech (2013). It is identified on the spatial viewer as PCT 725 on Lots 1, 2 and 3 DP812248 and PCT 724 as occurring to the east and west.

The vegetation in the Kemps Creek area has been dramatically altered with clearing for agriculture and removal of trees for various uses such as fence posts and firewood. The precise abundance of the various *Eucalyptus* species through the area is difficult to ascertain. *Eucalyptus sclerophylla* is obviously a major component within limited areas with stands still occurring south of Elizabeth Drive adjacent to Bill Anderson Park and the Christadelphian Heritage College Sydney. Scribbly Gum also appears to have been a major component of the canopy within Lot 3 DP 812284 prior to clearance as documented within the Eco Logical 2013 report, refer photo 88.

Photo 87: Looking westward along the remaining threatened species habitat

Photo 88: Scribbly Gum was an obvious common component of the site (photo Eco Logical 2013).

It is likely that *Hibbertia puberula* was widespread in localised patches across the site prior to development. It was observed to be co-occurring with and often intertwined amongst the remaining

Dillwynia tenuifolia noted on site. Although there is discrepancy in numbers, both the Eco Logical 2013 and Ecoplanning 2015 reports indicate the *Dillwynia* to have been widespread across the site prior to clearing.

Photo 89: Habitat and location of *H. puberula* on Lot 3 DP 812284.

Photo 90: *H. puberula* co-occurring with *Dillwynia tenuifolia,* Lot 3 DP 812284

Photo 91: *H. puberula* petal dehiscence prior to 11.24 am.

Photo 92: *H. puberula* interwtinned amongst *Dillwynia tenuiifolia.*

Photo 93: Close up photo of *H. puberula,* one partial flower remains at 11.24am.

Photo 94: *H. puberula* showing petal dehiscence 11.24 am

Photo 95: *H. puberula* floral structure, petal dehiscence prior 11.22am 9/11/2018.

Lot 1 & 2 DP812284 Clifton Avenue, Kemps Creek in the Penrith local government area

Potential habitat is likely to occur within remnant vegetation located on Lots 1 and 2 DP812284 on Clifton Avenue.

No access was granted therefore site assessment was limited to "through the fence" observation made from the adjoining property (90 Clifton Road), spatial viewer information and literature review of the Envirotech 2013 assessment.

Several plants of *H. puberula* were observed by Jan Miller, Steve Douglas and confirmed by Robert Miller approximately 5-6 metres from the fence line. Although without petals, the plants were just discernible due to the coloration of the open calyxes. Therefore, the site is known habitat for the species. Other threatened species noted include *Dillwynia tenuifolia* and *Pultenaea parviflora.* The vegetation was assessed as potential suitable habitat for a range of other threatened taxa as it is contiguous to the known habitat on Lot 3 and a number of co-occurring species were noted. The vegetation of the general area has been variously described as PCT 883 by Eco Logical Australia (2013), Ecoplanning (2015) and the Vegetation 100km consolidated layer in the Spatial Viewer, and Shale Gravel Transition Forest by Envirotech (2013). It is identified on the spatial viewer as PCT 725 on Lots 1, 2 and 3 DP812284 and PCT 724 as occurring to the east and west.

Photo 96: Bushland on Lot 2 DP812284, photo taken through fence.

Note: Subtle variation in elevation and possible substrate consistency providing periodic damp conditions supporting range of species e.g. *Xanthorrhoea minor* and potential habitat for threatened plants such as *Grevillea parviflora* and *Hibbertia* species.

An environmental assessment on this block by Envirotech 2013 noted a relatively intact flora community and that there was a healthy seed bank evidenced by the regeneration of native vegetation in disturbed portions of the property. Envirotech considered the site to have high species diversity including "well-represented herbaceous, understory and canopy layers that were clearly identifiable". Weeds were confined to the perimeter of the property.

Photo 97: *Dillwynia tenuifolia* and habitat of the two observed *H. puberula* plants on Lot 2 DP812284.

Envirotech (2013) found no threatened fauna or individual flora species to be present on the site at the time of inspection. The habitat potential of the site for threatened species was considered to be relatively high. The Endangered Ecological Community Shale Gravel Transition Forest was detected on the site. The non-detection of threatened species is likely to be attributable to the survey being undertaken on 20 August 2013, outside the flowering period.

Lot 22 DP 60122, 1541A Elizabeth Drive Kemps Creek and Lot 2 DP 587135, 146B Clifton Avenue Kemps Creek

These two blocks in the Kemps Creek area are assessed as having a low to moderate probability of occurrence for *Hibbertia puberula*.

The majority of the understorey on Lot 2 DP 587135, 1468 Clifton Avenue could not be observed. It is included as potential habitat based on its continuity and close proximity to known habitat. The area is mapped as PCT 724 thinned on the spatial viewer.

Lot 22 DP60122 was assessed by ''through the fence'' inspection. The area is mapped as PCT 724 thinned on the spatial viewer. Much of the observable portions of the site are disturbed with weeds and fill dumping. Small areas were noted to contain an intact ground layer.

Photo 98: Lot 22 DP 60122, photo taken from Lot3 DP812284.

Note: small areas of regenerating native vegetation and intact ground layer occur within Lot 22 DP 60122. These provide potential habitat for threatened taxa.

Photo 99: View from south western corner of Lot 3 DP812284 into Lot 22 DP 60122.

Note: degradation of habitat by fill dumping and invasion of weeds, notably dense swathes of *Eragrostis curvula.*

Photo 100: Evidence of clearing, fill dumping and weed invasion degrading the habitat potential for threatened species Lot 22 DP 60122.

Lot 47 DP 734584 146 – 196 Clifton Avenue Kemps Creek

The block of land to the north of Lot 3 DP812284 is cleared and under investigation. It is most likely that this block supported populations of *H. puberula* prior to clearing. From the most recent 31/10/2018 Google Earth imagery no habitat now remains in Lot 47 (referPhoto 103). A narrow strip of low potential habitat remains roadside.

Photo 101: Street view Google earth November 2016 of block to the north of Lot 3 DP812284.

Photo 102: Street view Google earth November 2016 of block to the north of Lot 3 DP812284.

Photo 103: Location of Lot 47 DP 734584, Lot 3 DP812284, Lot 2 DP587135 and Lot 22 DP601022.

Bushland Remnants Lot 4 DP812284, 373 - 381 Clifton Road and Lot 6 DP812284, 316 Clifton Road, Kemps Creek

There are two blocks on the east side of Clifton Road that both have suitable habitat type although they are disturbed. These blocks have low to moderate probability for the species to occur.

The assessment was made from data shown in the Spatial Viewer from two BAM plots located on Lot 6. Species recorded include:

BIO WSAN 13: *Eucalyptus fibrosa* 15% coverage, *Eucalyptus globoidea* 1%, *Melaleuca decora* 2% and *Melaleuca nodosa* with a 15% coverage. Other species recorded each with a 1% coverage include: *Ozothamnus diosmifolius*, *Dillwynia sieberi*, *Dodonaea viscosa*, *Bursaria spinosa*, *Exocarpos* *cupressiformis*, *Aristida vagans*, *Lomandra gracilis*, *Daviesia ulicifolia*, *Dillwynia parvifolia*, *Pultenaea microphylla*, *Einadia hastata*, *Phyllanthus hirtellus*, *Pratia purpurascens*, *Eragrostis leptostachya*, *Entolasia stricta*, *Lepidosperma gunnii*, *Lepidosperma laterale*, *Cyathochaeta diandra*, *Lomandra longifolia*, and *L. multiflora*.

The only weed recorded in the BAM data is *Eragrostis curvula* with a 2% coverage.

BIO WSAN 14: *Eucalyptus globoidea* 30%, *Melaleuca decora* 2%, *Bursaria spinosa* 1% and *Cassinia uncata* 1% coverage. Ground layer species recorded cover 45% of the ground layer. They include: *Einadia hastata*, *Lomandra multiflora*, *Entolasia stricta*, *Eragrostis brownii*, *Dichelachne micrantha, Cynodon dactylon* and with *Microlaena stipoides* a 40% coverage.

Weeds in total had an 8% coverage, species recorded are: *Axonopus affinis*, *Sporobolus creber*, *Hypochaeris radicata*, *Sida rhombifolia*, *Eragrostis curvula* 1%, *Senecio madagascariensis*, and *Setaria parviflora*.

Photo 104: Google Earth image of Lot 6 DP812284 viewed from Clifton Road.

Remnant Vegetation North of Elizabeth Drive, Kemps Creek

The following Lots contain potential habitat for *Hibbertia puberula*: Lot 1 DP747285 1521 – 1539 Elizabeth Drive, Lot 1 DP1212980 1503 Elizabeth Drive, Lot 10 DP 1087346 1495 Elizabeth Drive Lot 16 DP2566 1491 Elizabeth Drive and Lot 1 DP 1o90754 1481-1489 Elizabeth Drive.

The two vegetation remnants north of Elizabeth Drive and south of Lot 1 & 2 DP812284 Clifton Avenue were assessed by ‘’over the fence’’ and ‘’drive-by’’ observation as access was not granted at the time of survey. Both sites were noted to have potential habitat from information contained within the spatial viewer, field observation revealed the small observable areas to be in poor condition and with low habitat suitability. Most of the vegetation was not able to be seen from the roadside.

The majority of the largest remnant Lot 1 DP716403 1521 – 1539 Elizabeth Drive was not visible from the road. It is a large block extending northward and adjoining Lot 1 & 2 DP812284 Clifton Avenue. There is no BAM Plot data available for this site. The spatial viewer maps two vegetation types PCT 1067 thinned and PCT 725 thinned providing potential likely habitat for the species. The remnant is bordered by a wholesale nursery in the west and a quarry to the east. Numerous site disturbances such as large areas of fill emplacement are observable on Google Earth Imagery providing evidence of degradation of habitat across much of the site.

The smaller remnant is bordered by the quarry on two sides and rural residential properties on Elizabeth Drive, consequently the impact of edge effects is likely to be high. Two BAM plots are located in this remnant and the Spatial viewer maps the site as PCT 725. The information provides some insight into the habitat.

BIO WSAN 9: *Angophora floribunda*, *Eucalyptus tereticornis*, *Melaleuca decora, Acacia decurrens*, *Ozothamnus diosmifolius*, *Bursaria spinosa*, *Dillwynia sieberi*, *Themeda triandra*, *Glycine tabacina*, *Einadia trigonos*, *Opercularia diphylla*, *Brunoniella australis*, *Centella asiatica*, *Pratia puberula*, *Polymeria calycina*, *Microlaena stipoides*, *Aristida vagans*, *Entolasia marginata*, *E. stricta*, *Paspalidium distans*, *Dichelachne crinita*, *Echinopogon caespitosus*, *Lomandra multiflora*, *Carex inversa*, *Dichondra repens*, *Lepidosperma laterale*, *Cynodon dactylon*, *Lomandra filiformis* and *Cheilanthes sieberi*.

Weeds recorded in the BAM Plot include: *Senecio madagascariensis*, *Ehrharta erecta*, *Asparagus asparagoides*, *Cirsium vulgaris*, *Pennisetum clandestina*, *Cuscuta campestris*, *Sida rhombifolia*, *Opuntia stricta*, *Plantago lanceolata*, *Tradescantia fluminensis* and *Hypochaeris radicata*.

BIO WSAN 10: *Angophora subvelutina* 15%, *Eucalyptus tereticornis* 5%, *Allocasuarina littoralis*, *Acacia decurrens*, *Ozothamnus diosmifolius*, *Acacia elongata*, *Cryptandra spinescens*, *Eragrostis brownii*, *Themeda australis*, *Glycine clandestina*, *Solanum prinophyllum*, *Hibbertia aspera*, *Microlaena stipoides* 50%, *Panicum simile*, *Eragrostis brownii*, *Cynodon dactylon*, *Lomandra multiflora*, *Juncus usitatus*, *Dichondra repens*, and *Lepidosperma laterale*.

Weeds recorded in the BAM Plot include: *Ligustrum lucidum*, *Verbena bonariensis*, *Setaria parviflora*, *Bidens pilosa*, *Sonchus oleraceus*, *Eragrostis curvula*, *Senecio madagascariensis*, *Cyperus eragrostis*, *Ehrharta erecta*, *Anagallis arvensis*, *Araujia sericifera*, *Passiflora subpeltata*, *Chloris gayana*, *Axonopus compressus*, *Conyza* sp., *Sida rhombifolia*, and *Asparagus asparagoides*.

The representativeness of the habitat information contained within the BAM plot data is unknown. It is also unknown whether or not localised habitat niches prevail within the broader vegetation type as observed at other locales at Kemps Creek. Accordingly, the presence of *Hibbertia puberula* could not be ruled out but the likelihood of occurrence was assessed as low.

Photo 105: Location of BAM plots BIO WSAN 9 and BIOWSAN 10.

Note: Labels show the location of Lot 1 DP716403, Lots 4 and 5 DP255566, Lot 1 DP1212980 and Lot 230 DP1134016.

SUEZ Kemps Creek Resource Recovery Park and Landfill, Elizabeth Drive, Kemps Creek

Remnant vegetation exists on the western margin of the Suez facility which is managed under the facilities' conditions of consent.

The vegetation is mapped as PCT 835 Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats intact and PCT 849 - Grey Box - Forest Red Gum grassy woodland on flats - Scattered Trees on the spatial viewer.

Survey of this site was incorporated into the survey strategy to:

- confirm that the habitat was not suitable for the subject species,
- check habitat because suitable habitat is mapped as occurring proximally, and to
- facilitate over the fence inspection of adjoining properties mapped as containing the suitable habitat and where access was not granted.

Photo 106: Intergrading vegetation between PCT 849 and PCT835 between the Suez facility and Badgery's Creek.

Understorey species noted at the site included *Melaleuca decora*, *Bursaria spinosa*, *Einadia hastata*, and *Hibbertia aspera*, with a relatively dense grassy and herbaceous layer.

This is not suitable habitat for *Hibbertia puberula.*

Photo 107: Mown mixed native / exotic grassland/herbland at edge of the Suez western access road.

A diverse derived grassland herbland exists at the interface of the remnant vegetation on the SUEZ site. Weeping Meadow Grass (*Microlaena stipoides*) is the dominant grass with common herbaceous species such as *Brunoniella australis*, *Goodenia hederacea, Caesia parviflora, Cheilanthes sieberi, Commelina cyanea, Dichondra repens, Lomandra filiformis, Oxalis perennans, Lobelia purpurascens, Tricoryne simplex, Veronica plebeia,* and *Wahlenbergia gracilis* noted.

Lot DP860456 South of Suez, Elizabeth Drive, Kemps Creek.

Inspection of Lot DP860456 was not granted. The area has been excluded from the certification area due to pending investigations.

The determination of potential habitat occurring on Lot DP860456 was therefore based on the information contained within the spatial viewer and google earth imagery. Drive-by inspection was constrained by the high volume of trucks entering and exiting the site and the adjoining Suez approved facility. There is a moderate probability that the species occurred there, as the spatial viewer identifies the area to have contained both PCT 725 and 724. Lot 4 is now mostly cleared and under investigation, with high volumes of fill emplacement being observe adjacent Elizabeth Drive and the Suez facility 1.

Photo 108: Lot DP860456 viewed from Elizabeth Drive, Google Earth image taken prior to clearing.

Photo 109: Fill batter at northern end of Lot DP860456, South of Suez facility.

Note: This area is identified as not to be certified, area under Investigation. Photo taken through fence from the adjoining SUEZ facility.

Photo 110: Lot 4 DP860456 showing moist swale in the central portion of image prior to clearance and fill emplacement.

Photo 111. Google Earth Imagery 31/10/2018 Lot 4 DP860456 showing high volume of fill emplacement across most of the site. A small area remains providing some habitat potential.

Cross and Western Streets, Kemps Creek

This area of bushland between Cross Street, Western Street and Elizabeth Drive, and adjacent to the Bill Anderson Park, was included within the survey for this assessment as a surrogate site, as the presence of threatened taxa here is well documented and the site has previously been assessed by CFFIS in 2002 and NPWS *Dillwynia tenuifolia* survey CFFIS 2001.

This current survey revealed significant decline of the apparent population of all recorded threatened species. It is likely in most cases to be attributable to the fire regime in combination with drought. Areas were noted to be impacted by anthropogenic factors, mostly in association with illegal dumping of waste including asbestos and other rubbish requiring remediation. This has resulted in the bulldozing of tracks which facilitates the spread of invasive weed species through the displacement of weed seed infected soils and the infilling of minor habitat swales which previously supported *Grevillea parviflora*.

Despite the signage the area is poorly managed and is an example demonstrating that non-clearance is not protection without fencing and appropriately allocated management funds. The site requires selective management burns, but this should be avoided until the site is fully secured by barriers to exclude indiscriminate access by rubbish dumpers.

Photo 112: Bushland remnant at Cross Street Kemps Creek, adjacent to Bill Anderson Park.

Photo 113: Suppressed understorey under canopy at Cross Street bushland.

Photo 114: Cross Street bushland showing track bulldozed to remove dumped asbestos.

Photo 115: Disturbed bushland verge adjacent Bill Anderson Park.

Note scattered occurrences of *Dillwynia tenuifolia* and assorted indigenous grasses and forbs. The invasive *Eragrostis curvula* is common along the bushland margin and is a serious threat to the biodiversity of the remnant.

Photo 116: Chronic rubbish dumping in bushland on the verge, Western Street, Kemps Creek

Photo 117: Chronic rubbish dumping in bushland on the verge, Western Street, Kemps Creek

Jamisontown Vicinity, Huntington Reserve and fields in the area

During the course of the field survey many areas were traversed by car to the designated target survey locations. Targeted ‘drive-by’ assessments were selected on route to sample both identified PCTs and unidentified derived habitats in light of the high diversity of species located under the powerline easement adjacent to the Wianamatta Regional Park. An example of such an area is in the Jamisontown vicinity.

Review of Google Earth Imagery identified areas proposed for future urban development in the Jamisontown vicinity that appeared to have the prospects of derived native grassland habitat east of Tench Avenue and east and west of Blaikie Road. ‘Drive-by’ assessment revealed the area to be unsuitable habitat for *Hibbertia puberula* (refer photos 118 and 119). Dense swathes of exotic grasses and/or herbaceous species dominate the majority of the landscape. Some areas contain wetland and riparian values.

Photo 118: View from Tench Avenue looking east toward Blaikie Road.

Note: area appears to be dominated by a nutrified exotic grassland herbland, unsuitable habitat.

Photo 119: Fields in Tench and Blaikie Roads, Jamisontown.

Note: left photo looking south east toward Anakai Drive, dense swathes of exotic vegetation blanket the landscape. Right photo, exotic weeds dominate the area adjacent to the wetland habitat along School House Creek. Unsuitable habitat for *Hibbertia*.

4.5.2 DETERMINATION OF SPECIES POLYGONS

Based on the available vegetation mapping, site survey and knowledge of the species habitat requirements, the following maps show the polygons of likely habitat and the estimated probability for the species to occur.

Hibbertia puberula subsp. *puberula* was found to be present within the powerline easement, coloured yellow on map 11. This area is outside the footprint.

Areas shown in dark orange on Map 16 are in the proposed transport corridor through the Park, and in the proposed transport corridor to the north of Captain Cook Drive. There is moderate probability for the species to occur here. Areas of the regional park adjacent to the footprint and in the southeastern section also have moderate probability for the species.

In the eastern end of the northern corridor there are sections with low probability.

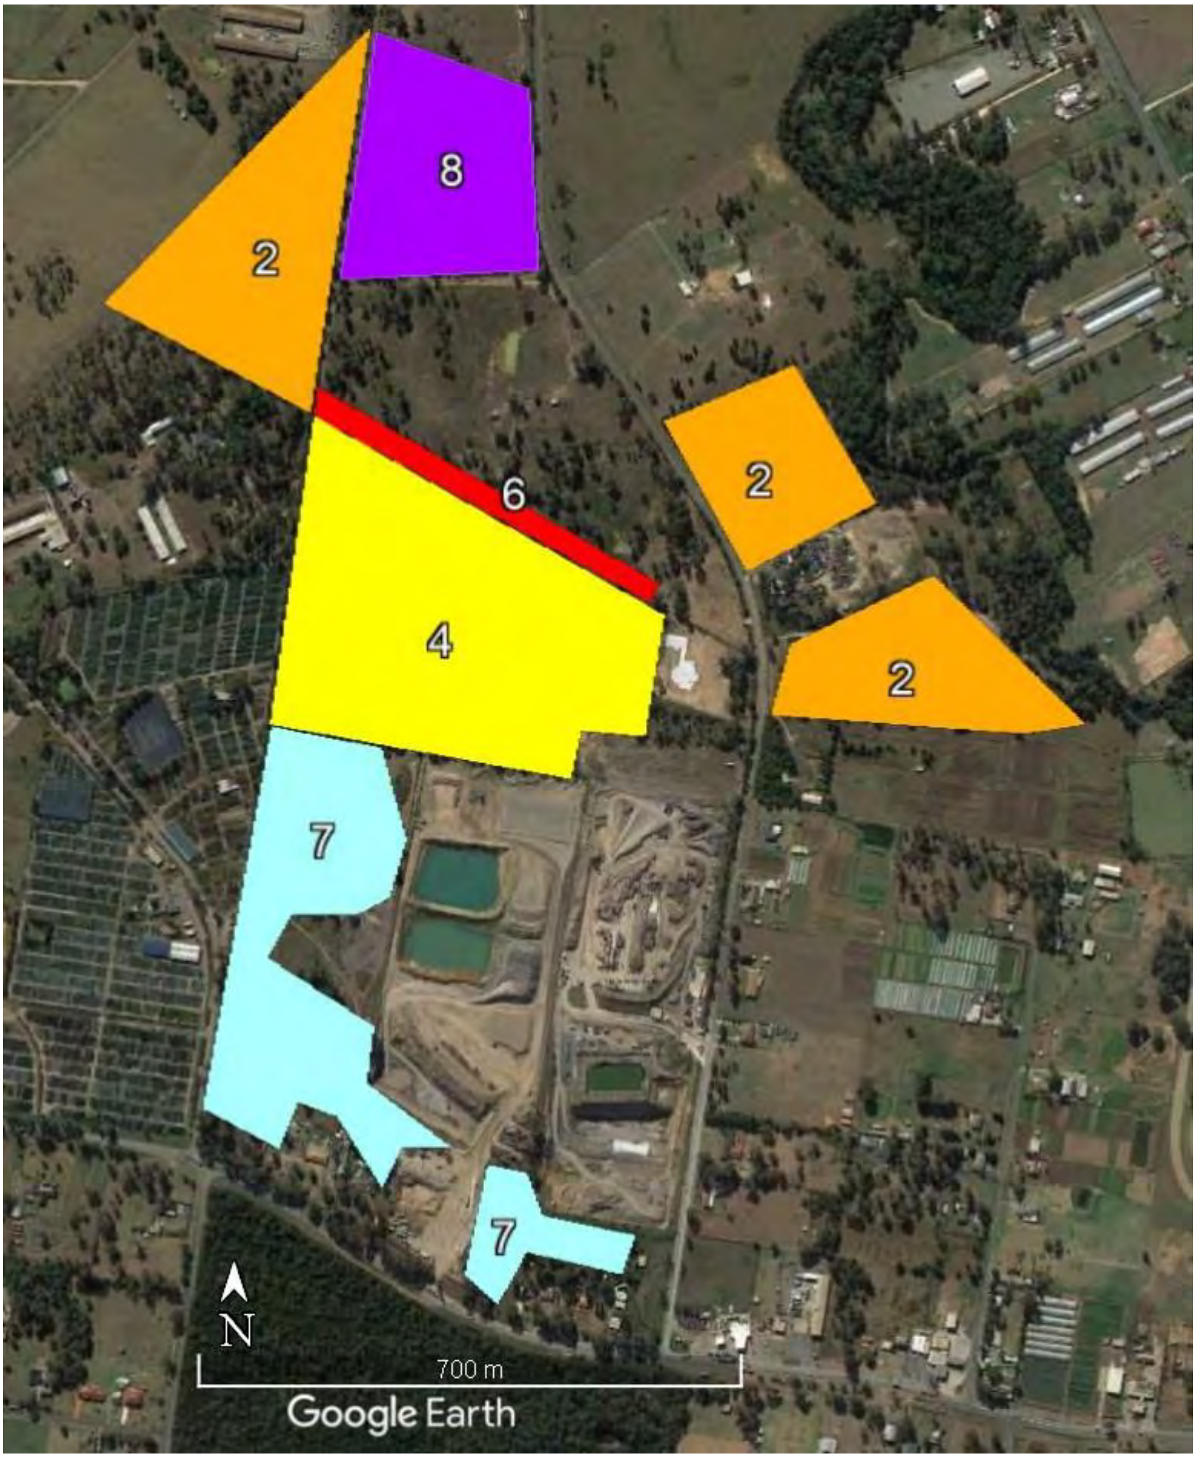
Map 16: Wianamatta Regional Park potential habitat sites.

Key:
In footprint, moderate probability for the species – dark orange - 1
Proximate to the footprint, moderate probability for the species – pale orange - 2
In the footprint, low probability for the species – olive green - 3
Proximate to the footprint, species known to be present – yellow - 4

Map 17: Ropes Creek area potential habitat sites.

Map 18: Shepherd Street Colyton vicinity potential habitat site.

Key: Areas are outside the footprint, low probability of occurrence - peach colour - 5



Map 19. Kemps Creek area potential habitat sites.

Key:

Removed from certification area, species known to be present – red - 6

Proximate to the footprint, species known to be present – yellow - 4

Proximate to the footprint, species moderate probability – pale orange - 2

Proximate to the footprint, species low probability – pale blue - 7

Proximate to the footprint, moderate probability prior to clearing – purple - 8

Map 20: Partially cleared block south of SUEZ landfill site.
Key: Adjacent footprint, moderate probability prior to clearing – purple - 8

4.5.3 ESTIMATE OF AREA OF HABITAT

Greater Penrith to Eastern Creek Urban Release Investigation Area

Wianamatta Regional Park and northern corridor

In footprint, moderate probability, 34 ha.

In footprint, low probability, 3.5 ha.

Proximate to the footprint, moderate probability, 77 ha.

Powerline easement adjacent Wianamatta Regional Park

Outside footprint, species is present, 4 ha.

Ropes Creek vicinity

Outside footprint, low probability, 10 ha.

Colyton vicinity

Outside footprint, low probability, 1.1 ha.

Western Sydney Aerotropolis Growth Area

Kemps Creek area

Removed from certification area, species is present, 1.47 ha

Proximate to the footprint, species is present, 14.4 ha

Proximate to the footprint, moderate potential, 15.6

Proximate to the footprint, low potential, 10.25 ha

Proximate to the footprint, moderate potential prior to clearing, 6.25 ha.

South of SUEZ landfill

Proximate to the footprint, moderate potential prior to clearing, 4.4 ha.

In summary, a total of 37.5 ha of potential habitat for the species lies within the transport corridor.

A further 20 ha where the species is known to be present, and 125 ha of potential habitat, are located within the growth area proximate to potential development and are therefore at risk of edge effects and anthropogenic impacts.

5. Information used in the assessment

Information used in this assessment includes taxonomic papers, BioNet and ALA records of the target species, Critically Endangered Listing, online Threatened Species profile and associated documents, personal observations and site inspections, and the spatial viewer including the layers: survey access and coverage, (BAM plots, polygons and transects), PGA layer and geology and soils.

Employment Record

1993 - present

Cumberland Flora and Fauna Interpretive Services

Principal - flora surveys, plant identifications, vegetation assessment, project impact assessment, bush regeneration, rehabilitation, habitat enhancement, seed collection and propagation services.

1990 - 1997 **Sylvan Grove Native Gardens**

Curator of gardens and adjoining bushland - maintenance of and improvement to the plant collection, training and supervision of staff, liaison with other botanic gardens, guided tours, technical advice.

1982 - 1990 **Sylvan Grove Native Gardens**

Horticulturist Specialising in Australian Flora - collection, propagation, identification, and growing of native plants.

CUMBERLAND FLORA & FAUNA INTERPRETIVE SERVICES INFORMATION AND RELEVANT EXPERIENCE

Cumberland Flora and Fauna Interpretive Services have provided technical expertise since 1993 to numerous clients including Local Government, NSW Roads and Maritime, NSW Office Environment Heritage NPWS and community groups. Following is a list of some of our projects and clients:

REPORT	CLIENT
Expert advice for Conservation Assessment of *Solanum celatum* Eren Delgado 16/04/2018, Science Division, NSW Office of Environment and Heritage	OEH
Saving our Species (SoS) project for *Pomaderris adnata* a post fire population census Grid D 2018	OEH
Provision of expert advice to update the current ecological data for southern NSW threatened flora species, as part of the review of biodiversity assessments under the Biodiversity Conservation Act 2016.	OEH

REPORT	**CLIENT**
Expert witness in botany Residents Against Intermodal Development Moorebank Incorporated v NSW Minister for Planning and Anor – NSW Land & Environment Court Class 1 Proceedings No. 2017/81889. Review of project documentation, in particular the various biodiversity assessments including the BAM assessment for the project and Individual Expert Witness report of Dr David Robertson 15 October 2017; Site inspections to identify the location of and/or potential habitat for *Hibbertia fumana*, *Hibbertia puberula*, *Grevillea parviflora*, *Persoonia nutans*, *Acacia bynoeana*, provision of an expert report in accordance with Division 2 of Part 31 of the UCPR; confer with the other parties experts at a joint conference and produce a joint expert report; and f appear at the section 34 conciliation conference	EDO
Saving our Species (SoS) project for *Pomaderris adnata* a population census 2017	OEH
Central Coast Creek Monitoring Evaluating and Reporting 2016 – Vegetation Consultant	OEH
Great Lakes Creek Monitoring Evaluating and Reporting 2016 – Vegetation Consultant	OEH
Northern Beaches Creek Monitoring Evaluating and Reporting 2016 – Vegetation Consultant	OEH
Northern Beaches Creek Monitoring Evaluating and Reporting 2015 – Vegetation Consultant	OEH
Clarence Colliery Discharge Investigation April 2015	OEH
Vegetation Assessment as part of the Lachlan Wetlands Condition Assessment Project October 2013 – May 2014	Lachlan Catchment Management Authority
Field expertise and guidance in the Sydney basin to PhD candidate Karen Muscat studying the molecular phylogenetics and morphology of the genus Dianella with close scrutiny of the variation in the D. *caerulea* group of species in eastern Australia	Volunteer to University of Melbourne
Survey for *Pomaderris adnata* to determine population size, structure, occupancy and threats 2014	NPWS Illawarra Region
Survey of *Hibbertia stricta* subsp. *furcatula* (Hibbertia species ‘Menai’) to determine population size, structure, occupancy and threats. Collection of voucher herbarium material for taxonomic review June 2014	OEH
Survey of the southern populations of *Hibbertia stricta* subsp. *furcatula* (Hibbertia species ‘Menai’) to determine population size, structure, occupancy and threats May 2014	OEH

Ongoing research projects:

Private taxonomic research into the Australian plant genera *Prostanthera*, *Westringia*, *Dianella*, *Thelionema*, *Viola* and *Hibbertia*.

Private research into the invertebrate fauna of the Illawarra with particular emphasis on the Mayfly genus *Atalophlebia*

Flora of Bankstown" a botanical inventory

Botanical inventories of the Sublime Point and Maddens Plains precincts in the Illawarra Escarpment State Conservation Area

Other Publications & Reports

Miller, R.T. (1984 to 2006) numerous papers for the Prostanthera and Westringia Study Group Newsletters.

Miller, R.T. (1991) Vegetation Consultant on Eloura Nature Reserve Vegetation Survey: Report to Liverpool City Council, Greening Australia.

Miller, R.T. Vegetation Consultant on Salt Pan Creek Stage 1 Vegetation Survey: Report to Bankstown City Council, Ian Olsen.

Gibson, C.P. & Miller, R.T. Plant Species List for Bankstown's Natural Heritage: McLaughlin, L., BCC.

Gibson, C.P. & Miller, R.T. Flora of Bankstown Scientific Inventory of Botanical Heritage: Report to Australian National Parks and Wildlife Service, Gibson, C.P. and Miller, R.T. (in preparation).

Nomination of *Prostanthera saxicola* R. Br. s. str. As an Endangered Species under the NSW TSC Act November 2011

Special Projects

- "Flora of Bankstown" a botanical inventory
- Founder & Convener Cookson's Landcare Group Bulli (2003 – 2007)
- President, Society for Growing Australian Plants, East Hills Region, 1987-1995.

- Vice President, Society for Growing Australian Plants, East Hills Region, 1996.
- Plant Steward, Society for Growing Australian Plants, East Hills Region, 1987-1996.
- Leader of the Prostanthera Study Group Australian Plant Society, 1992 - 2010.
- Editor and publisher of Prostanthera & Westringia Study Group's Newsletter *The National Mint* and the Study Groups' Journal – *Lasianthos*.
- Vice President and Founding Member, Bankstown Bushland Society.
- Coordinator Grants Application, Bankstown Bushland Society.
- Bushland Regeneration Grants Project Manager, Bankstown Bushland Society:

- Deverall Park Restoration and Rehabilitation Swamp Woodland ($17,880).
- The Crest of Bankstown Restoration and Rehabilitation ($27,850).
- Airport and Ashford Reserves Restoration and Rehabilitation Swamp Woodland ($45,000).

- Co-recipient of Save the Bush grant for Flora of Bankstown by Hon. Ross Kelly, Minister for Arts, Sports and Environment, 1992-93 ($11,050).
- Founding Member of Illawarra Grevillea Park, Bulli.
- Curator, Lamiaceae collection, Illawarra Grevillea Park, Bulli.
- Former Bankstown City Council's Bushfire Taskforce Community Representative.
- Former presenter of an adult education course in gardening at Bankstown Evening College.
- Development and curation of a private regional herbarium.
- Expert Witness for NSW Police murder trial
- Former appointee as Trustee of the Georges River State Recreational Trust by the Minister for the Environment (the Hon. Tim Moore).

Appendix 2. *Hibbertia puberula* subs. *puberula* collection records 2018

CUMBERLAND FLORA & FAUNA INTERPRETIVE SERVICES

FAMILY: Dilleniaceae

GENUS: *Hibbertia*

SPECIES: *puberula*

DET.: Robert T. Miller

COLLECTOR(s): Robert T. Miller & Jan Miller

DATE: 28/10/2018 **COLLECTING No.**

LOCALITY: -33.681349 150.715089 Opposite the intersection of Smeeton, Taylor and Nutt Roads in bushland Londonderry NSW 2753. North of Fire Trail

HABITAT: PCT No: 883 Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion Castlereagh Scribbly Gum Woodland

HABIT: small sprawling subshrub with occasional +/- semierect wiry branches arising from a rootstock.

NOTES: Localised in heath patch of *Banksia spinulosa*, *Grevillea mucronulata*, *Philotheca salsolifolia*, *Acacia bynoeana*, *Patersonia sericea*, *Cyathochaeta diandra* etc., within *Eucalyptus sclerophylla Angophora bakeri* Woodland

CUMBERLAND FLORA & FAUNA INTERPRETIVE SERVICES

FAMILY: Dilleniaceae

GENUS: *Hibbertia*

SPECIES: *puberula*

DET.: Robert T. Miller

COLLECTOR(s): Robert T. Miller & Jan Miller

DATE: 28/10/2018 **COLLECTING No.**

LOCALITY: -33.681753 150.716233 Bushland verge Southern Corner Smeeton, Taylor and Nutt Roads bushland Londonderry NSW 2753

HABITAT: PCT No: 883 Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion Castlereagh Scribbly Gum Woodland

HABIT: small sprawling subshrub with occasional +/- semierect wiry branches arising from a rootstock.

NOTES: Disturbed road verge / bushland from recent road works with weedy fill dumping

2 plants noted – population size unknown

CUMBERLAND FLORA & FAUNA INTERPRETIVE SERVICES

FAMILY: Dilleniaceae

GENUS: *Hibbertia*

SPECIES: *puberula*

DET.: Robert T. Miller

COLLECTOR(s): Robert T. Miller, Jan Miller & Stephanie Clark

DATE: 1/11/2018 **COLLECTING No.**

LOCALITY: Castlereagh Nature Reserve Powerline Trail vicinity. Opposite the intersection of The Northern Road and Whitegates Road, Berkshire Park. South of North Trail along unnamed track.

-33.671177 150.753032 -33.672284 150.75167 -33.671676 150.75272

HABITAT: Mapped PCT No: 883 Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion Castlereagh Scribbly Gum Woodland

Associated species: *Eucalyptus sclerophylla, Corymbia gummifera*, *Eucalyptus sideroxylon*, *Allocasuarina littoralis*, *Kunzea ambigua*, *Hakea sericea*, *Bossiaea rhombifolia, Micromyrtus minutiflora, Dillwynia tenuifolia*, *Petrophile* sp., *Brachyloma daphnoides*, *Dillwynia tenuifolia*, *Styphelia laeta*, *Dianella revoluta*, *Patersonia sericea*, *Goodenia hederacea*, *Entolasia stricta* etc.

HABIT: small sprawling subshrub with occasional +/- semierect wiry branches arising from a rootstock.

NOTES: Disturbed bushland from historic laterite extraction – extensive laterite deposits observed in the general vicinity

30 plants noted

CUMBERLAND FLORA & FAUNA INTERPRETIVE SERVICES

HABITAT: Derived shrubland/grassland/herbland – unmapped significant vegetation with many threatened species adjoining open forest Mapped as PCT 725 Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion

Associated species: *Allocasuarina littoralis, Melaleuca decora, Leptospermum parvifolium*, *Melaleuca nodosa*, *Grevillea mucronulata*, *Pimelea linifolia*, *Micromyrtus minutiflora*, *Dillwynia tenuifolia*, *Pultenaea parviflora*, *Hibbertia pedunculata*, *H. diffusa*, *Brachyloma daphnoides*, *Dodonaea falcata*, *Lissanthe strigosa*, *Acacia elongata*, *A. ulicifolia*, *Astroloma humifusum*, *Patersonia sericea*, *Phyllanthus hirtellus*, *Gompholobium* sp., *Pomax umbellata*, *Dianella revoluta*, *Lomandra multiflora*, *Lepidosperma laterale*, etc.

HABIT: small sprawling subshrub with occasional +/- semierect wiry branches arising from a rootstock.

NOTES: 15+ plants noted in two patches. These are additional patches from the one patch observed on the 29/10/18 brief inspection. Mostly nonflowering with petal dehiscence near complete 12.38

CUMBERLAND FLORA & FAUNA INTERPRETIVE SERVICES

FAMILY: Dilleniaceae

GENUS: *Hibbertia*

SPECIES: *puberula*

DET.: Robert T. Miller

COLLECTOR(s): Robert T. Miller, Jan Miller & Steve Douglas

DATE: 9/11/2018 **COLLECTING No.**

LOCALITY: TreeServe property: Lot 3 DP 812284, 90 Clifton Avenue Kemps Creek

HABITAT: Derived shrubland/grassland at verge of extensive fill mound growing on disturbed soil with laterite nodules often intertwined with *Dillwynia tenuifolia*.

Remnant trees observed in the general vicinity include *Eucalyptus sclerophylla*, *E. fibrosa*,

E. eugenioides, *E. longifolia* and *E. tereticornis.*

Large shrubs: *Allocasuarina littoralis, Melaleuca decora, Melaleuca nodosa*.

Three additional threatened species were noted: *Dillwynia tenuifolia* (common), *Pultenaea parviflora* and *Persoonia nutans* (1 plant).

HABIT: small sprawling subshrub with occasional +/- semierect wiry branches arising from a rootstock.

NOTES: 20+ plants noted. Mostly +/- finished flowering with petal dehiscence near complete at 11 AM.

Two additional plants observed trough the fence within the adjacent property to the south.

Appendix 3. *Hibbertia puberula* subs. *puberula* collection records 2007

Field notes compiled by Miller and Miller & Gibson

Site: Lucas Heights Site 1 16/10/07

Abundance: extremely localised, rare < 12 plants noted.

Field notes: Lucas Heights Soil Landscape, Gentle plateau slope, skeletal soil above first sandstone outcropping +/- intermittent seepage zone. Vegetation sparse and stunted probably from the impact of drought and fire episode > 2 years. All *Hibbertia* appeared to be seedlings at this locale. Open Woodland / heath – Canopy: *Eucalyptus haemastoma*? and Stringybark species. Associated understorey: *Banksia ericifolia, B. oblongifolia, Leptospermum arachnoides, Grevillea sericea, Xanthorrhoea* sp., *Cyathochaeta diandra, Burchardia umbellata, Hypoxis hygrometrica*.

Site: Simmos Beach Recreation Reserve Macquarie Fields, Habitat 1 Ridgetop Laterite

Field notes: Very disturbed site (past trailbike/FWD and possible laterite extraction but now protected and regenerating. Open Woodland/Laterite Heath: *Eucalyptus punctata.* Associated understorey species: *Exocarpos cupressiformis, Goodenia hederacea, Pomax umbellata, Brachyloma daphnoides, Patersonia sericea, Gompholobium minus, Leptospermum parvifolium, Kunzea ambigua, Persoonia laurina, Micrantheum ericoides.*

Site: Simmos Beach Recreation Reserve Macquarie Fields, Habitat 2 Easterly Plateau slope above Georges River

Abundance: Very localised but locally common c. 20 plants noted.

Field notes: Soil: fine sand with clay component, undisturbed habitat, walking track only. Habit: compact wiry shrub 30-60cm wide with many lax stems arising from a rootstock. In Open Woodland. *Eucalyptus sclerophylla? E. punctata, Angophora bakeri*. Associated understorey: *Melaleuca nodosa, Lambertia formosa, Leptospermum trinervium, Callistemon linearis, Kunzea ambigua, Kunzea capitata, Coronidium oxylepis, Xanthorrhoea sp., Stipa pubescens, Themeda australis*.

Site: Simmos Beach Recreation Reserve Macquarie Fields, Habitat 3 Upperslope/headwaters of upper drainage line.

Field notes: Undisturbed. *Eucalyptus punctata, E. sclerophylla*? and *Angophora bakeri*. Associated understorey: *Kunzea ambigua, Melaleuca nodosa, Gompholobium minus, Isopogon anemonifolius, Leucopogon, Kunzea capitata, Xanthorrhoea* sp. Dominated by *Kunzea* and *Melaleuca nodosa*.

Site: Simmos Beach Recreation Reserve Macquarie Fields, Habitat 4 Laterite Ridgetop.

Field notes: *Angophora bakeri. Leptospermum parvifolium* (dominates), *Kunzea ambigua, Petrophile sessilis, Micrantheum ericoides, Kunzea capitata, Lambertia formosa, Pimelea linifolia, Stipa pubescens*.

Site: Keith Longhurst Reserve (formerly The Basin Reserve) Georges River Road Kentlyn Habitat 1: Lateritic Heath

Field notes: *Eucalyptus* sp. (Stringybark), *E. squamosa, Allocasuarina littoralis, Angophora hispida*. Associated understorey*: Leptospermum trinervium* (narrow-leaved form), *Petrophile sessilis, Persoonia lanceolata, Isopogon anemonifolius, Hakea laevipes, H. sericea, Grevillea diffusa, Actinotus minor, Cyathochaeta diandra, Entolasia stricta, Caustis flexuous*.

Site: Keith Longhurst Reserve (formerly The Basin Reserve) Georges River Road Kentlyn Habitat 2: Lateritic Heath

Field notes: Soil very fine sandy loam. Habit: low +/- prostrate shrub sprawling through sedges. *Angophora hispida, Corymbia gummifera, Allocasuarina littoralis*. Associated understorey: *Leptospermum trinervium* (narrow-leaved form), *Petrophile sessilis, Persoonia lanceolata, Pultenaea elliptica, Isopogon anemonifolius, Banksia spinulosa, Grevillea diffusa, Actinotus minor, Cyathochaeta diandra, Entolasia stricta*.

Site: Keith Longhurst Reserve (formerly The Basin Reserve) Georges River Road Kentlyn Habitat 3

Field notes: Soil sandy loam with small sandstone outcroppings. Open Forest *Eucalyptus punctata*, E. sp. (Stringybark), and *Corymbia gummifera.* Associated understorey: *Hakea laevipes, Leptospermum parvifolium, Isopogon anemonifolius, Lissanthe strigosa, Grevillea diffusa, Hakea sericea, Acacia linifolia, Themeda australis, Lomandra obliqua, Lomandra cylindrica, Cyathochaeta diandra*.

Site: Keith Longhurst Reserve (formerly The Basin Reserve) Georges River Road Kentlyn Habitat 4

Field notes: Soil: fine sandy loam scattered lateritic fragments. Open Forest with grassy and herbaceous understorey comprised of *Eucalyptus punctata*, E. sp. (Stringybark), and *Corymbia gummifera.* Associated understorey: *Leptospermum parvifolium, Isopogon anemonifolius, Lissanthe strigosa, Grevillea diffusa, Goodenia hederacea, Stipa pubescens, Themeda australis, Entolasia stricta, Hypoxis hygrometrica, Hovea linearis, Cryptandra* sp., *Lobelia dentata, Patersonia sericea, Cyathochaeta diandra* and *Xanthorrhoea* sp.

Site: Peter Meadows Reserve Old Kent Road Kentlyn

Field notes: Soil: sandy, lateritic. Lateritic Ridgetop Heath *Eucalyptus sclerophylla, E. squamosa, Angophora hispida* heath. Lateritic Ridgetop Heath /Woodland interface: *Eucalyptus sclerophylla, E. punctata, Angophora hispida*. Associated understorey species: *Petrophile sessilis, Lambertia formosa, Kunzea capitata, Leptospermum arachnoides, Brachyloma daphnoides, Hakea laevipes, Xanthorrhoea sp., Actinotus minor, Pultenaea elliptica, Hakea sericea, Gompholobium minus, Goodenia hederacea* and *Entolasia stricta*.

Site: Freres Crossing Reserve, Freres Road Kentlyn 2/11/07, Ridgetop slopes

Field notes: *Eucalyptus punctata, Syncarpia glomulifera* Associated understorey: *Hakea laevipes, Persoonia linearis, Leptospermum trinervium, Isopogon anemonifolius, Gompholobium minus,* *Acacia terminalis, Gonocarpus tetragynus, Brachyloma daphnoides, Eriostemon australis, Grevillea diffusa, Hibbertia diffusa, Hypoxis hygrometrica, Xanthorrhoea* sp.*, Themeda australis, Lomandra obliqua, Entolasia stricta.*

Site: Freres Crossing Reserve, Freres Road Kentlyn 2/11/07, Ridgetop

Field notes: *Eucalyptus punctata, Angophora costata*, Stringybark sp. Associated understorey*: Allocasuarina littoralis, Kunzea ambigua, Acacia terminalis, Brachyloma daphnoides, Hypoxis hygrometrica, Themeda australis* and *Stipa pubescens*.

Site: Ella Avenue Barden Ridge (formerly Lucas Heights) 20/11/07 Below Detention Basin

Field notes: Localised in drainage line. Site impacted by housing development – weed invasion occurring due to urban runoff and sedimentation. *Eucalyptus punctata*, E. sp. (Stringybark), *E. haemastoma, Corymbia gummifera, Angophora hispida*. Associated understorey: *Hakea sericea, Banksia oblongifolia, Leptospermum polygalifolia, L. arachnoides, Lambertia formosa, Kunzea ambigua, Grevillea sericea, Epacris pulchella, Banksia spinulosus, B. marginata, Isopogon anemonifolius, Hakea laevipes, Phyllota phylicoides, Actinotus minor, Patersonia sericea, Xanthorrhoea resinosa, Stipa pubescens, Xanthosia tridentata, Lomandra obliqua, Cyathochaeta diandra, Lepyrodia scariosa, Schoenus brevifolius, Lindsaea linearis*.

Site: Ella Avenue Barden Ridge (formerly Lucas Heights) 20/11/07 Downslope of Detention Basin

Field notes: Scattered through sedges - relatively rare at edge of wet heath/swamp. *Eucalyptus haemastoma*, E. sp. (stringybark), *E. punctata*. Associated understorey: Sedges dominate understorey: *Leptocarpus tenax, Schoenus brevifolius, Xanthorrhoea resinosa, Leptospermum polygalifolia, Banksia oblongifolia, Actinotus minor, Dampiera stricta, Epacris pulchella, Entolasia stricta, Deyeuxia decipiens.*

Site: Little Forest Lucas Heights 20/11/07

Field notes: Soil: fine sandy loam with clay content, +/- impeded drainage, Lucas Heights Soil Landscape, Localised in narrow zone in upper drainage line. *Eucalyptus oblonga, E. haemastoma, Corymbia gummifera, Angophora hispida.* Associated understorey: *Callistemon citrinus, Banksia oblongifolia, Leptospermum polygalifolia, L. arachnoides, Lambertia formosa, Kunzea ambigua, Grevillea diffusa, G. sericea, Melaleuca thymifolia, Callistemon linearis, Hakea sericea, H. teretifolia, Acacia linifolia, Mirbelia rubiifolia, Actinotus minor, Patersonia sericea, Xanthorrhoea resinosa, Stipa pubescens, Xanthosia tridentata, Lomandra obliqua, Cyathochaeta diandra, Schoenus brevifolius*.

Site: Voyager Point Adjacent Old Single Mens Quarters

Field notes: Soil: Fine sand atop of lateritic gravels – Surface layer -Well drained, Aspect: easterly Slope: 0-2. Open Woodland: *Eucalyptus sclerophylla, E. parramattensis, Angophora bakeri*. Understorey diverse open to moderately dense with well-developed ground layer. Dominant Associated Shrub Species: *Melaleuca nodosa, Petrophile sessilis, Leptospermum parvifolium, L.*

trinervium, Banksia spinulosa, Hakea laevipes, Kunzea ambigua, Persoonia lanceolata, Callistemon linearis, Hakea sericea, Acacia brownii, Daviesia acicularis. Dominant Associated Ground Layer Species: *Platysace ericoides, Hovea linearis, Lomandra obliqua, Lepyrodia scariosa, Austrostipa pubescens, Austrodanthonia tenuior, Cyathochaeta diandra*.

Site: Voyager Point adjacent Sirius Drive

Field notes: Soil: Fine sand and laterite – Surface layer -Well drained. Aspect northerly slope 0-2. Open Woodland: *Eucalyptus sclerophylla, Angophora bakeri* and *Eucalyptus oblonga*. Understorey diverse, open to moderately dense with well-developed ground layer. Dominant Associated Shrub Species: *Petrophile sessilis, Leptospermum trinervium, Banksia spinulosa, Babingtonia densiflora, Brachyloma daphnoides, Kunzea ambigua, Persoonia levis, Grevillea sericea, Hakea sericea, Isopogon anemonifolius, Melaleuca nodosa, Lambertia formosa, Philotheca scaber, Styphelia laeta.* Dominant Associated Ground Layer Species: *Platysace ericoides, Dianella revoluta, Lomandra obliqua, Lepyrodia scariosa, Austrostipa pubescens, Cyathochaeta diandra.*

Site: Yeramba Lagoon 2/1/07 Ridge slopes 1

Field notes: Shelving sandstone terraces. Soil: Sandy loam. Surface layer: Well drained but drainage impeded by sandstone bedrock. Aspect: westerly slope: 5. Open Woodland: *Eucalyptus racemosa, Corymbia gummifera, Eucalyptus oblonga & Angophora bakeri.* Understorey diverse, open grassy site. Dominant Associated Shrub Species: *Petrophile sessilis, Leptospermum polygalifolium, Banksia oblongifolia, B. spinulosa, B. marginata, Kunzea ambigua, Persoonia levis, Grevillea sericea, Hakea sericea, Grevillea sericea, Hakea laevipes, Leptospermum arachnoides, Epacris microphylla, Hibbertia stricta.* Dominant Associated Ground Layer Species: *Actinotus minor, Schoenus moorei, Austrostipa pubescens, Themeda australis, Entolasia stricta, Lomandra multiflora.*

Site: Yeramba Lagoon 2/1/07 Ridge slopes 2

Field notes: Ridge slopes – shelving sandstone terraces. Soil: Sandy loam. Surface layer: Well drained. Aspect: northwest. Slope: 5. Interface between Woodland*: Eucalyptus oblonga, Corymbia gummifera, Eucalyptus punctata* Open Woodland: *Eucalyptus racemosa, Corymbia gummifera, Eucalyptus oblonga & Angophora bakeri.* Understorey diverse and well developed moderately dense. Dominant Associated Shrub Species: *Petrophile sessilis, Leptospermum trinervium, B. marginata, Hibbertia stricta*, *Leucopogon microphyllus, Lambertia formosa, Callistemon linearis, Melaleuca thymifolia, Gompholobium grandiflora, Epacris microphylla, Lasiopetalum ferrugineum.*

Dominant Associated Ground Layer Species: *Themeda australis, Entolasia stricta, Burchardia umbellata*, *Actinotus minor, Lomandra obliqua, Schoenus moorei, Austrostipa pubescens.*

Site: Blackwall 2/1/07 Ridgetop / Plateau

Field notes: Soil: relatively deep sand. Aspect: Northerly Slope: < 2. Open Woodland: *Corymbia gummifera, Eucalyptus racemosa, E. punctata, and E. oblonga.* Understorey diverse. Dominant Associated Shrub Species: *Brachyloma daphnoides, Banksia spinulosa, Petrophile sessilis, Leptospermum trinervium, L. parvifolium, Isopogon anemonifolius, Babingtonia densifolia, Dillwynia* *retorta, Philotheca scabra, Grevillea sericea, Gompholobium glabratum, Xanthorrhoea media, Kunzea ambigua, Bossiaea heterophylla, Acacia myrtifolia.* Dominant Associated Ground Layer Species: *Phyllanthus hirtellus, Pomax umbellata, Austrostipa pubescens, Themeda australis* and *Cyathochaeta diandra.*

Site: Mickeys Point 2/1/07 Ridgetop / Plateau

Field notes: Soil: lateritic. Aspect: North east Slope: < 2. Open Woodland / Heath: *Eucalyptus racemosa, Angophora hispida,* and *Allocasuarina littoralis.* Understorey diverse. Dominant Associated Shrub Species: *Petrophile sessilis, Leptospermum trinervium, Hakea sericea, Persoonia levis, Kunzea ambigua, Styphelia triflora, Isopogon anemonifolius, Brachyloma daphnoides, Babingtonia densifolia, Hemigenia purpurea, Hibbertia stricta*. Dominant Associated Ground Layer Species: *Actinotus minor, Baeckea ramosissima, Poranthera ericoides, Lomandra obliqua, Austrostipa pubescens, Entolasia stricta.*

Strategic Assessment for the Little Eagle *Hieraaetus morphnoides* in the Growth Areas of Greater Macarthur and Wilton

1. Introduction

Purpose

The purpose of this report is to assess the likelihood of occurrence and potential impacts of the urban growth in the Greater Macarthur and Wilton areas on the Little Eagle *Hieraaetus morphnoides*. In particular, this report will assess the presence of breeding and foraging habitat within these growth areas as required under the Biodiversity Assessment Method. It will also discuss conservation measures required to mitigate potential impacts.

The Little Eagle is listed in New South Wales as vulnerable under the *Biodiversity Conservation Conservation Act* 2016 and is an uncommon species found in open forests and woodlands. It shows a preference for areas containing a mosaic of open woodland and open grasslands with scattered trees, but can also be found along timbered watercourses and the edges of forest remnants. Records for this species exist in and around the area to be impacted by the urban development. However, the species is encountered infrequently in this area and its interactions with local habitat have not been well studied.

The existence of potential habitat for the Little Eagle and of records for the species within the area has meant that a more detailed assessment of the likelihood of impacts from the development in the area is required, particularly of the species' potential for foraging and breeding in the area. Targeted surveys could gather this information, but the survey effort required to collect sufficient data would be great and in the order of hundreds of hours in the appropriate seasons over several years. This would also require tracking of individual birds to gather information on foraging, breeding locations and behaviour at nests etc. Access to several potential habitat areas also proved difficult during the survey period. Knowledge of the habitat structure and plant community types (PCTs) that the Eagle has been recorded in within the growth area and of the ecology of the species can be used as a surrogate for this fieldwork.

Project Context

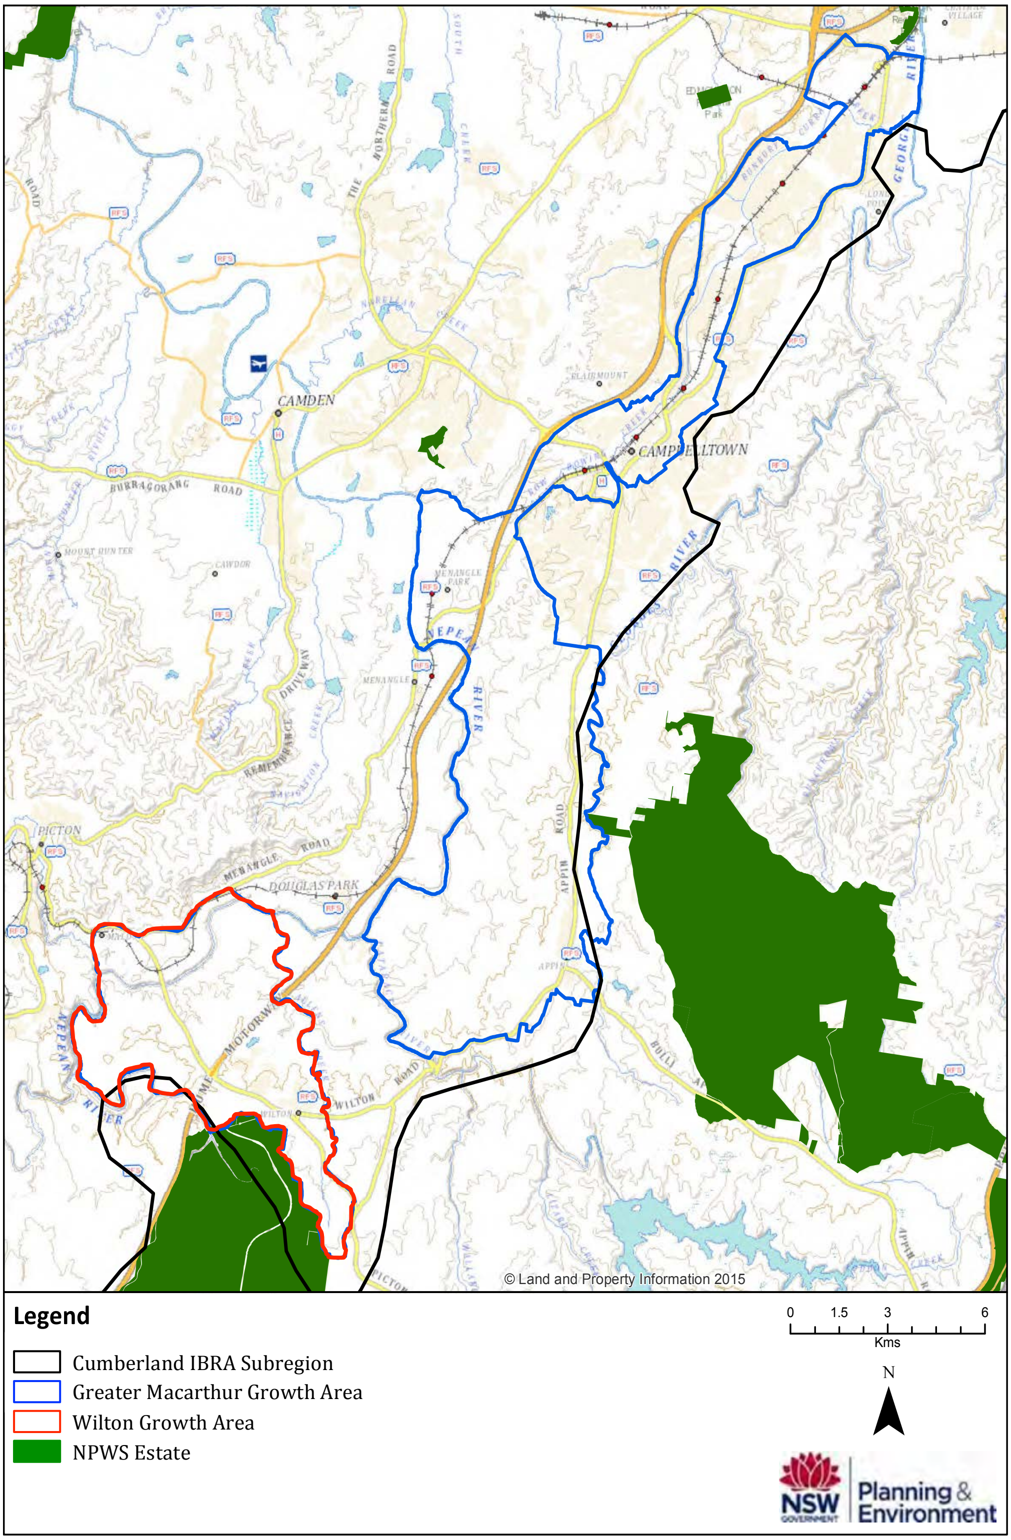
The Department of Planning and Environment is leading a strategic biocertification of several identified growth areas within Western Sydney. The strategic biodiversity assessment is an integral part of the Cumberland Plain Conservation Plan that will determine the impact of urban development on threatened species and ecological communities within these growth areas. The Plan will also provide conservation measures to mitigate any impact, as specified by NSW and Commonwealth environmental legislation.

The timeframe for this project, and difficulties in accessing private lands have resulted in some survey challenges for the project. Only 68% of the potential habitat available for this species in the Wilton and Greater Macarthur Growth Areas has been successfully surveyed. Significant areas of the Greater Macarthur Growth Area were unable to be adequately surveyed due to restrictions around land access. Around 900 hectares of potential habitat was not surveyed within this growth area. In particular PCTs 849 Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion, 850 Grey Box - Forest Red Gum grassy woodland on shale of the Cumberland Plain, Sydney Basin Bioregion and 1395 Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion were unable to be adequately surveyed.

Study Area

The study area is in the Macarthur and Wilton areas, which extend from the southern parts of Liverpool, down to Appin, across to Wilton and then towards the area between Wilton and Picton. The area is within the Cumberland IBRA subregion and the location is shown in Figure 1. The area is bound within a latitude range from -33.88 to -34.33 and a longitude range of 150.55 to 150.97.

Figure 1. Location of Growth Areas and the Cumberland IBRA Subregion.



Survey Methods

Vegetation maps (as supplied by The Department of Planning and Environment NSW) of the Greater-Macarthur Growth Area and the Wilton Growth Area were used to select patches of remnant vegetation that may provide suitable habitat for the Little Eagle. Fifty potential sites were chosen from these maps. Sufficient access was feasible for 40 of these remnants.

The remnants were visited over 4 days from the 18-06-2018 to the 21-06-2018 inclusive. Each site was surveyed for between 0.5 and 1.0 hours. The aim was to collect qualitative data on each of the following:

habitat structure -	tree height range, DBH range, canopy cover, tree maturity, shrub density, grass cover, ground cover
habitat quality -	tree age diversity, shrub layer diversity, presence of woody weeds, evidence of regeneration
connectivity -	degree of connectivity, relative width of corridor to other remnants, presence of gaps in vegetation
aspect and slope -	slope steepness, direction of slope and relationship of site to structural features e.g. watercourses etc.
avian species -	overall diversity, species composition, presence of feral species

The aim was to assess if these sites contained suitable habitat for foraging and breeding and whether they allowed for dispersal of prey and the target species into and out of the remnants. The extent of suitable habitat across the growth areas was then used to estimate the likelihood of the Eagles using the area for foraging and/or breeding.

The Atlas of Living Australia (ALA) and the bird database from the Cumberland Bird Observers Club Inc. (CBOC) were searched for atlas records of the Little Eagle. The records within the Atlas of Living Australia had data mainly from the BioNet Atlas of NSW Wildlife with a few records from un-named individuals contributing directly to the ALA atlas. At the time of access the CBOC bird atlas had over 20,000 survey results for the section of the Cumberland IBRA sub-region that lies within the County of Cumberland. These 2 data sets combined would have captured most of the data on the Eagle for this area.

Justification for Use of an Expert Report

The presence of suitable habitat for foraging and breeding for the Little Eagle combined with the low density for this species and the difficulties with gaining sufficient access for surveys to establish the presence and habitat use by the Eagle in the growth area has meant that survey effort alone has not be able to establish the potential importance of the area for this Eagle.

An expert in the breeding and foraging ecology of the Eagle would be required to assess the importance of the habitat remnants and the likelihood of occurrence within the growth areas. The Eagle is a forest and woodland specialist whose major food in its breeding season is mainly ground foraging mammals, birds and reptiles, although it also takes birds from the tree canopy. Therefore, an expert would also need to also be expert on the avifauna populations occurring in forest and woodland in the Cumberland IBRA Subregion.

The report will address the food resources and foraging space of this raptor as well as the Eagle's potential nest sites and breeding habitat within the growth areas.

Credentials of the Experts Preparing this Report

Dr. Tony Saunders
BSc University of Sydney 1976, PhD University of Western Sydney 2005.

Company Director and Avian Ecologist, Merops Services Pty Ltd 1995 to present.

Relevant experience in surveys and the study of woodland and forest birds of the Cumberland plain:

- Cumberland Plain woodland bird surveys for the NSW Bird Atlas and then for the CBOC Bird Atlas 1982 to the present.
- Cumberland Plain woodland bird surveys on the UWS Hawkesbury Campus 1998 to 2005.
- Woodland bird surveys for Holroyd Council's reserves and parklands 2008 to 2011.
- Survey for threatened woodland birds in proposed urban development of the former ADI site at Penrith 2002.
- Survey for threatened woodland birds in proposed rural subdivision at Badgerys Creek 2006.
- Presented the opening presentation ' Birds of the Cumberland Plain. What was there? What have we lost?' at the ABSA Conference 2016.
- Presented 'Trends in woodland birds of the Cumberland Plain' at the RZS of NSW Conference in 2016.
- Avifauna surveys of sites for development applications and assessment of status of threatened bird species with recommendations for minimising impact of development on these species within the Cumberland Plain and eastern New South Wales. (21 years)
- Bird habitat assessment of managed landscapes and natural habitat areas and recommendations for habitat enhancement and rehabilitation for birds. (21 years)

Relevant publications relating to woodland birds of the Cumberland Plain:

- Saunders, T. (2016). Birds of the Cumberland Plain. What was there? What have we lost? Abstract from ‘Birds of the Cumberland Plain: Past distributions, present studies and the outlook for their future’ Australian Bird Study Association Conference - 23 January 2016. *Corella* **40**: 46.
- Saunders, T. (in prep.). Trends in woodland bird populations in the Cumberland Plain. *Australain Zoologist.*

Dr. Stephen Debus
Bachelor Arts (Biology/Behavioural. Science), Dip. Natural Resources (Wildlife), MSc. (Zoology), PhD (Zoology)

Adjunct associate lecturer/research associate, Zoology University of New England, Armidale. 2004 to present
Senior Ecologist (casual) Eco Logical Australia 2014 to present

Relevant experience in surveys and the study of the Little Eagle *Hieraaetus morphnoides* and of woodland birds:

- Birds of Prey Monitoring project: nest sites and productivity of threatened raptors on the tablelands – field survey and report (Northern Tablelands Local Land Services 2017-18)
- Regent Honeyeater, Swift Parrot, raptor and woodland bird surveys and reporting (North West Local Land Services 2015-18)
- Co-supervising, and finding all 13 Little Eagle nests and sharing the fieldwork for, a UNE Zoology student Honours project near Armidale in 2017 on the breeding habitat and nest-site characteristics of the Eagle (Candice Larkin, B Zool. Hons thesis duly submitted and awarded)

Relevant publications relating to foraging and breeding biology of the Little Eagle *Hieraaetus morphnoides*:

2. Species Information

Species Description

The Little Eagle is a smaller bird than the Wedge-tailed Eagle and about the same size as the Whistling Kite. However, it is more robust than the Whistling Kite with shorter wings and a shorter square-edged tail. It glides and soars on flat wings or slightly raised wings when gaining height. The head is short and broad compared with the Whistling Kite. There is a light morph which is light and dark brown with light rufous underparts. The underwings have a distinctive pale 'M' pattern and the tail is barred (Debus 2012). When observed from underneath they appear to have dark leading and trailing edges to the underwing, compared with the Whistling Kite which only has dark trailing edges to the wing (pers. obs.). The dark morph has a rufous body with slightly darker brown wings, which from the underside appear all dark except for pale inner primaries (Debus 2012).

Life Cycle

Little Eagles will form pairs in breeding territory, but are solitary outside the breeding season (Debus 1993). In New South Wales, nest building or renovation occurs in August, egg laying from August to September, incubation lasts from 37-39 days with hatching from October to December, fledging occurs from December to January and post-fledglings are dependent on adults for 2 or more months after that (Olsen 2014, Olsen et al. 2017, Debus et al. 2007, Debus and Ley 2009, Debus 2011). Banded individuals have been recovered up to 26 years after banding and banding data suggest that birds occupy a home range or wintering range for at least 6-10 years (Debus 2015).

Breeding has been reported during October and November in the Cumberland County from the Royal National Park and Warriewood on the northern beaches of Sydney, but no nests were recorded within the Cumberland Plain (CBOC Atlas accessed 29-06-2018). However, they have bred within the Cumberland Plain at Cobbity in 1978 (Hoskin *et al.* 1991).

Distribution and Abundance

The Little Eagle is endemic to Australia, but is not found in Tasmania (Olsen et al. 1993). The New Guinea form is now a separate species (Debus 2017). The global population is estimated to be a maximum of 80,000 (Debus 2017). It is considered to be resident for at least several consecutive years at nesting sites (Debus et al. 2007, Debus and Ley 2009). It may also be a partial migrant with some movement north in the non-breeding period (Olsen 1995). It is capable of traversing the continent (>2000 km: Debus 2015), and a satellite-tracked breeding male near Canberra wintered in the Top End of the Northern Territory before returning (Dabb 2018).

The Little Eagle is considered moderately common and a partial nomad in New South Wales (Morris et al. 1981). They are found throughout New South Wales, but are more common in the western two-thirds of the state (Cooper et al. 2014). It was rarely noted in lightly timbered country of the Cumberland County prior to the 1950s (Hindwood and McGill 1958) but had become a frequent visitor over the next 30 years (Hoskin 1991). It is often recorded from western Sydney in lightly timbered country away from areas of dense urbanisation (Patrick 2016). It is reported as an uncommon resident of open forest and farmland in the Shoalhaven area and has been reported in the Picton/Wilton area (Chafer *et al.* 1999).

Little Eagles have declined by 14% nationally between the two national bird atlases over an approximately 20-year period (Barrett *et al.* 2003), and declined by 39% in New South Wales over the same period (Barrett *et al.* 2007). The reporting rates in the NSW Bird Atlas declined by 70% since the mid-1980s (Cooper *et al.* 2014).

The CBOC Atlas (accessed 29-06-2018) holds 336 records of the Eagle. Each survey detected mostly a single bird, but sometimes pairs. Four birds, two adults and two fledglings, were recorded in the Royal National Park. Two hundred and seventy nine of the 336 records for the County were recorded from the Cumberland Plain and 35 of those records are from inside the growth areas or within 5 kilometres of the growth area boundaries. The highest reporting rate was 2.2% for the Cumberland Plain for records prior to 1970, but after declining to 0.8% during the 1970s, recovered in the 1990s and the Eagle has been recorded in 1.3% of surveys since the year 2000 (Saunders in prep.).

The declines are thought to be due to loss of woodland habitat (Cooper et al. 2014), disturbance to nests, loss of breeding habitat, urbanisation and high density rural subdivision and subsequent competition for remaining habitat by Wedge-tailed Eagles (Debus et al. 2007, Debus and Ley 2009, Debus 2011, Dabb 2018). Declines in the ACT and NSW may also be due to control of rabbits, which are a major prey item, and the use of Pindone for rabbit control, which possibly affects the predator as well through secondary poisoning from eating baited rabbits (Olsen et al. 2013). Urban encroachment not only affects nesting woodland habitat but also the surrounding open areas used for foraging (Walsh and Beranek 2017) and nesting and foraging areas may become disjunct (ACT Government 2008). They are easily disturbed while nesting (Cupper and Cupper 1981) and will flush from the nest when approached to within 50 to 140 metres (Debus *et al.* 2007).

Breeding density in eastern NSW has been estimated at 1 pair per 1600 hectares in the early 1980s (Debus 1984) and one pair per 2100-3000 hectares since 2000 (Debus 2017). Active nests in eastern NSW are between 2 and 5 kilometres apart and birds will forage up to at least 1.8 kilometres from the nest (Debus 1984, Debus and Ley 2009); average inter-nest distance in contiguous wooded habitat is 3.6 km (Larkin and Debus unpublished data). Walsh and Beranek (2017) found that the Eagles will forage up to 3 kilometres from the nest, which gives a minimum breeding/ foraging territory of 2800 hectares. In the ACT, active nests were on average 5 km apart (Rae *et al.* 2018), and one post-breeding adult male had an elongated foraging range of 6500 hectares, with foraging journeys of 10-20 km, around the outer edge of Canberra (Brawata and Gruber 2016).

Habitat Requirements

Little Eagles prefer open woodland, but are also found along forest edges, timbered watercourses through open country and open grazing country (Hollands 1984, Taylor and Canberra Ornithologists Group 1992, Olsen *et al.* 1993). They hunt over most open habitats and will seek areas where there is a mosaic of treed habitat and open country

(Debus 1993, Cooper et al. 2014). They can also be found in woodland associated with wetlands (Debus 1993, CBOC Atlas accessed 29-06-2018).

They will nest in tall living eucalypts between 5 and 30 metres tall in open forest, woodland, and remnant woodland in farmland (Debus 1993, Debus *et al.* 2007, Debus and Ley 2009). Nests are generally between 13 and 20 metres above ground (Debus 1993, Debus and Ley 2009, T. Saunders pers. obs.). They prefer to nest in dense woodland adjacent to open habitat e.g. grassy woodland for foraging (Debus 1993, Debus and Ley 2009, Debus 2011). Nests are typically in an emergent eucalypt, the tallest in the stand and often with the largest girth, in woodland patches at least 4.8 hectares in size (average 85 ha); mostly within 200 m of an edge; more distant from sealed roads (average 838 m) than gravel roads (average 546 m) than tracks (average 304 m), at least 38 m from the nearest dwelling (average 457 m), and at least 1 km from suburbia (Larkin and Debus unpublished data). Near Canberra, nests were at least 215 m from a dwelling, at least 122 m from an urban edge, and farther from sealed roads (average 710 m) than gravel roads (260 m) or footpaths (average 90 m) (Rae *et al.* 2018). The minimum nesting requirements as per a review of the literature are provided in Tables 1 and 2 below.

Table 1. Minimum distances of active Little Eagle nests from developments in 2 studies:

Parameter	Armidale (C. Larkin et al. unpubl.)	Canberra (Rae et al. 2018)
Dwelling	38 m	215 m
Urban area	1 km	122 m
Industrial building	–	65 m
Sealed road	65 m	31 m
Unsealed road	135 m	29 m
Track/path	34 m	24 m

Table 2. Minimum criteria for active Little Eagle nest-site characteristics (Armidale, C. Larkin *et al.* unpublished data):

Parameter	Measurement
Woodland patch size	4.8 ha
Nest-tree height	20.5 m
Reference tree height*	14.6 m
Nest-tree DBH**	37 cm
Reference tree DBH*	54 cm
Nest height	15 m

*Reference trees are other trees within the nest stand (within 25 m of the eagle's nest tree)
**Diameter at breast height

Foraging requires open woodland areas and open grasslands adjacent to woodlands because the preferred prey includes mainly ground foraging prey species. These are across a broad range of prey species and include insects, reptiles, birds, mammals and carrion. The prey types that have been recorded for the Little Eagle are listed as follows:

Insects	grasshoppers, beetles, cicadas (Debus 1993, 2017)
Reptiles	Bearded Dragon, Eastern Blue-tongue, Cunningham's Skink, goannas (Debus 1993, Debus *et al.* 2007, Debus 2017)
Birds	Crimson and Eastern Rosellas and other parrots, Galah, Australian Magpie-lark, Peaceful Dove, Common Starling, ducks, pigeons, small to large passerines (Debus 1993, Debus *et al.* 2007, Olsen *et al.* 2010, Debus 2017, Rae *et al.* 2018)
Mammals	Rabbit, Hare, Mouse, Rat, Cat, *Antechinus*, bandicoot, possums (Debus 1993, Debus *et al.* 2007, Walsh & Beranek 2017)
Carrion	macropods, Hare, Sheep, Fox (Debus 1993, Olsen *et al.* 2010, Debus 2017)

There is some information on local vegetation types within the Cumberland County that are preferred by the Little Eagle. One hundred and twenty-six records out of the 325 records held with the CBOC Atlas (accessed 29-06-2018) contain information about the habitat type where the Eagle was encountered. In order of most to least common they were:

Pastureland with Scattered Trees	27%
Cumberland Plain Woodland	22%
Heath	15%
Urban Parkland	10%
Tall Forest	8%
Sandstone Woodland	8%
Rainforest	8%
Swamp and River Woodland	2%

The OEH Threatened Species Data Collection indicates that the Little Eagle has the potential to inhabit the following plant communities within the Wilton and Greater Macarthur Growth Areas:

830	Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain
835	Forest Red Gum – Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain
850	Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain
883	Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain
1800	Wetlands

The habitat requirements discussed above have been used in this report to identify important habitat areas. They have been grouped into the habitat criteria listed below. The greater the number of criteria that are met the more likely it is that the remnant will provide habitat for Little Eagle.

1. Site contains tall open forest or woodland.
2. Site is near or along a timbered watercourse.
3. Site contains one or more of the following PCTs: -
   830, 835, 849, 850, 883 and 1395.
4. Site contains a mosaic of open grazing land and woodland.
5. Site contains ground foraging prey species
   e.g. rabbits, hares, mice, passerines, parrots and pigeons.
6. Site has open grassy areas around the edges of remnants, timbered corridors and watercourses.
7. Site has tall or emergent trees suitable for nesting.

3. Description of the Study Area's Relevance to the Little Eagle

Land Use History

Much of the northern half of the Greater Macarthur growth area has been developed as residential, commercial and industrial land decades ago and any remaining habitat can only be found along watercourses and on steep slopes where these developments are not appropriate. Much of this area would have been a mix of cleared grazing land and bushland prior to this stage of development.

The southern half of the Greater Macarthur and the Wilton growth areas contain older small towns, which now have a few larger new residential developments. These occupy only a small area within the growth areas. Much of the land consists of small to medium rural holdings and grazing agricultural land that was cleared for farming decades ago. Throughout this area there are many watercourses that are tributaries to either the Georges or Nepean rivers and the forests along these watercourses has largely been left intact with some clearing or thinning at the edges. Many of the remnant patches and forested watercourses have been affected by woody weed invasion since development in the area.

Landscape Context

The growth areas follow the transport corridor along the Hume Motorway that connects the area to the south-western areas of greater Sydney to the north. The area abuts intact, contiguous, forested areas to the east and to the south. These are in water catchments or national park reserves, which cover hundreds of square kilometres. The western edge abuts mostly cleared rural holdings either side of the Nepean River and then further west to the Warragamba Dam water catchment area.

Much of the region is in the western half of the Cumberland IBRA subregion, which contains most of the remaining large woodland remnants and is an important area for this reason. The woodlands of the Cumberland Plain are threatened ecological communities and have been prioritised by the Office of Environment and Heritage for habitat protection and enhancement (DECCW 2010).

Native Vegetation

The remnant native vegetation within the growth areas is mainly eucalypt forest and woodland. Forested areas on steep slopes and along watercourses have largely been left intact and often contain a structurally and species diverse understorey. Woodland areas remaining on flat or gently undulating land have a few scattered dense patches of understorey, but are mostly open woodland with a grassy understorey. Many of the remnant patches have been invaded by woody weeds and many woodland remnants are subjected to grazing pressure and are clear of any understorey. Some of the remnants have also been thinned and have only scattered paddock trees along their edges.

The following plant community types are found in these remnants within the growth areas:

PCT Codes and Names

- 830 Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion
- 835 Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion
- 849 Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion
- 850 Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion
- 877 Grey Myrtle dry rainforest of the Sydney Basin Bioregion and South East Corner Bioregion
- 883 Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion
- 1081 Red Bloodwood - Grey Gum woodland on the edges of the Cumberland Plain, Sydney Basin Bioregion
- 1083 Red Bloodwood - scribbly gum heathy woodland on sandstone plateaux of the Sydney Basin Bioregion
- 1181 Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion
- 1292 Water Gum - Coachwood riparian scrub along sandstone streams, Sydney Basin Bioregion
- 1395 Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion

Potential Habitat

Most of the uncleared areas in the northern half of the Greater Macarthur growth area are remnant forest patches along watercourses that were unsuitable for development. They are small, often isolated and mostly surrounded by urban development with little or no open areas surrounding each remnant to act as buffers. Some have open areas within them that have mown grass and are now parkland. Few of the reserves have open edges or grazing areas around them and as such do not provide suitable foraging habitat. This area has a major watercourse near the eastern edge, which is the Georges River. This river would provide access to the reserves that provide some suitable resources for the Eagle.

The southern half of the Greater Macarthur and the Wilton growth areas have small areas of urban development and larger areas of open grazed pastureland and rural holdings. There are very large remnants of forest and woodland that mainly follow watercourses that are connected to either the Georges or Nepean Rivers. In the south and east sections of the growth areas many of these forest remnants are also part of contiguous habitat into water catchment reserves or national parks. The forest remnants often border open areas with scattered trees and provide good edge habitat for the Eagle. There are many areas, which have a mosaic of open grazed land and small patches of open forest and woodland.

Some 40 sites, scattered over the whole length of the growth areas, were sampled for habitat quality and their ability to provide foraging and nesting resources for the Eagle. Fifty potential sites were selected based on the vegetation maps of the area but access into much of the area was difficult. The habitat requirements for the Eagle are described in detail in Section 2 of the report and are grouped into seven different criteria for assessing suitable habitat. Details of each site's location, their PCTs and which of the criteria were satisfied are listed below (see Table 3) and a more-detailed description of each site can be found in Appendix 1. All of the sites met at least one of the criteria and 20 of the sites meet at least 5 of the 7 criteria. The PCTs where the Eagle has been observed from previous records (BioNet Atlas of NSW Wildlife, accessed 29-06-2018) include 830 Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion, 835 Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion, 849 Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion, 850 Grey Box - Forest Red Gum grassy woodland on shale of the Cumberland Plain, Sydney Basin Bioregion, 883 Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion and 1395 Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion, which were recorded on many sites.

These sites represent only a small portion of the forest remnants within the growth areas, yet nearly all sites satisfied many of the criteria used to assess whether suitable habitat existed on-site for the Eagle. This implies that most of the remaining forest and woodland habitat in the area is potential Eagle habitat, especially as the remnants are tall, have open edges and follow watercourses. Open areas that exist adjacent to the forest and woodland remnants, and especially where there is a mosaic of open grazing areas and woodland remnants provide potential habitat. All forest, woodland and open areas that provide potential habitat will be shown as species polygons in Section 4 of this report. It should be noted that some of the important open areas adjacent to forest and woodland remnants overlap with the proposed urban development footprint.

Although there is much potential breeding habitat within the growth areas, BAM defines breeding habitat as live (occasionally dead) large old trees within suitable vegetation AND the presence of an adult with nesting material; or an individual on a large stick nest in the top half of the tree canopy. Adults with nesting material or their presence on a large stick nest were not observed during surveys. These criteria would need to be met to confirm the presence of breeding habitat within the growth areas.

Table 3. Criteria relating to habitat resources for the Little Eagle that were satisfied for each of the study sites.

Site No.	Latitude	Longitude	PCTs	Criteria Satisfied

40	-34.20781	150.63328	1081	1,2,4,5,6,7

Criteria:
1. Site contains tall open forest or woodland.
2. Site is near or along a timbered watercourse.
3. Site contains one or more of the following PCTs - 830, 835, 849, 850, 883, 1181 and 1395.
4. Site contains a mosaic of open grazing land and woodland.
5. Site contains ground foraging prey species e.g. rabbits, hares, mice, passerines, parrots and pigeons.
6. Site has open grassy areas around the edges of remnants, timbered corridors and watercourses.
7. Site has tall or emergent trees suitable for nesting.

4. Assessment of Species Presence and Suitable Habitat

Species Records for the Greater Macarthur and Wilton Growth Areas

There were 78 records for the Little Eagle from the area containing the urban development area (ALA Atlas and CBOC Atlas, accessed 29-06-2018). The list of records is shown in Table 4 and the distribution of these records is shown in Figure 2.

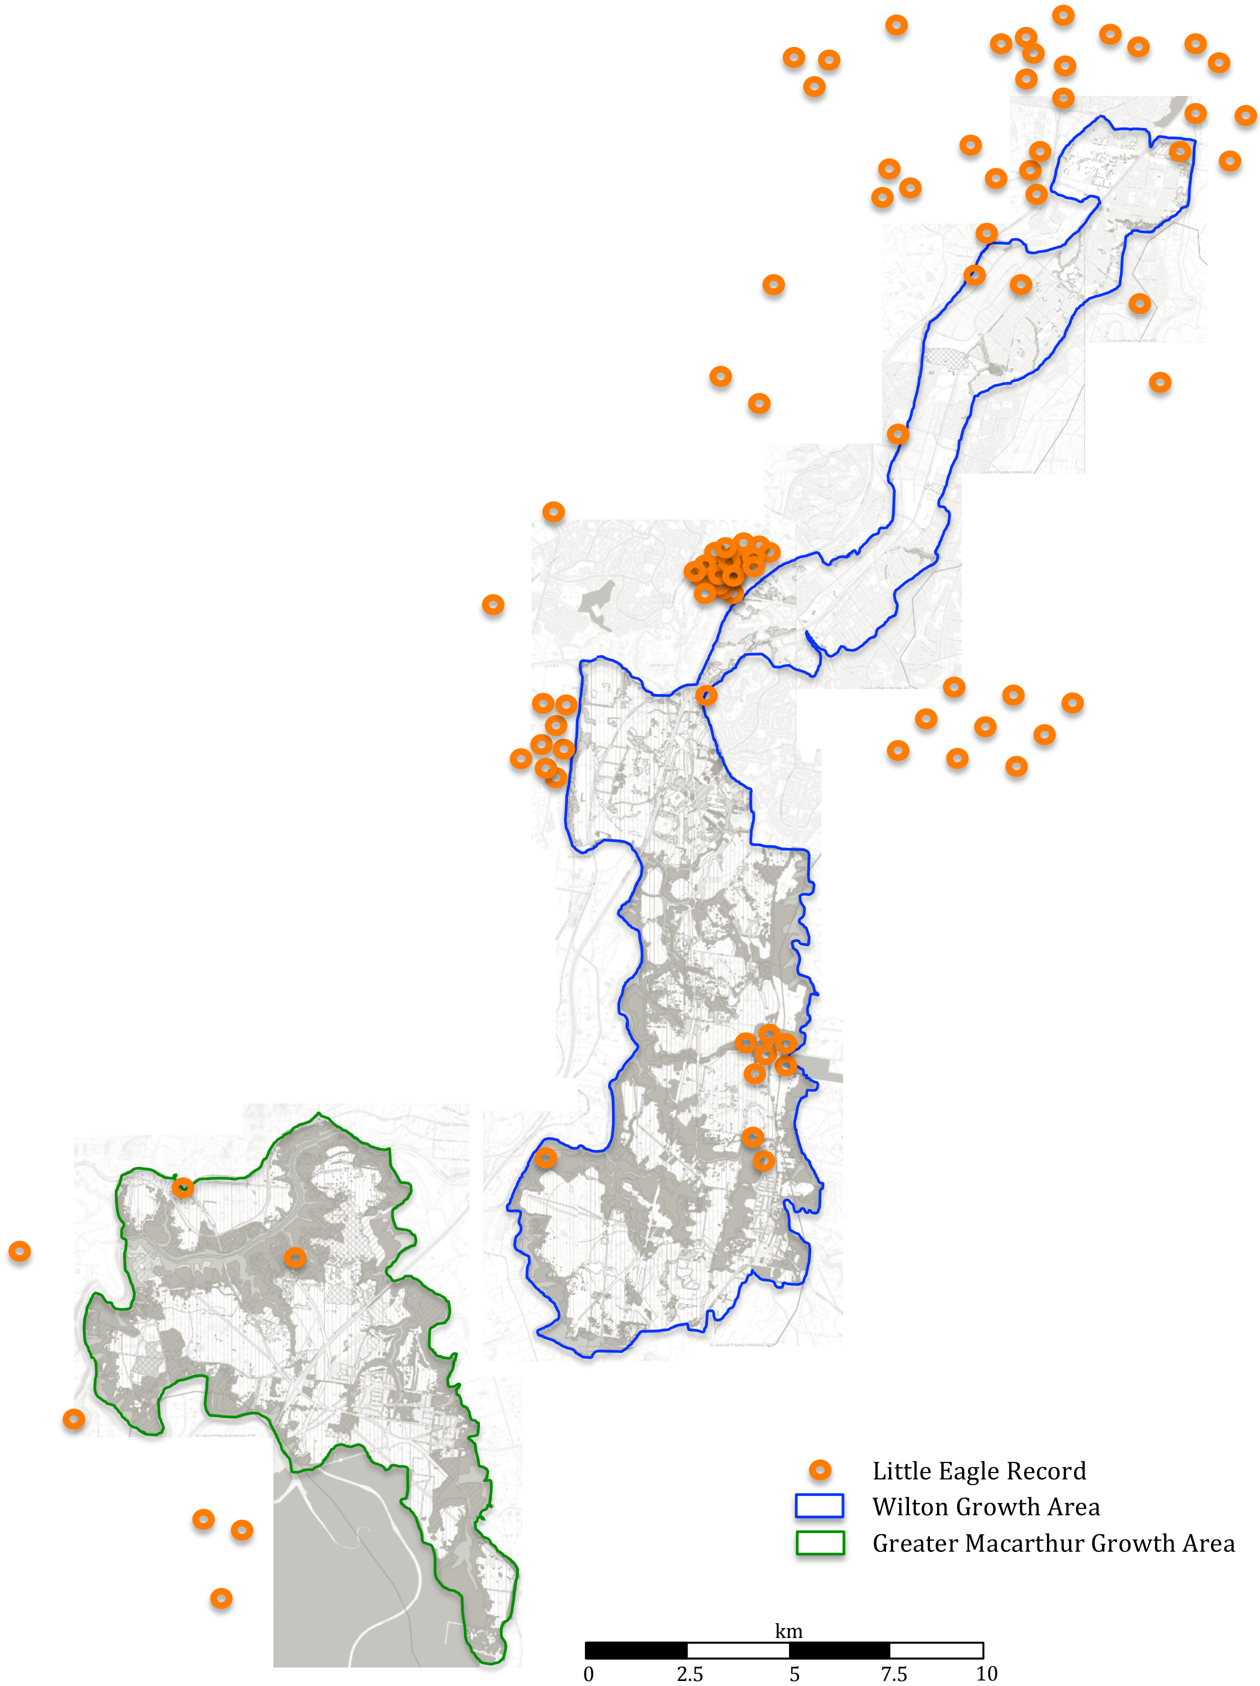

Figure 2. Species records for the Little Eagle *Hieraaetus morphnoides* in and around the Greater Macarthur and Wilton Growth Areas (source ALA and CBOC Inc.).

Of these 78 records, 15 were within the Greater Macarthur growth area and the Wilton growth area. The other 63 records are within 5 kilometres of the boundaries of the growth areas. There was no discernible seasonality in the records, although they were slightly more common from January through to May (the post-breeding dispersal phase). Records from August to December raise the possibility of the Eagle breeding in the vicinity of the growth areas or within 10 km. For instance, possible breeding behaviour (mating) was observed near Camden where a pair was regularly seen, although no nest was found on the site (a 1600 ha agricultural research station: Starr *et al.* 2004). Most of the Eagle records are associated with large patches of open woodland that occur within open grassland areas, such as pastureland and parkland; some are found in forest along watercourses and were obtained close to the edges of remnant forest. A few records were from woodlands associated with wetlands. The records support the conclusion that a mosaic of open woodland and open grassland with scattered trees provides important habitat for the Eagle. We are not aware of any previous habitat assessments for the Little Eagle in the study area.

Assessment of Suitable Habitat in the Growth Areas, Distribution Polygons and Justification for Determination

The areas of potential breeding and foraging habitats for the Greater Macarthur growth area are shown in maps 1 to 7 in Figure 3. The areas of potential breeding and foraging habitats for the Wilton Growth Area are shown in maps 1 to 3 in Figure 4. The existing remnant patches containing potential habitat for the Eagle are shown as an overlay over the vegetation maps. Sites where the habitat structure, plant community type and placement in the landscape all indicate potential breeding habitat breeding and foraging habitat for the species are shown in red. Some areas have potential as foraging habitat but a low likelihood for breeding and these are shown in orange. Some of these areas are within the proposed urban development footprint and have been included because they satisfy several of the following conditions. They contain good edge habitat adjacent to an existing habitat remnant e.g. open areas with scattered trees, provide good foraging habitat, provide connectivity between existing remnants, contain a mosaic of woodland patches and open grassland, broaden a connecting corridor or protect an edge habitat (shown in yellow). They also provide a buffered foraging area between habitat areas and the urban development footprint. Other areas, which also satisfied any of these same conditions and that are not within the urban development footprint, are included as they are areas where habitat enhancement would improve the Eagle's access to resources within the growth areas (shown in green).

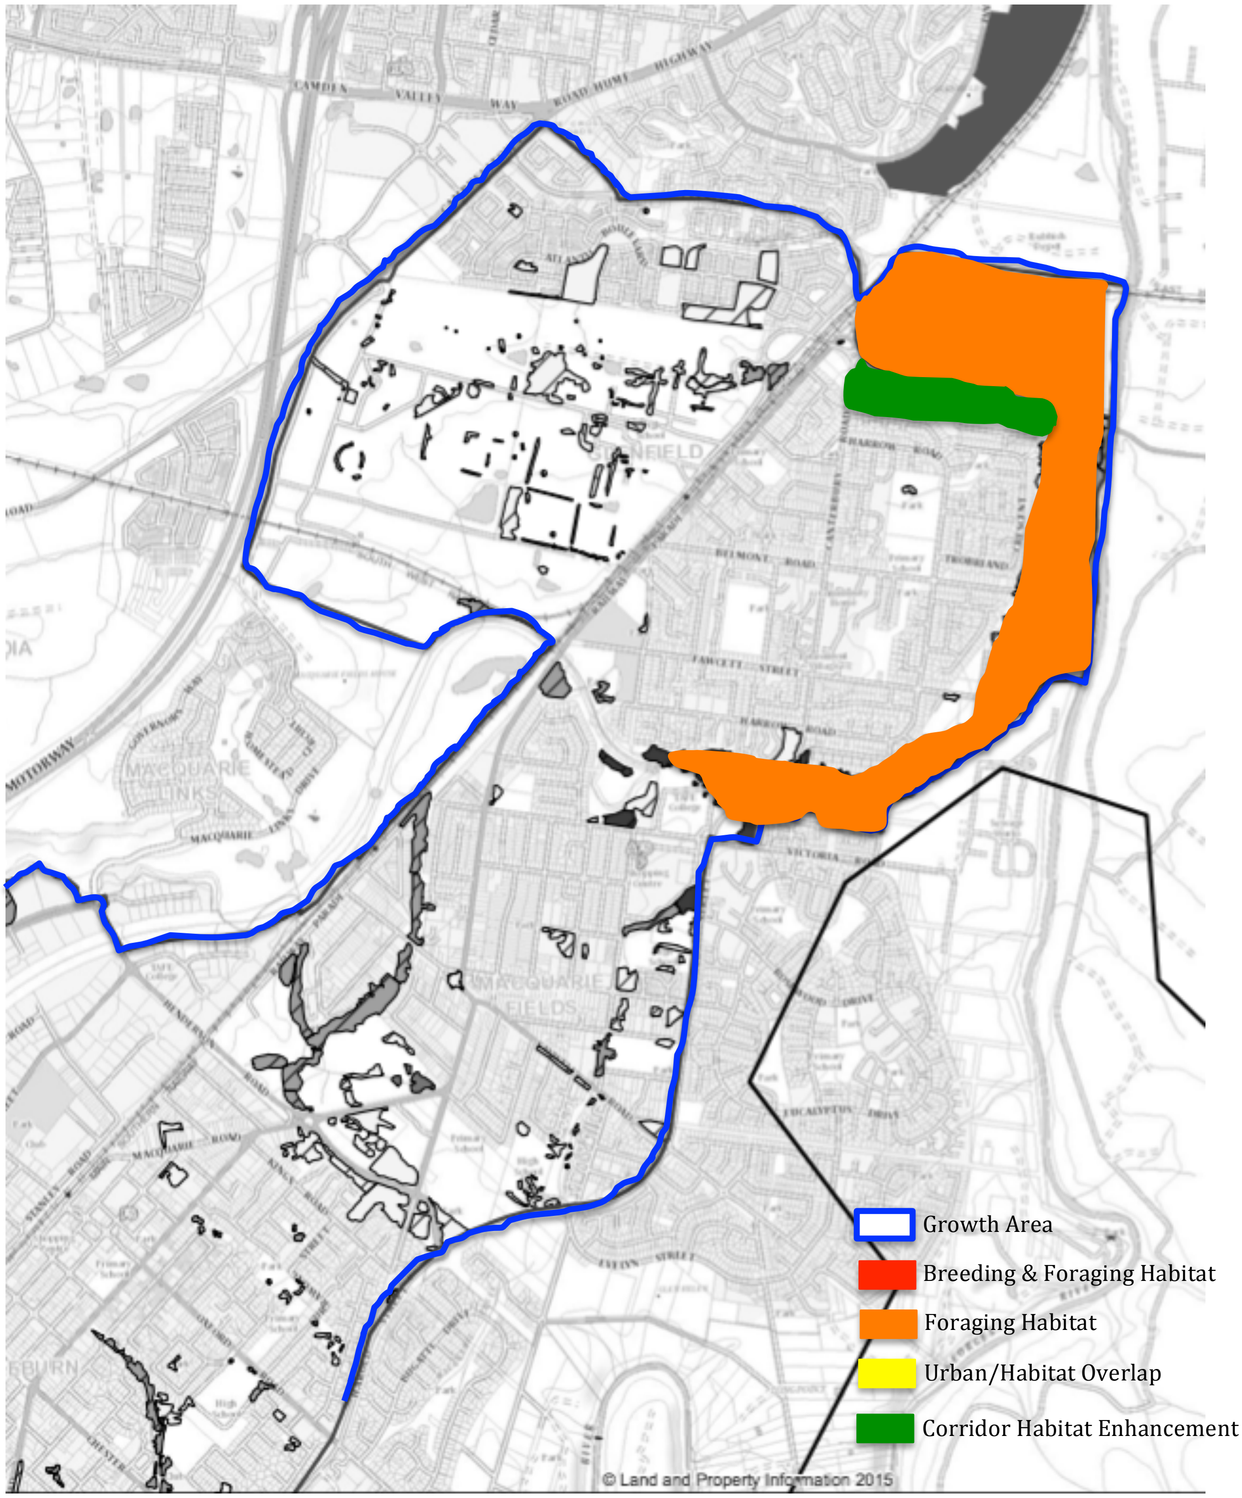

Figure 3. Potential breeding and potential foraging habitat for the Little Eagle in the Greater Macarthur growth area (Map 1). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

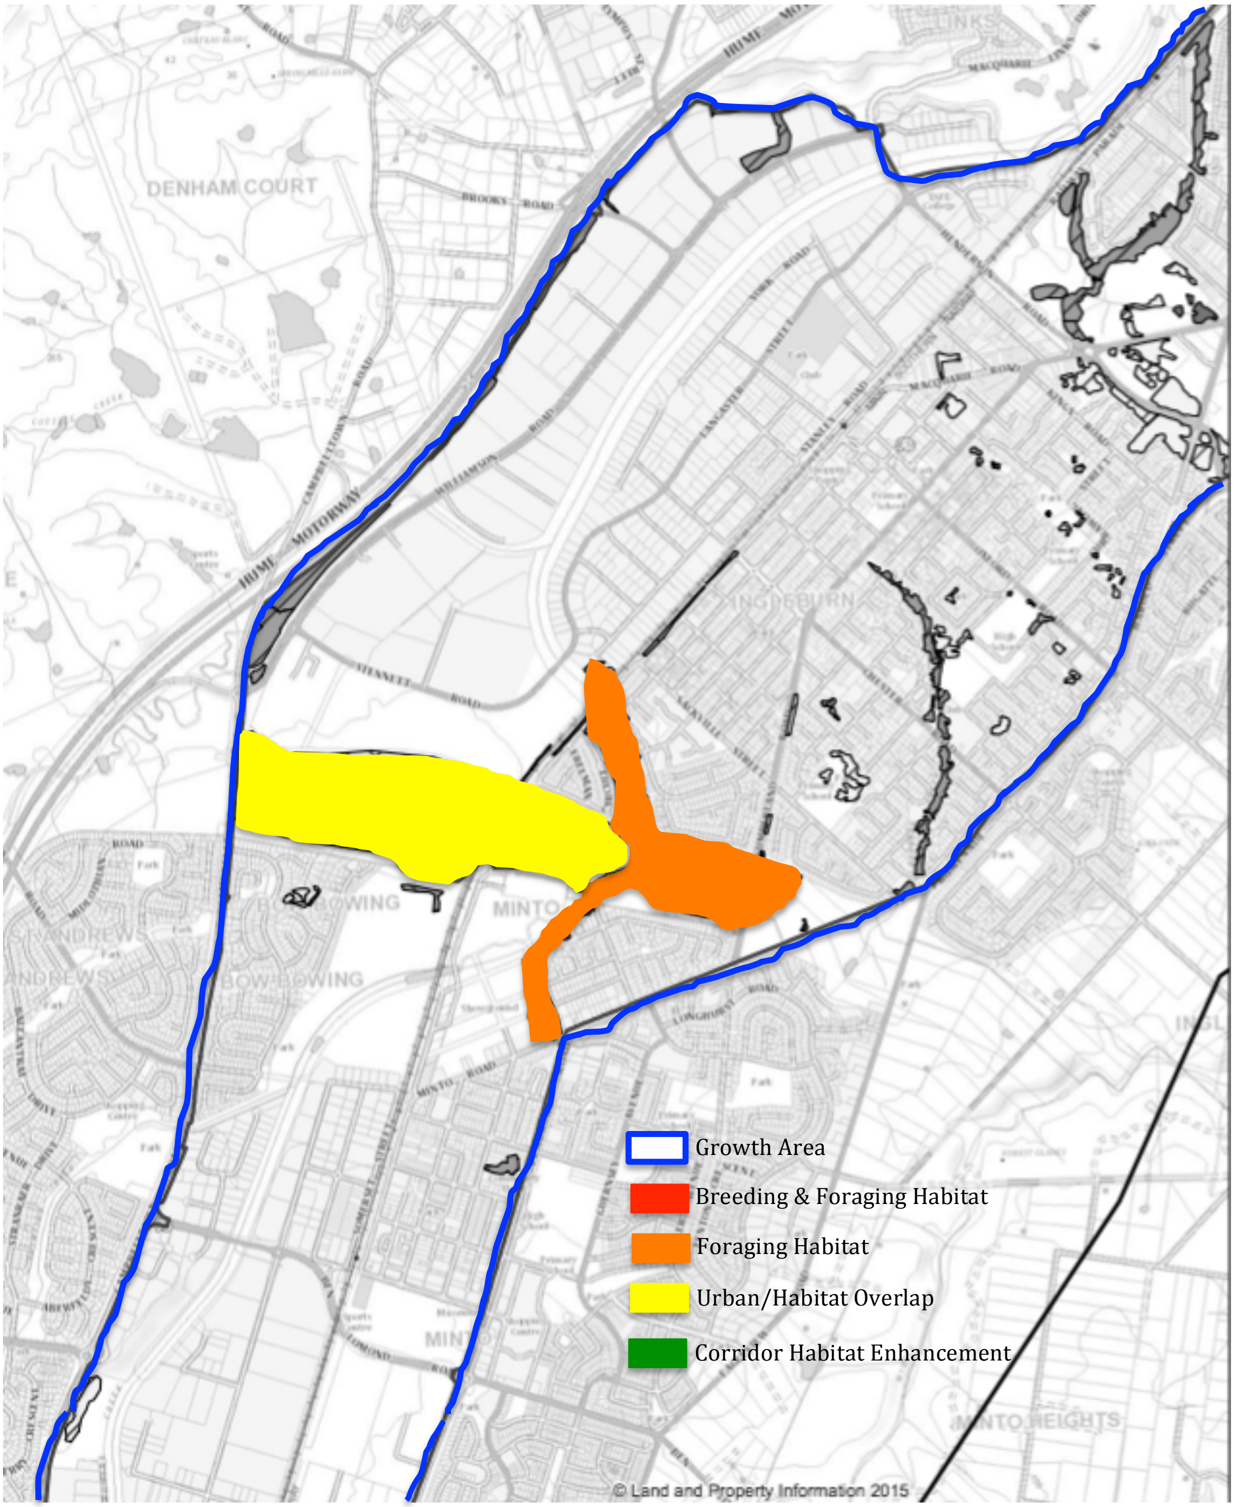

Figure 3. Potential breeding and potential foraging habitat for the Little Eagle in the Greater Macarthur growth area (Map 2). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

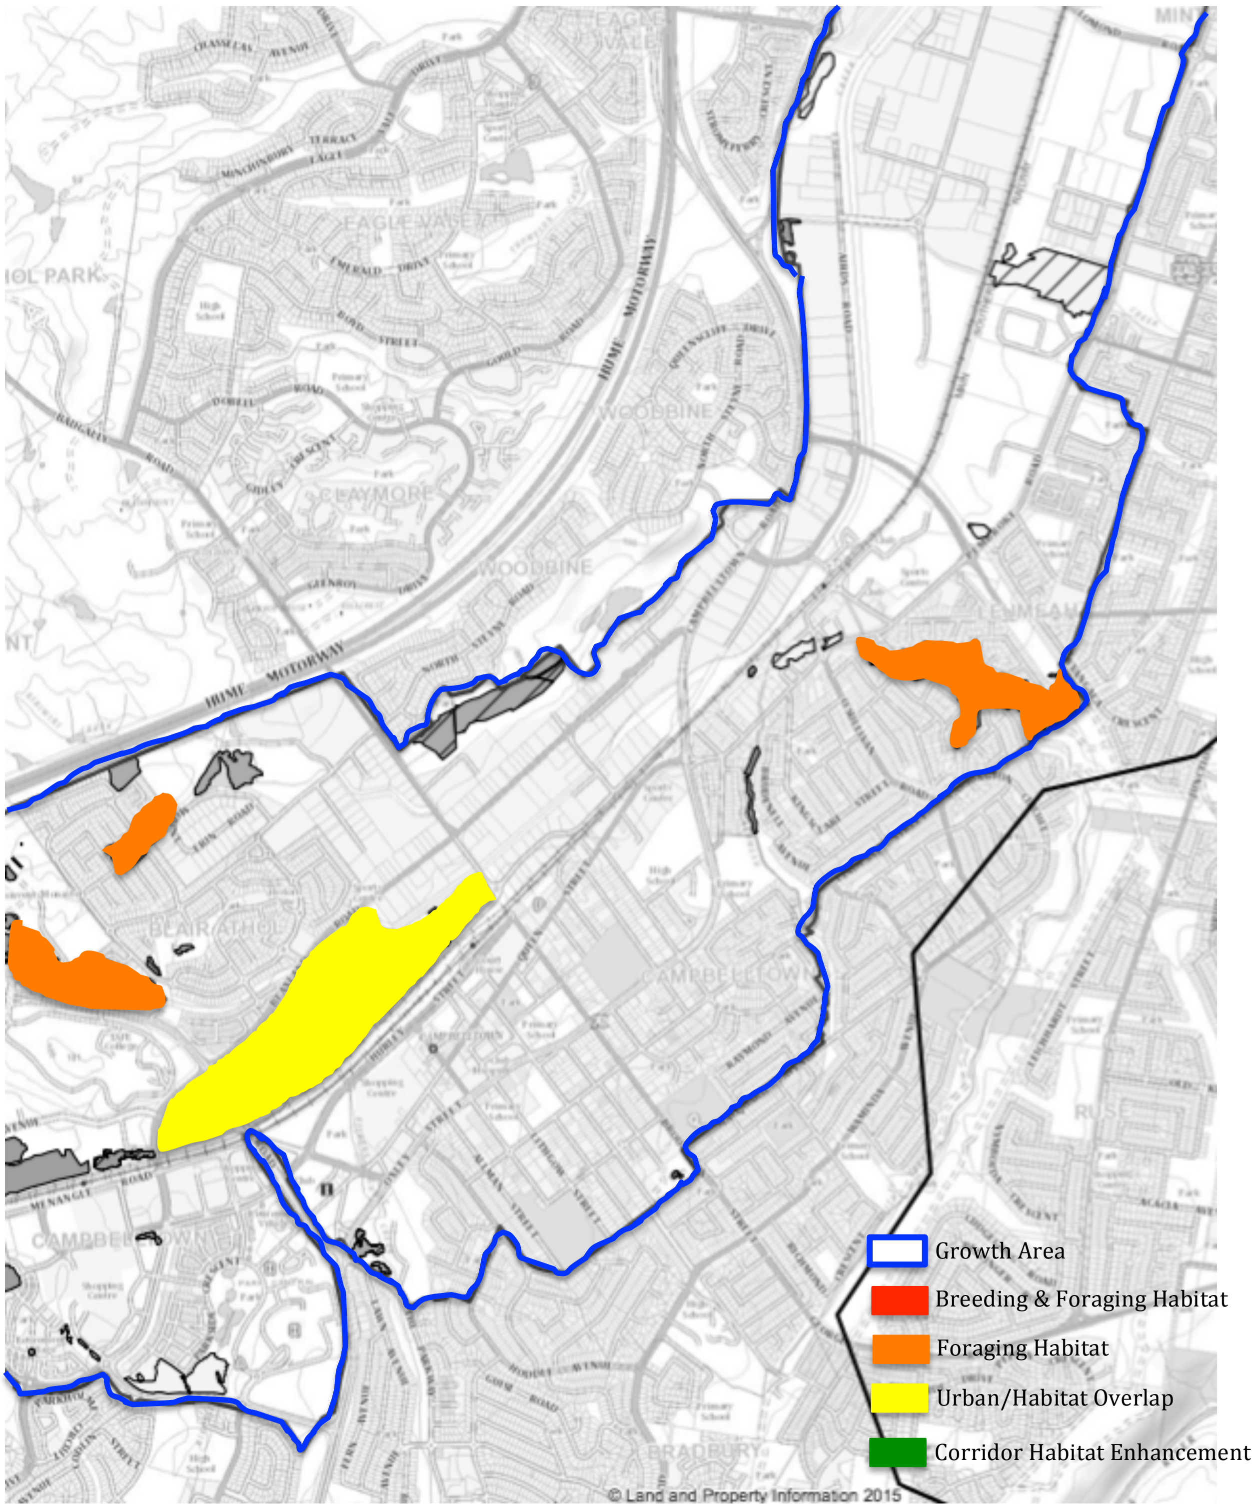

Figure 3. Potential breeding and potential foraging habitat for the Little Eagle in the Greater Macarthur growth area (Map 3). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

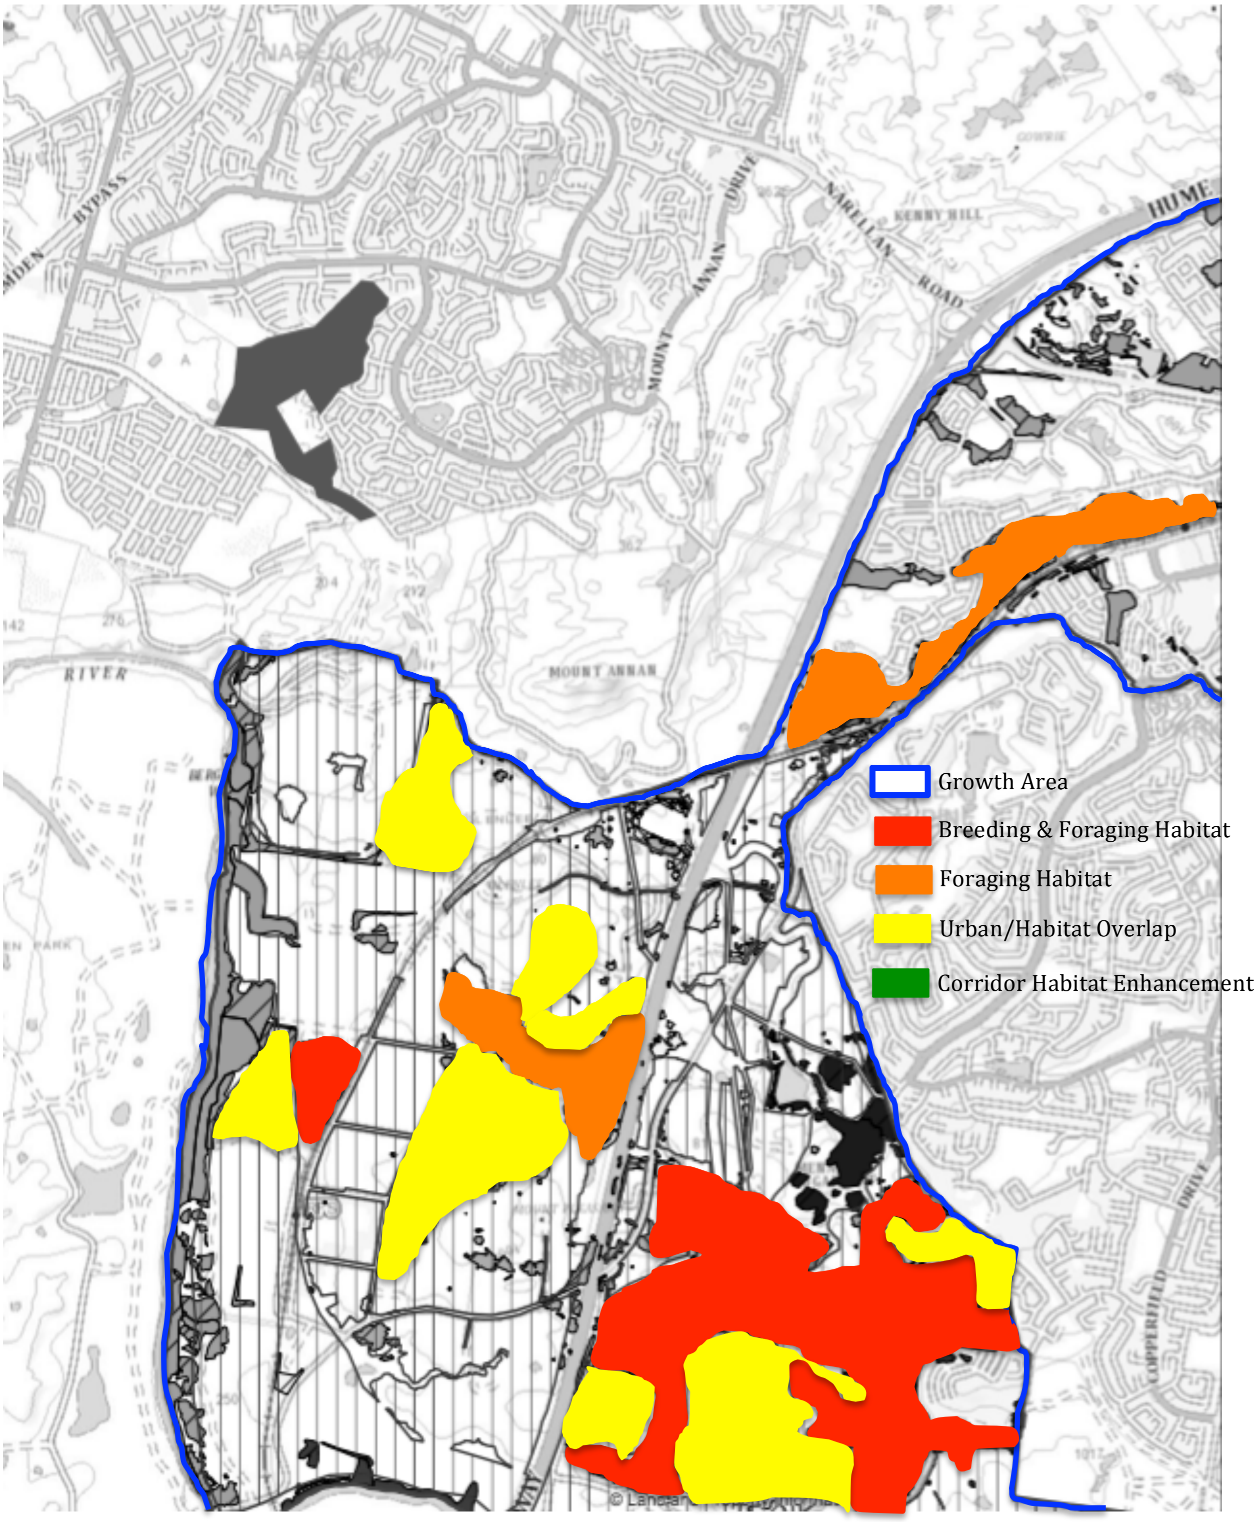

Figure 3. Potential breeding and potential foraging habitat for the Little Eagle in the Greater Macarthur growth area (Map 4). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

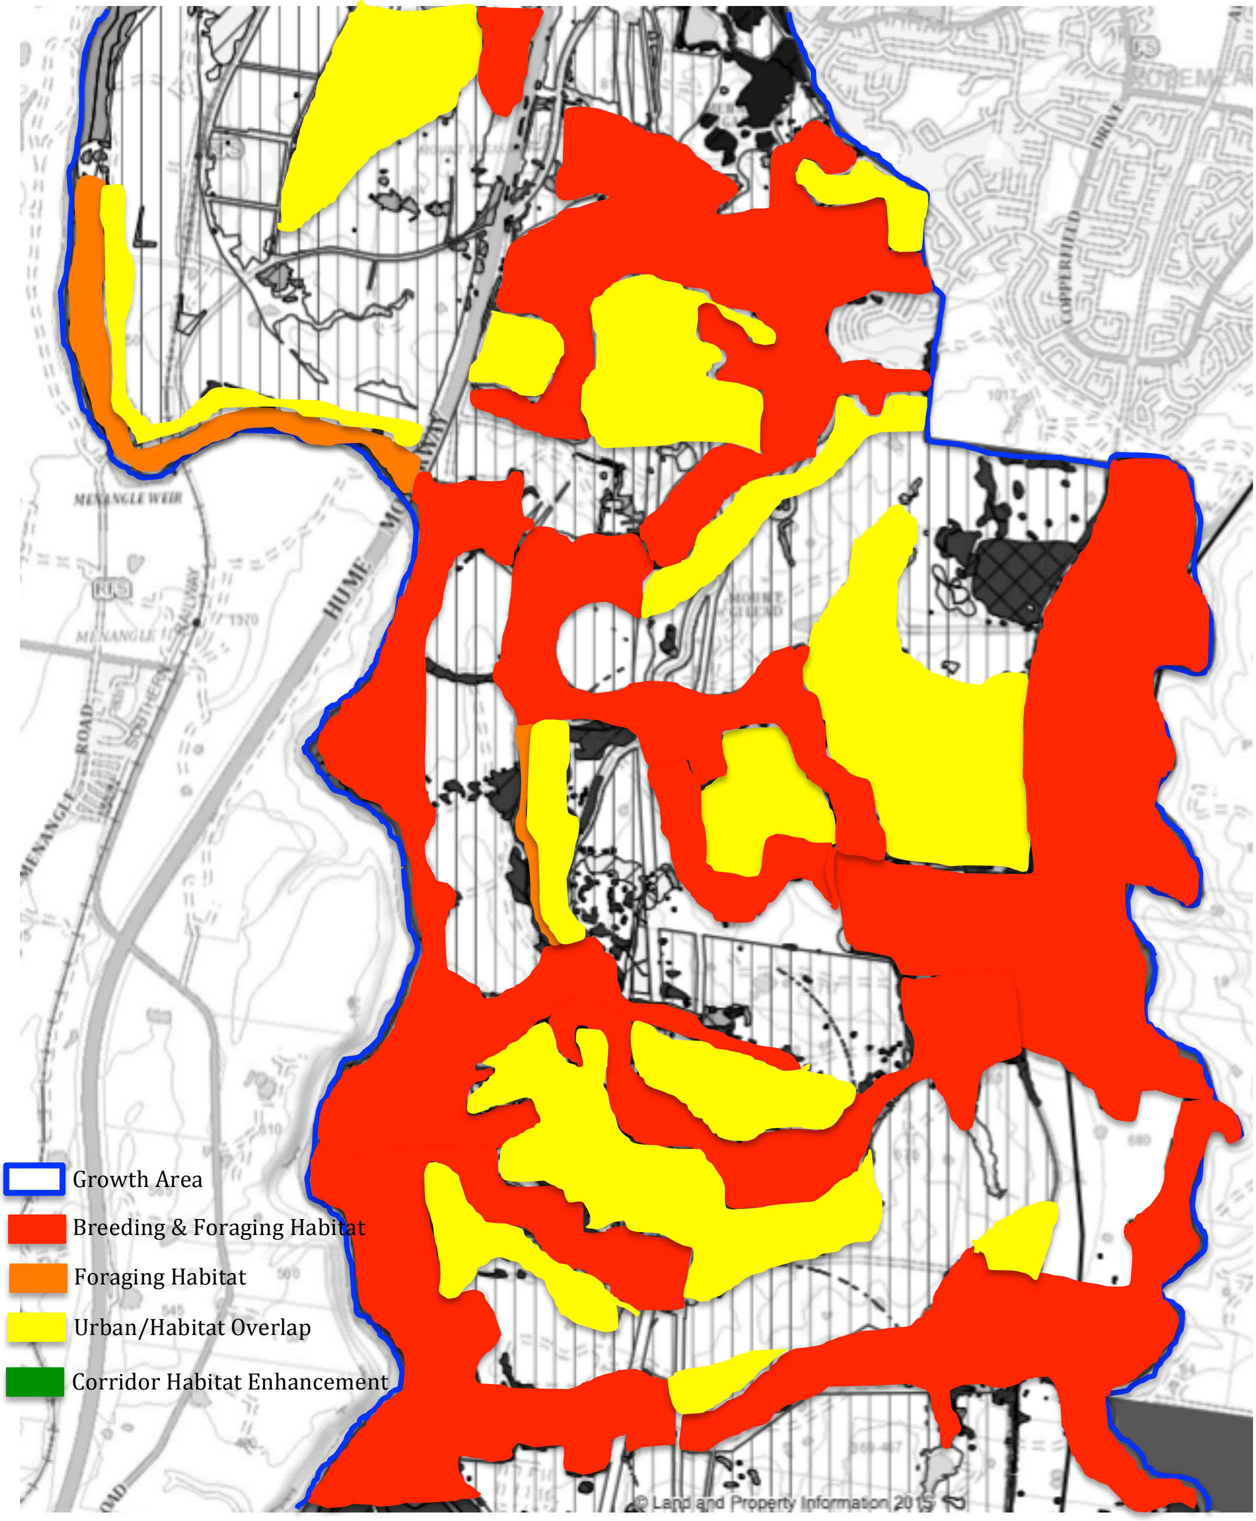

Figure 3. Potential breeding and potential foraging habitat for the Little Eagle in the Greater Macarthur growth area (Map 5). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

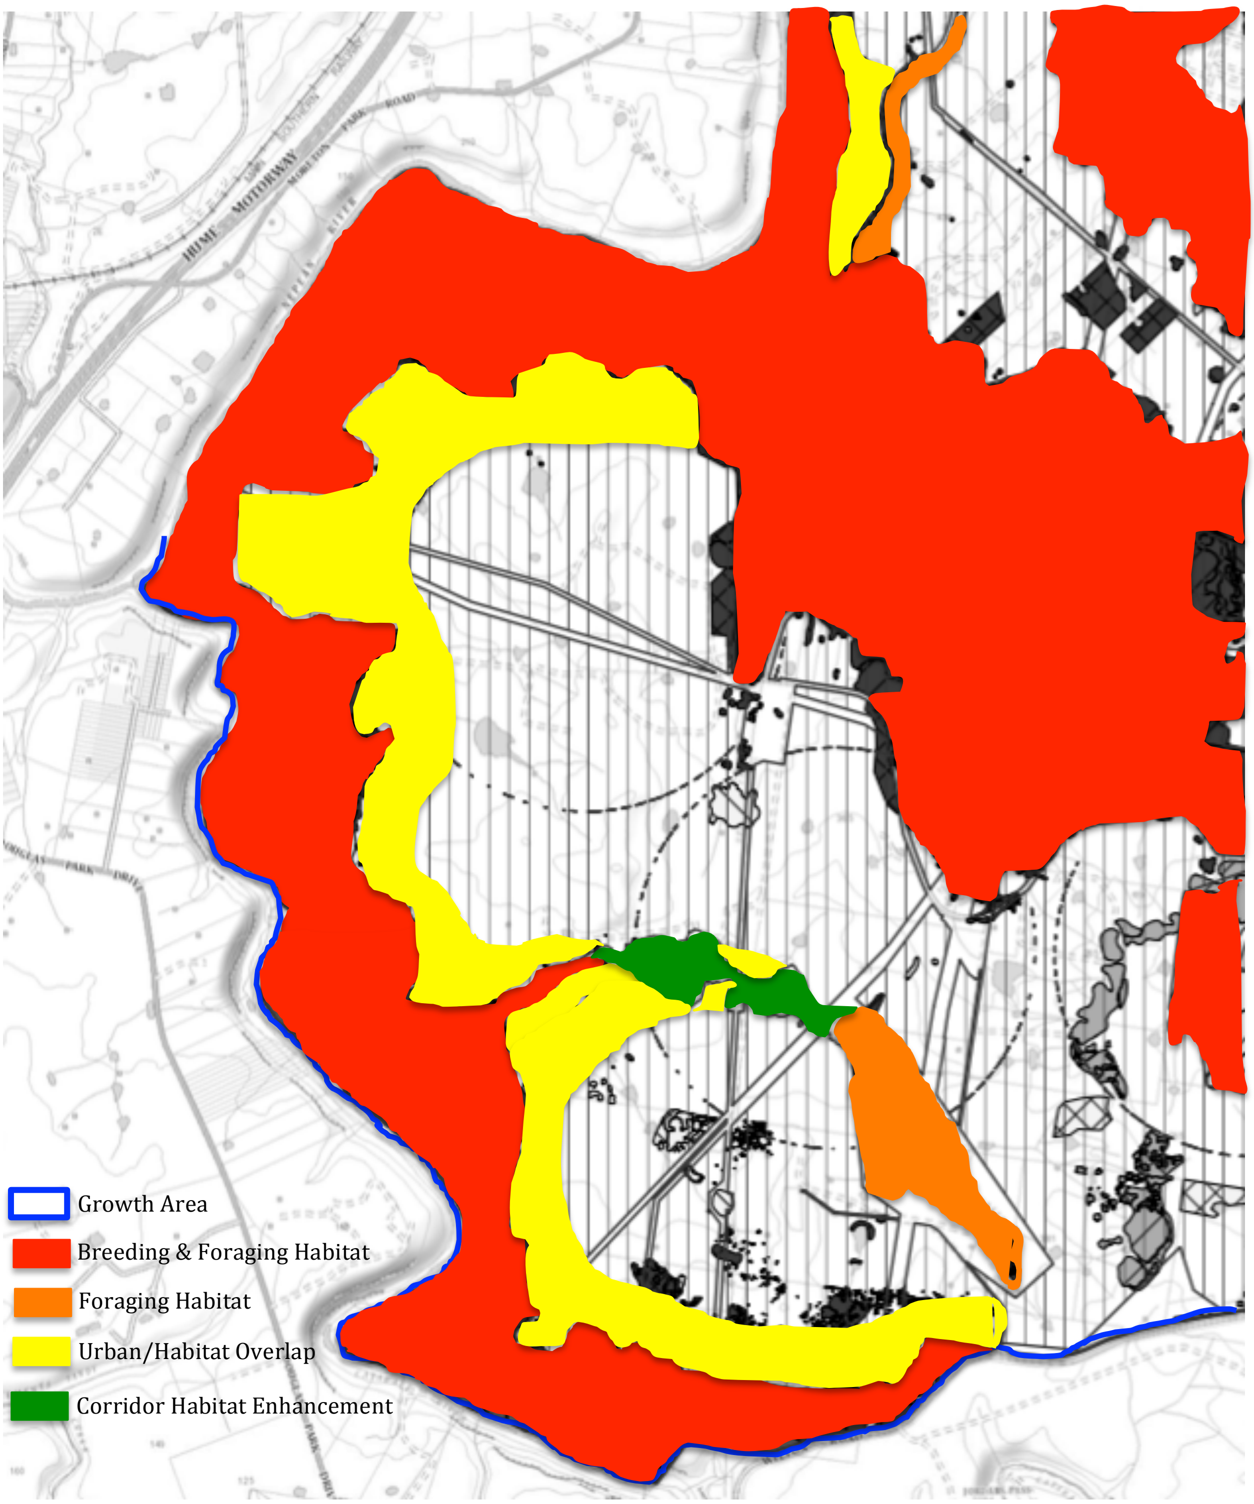

Figure 3. Potential breeding and potential foraging habitat for the Little Eagle in the Greater Macarthur growth area (Map 6). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

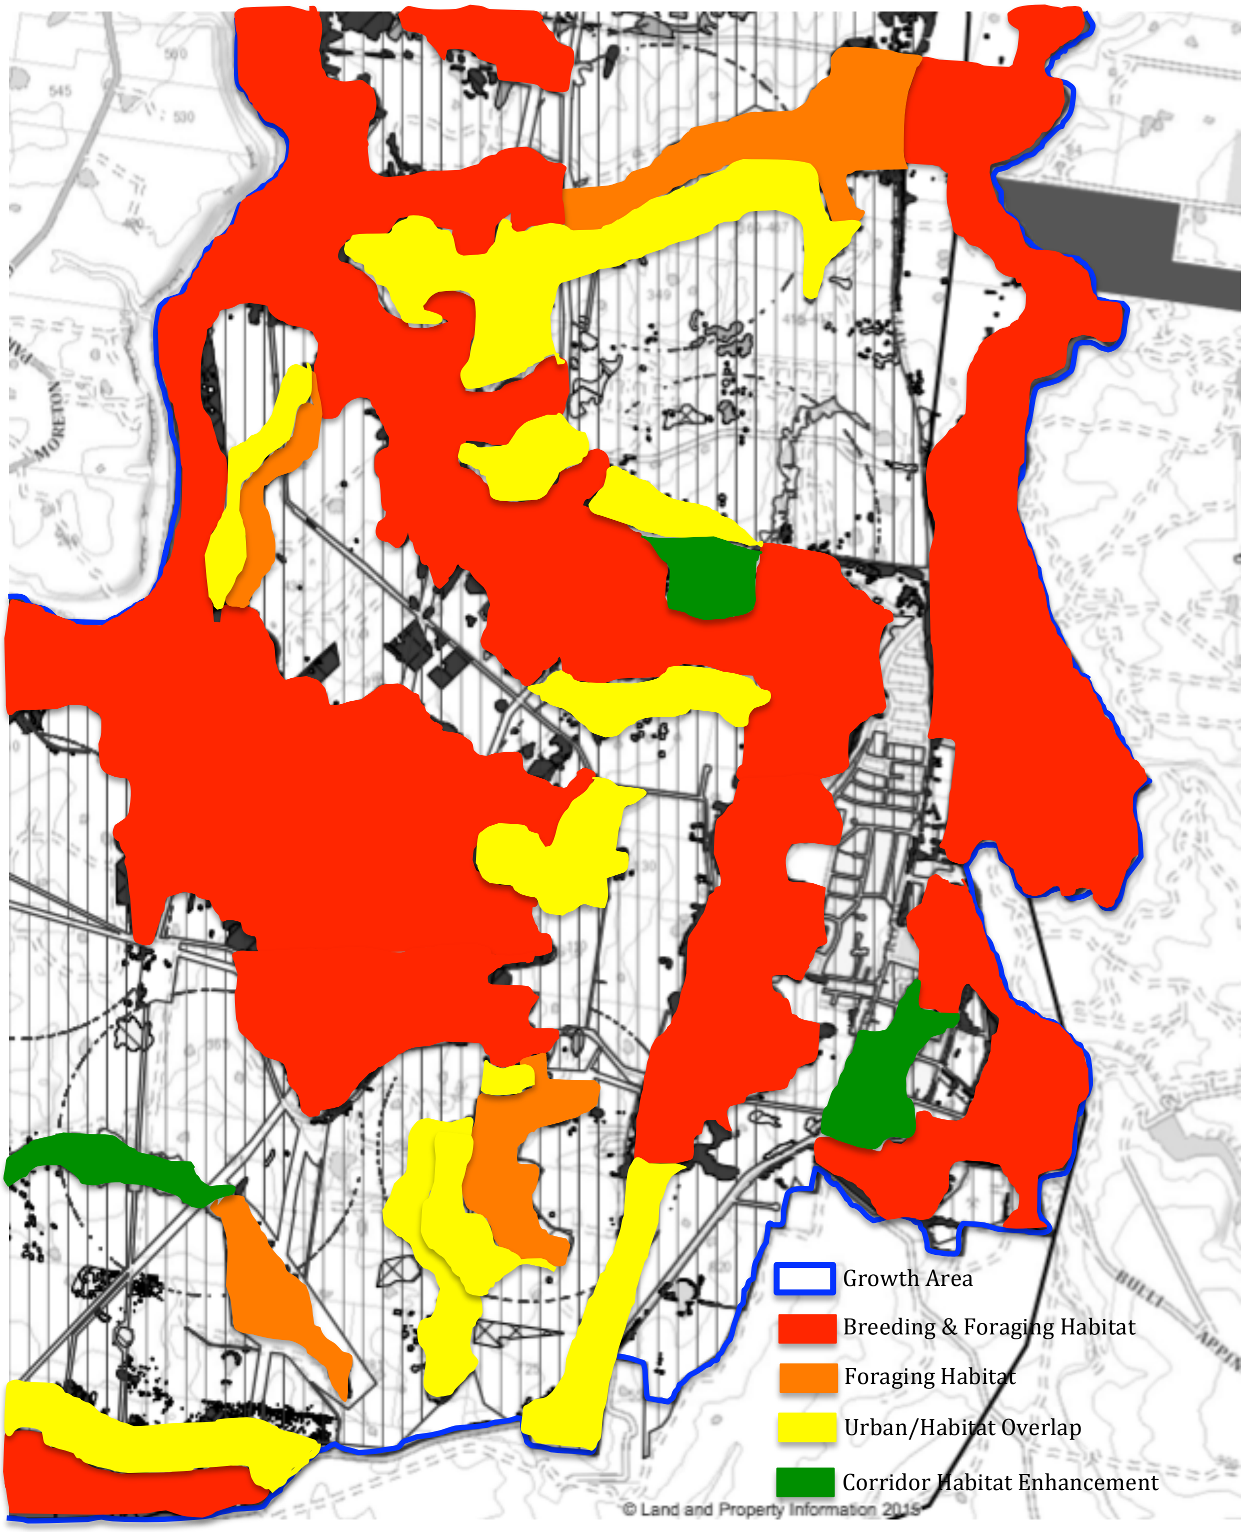

Figure 3. Potential breeding and potential foraging habitat for the Little Eagle in the Greater Macarthur growth area (Map 7). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

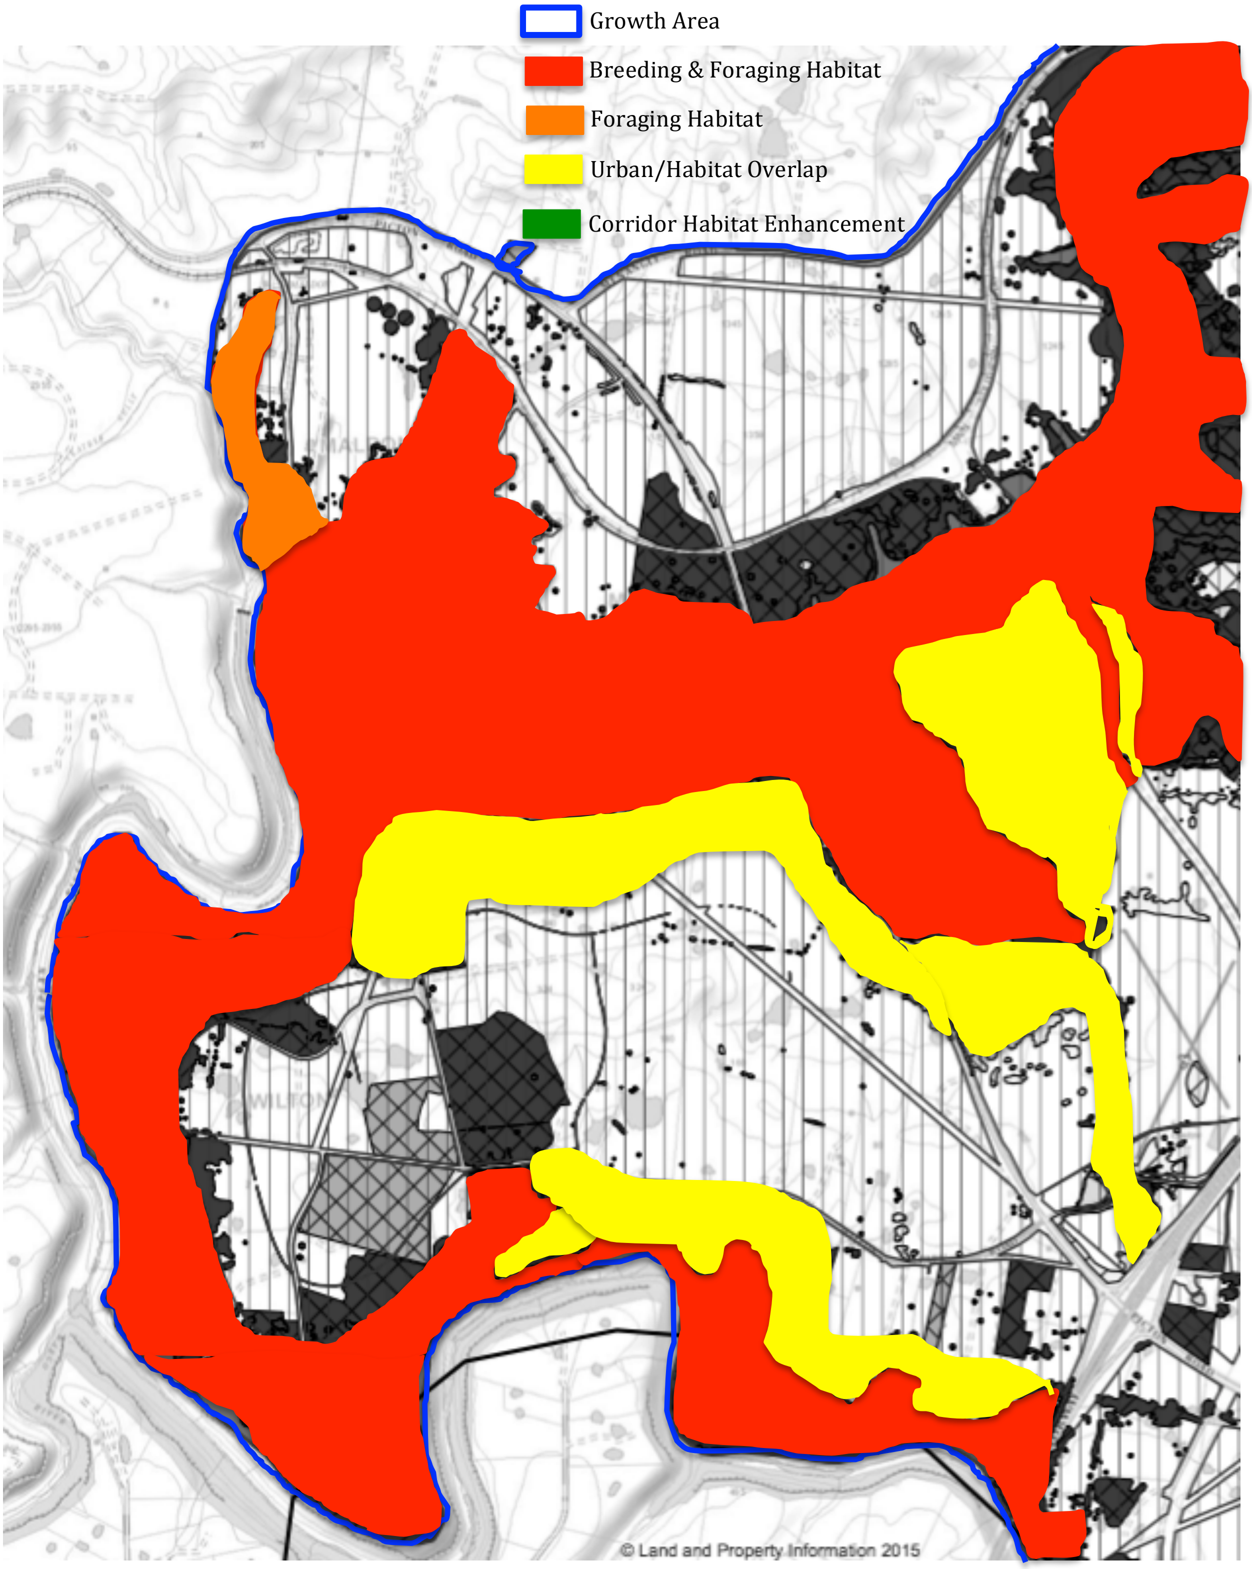

Figure 4. Potential breeding and potential foraging habitat for the Little Eagle in the Wilton growth area (Map 1). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

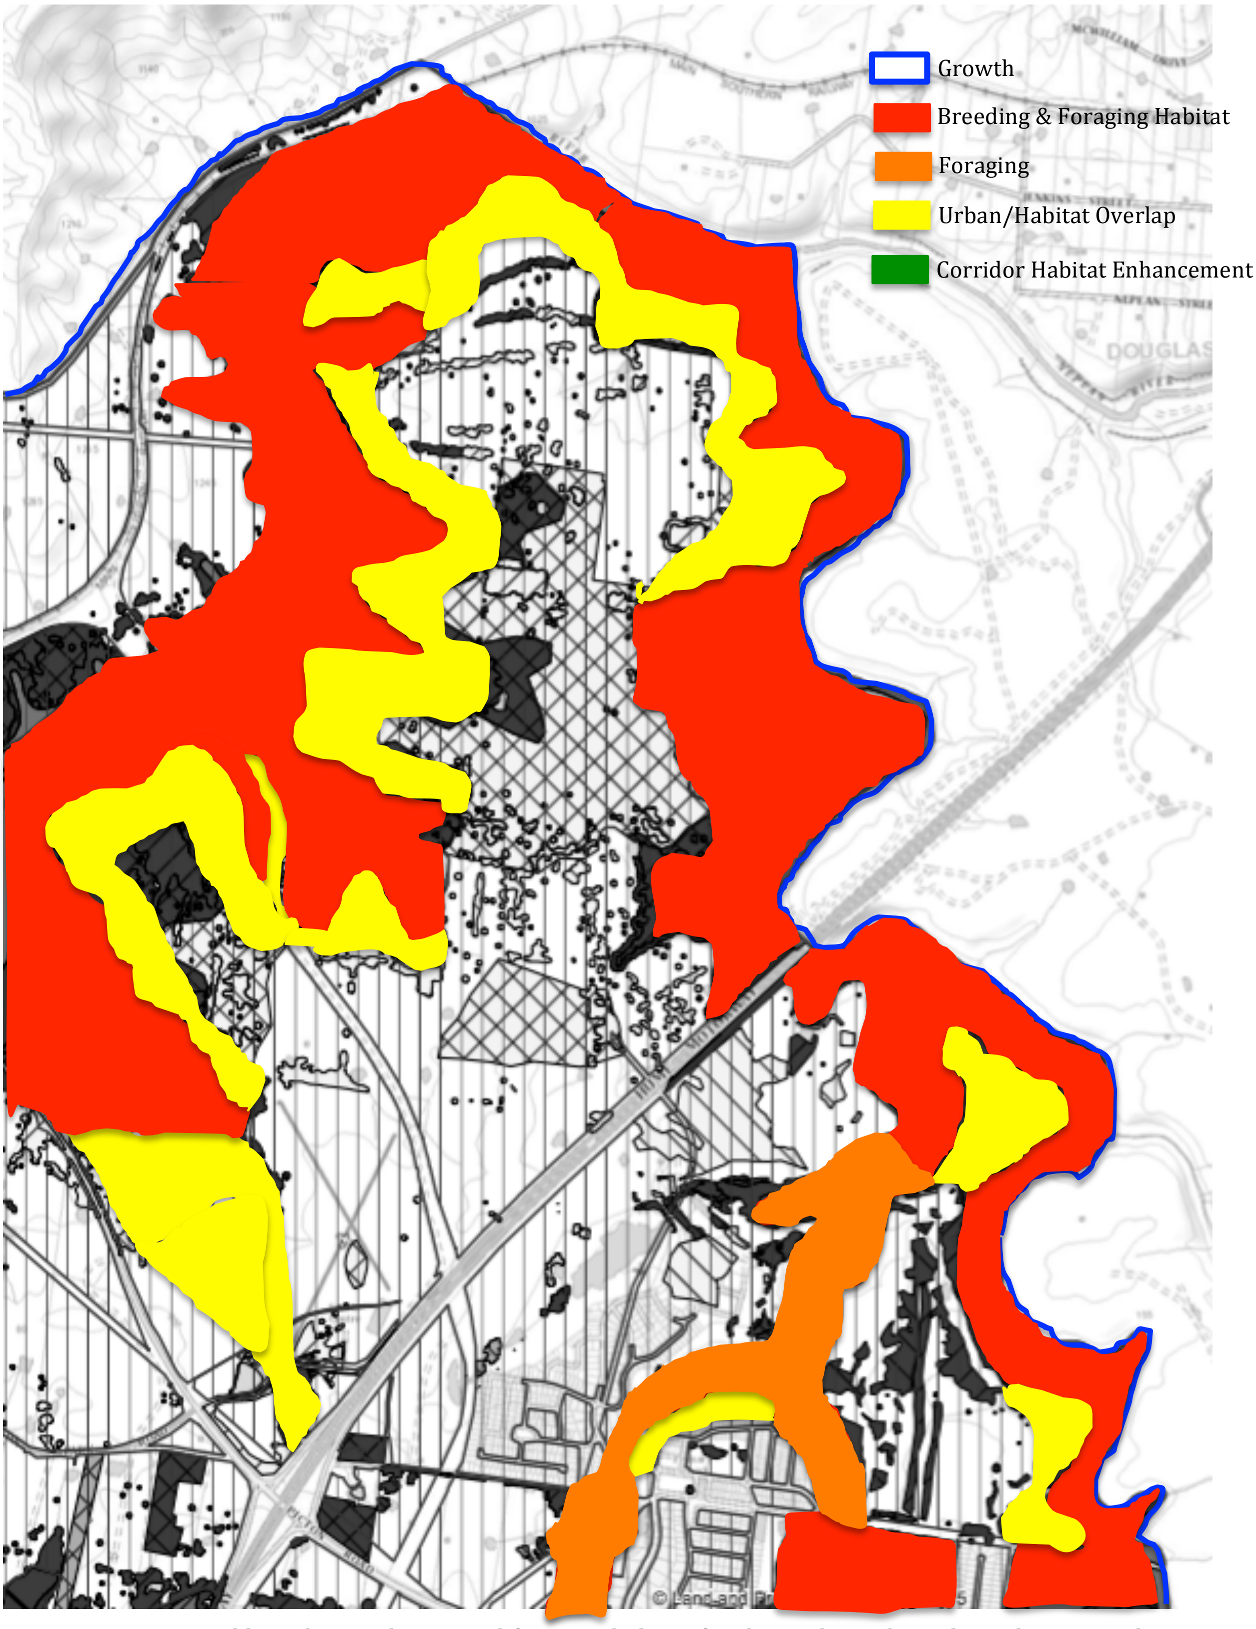

Figure 4. Potential breeding and potential foraging habitat for the Little Eagle in the Wilton growth area (Map 2). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

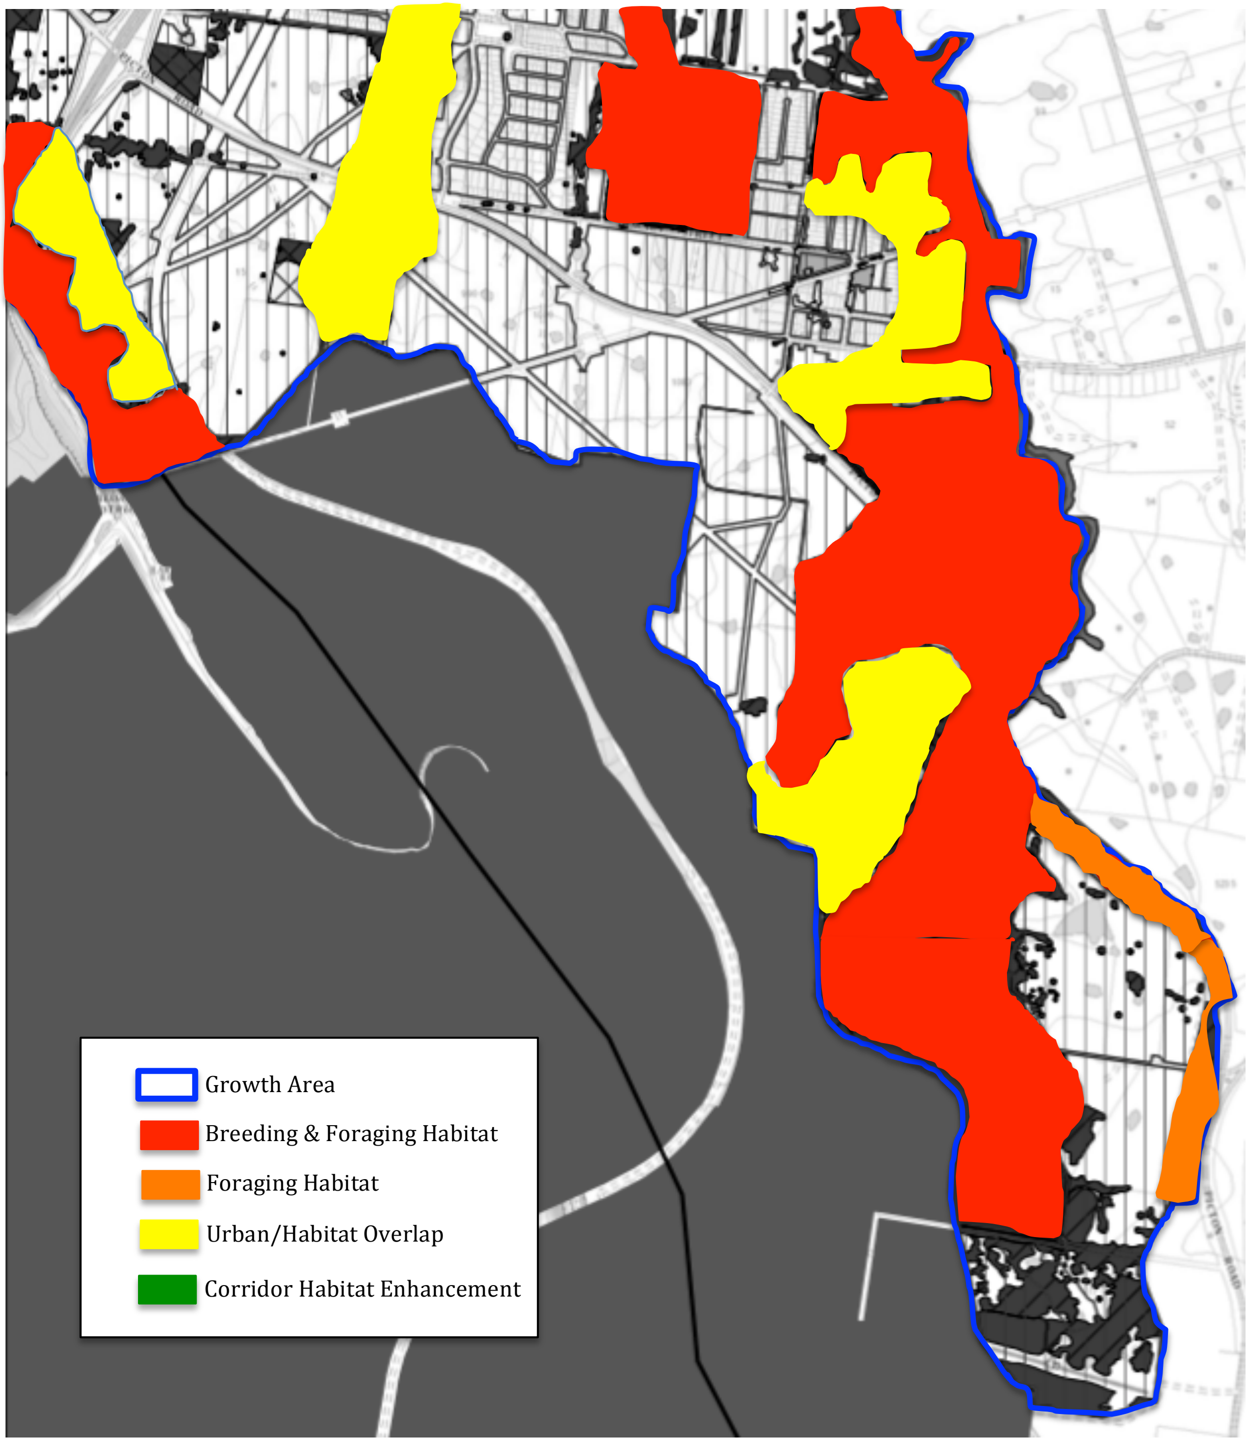

Figure 4. Potential breeding and potential foraging habitat for the Little Eagle in the Wilton growth area (Map 3). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

Assessment of the Likelihood of Species Presence in the Growth Areas, Distribution, Population Estimate and Justification for Determination

There is a very high likelihood of Little Eagles occurring within the growth areas at any time of the year. The habitat remnants within the growth areas are tall open forests and woodland, are mostly along watercourses and have abundant edges. There are also areas of open woodland dispersed through open grazing land with scattered trees. These factors provide good foraging habitat for the Eagle. The Eagle has also been recorded in most of the plant community types that occur within the growth areas, and again this aspect supports a high likelihood of Little Eagles occurring in the site.

No nests have ever been recorded in the growth areas and no evidence of breeding was observed during surveys by Biosis or by the authors. Although breeding has not been observed within the growth areas it is very likely that they forage in the area while breeding outside the growth areas. As the Little Eagle is considered to be resident for at least several consecutive years while nesting it is likely that if nesting has occurred within the growth areas it should have been detected. However, the Eagle has nested in similar situations elsewhere and nesting within the growth areas would also be possible as there is suitable nesting habitat within the growth areas. This view is supported by the occurrence of records for the Eagle within and around the growth areas in the breeding season, and the mating pair observed by Starr *et al.* (2004) near Camden.

The minimum requirements for Little Eagle nests are described in Tables 1 and 2. The Greater Macarthur and Wilton growth areas are more similar to Canberra than to Armidale. Armidale is a large town surrounded by a mosaic of remnant patches of vegetation and cleared grazing pastureland, whereas, Canberra and the growth areas are more spread-out and scattered along transport corridors. This implies that the minimum nesting requirements for Canberra in Table 1 are more relevant to this study.

The distribution of records and the size of a breeding territory at about 3 kilometres radius, as reported in the literature (see above), suggest that there are likely to be 4 to 6 breeding pairs in the area. There is likely to be a pair at the north end of the Greater Macarthur growth area as there are 36 records from this area. The sightings are associated with the large rural subdivision areas with scattered woodland remnants around Kemps Creek and with the Georges River woodland corridor. Sightings within the growth area suggest that the Eagles come in for foraging. It is possible that more than one pair is associated with this area.

The next important area is towards the middle of the Greater Macarthur growth area with another 34 records from this area. The sightings are centred on the Mount Annan Botanical Gardens and the area of woodland mosaic between Camden Park and the Nepean River. These two areas are 5 kilometres apart and there is sufficient habitat to support another 2 pairs of Eagles here. There is also much suitable foraging habitat east of these two locations within the growth area that provide foraging habitat. Although there was only one sighting within this part of the growth area it is likely that they would have been detected more frequently with more survey effort.

The next important area is in the south of the Greater Macarthur growth area along the forest edges found along Appin Road and around Appin. There is likely to be another pair here that could nest within or adjacent to the growth area. There are open grassland areas on the edges of forest remnants and along watercourses associated with the Nepean River that provide good foraging and breeding habitat. There is also likely to be another pair associated with the Nepean River around the Wilton to Pheasants Nest area. There were 7 sightings in this area and 2 of them were within the Wilton growth area.

In summary, the evidence suggests that the Little Eagle is found within the growth areas of Greater Macarthur and Wilton and that there are likely to be 4 to 6 pairs resident in the area. However, no evidence of breeding as defined by the presence of a bird on a nest or by the presence of pairs of birds in suitable habitat was observed within the growth areas. The presence of suitable foraging habitat within these growth areas means that protection of habitat within them may be critical to the continued presence of the Eagle in the area. It will also be important to provide a 100 m to 200 m buffer of open grassy woodland between any urban development and forest remnants to not only provide foraging habitat but also to prevent disturbance during nesting attempts within the growth areas.

5. Information Used in the Assessment

Data:

Atlas of Living Australia - occurrences of Little Eagle and Square-tailed Kite in Liverpool, Campbelltown and Wollondilly LGAs. (accessed 29-06-2018). <https://biocache.ala.org.au/occurrences/search>

6. Curriculum Vitae

Dr Tony Saunders

Name: Anthony Stephen John Saunders

Contact Details: 1878 Taralga Road Laggan NSW 2583 0409 399 849

Academic Qualifications:

BSc University of Sydney 1976
Dip Ed Sydney Teachers College 1977
PhD University of Western Sydney 2005

Other Qualifications:

LR Drivers Licence
Public Vehicle Driver Authority
Work Health & Safety General Construction Induction (White Card)
Chemical Use and Handling Certificate
Resuscitation Certificate
Emergency Care Certificate
Anaphylaxis Training Certificate
Drone Essentials Certificate

Fields of expertise:

Bird habitat assessment on reserves, lands in production and potential offset property.
Bird monitoring in natural, modified and managed habitats.
Assessment of likelihood of threatened woodland bird species occurrence on development sites.
Coordinating projects between government and non-government organisations.
Coordination of volunteers collecting wildlife data.
Ecotourism: guiding general interest and specialists groups in flora and fauna.
Environmental and science education at high school, TAFE, and university levels.
Habitat management for terrestrial woodland birds and other wildlife.
Presentations on ecology to public interest groups and at professional workshops.
Remote area wildlife atlassing.
Wildlife database design and management.
Land for Wildlife assessments and habitat enhancement planning.

Professional positions held:

2010 - 2018	Merops Services Pty Ltd (director, avifaunal ecologist). Environmental and landscape consultant and contractor, flora and fauna surveys, habitat enhancement plans.
2013 - 2018	Land for Wildlife Assessor for Community Environment Network
1995 - 2010	Merops Services (avifaunal ecologist). Environmental and landscape consultant and contractor.
2006 - 2018	Part-time teacher, mainly science, but also industrial arts, English and maths, Crookwell High School, Goulburn High School and Trinity Grammar School.
1997 - 2005	Part-time bird guide and ecotourism bus driver.
1993 - 2004	Part-time lecturer, supervisor and demonstrator, University of Western Sydney (biology, ecology and field survey techniques).
2001 - 2004	Atlas Facilitator, Birds Australia (organising remote atlassing, facilitating data exchange and communication between Birds Australia, state government organizations and other non-government organisations).
1997	Field Technical Officer, Birds Australia (monitoring breeding success of endangered bird species).
1996	Field Technical Officer, University of Western Sydney (reptile, bird and plant survey techniques and data analysis).
1978 - 1994	High School Science Teacher at Marsden, Heathcote, Penrith and Kingswood High Schools.

Other volunteer positions held:

2014 - 2017	Assistant to Co-ordinator of the Sydney Bird Fair.
2009 – 2018	President - Crookwell Native Flora and Fauna Club.
2013 - 2018	Secretary - Grabine/Foggs Crossing Landcare Group
2001 - 2018	Avifaunal Advisor and Education Officer for Oolong Sanctuary, Dalton.
1997 - 2010	Project Manager for Atlas of Birds of the County of Cumberland.
2010 - 2018	Technical advisor to the Cumberland Bird Observer's Club's Atlas Databasae Management Committee.
1996 - 2009	Committee Member - CBOC (Cumberland Bird Observers Club Inc.).
1998 – 2014	CBOC representative to Bird Interest Group Network (BIGnet).
1997 - 2002	Faunal Advisor for the Hawkesbury Rainforest Network.
1999 - 2002	Member of Steering Committee of Birds in Backyards for Birds Australia.
1998 - 1999	Consultant to Birds Australia Birds for Birds in Backyards Project.
1998 - 2003	Regional Organiser for Sydney and the Blue Mountains, NSW facilitator and NSW/ACT representative on the Steering Committee for the National Bird Atlas for Birds Australia.
2002	Representative on NSW NPWS Wildlife Issues Advisory Panel for Birds Australia.

Relevant experience:

Co-ordination, facilitation and organization of exhibits and presentations at field-day events and indoor venues. This has involved allocating space, providing necessary facilities and setting-up audio-visual equipment for exhibitors and presenters (18 years)

Co-ordinator of volunteers for the CBOC Inc. and the Birds Australia national birds atlas. (13 years)

Facilitated the BIGnet data exchange agreement between Birds Australia, NSW Bird Atlassers, Canberra Ornithologists Group and the Cumberland Bird Observers Club. Facilitated bird data exchanges between Birds Australia, NSW State Forests and NSW DECC. (4 years)

Presenter at seminars for Bushcare, Landcare, Greening Australia, Wires and local councils, conservation societies and garden clubs on habitat management for birds and bird survey techniques. (32 years)

Educator at public, tertiary and secondary levels in the area of bird habitat management and bird survey methodology. (23 years)

Ecotourism and bird guiding (19 years).

Undertaking avifauna surveys of sites for development applications and assessment of status of threatened bird species on sites and making recommendations for minimising impact of development on these species.

Bird habitat assessment of managed landscapes and natural habitat areas and recommendations for habitat enhancement and rehabilitation for birds. (21 years)

Design, building and management of the bird database for the birds of the County of Cumberland on behalf of CBOC Inc. (16years)

Membership and professional affiliations:

Australian Bird Study Association
Australian Bush Heritage
Birdlife Australia
Crookwell Native Flora and Fauna Society
Cumberland Bird Observers Club
Ecological Consultants Association of NSW
Grabine/Foggs Crossing Landcare Group
Greening Australia
NSW Bird Atlassers
Royal Zoological Society (Scientific member)
Wildlife Preservation Society of Queensland

Saunders, T. in prep. Trends in woodland bird populations on the Cumberland Plain.

Thesis:

Saunders, A.S.J. 2006 Comparative Foraging Ecology of the Noisy Friarbird *Philemon corniculatus* and the Red Wattlebird *Anthochaera caruncalata* in central eastern New South Wales.

Dr Stephen Debus

Abridged CV: Stephen John Stewart DEBUS

BA (Biol./Behav. Sc.), Dip. Natural Resources (Wildlife), Dip. Ed. (Sci.), MSc. (Zool.), PhD (Zool.)

Contact details:

Ph: 02 6773 2510 (BH), 02 6772 1710 (AH), mobile: 0409 779 766

Addresses: Zoology, University of New England, Armidale NSW 2351 (business)
PO Box 1015 (6 Holloway St), Armidale NSW 2350 (private)

Website www.une.edu.au/staff-profiles/ers/sdebus

Professional capacities:

Vertebrate fauna surveys. Research and survey of threatened forest and woodland birds, particularly raptors and owls. Ecology/biology/behaviour of birds, especially predatory species. Conservation and management of threatened bird species. Distribution, status and biology/ecology of NSW birds. Reviews and biological profiles of bird species. Editing ornithological papers. Peer review of ornithological documents/EISs/species impact statements. Impact assessment (avifauna). Review of conservation status of NSW fauna.

Computer skills:

Proficient in Word and Excel, limited experience with GIS and ArcView

Employment:

Eco Logical Australia 2011-18 (casual; senior ecologist: fauna survey and report)

EA Systems (now EnviroAg Australia) 2000-14 (casual; ecologist: fauna survey and assessment)

Research assistant, Zoology, UNE, casual 1984-2014 (field ornithology: bird banding, bird surveys/censusing, ecological studies)

Tutor/demonstrator, Zoology UNE (casual), 2007-13

NSW Dept Environment & Climate Change, 2008-09 (temporary) (threatened species officer: Project Officer, NSW Scientific Committee)

Research Assistant, Ecosystem Management UNE (casual), 2008-09 (bird survey)

Post-doctoral research fellow, Zoology, UNE, 2005-07 (ecology of woodland birds)

Junior research fellow, Zoology, University of New England, 1990-1993, 1998-2004 (ecology of rare forest owls in relation to habitat and forest management; ecology and management of birds)

Technical officer, University Partnerships Pty Ltd (UNE), 1995-1996 (fauna survey and report, Eastlink EIS)

Casual assistant demonstrator, Depts Zoology and Ecosystem Management, UNE, 1988-2002 (field practical classes on population ecology and behavioural ecology of birds)

Casual teacher, New England Institute of TAFE, 1987-1993 (bird biology: including laboratory and field practical classes on classification, identification and ecology)

Field technician, National Parks & Wildlife Service Armidale, 1986 (fauna inventory, vegetation sampling and analysis)

Research assistant, Department of Ecosystem Management, University of New England, casual 1986-1987 (field survey of vegetation and fauna)

Honorary position:

Adjunct associate lecturer/research associate, Zoology UNE, 2004-2017 (includes collaborative research and publication, co-supervision of Honours/Masters/PhD students)

Consultant biologist:

Whitehaven Coal 2018 (field survey, assessment and report on potential BioBank site for Regent Honeyeater)

Northern Tablelands Local land Services 2017-18 (Birds of Prey Monitoring project: nest sites and productivity of threatened raptors on the tablelands – field survey and report)

North West Local Land Services 2015-18 (Regent Honeyeater, Swift Parrot, raptor and woodland bird surveys and reporting)

28 South Environmental 2013-2018 (threatened fauna survey/assessment and report)

Fenner School of Environment and Society, Australian National, University 2016-17 (Regent Honeyeater surveys and data submission)

3E Environmental 2012-17 (flora & fauna survey and reporting)

BirdLife Australia – Northern NSW (for Bundarra-Barraba Operations Group of the Regent Honeyeater Recovery Team), 2007-17 (Regent Honeyeater/woodland bird survey and monitoring)

Southern New England Landcare 2014-16 (fauna surveys on farms, data submission, landholder workshop, report review)

James Warren & Associates 1997-2016 (fauna survey and reporting)

Conacher Environmental Group 2008, 2015 (fauna survey and report)

Ecotone Environmental Services 2012-13 (peer review of threatened fauna assessment; targeted fauna survey: federally listed birds)

NSW National Parks & Wildlife Service/Dept Environment & Conservation/DECC 1987-2013 (fauna survey, review of avifaunal component of environmental impact statements/ fauna impact statements/fauna reports, preparation of recovery plans and species profiles for threatened species)

Australian Museum, 1995, 2012 (review of fauna impact statement, avifauna; feather sampling of wild-caught birds for DNA analysis)

Cumberland Ecology 2004-2012 (fauna survey and report)

Arnhem Environmental 1996-2012 (fauna survey)

Eco Logical Australia 2010-2011 (threatened bird research, fauna database compilation)

Warkworth Mining Ltd 2008, 2011 (avifauna survey and report)

Terra Consulting/Geolyse/Orogen 2004-11 (fauna survey and assessment)

State Forests of NSW 1987-2009 (fauna survey, review of avifaunal component of environmental impact statements/fauna impact statements/fauna reports, fauna survey worskhop)

TransGrid 2009 (investigation and report: bird-related outages on 500 kV transmission lines)

Earth Services 2007-08 (fauna survey and report)

Armidale Dumaresq Council 2006-08 (fauna assessment)

Tamworth Regional Council 2007-08 (starling control/raptor assessment)

PLACE Environmental 2006-07 (fauna assessment)

ACT Planning & Land Authority 2005-06 (fauna survey and assessment)

Greenloaning Biostudies 1996-2004 (fauna survey)

Burnett Shire Council 2003 (fauna survey and assessment)

Inverell Shire Council 2003 (fauna assessment)

HWR Ecological 2003 (fauna survey)

WBM Oceanics 1999-2002 (fauna survey)

Resource Strategies 1999 (fauna survey)

Network Design & Construction Ltd, 1999 (fauna survey)

Woodward-Clyde Pty Ltd, 1994-1999 (fauna survey)

Telstra Environmental Evaluation Team 1998 (fauna survey and report)

Maunsell Pty Ltd, 1995-97 (fauna survey, review of environmental assessment)

Austeco Pty Ltd, 1990-1997 (fauna survey)

North-west Ecological Services 1997 (fauna survey)

ANCA 1995-1996 (fauna survey, Jervis Bay National Park)

SA National Parks & Wildlife Service, 1995 (fauna survey)

Grants and awards:

Search for Red Goshawk in NSW: $1,000 from the Australian Bird Environment Fund (Bird Observers Club of Aust.), 1987.

Distribution, status and habitat requirements of the Sooty Owl in northern NSW: $2,000 as a Cayley Memorial Scholarship (Gould League of NSW) 1990-93; with Associate Professors Hugh Ford & Harry Recher (UNE), $34,280 from WWF Australia and $64,835 from ANPWS (Endangered Species Program) 1990-93.

Will wildlife corridors work for sedentary birds?: with Professor Hugh Ford, $42,565 from the NSW Environmental Trust 2005, $43,359 in 2006-07.

Bird Observers Club of Australia: Distinguished Service Award, 2005 (editing the *Australian Bird Watcher*/*Australian Field Ornithology* for 21 years 1984-2005).

Royal Zoological Society of NSW Whitley Award, 2013 (*Birds of Prey of Australia: A Field Guide*, 2nd edn, best vertebrate guide in 2012)

BirdLife Australia's D.L. Serventy Medal for publication in ornithology, 2015

Voluntary work:

Editor: *Australasian Raptor Association News* 1980-1989 and *Boobook* (re-named) 2004-17 (biannual journal for bird-of-prey enthusiasts); *Australian Field Ornithology* 1984-2015 (quarterly journal)

Sub-editor: *Corella* Wedge-tailed Eagle special issue, 2007; White-bellied Sea-Eagle special issue, 2009; rare raptors special issue, 2011

Committee member: Australian Bird Study Association 1981-1988, 2005-17; Birds Australia Northern NSW Group 1996-99, 2004-12, 2015-17; Australasian Ornithological Conference 2009 organising committee 2008-09; ABSA/BirdLife Southern NSW conference organising committee 2013-14

Regent Honeyeater Recovery Team: Bundarra-Barraba Operations Group rep, 2008-18

Red Goshawk National Recovery Team 2014-18

Publications:

~130 refereed papers (selection appended), books and book contributions, theses: see appended list

Strategic Assessment for the Square-tailed Kite *Lophoictinia isura* in the Growth Areas of Greater Macarthur and Wilton

1. Introduction

Purpose

The purpose of this report is to assess the likelihood of occurrence and potential impacts of the urban growth in the Greater Macarthur and Wilton areas on the Square-tailed Kite *Lophoictinia isura*. In particular, this report will assess the presence of breeding and foraging habitat within these growth areas as required under the Biodiversity Assessment Method. It will also discuss conservation measures required to mitigate potential impacts.

The Square-tailed Kite is listed in New South Wales as vulnerable under the *Biodiversity Conservation Act 2016* and is an uncommon species found in coastal and sub-coastal forests and woodlands. Inland, it shows a preference for timbered watercourses, though not necessarily strictly so near the coast, and is a summer breeding migrant to south-eastern Australia, arriving in September and leaving by March. Records for this species exist in and around the area to be impacted by the development. However, the species is encountered infrequently in this area and its interactions with local habitat have not been well studied.

The existence of potential habitat for the Square-tailed Kite and of records for the species within the area has meant that a more detailed assessment of the likelihood of impacts from the development in the area is required, particularly of the species' foraging and breeding use of the area. Targeted surveys could gather this information, but the survey effort required to collect sufficient data would be great and in the order of hundreds of hours in the appropriate seasons over several years. This would also require tracking of individual birds to gather time budgets and breeding locations and behaviour at nests etc. Access to several potential habitat areas also proved difficult during the survey period. Knowledge of the habitat structure and plant community types (PCTs) that the Kite has been recorded in within the development area and of the ecology of the species can be used as a surrogate for this fieldwork.

Project Context

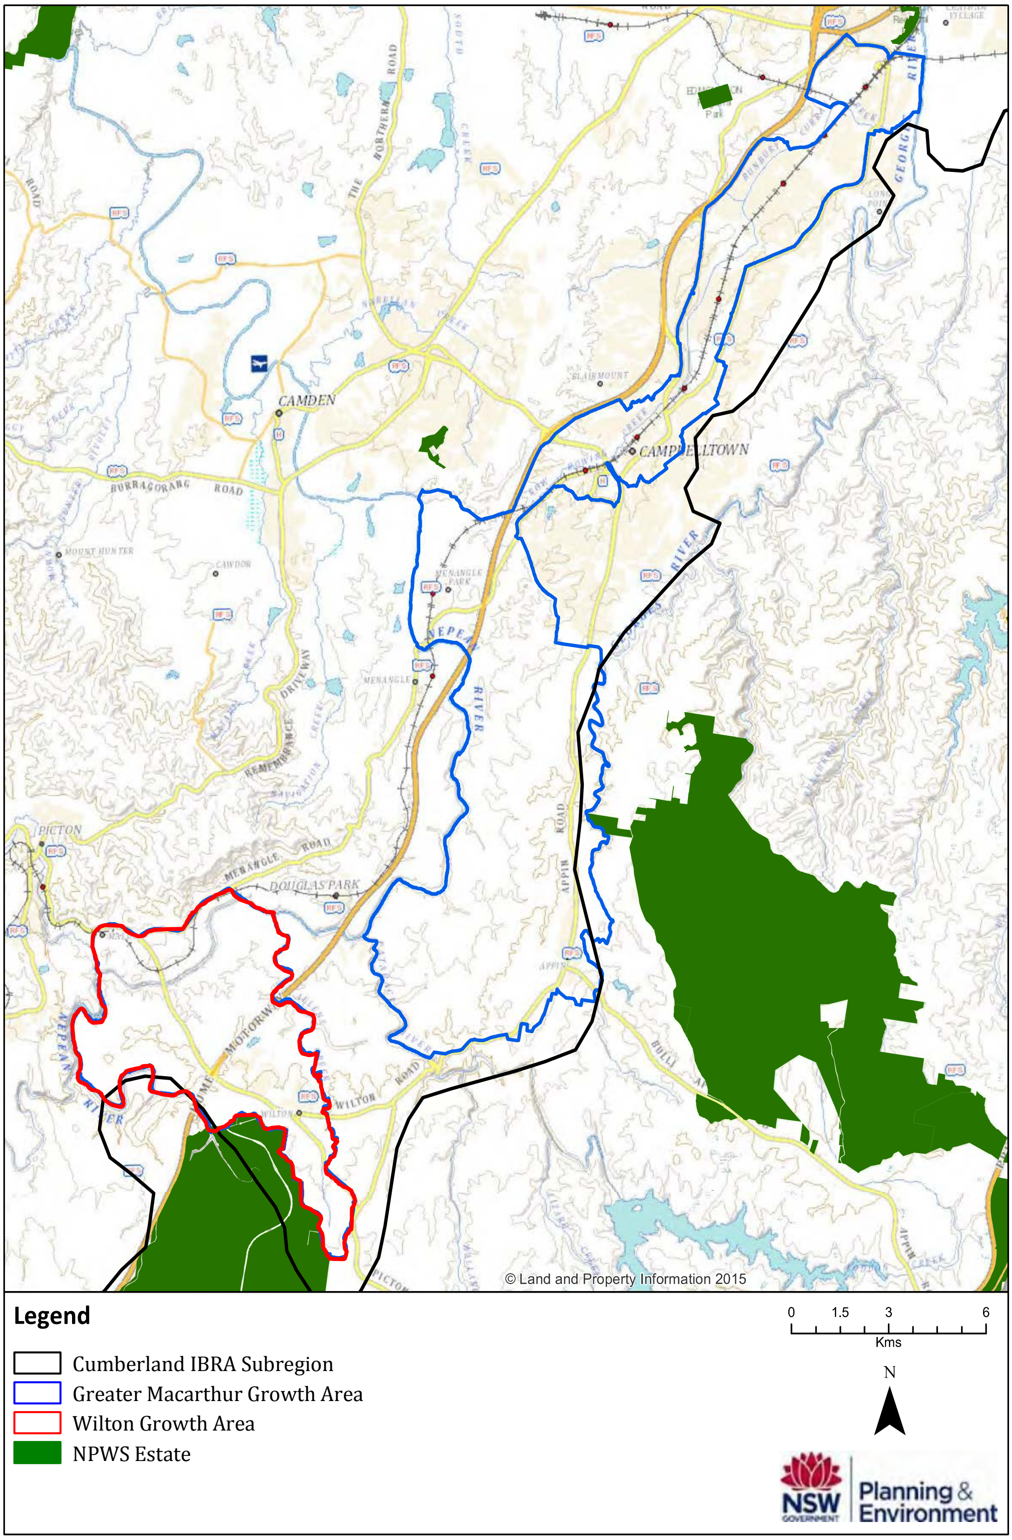
The Department of Planning and Environment is leading a strategic biocertification of several identified growth areas within Western Sydney. The strategic biodiversity assessment is an integral part of the Cumberland Plain Conservation Plan that will determine the impact of urban development on threatened species and ecological communities within these growth areas. The Plan will also provide conservation measures to mitigate any impact, as specified by NSW and Commonwealth environmental legislation.

The timeframe for this project, and difficulties in accessing private lands have resulted in some survey challenges for the project. Only 68% of the potential habitat available for this species in the Wilton and Greater Macarthur Growth Areas has been successfully surveyed. Significant areas of the Greater Macarthur Growth Area were unable to be adequately surveyed due to restrictions around land access. Around 363 hectares of potential habitat was not surveyed within this growth area, and only 35% of PCT 850 Grey Box-Red Gum grassy woodland on shale of the southern Cumberland Plain within this growth area was successfully accessed for survey.

Study Area

The study area is in the Macarthur and Wilton areas, which extend from the southern parts of Liverpool, down to Appin, across to Wilton and then towards the area between Wilton and Picton. The area is within the Cumberland IBRA subregion and the location is shown in Figure 1. The area is bound within a latitude range from -33.88 to -34.33 and a longitude range of 150.55 to 150.97.

Figure 1. Location of Growth Areas and the Cumberland IBRA Subregion.



Survey Methods

Vegetation maps (as supplied by The Department of Planning and Environment NSW) of the Greater-Macarthur Growth Area and the Wilton Growth Area were used to select patches of remnant vegetation that may provide suitable habitat for the Square-tailed Kite. Fifty potential sites were chosen from these maps. Sufficient access was feasible for 40 of these remnants.

The remnants were visited over 4 days from the 18-06-2018 to the 21-06-2018 inclusive. Each site was surveyed for between 0.5 and 1.0 hours. The aim was to collect qualitative data on each of the following:

habitat structure -	tree height range, DBH range, canopy cover, tree maturity, shrub density, grass cover, ground cover
habitat quality -	tree age diversity, shrub layer diversity, presence of woody weeds, evidence of regeneration
connectivity -	degree of connectivity, relative width of corridor to other remnants, presence of gaps in vegetation
aspect and slope -	slope steepness, direction of slope and relationship of site to structural features e.g. watercourses etc.
avian species -	overall diversity, species composition, presence of feral species

The aim was to assess if these sites contained suitable habitat for foraging and breeding and whether they allowed for dispersal of prey and the target species into and out of the remnants. The extent of suitable habitat across the growth areas was then used to estimate the likelihood of the Kites using the area for foraging and/or breeding.

The Atlas of Living Australia (ALA) and the bird database from the Cumberland Bird Observers Club Inc. (CBOC) were searched for atlas records of the Square-tailed Kite. The records within the Atlas of Living Australia had data mainly from the Bionet Atlas of NSW Wildlife with a few records from un-named individuals contributing directly to the ALA. At the time of access the CBOC bird atlas had over 20,000 survey results for the section of the Cumberland IBRA sub-region that lies within the County of Cumberland. These 2 data sets combined would have captured most of the data on the Kite for this area.

Justification for Use of an Expert Report

The presence of suitable habitat for foraging and breeding for the Square-tailed Kite combined with the low density for this species and the difficulties with gaining sufficient access for surveys to establish the presence and habitat use by the Kite in the development area has meant that survey effort alone has not been able to establish the potential importance of the area for this Kite.

An expert in the breeding and foraging ecology of the Kite would be required to assess the importance of the habitat remnants and the likelihood of occurrence within the growth areas. The Kite is a forest and woodland specialist whose major food in its breeding season is forest and woodland birds, particularly small to medium-sized passerines and the contents of their nests, but also in recent times introduced and native pigeons and doves, and an abundant native bird (the Noisy Miner *Manorina melanocephala*), all of which are increasing in urban and near-urban areas and fragmented bushland. Therefore, an expert would also need to also be expert on the avifauna populations occurring in forest and woodland in the Cumberland IBRA Subregion. The report will address the food resources and foraging space of this raptor as well as the Kite's potential nest sites and breeding habitat within the growth areas.

Credentials of the Experts Preparing this Report

Dr. Tony Saunders

BSc University of Sydney 1976.
Dip.Ed. Sydney Teachers College 1977.
PhD University of Western Sydney 2005.

Company Director and Avian Ecologist, Merops Services Pty Ltd 1995 to present.

Relevant experience in surveys and the study of woodland and forest birds of the Cumberland plain:

- Cumberland Plain woodland bird surveys for the NSW Bird Atlas and then for the CBOC Bird Atlas 1982 to the present.
- Cumberland Plain woodland bird surveys on the UWS Hawkesbury Campus 1998 to 2005.
- Woodland bird surveys for Holroyd Council's reserves and parklands 2008 to 2011.
- Survey for threatened woodland birds in proposed urban development of the former ADI site at Penrith 2002.
- Survey for threatened woodland birds in proposed rural subdivision at Badgerys Creek 2006.
- Presented the opening presentation ' Birds of the Cumberland Plain. What was there? What have we lost?' at the ABSA Conference 2016.
- Presented 'Trends in woodland birds of the Cumberland Plain' at the RZS of NSW Conference in 2016.
- Avifauna surveys of sites for development applications and assessment of status of threatened bird species with recommendations for minimising impact of development on these species within the Cumberland Plain and eastern New South Wales. (21 years)
- Bird habitat assessment of managed landscapes and natural habitat areas and recommendations for habitat enhancement and rehabilitation for birds. (21 years)

Relevant publications relating to woodland birds of the Cumberland Plain:

2. Species Information

Species Description

Adult Square-tailed Kites are brown with a white crown and face, with dark streaked rufous nape and underparts. The tail is about half the total length and is grey-brown with a dark terminal band (Debus 2012). They can be confused with other raptors, but can be distinguished by the white cap (in adults), long and widely splayed, boldly banded primaries when soaring or gliding on upswept wings, slender bill, small feet and very short legs hidden by feathers when perched and with the long wing tips crossing below the tail tip at rest (Debus 2017). It can often be observed circling low over the tree canopy on upswept wings with spread 'fingers' (Saunders pers. obs.).

Life Cycle

Square-tailed Kites usually occur singly, in pairs or (in the post-fledging period) family groups of adult(s) and fledgling(s) (Debus 2017). The highest count in one survey within the Cumberland County was 4 (CBOC Atlas accessed 29-06-2018), and most records for the Cumberland IBRA subregion were of single birds (ALA accessed 29-06-2018). They are generally solitary during the non-breeding season (Debus 1993). They appear to be long term monogamous as breeding pairs, as they are intolerant of other adults of the same species within their breeding territory and they occupy the same nest site for many years (Debus *et al.* 1993; Bischoff *et al.* 2000). In eastern New South Wales, nest building occurs in July to October, laying in August, incubation in September to November, hatching occurs in September to October, nestlings occur from October to December and fledglings from November to December (Debus 1996; Bischoff *et al.* 2000; Brown *et al*. 2000; Griffiths *et al.* 2002; Lutter *et al.* 2003,2004; Stowe 2009). In the Cumberland County breeding has been recorded from July to February (CBOC Atlas, accessed 29-06-2018). Nestlings remain in the nest for between 55 and 60 days (Barnes *et al.* 1999, 2001; Lutter *et al.* 2003, 2004). Fledglings are dependent on the parents for about 2 months after which they generally disperse (Bischoff *et al.* 2000; Barnes *et al.* 2001; Lutter *et al.* 2003). The generational cycle is estimated to be 10 years (Garnett & Crowley 2000).

Distribution and Abundance

The Square-tailed Kite is an endemic species found over most of the Australian mainland and some larger offshore islands. It avoids the most arid, treeless central regions, where it is scarce or absent (Debus 2012). It is primarily found in open eucalypt forests, woodland and mallee where passerines are common (Garnett 1993). They are generally absent from south-eastern New South Wales during the non-breeding period (Debus 1993) and are considered to be a summer breeding migrant to the south east of New South Wales (Square-tailed Kite species profile, OEH Website, accessed 29-06-2018). Reporting rates were lower during the May to June period in the Central and South Coast regions of New South Wales (Cooper *et al.* 2014). The Kite has been recorded from August to April across the Cumberland County from the coast to the western edge of the Cumberland Plain, with a more widespread distribution in the northern half of the County (CBOC Atlas, accessed 29-06-2018). In the southern part of the Cumberland IBRA Subregion there are records from Liverpool, Macquarie Fields, Ingleburn, Appin, Wilton and Picton areas (ALA Atlas, accessed 29-06-2018, see Section 4 for more details of these atlas records). The latter area encompasses the Greater Macarthur and Wilton growth areas.

The global population of the Square-tailed Kite is estimated to be between 1000 and 10,000 birds (Ferguson-Lees and Christie 2001). Density estimates are based mainly on breeding territories. In the Bendigo area of Victoria the estimate was 25.8 pairs per 1000 km^2 of forest (Robinson *et al.* 2016). In northern coastal NSW the estimates vary from one pair per 120 km^2 to one pair per 170 km^2 (Debus 1996, Lutter *et al.* 2004).

There was a twofold increase in reporting rates in NSW over a 20-year period prior to 2006, mostly concentrated on coastal areas (Cooper *et al.* 2014). Barrett *et al.* (2007) reported a 40.8% increase in reporting rates for NSW, but this was not considered a significant change due to small sample size. Morris *et al.* (1981) reported that the Kite was scarce in coastal NSW based on records prior to the date of publication.

In the County of Cumberland there were only 2 records from more than 100 years ago (Hindwood & McGill 1958). Hoskin (1991) reported that the Kite was only a rare straggler to the County with only a few records. There has been an increase in the number of records over the last two decades and there are now breeding records for the County, from near Asquith in 2012 and 2013 and in Lane Cove National Park in 2015 (Patrick 2016). The Kite has also been recorded in the Shoalhaven area (Chafer *et al.* 1999). There were 40 records for the County in 2017 (CBOC Atlas, accessed 29-06-2018). It was seldom recorded in the Cumberland Plain prior to 1990 but has shown an increase in reporting rate from 0.5% in the 1990s to 2.5% since 2010 (Saunders in prep.). All records for the Liverpool, Campbelltown and Wollondilly Local Government Areas, which includes the growth areas, have been made since 2000 (ALA Atlas, accessed 29-06-2018). There is a recent breeding record for the Cumberland Plain (near Penrith), and recent breeding records for bushland within the Sydney suburbs (Asquith and South Turramurra) (Optland 2015; I. McAllan pers. comm.).

There have been suggestions as to why the Kite has increased in some areas. It appears to be adapting to urban bushland areas around coastal cities where it feeds on abundant native passerines and introduced bird species (Bischoff *et al.* 2000, Debus 2012). Lower competition from the Brown Goshawk *Accipiter fasciatus* (nestling predation) has been suggested as a possible explanation for the increase in breeding observed in the Bendigo area (Robinson *et al.* 2016), but reporting rates for the Brown Goshawk have increased from 2% to 7% over the last six decades in Cumberland Plain woodland sites where the Kite has also increased and so does not support this suggestion (Saunders in prep.).

Habitat Requirements

Square-tailed Kites are found mainly in coastal and sub-coastal eucalypt dominated forests and woodland, as well as treed areas in urban habitats (Debus 1993, Olsen 1995, Debus 2017), open forests and woodland (Cupper & Cupper 1981, Chafer *et al.* 1999, Barrett *et al.* 2007), passerine-rich woodlands when breeding and more open country when not breeding (Olsen *et al.* 1993) and open forests that are contiguous with very large areas of forest (Griffiths *et al.* 2002). They prefer timbered watercourses through open or cleared land and the margins between open and timbered country (Debus 1993).

When breeding, the Kite requires open forest where it can forage for nestlings in the canopy and approach the nest easily (Hollands 1984). Tall living eucalypt trees are chosen for nest sites (Debus 1993), especially where they are close to open edges (Lutter *et al.* 2004). They can tolerant human disturbance and use areas of urban bushland (Bischoff *et al.* 2000, Griffiths *et al.* 2002). Nests are mostly between 15 and 28 metres above ground in trees that range from 20 to 40 metres tall (Cupper & Cupper 1981, Bischoff *et al.* 2000, Barnes *et al.* 2001, Griffiths *et al.* 2002, Lutter *et al.* 2003, 2004, Stowe 2009 and Optland 2015). The minimum requirements for nesting based on the literature review are described in Tables 1 and 2 below.

Table 1. Minimum distances of active Square-tailed Kite nests from developments (collated from various studies cited by Debus 2017, eastern/south-eastern Australia):

Parameter	
Dwelling	60–70 m
Urban area	Within*
Industrial building	–
Sealed road	5–10 m**
Unsealed road	15 m
Track/path	0 m#

*In the carpark of a suburban facility (animal hospital) in a bushland setting
**Almost overhanging the verge of a highway
#Directly over a trail-bike track

Table 2. Minimum criteria for active Square-tailed Kite nest-site characteristics (collated from various studies cited by Marchant and Higgins 1993 and Debus 2017, eastern/south-eastern Australia):

Parameter	Measurement
Forest/woodland patch size	5 ha*
Nest-tree height	20 m
Reference tree height**	10 m
Nest-tree DBH#	30 cm
Reference tree DBH	–
Nest height	9 m

*In fragmented landscapes with much larger patches nearby
**Reference trees are other trees within the nest patch
#Diameter at breast height

There is some information on local vegetation types that are preferred by the Square-tailed Kite. One hundred and twenty one records out of the 289 records held with the CBOC Atlas (accessed 29-06-2018) contain information about the habitat type where the Kite was encountered. In order of most to least common they were:

Tall Forest	17%
Sandstone Woodland	17%
Pastureland with Scattered Trees	17%
Urban Parkland	14%
Cumberland Plain Woodland	13%
Swamp and River Woodland	9%
Heath	9%
Freshwater Wetlands	4%

The OEH Threatened Species Data Collection indicates that the Square-tailed Kite has the potential to inhabit the following plant communities within the Wilton and Greater Macarthur Growth Areas:

835	Forest Red Gum – Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion
850	Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion
1181	Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney
1800	Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion

The habitat requirements discussed above have been used in this report to identify important habitat areas. They have been grouped into the habitat criteria listed below. The greater the number of criteria that are met the more likely it is that the remnant will provide habitat for Square-tailed Kite.

1. The site contains tall open forest or woodland.
2. The site is near or along a timbered watercourse.
3. The site contains one or more of the following PCTs - 835, 849,850 and 1181.
4. Canopy foliage nesters, particularly honeyeaters, are common on site.
5. The site contains urban edge tolerant bird species e.g. Noisy Miner, Red Wattlebird, Lorikeets, Crested Pigeon or Spotted Dove.
6. Forest or woodland that has open edges around remnants, timbered corridors and along watercourses.
7. Forest or woodland that has tall trees (> 20m) near outer edges or emergent trees suitable for nesting.

3. Description of the Study Area's Relevance to the Square-tailed Kite

Land Use History

Much of the northern half of the Greater Macarthur growth area has been developed as residential, commercial and industrial land decades ago and any remaining habitat can only be found along watercourses and on steep slopes where these developments are not appropriate. Much of this area would have been a mix of cleared grazing land and bushland prior to this stage of development.

The southern half of the Greater Macarthur and the Wilton growth areas contain older small towns, which now have a few larger new residential developments. These occupy only a small area within the growth area. Much of the land consists of small to medium rural holdings and grazing agricultural land that was cleared for farming decades ago. Throughout this area there are many watercourses that are tributaries to either the Georges or Nepean rivers and the forests along these watercourses has largely been left intact with some clearing or thinning at the edges. Many of the remnant patches and forested watercourses have been affected by woody weed invasion since development in the area.

Landscape Context

The growth areas follow the transport corridor along the Hume Motorway that connects the area to the south-western areas of greater Sydney to the north. The area abuts intact, contiguous, forested areas to the east and to the south. These are in water catchments or national park reserves, which cover hundreds of square kilometres. The western edge abuts mostly cleared rural holdings either side of the Nepean River and then further west to the Warragamba Dam water catchment area.

Much of the region is in the western half of the Cumberland IBRA subregion, which contains most of the remaining large woodland remnants and is an important area for this reason. The woodlands of the Cumberland Plain are threatened ecological communities and have been prioritised by the Office of Environment and Heritage for habitat protection and enhancement (DECCW 2010).

Native Vegetation

The remnant native vegetation within the growth areas is mainly eucalypt forest and woodland. Forested areas on steep slopes and along watercourses have largely been left intact and often contain a structurally and species diverse understorey. Woodland areas remaining on flat or gently undulating land have a few scattered dense patches of understorey, but are mostly open woodland with a grassy understorey. Many remnants have been invaded by woody weeds and many woodland remnants are subjected to grazing pressure and are clear of any understorey. Some of the remnants have also been thinned and have only scattered paddock trees along their edges.

The following plant community types are found in these remnants within the growth areas:

Potential Habitat

Most of the uncleared areas in the northern half of the Greater Macarthur growth area are remnant forest patches along watercourses that were unsuitable for development. They are small, often isolated and mostly surrounded by urban development with little or no open areas surrounding each remnant to act as buffers. Some have open areas within them that have mown grass and are now parkland. Only the steeper slopes along the watercourse have any shrub layer, but they also have tall eucalypts that provide suitable foraging habitat and potential nesting trees. This area has a major watercourse near the eastern edge, which is the Georges River. This river would provide access to the reserves that provide some suitable resources for the Kite.

The southern half of the Greater Macarthur and the Wilton growth areas have small areas of urban development and larger areas of open grazed pastureland and rural holdings. There are very large remnants of forest and woodland that mainly follow watercourses that are connected to either the Georges or Nepean Rivers. In the south and east sections of the growth areas many of these forest remnants are also part of contiguous habitat into water catchment reserves or national parks. The forest remnants often border open areas with scattered trees and provide good edge habitat for the Kite.

Some 40 sites, scattered over the whole length of the growth areas, were sampled for habitat quality and their ability to provide foraging and nesting resources for the Kite. Fifty potential sites were selected based on the vegetation maps of the area but access into much of the area was difficult. The habitat requirements for the Kite are described in detail in Section 2 of the report and are grouped into seven different criteria for assessing suitable habitat. Details of each site's location, their PCTs and which of the criteria were satisfied are listed below (see Table 1) and a more-detailed description of each site can be found in Appendix 1. All of the sites met at least one of the criteria and 27 of the sites meet at least 5 of the 7 criteria. The PCTs where the Kite has been observed from previous records (Bionet Atlas of NSW Wildlife, accessed 29-06-2018) include 835 Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion, 849 Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion, 850 Grey Box - Forest Red Gum grassy woodland on shale of the Cumberland Plain, Sydney Basin Bioregion and 1181 Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion, which were recorded on many sites. Most of the larger remnants in the south Greater Macarthur and in the Wilton growth areas contain PCT 1395 Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion. Many of these sites contain emergent Grey Gums *Eucalyptus punctata,* which would provide nesting sites and this tree species would provide foraging opportunities because it is also popular with honeyeaters and other small passerines (Saunders and Burgin 2001).

These sites represent only a small portion of the forest remnants within the growth areas, yet nearly all sites satisfied many of the criteria used to assess whether suitable habitat existed on-site for the Kite. This implies that most of the remaining forest and woodland habitat in the area is potential Kite habitat, especially as the remnants are tall, have open edges and follow watercourses. Open areas that exist adjacent to the forest and woodland remnants, and especially between open woodland patches and timbered watercourses should also be accepted as potential habitat for the Kite. All forest, woodland and open areas that provide potential habitat will be shown as species polygons in Section 4 of this report. It should be noted that some of the important open areas adjacent to forest and woodland remnants overlap with the urban development footprint.

Table 3. Criteria relating to habitat resources for the Square-tailed Kite that were satisfied for each of the study sites.

Site No.	Latitude	Longitude	PCTs	Criteria Satisfied
1	-33.96801	150.90682	849	1,2,3,5,6,7

40	-34.20781	150.63328	1081	1,2,4,5,6,7

Criteria:
1. Site contains tall open forest or woodland.
2. Site is near or along a timbered watercourse.
3. Site contains one or more of the following PCTs - 835, 849,850, 1181 and 1395.
4. Canopy foliage nesters, particularly honeyeaters, are common on site.
5. Site contains urban edge tolerant bird species e.g. Noisy miner, Red wattlebird, Lorikeets, Crested Pigeon or Spotted Dove.
6. Forest or woodland has open edges around remnants, timbered corridors and along watercourses.
7. Forest or woodland has tall trees near outer edges or emergent trees suitable for nesting.

4. Assessment of Specie's Presence and Suitable Habitat

Species Records for the Greater Macarthur and Wilton Growth Areas

There were 32 records for the Square-tailed Kite from the area containing the urban development area (ALA Atlas and CBOC Atlas, accessed 29-06-2018). The list of records is shown in Table 2 and the distribution of these records is shown in Figure 2.

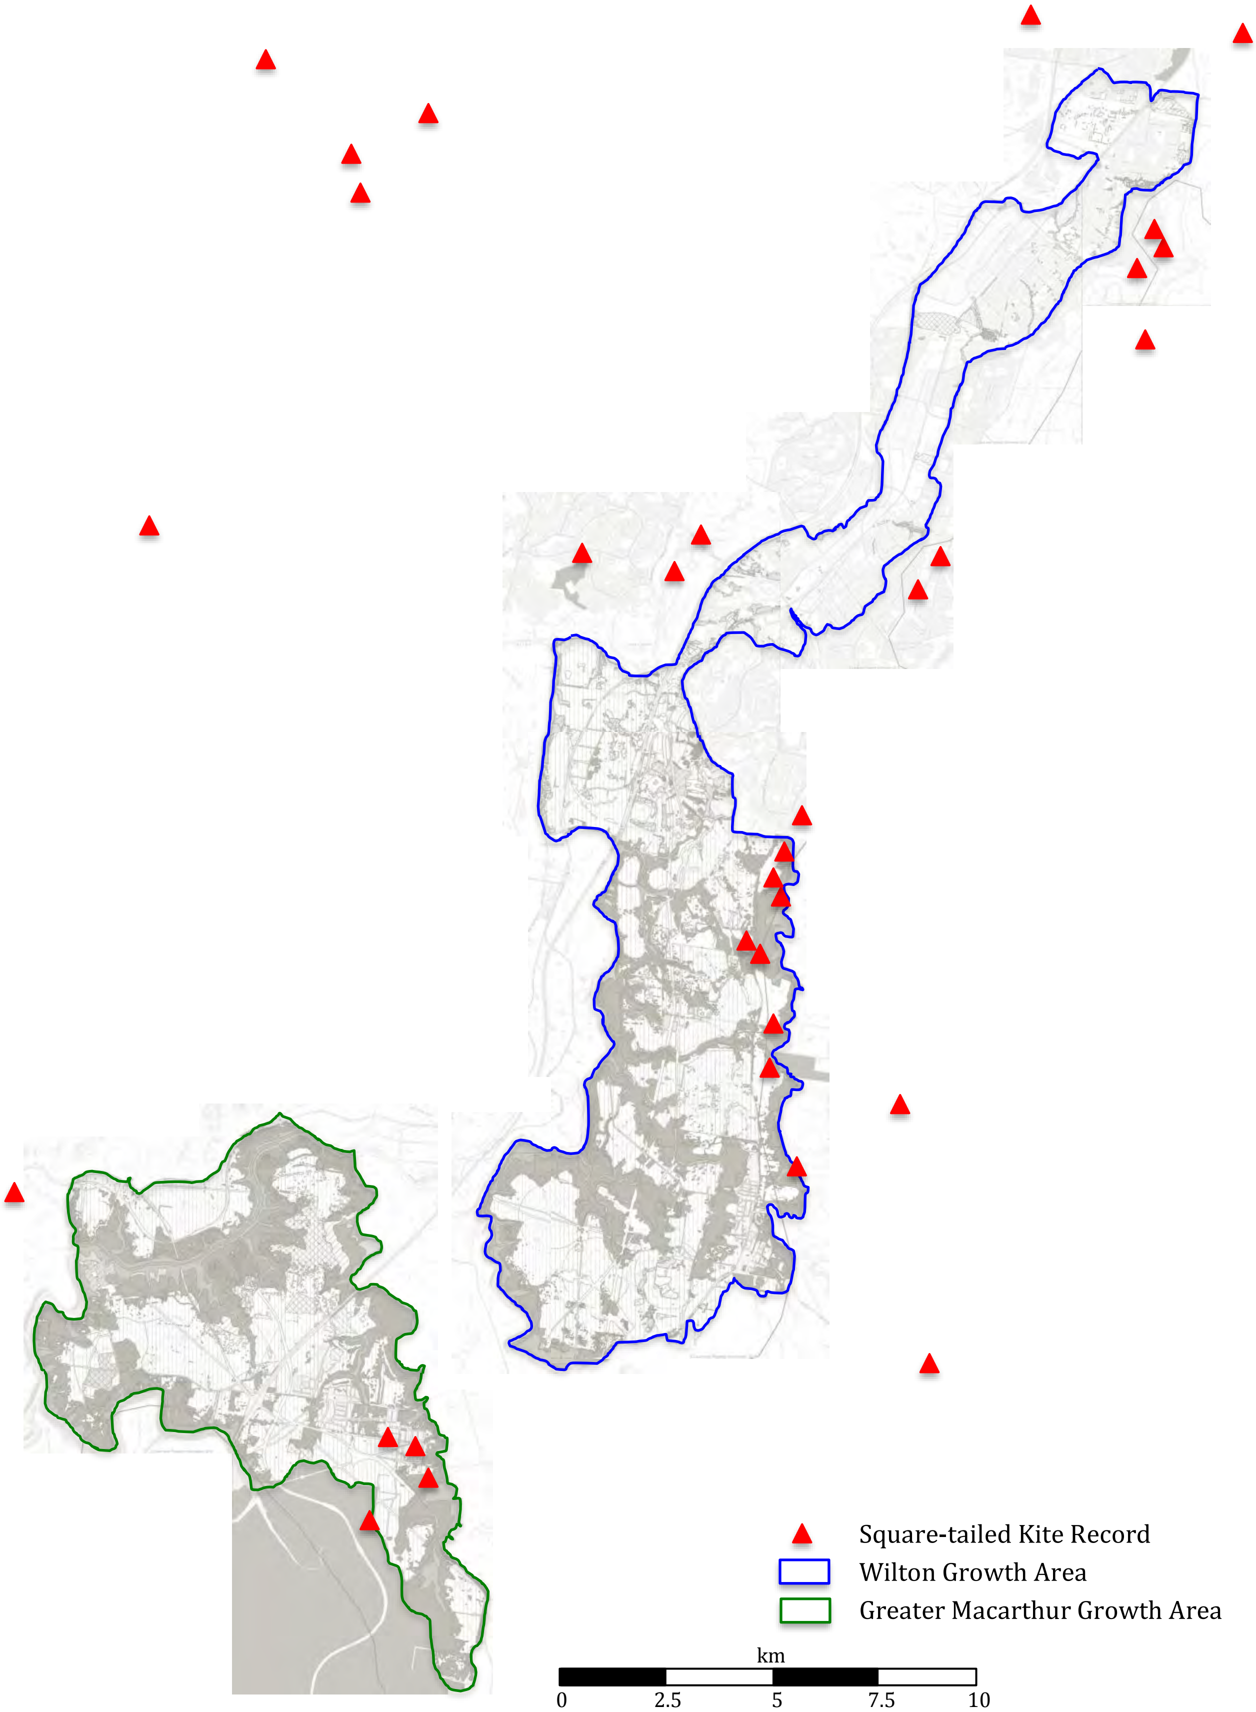

Figure 2. Distribution of records for the Square-tailed Kite *Lophoictinia isura* in and around the Greater Macarthur and Wilton Growth Areas (source ALA and CBOC Inc.).

Of these 32 records, 12 were within the southern half of the Greater Macarthur Growth Area and the Wilton Growth Area. Another 15 records are within 5 kilometres of the boundaries of the PGAs, with 11 of them just outside the northern section of the Greater Macarthur Growth Area. There were no records for July through to September with the majority of records from January through to April, being the post-breeding dispersal phase. Most of the records are associated with forest along watercourses and were made close to the edges of remnant forest. The records support that these two factors, timbered watercourses and forest edges, as being important habitat requirements for the Square-tailed Kite. These records also show that PCT 1395 Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion is an important plant community type for the Kite. We are not aware of any previous habitat assessments for the Square-tailed Kite in the study area.

Assessment of Suitable Habitat in the Growth Areas, Distribution Polygons and Justification for Determination

The areas of potential foraging habitat and potential breeding habitat for the Greater Macarthur Growth Area are shown in maps 1 to 7 in Figure 3. The areas of potential foraging habitat and potential breeding habitat for the Wilton Growth Area are shown in maps 1 to 3 in Figure 4. The existing remnant patches containing potential habitat for the Kite are shown as an overlay over the vegetation maps. These are sites where the habitat structure, plant community type and placement in the landscape, all indicate potential breeding and foraging habitat for the species (shown in red). Some habitat areas would provide potential foraging habitat but not breeding habitat (shown in orange). Some of the areas within the urban development footprint have been included because they satisfy several of the following conditions. They contain good edge habitat adjacent to an existing habitat remnant e.g. open areas with scattered trees, provide good foraging habitat, provide connectivity between existing remnants, broaden a connecting corridor or protect an edge habitat (shown in yellow). Other areas, which also satisfied any of these same conditions and that are not within the urban development footprint, are included as they are areas where habitat enhancement would improve the Kite's access to resources within the growth areas (shown in green).

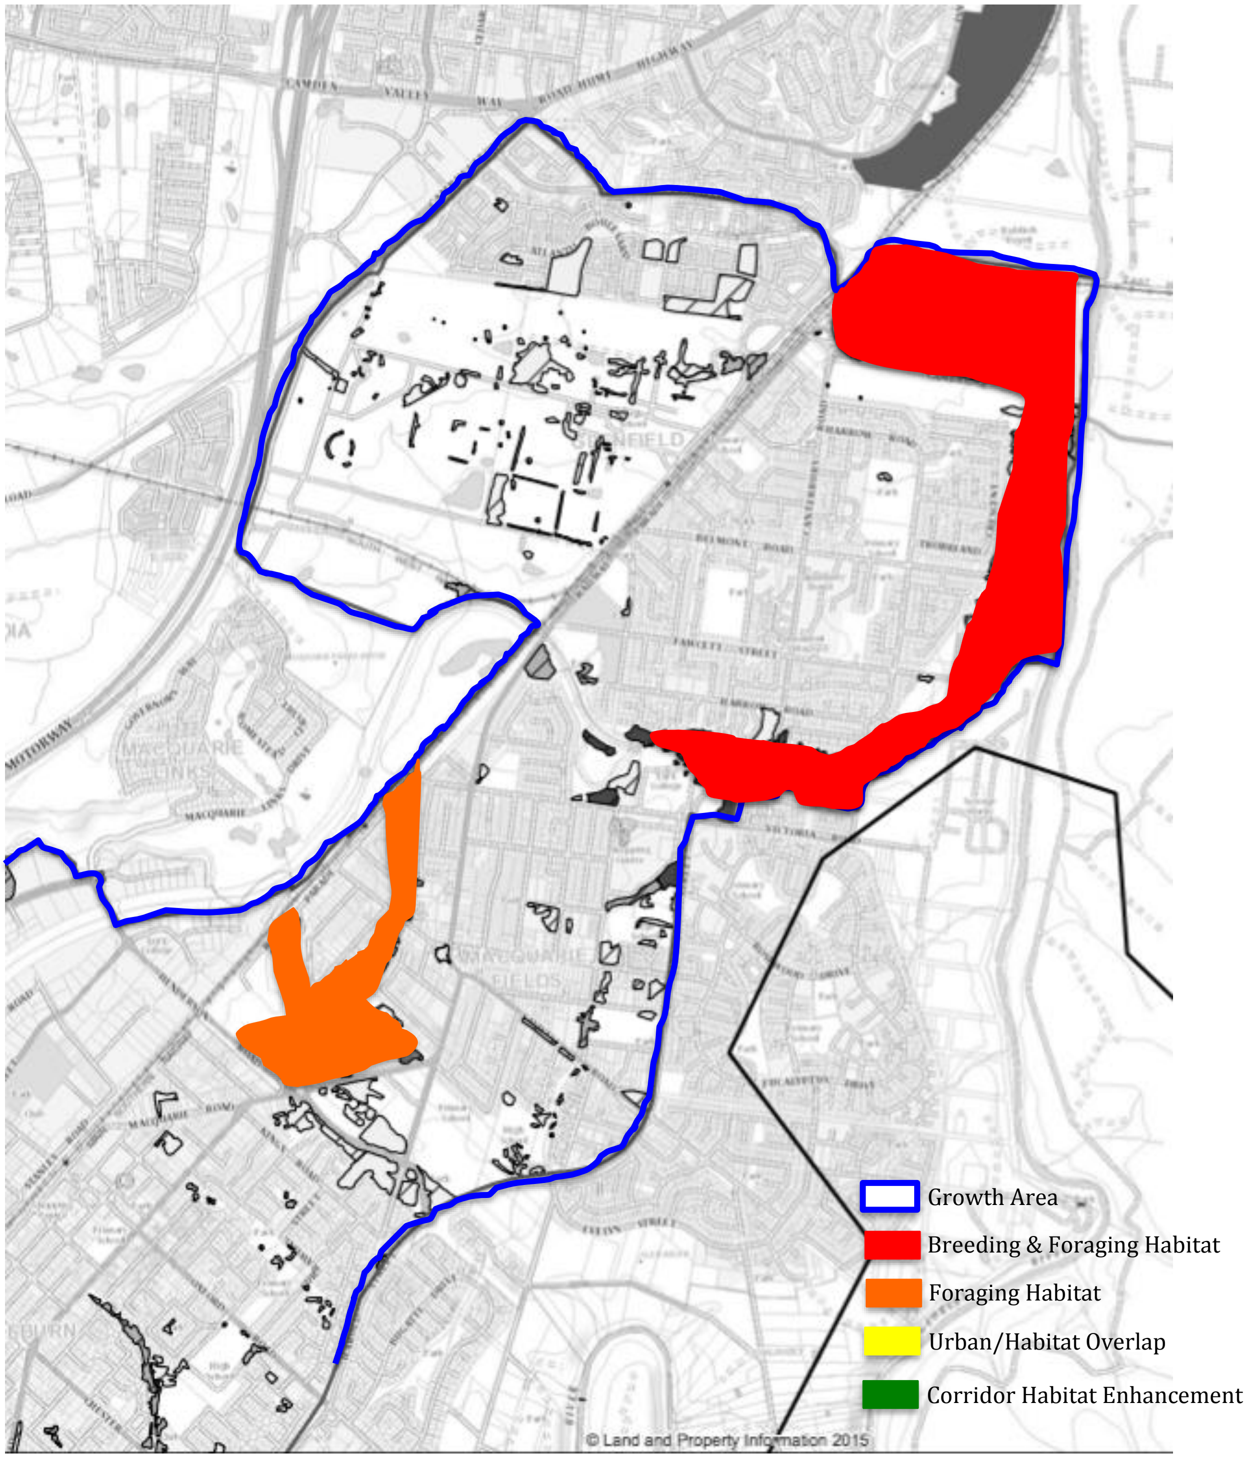

Figure 3. Potential breeding and potential foraging habitat for the Square-tailed Kite in the Greater Macarthur growth area (Map 1). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

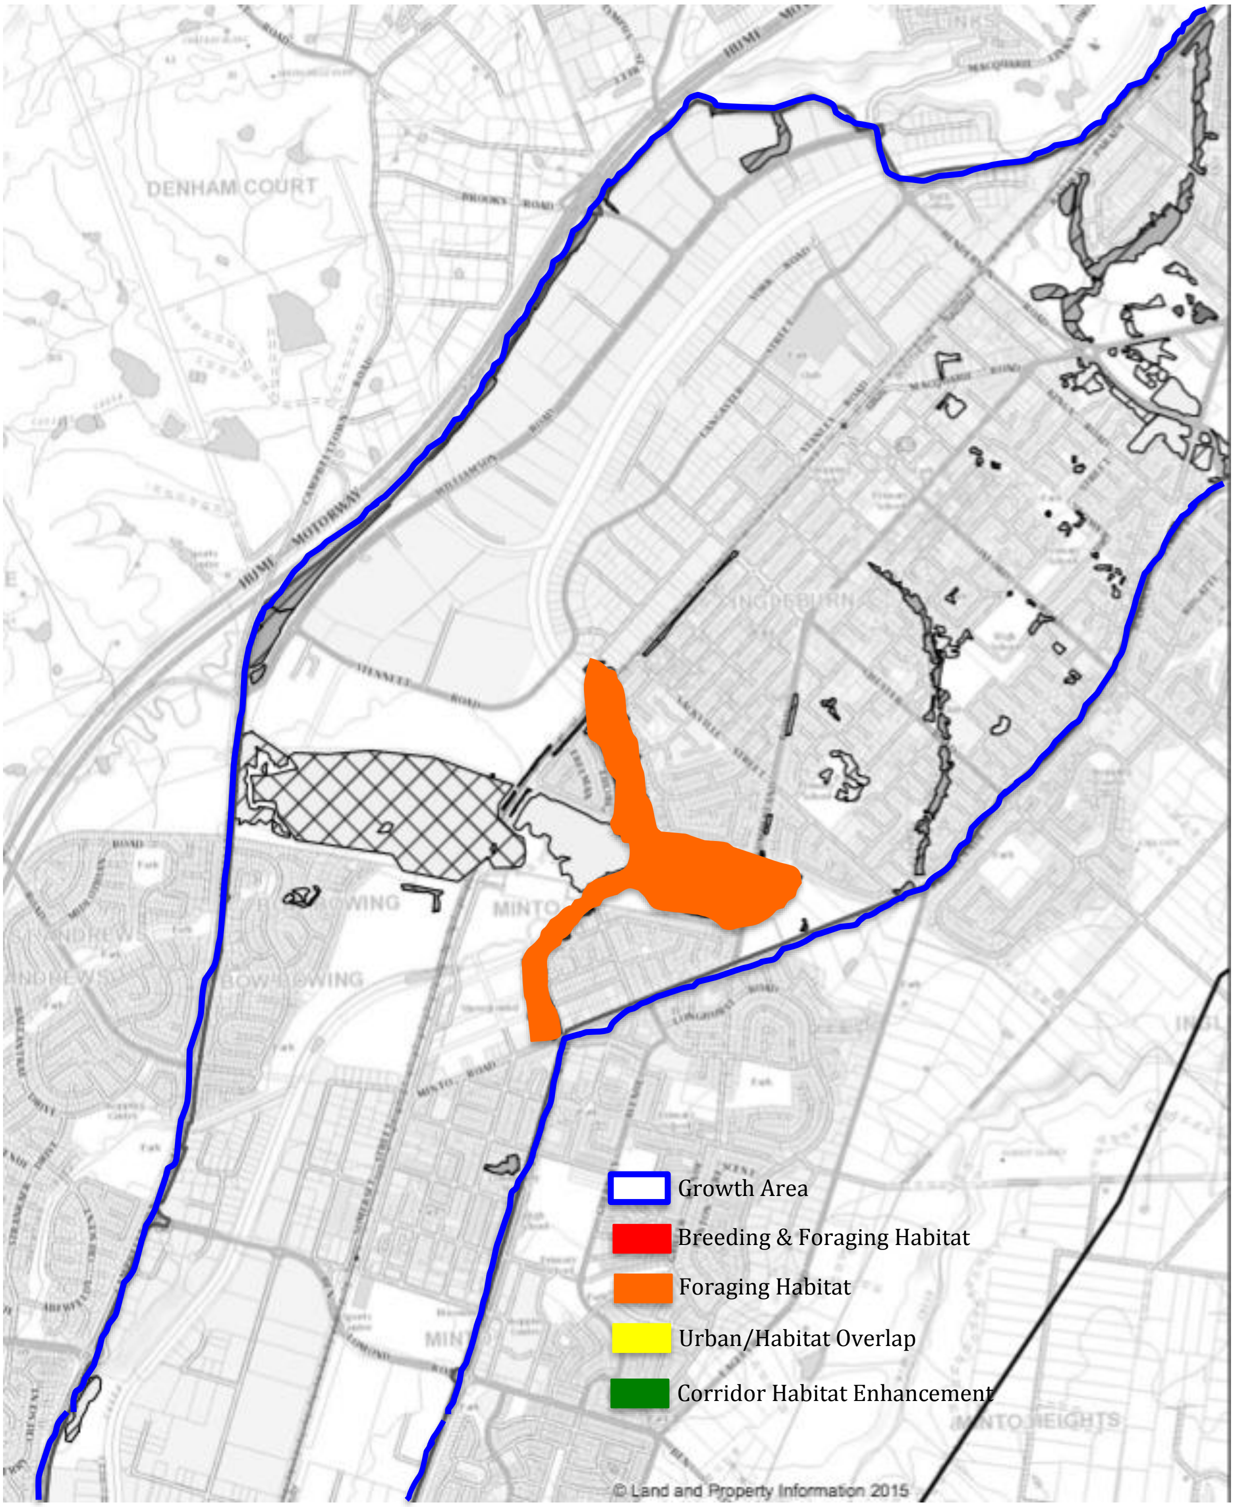

Figure 3. Potential breeding and potential foraging habitat for the Square-tailed Kite in the Greater Macarthur growth area (Map 2). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

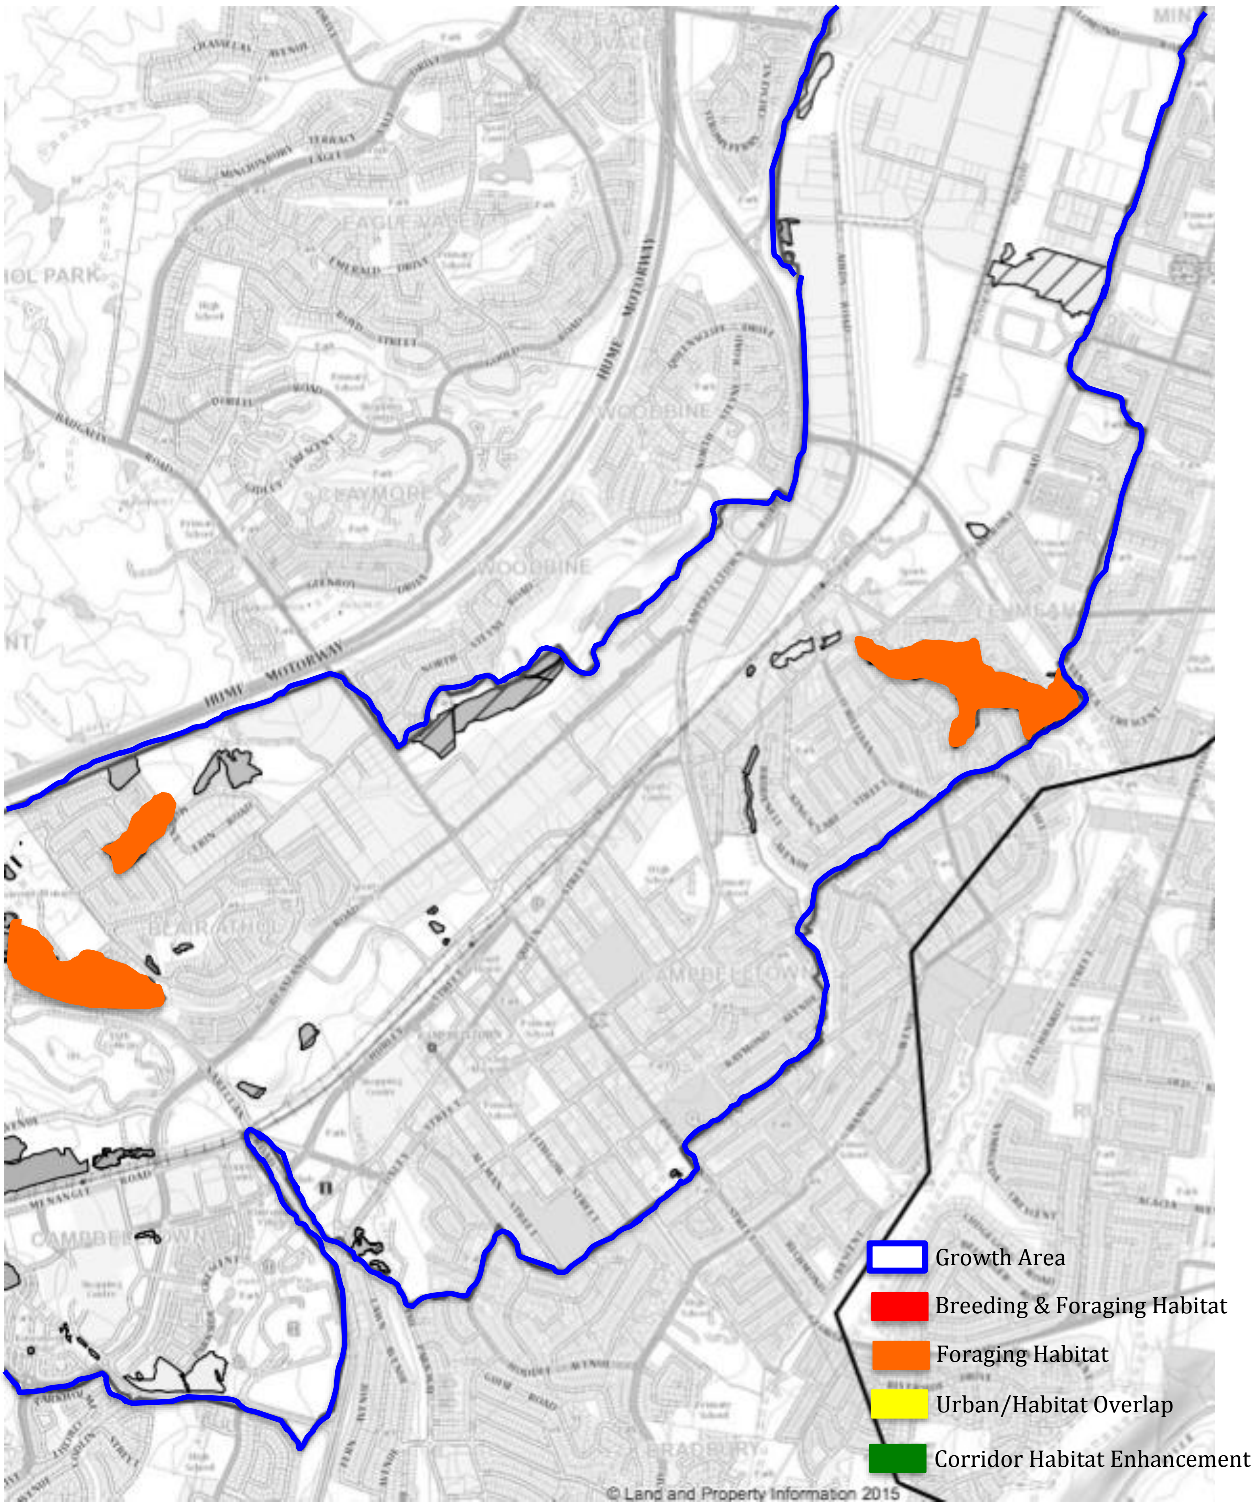

Figure 3. Potential breeding and potential foraging habitat for the Square-tailed Kite in the Greater Macarthur growth area (Map 3). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

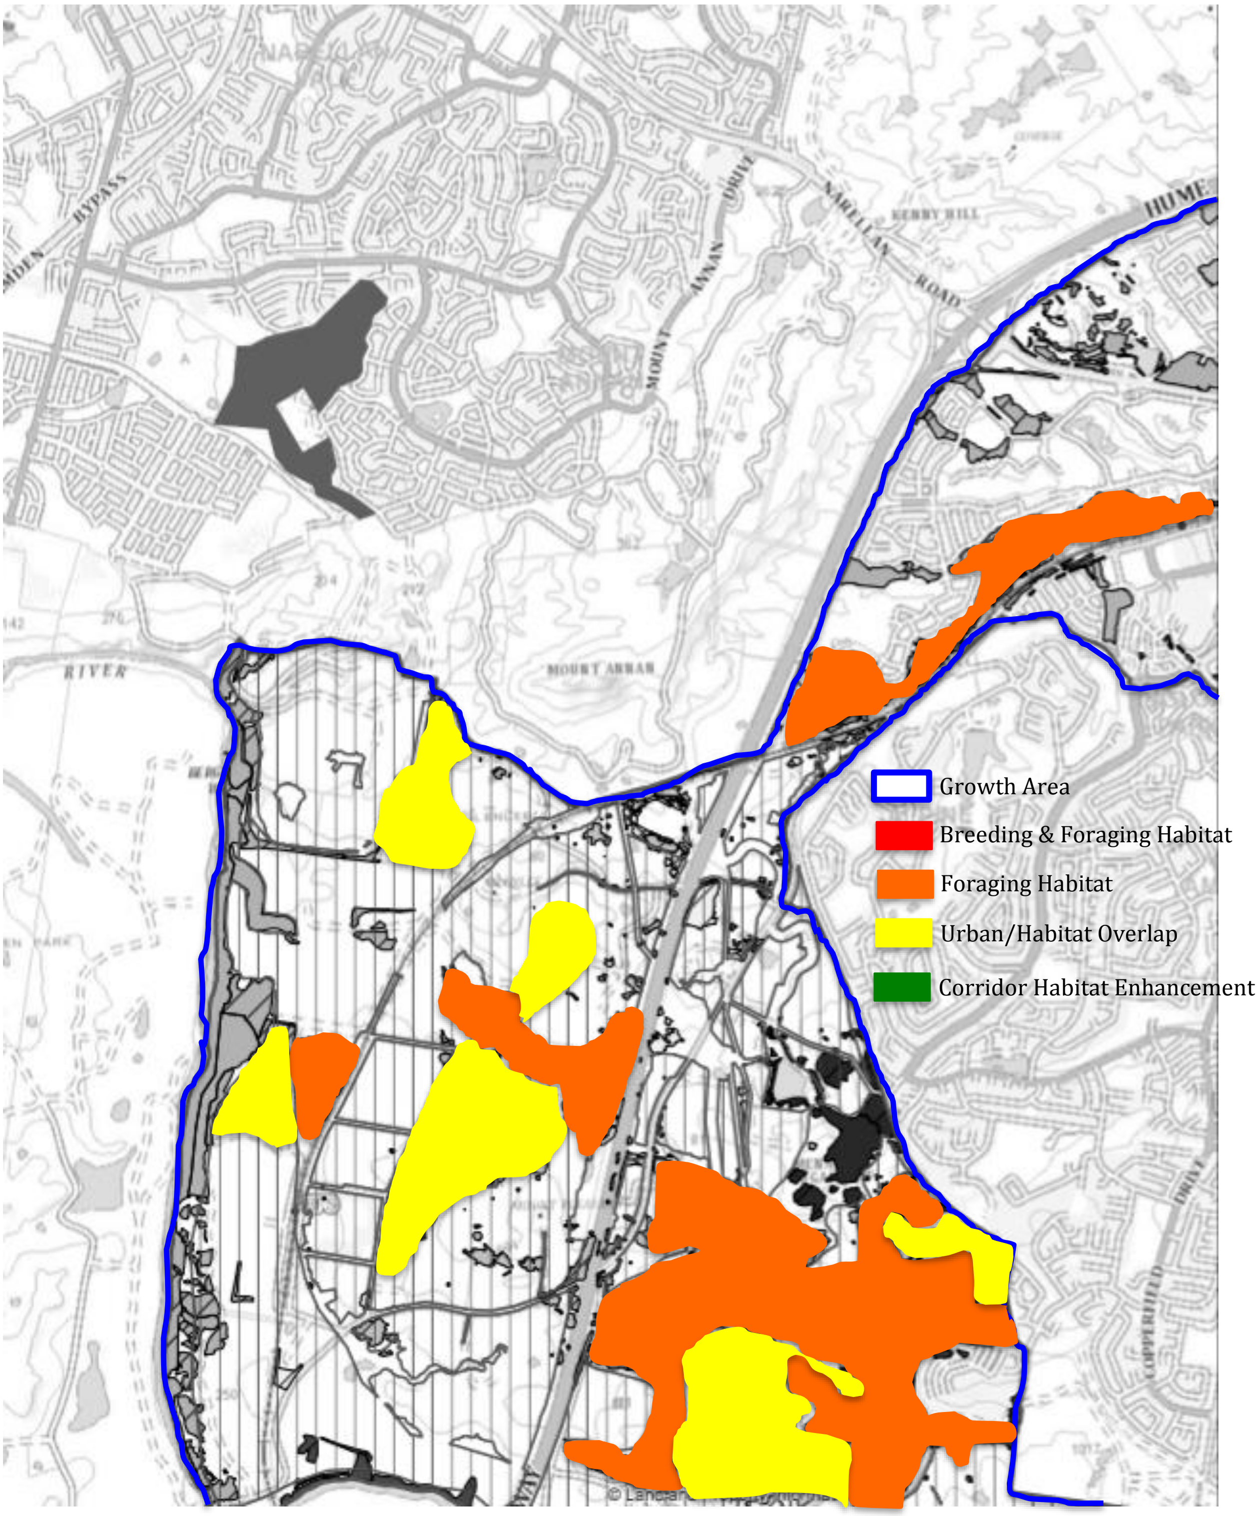

Figure 3. Potential breeding and potential foraging habitat for the Square-tailed Kite in the Greater Macarthur growth area (Map 4). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

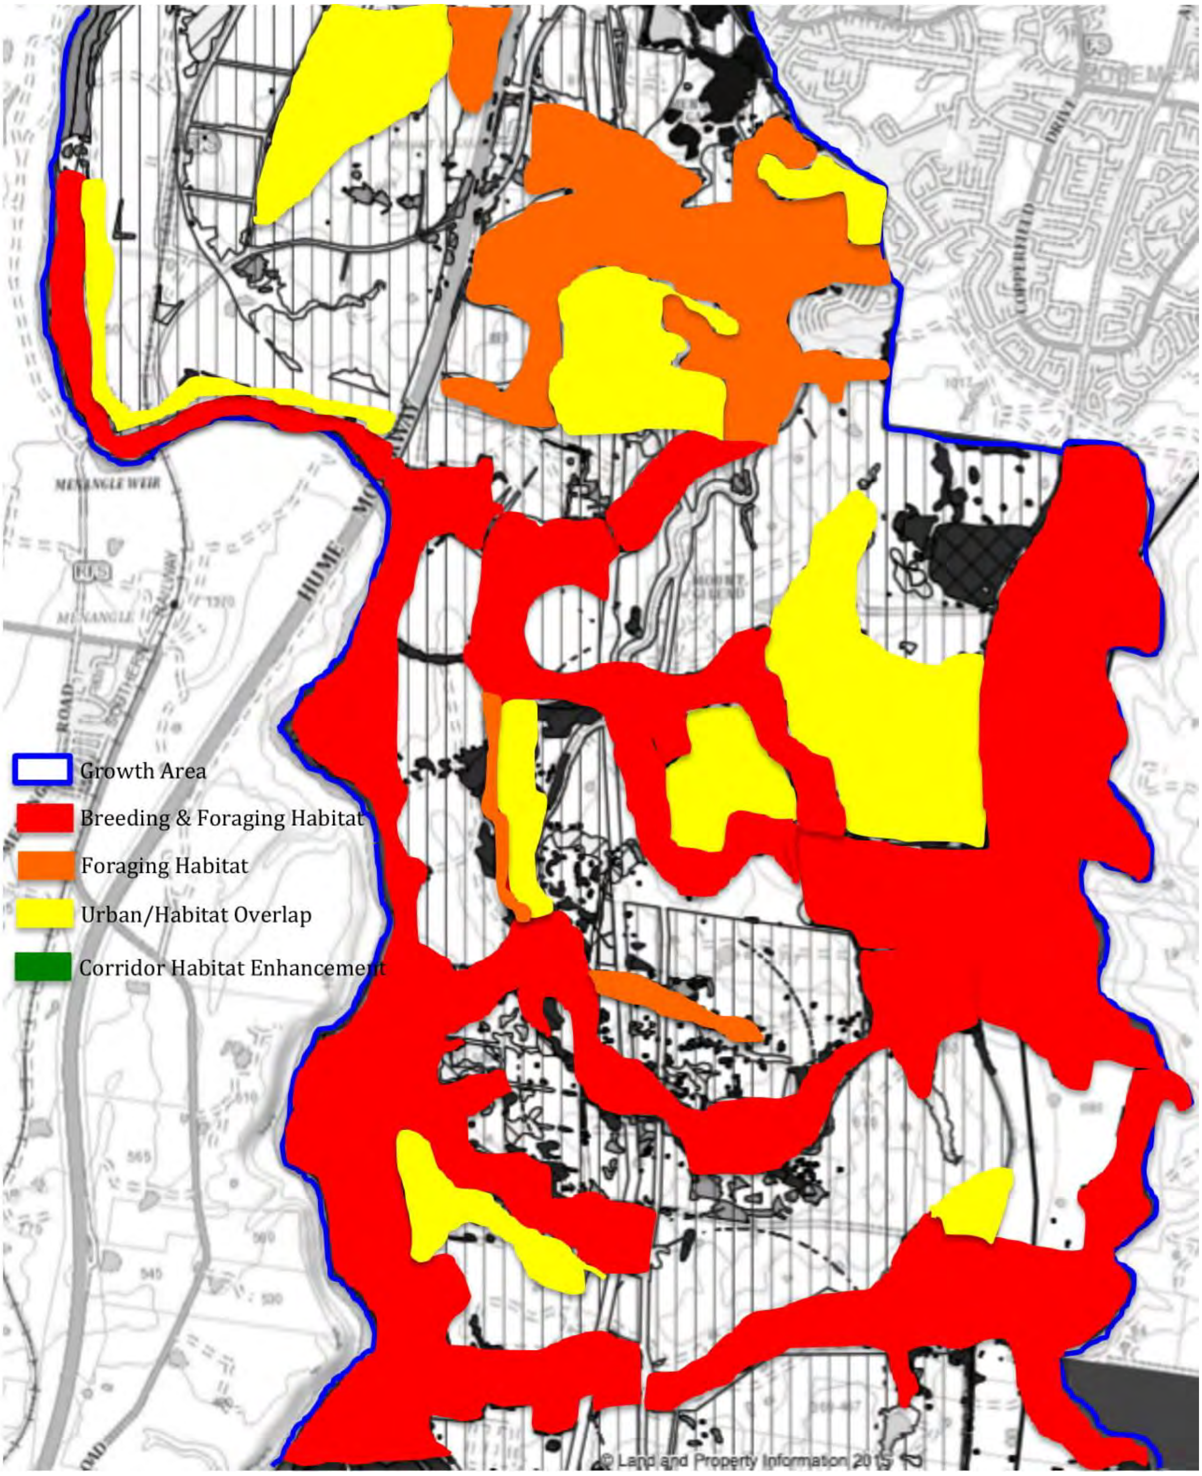

Figure 3. Potential breeding and potential foraging habitat for the Square-tailed Kite in the Greater Macarthur growth area (Map 6). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

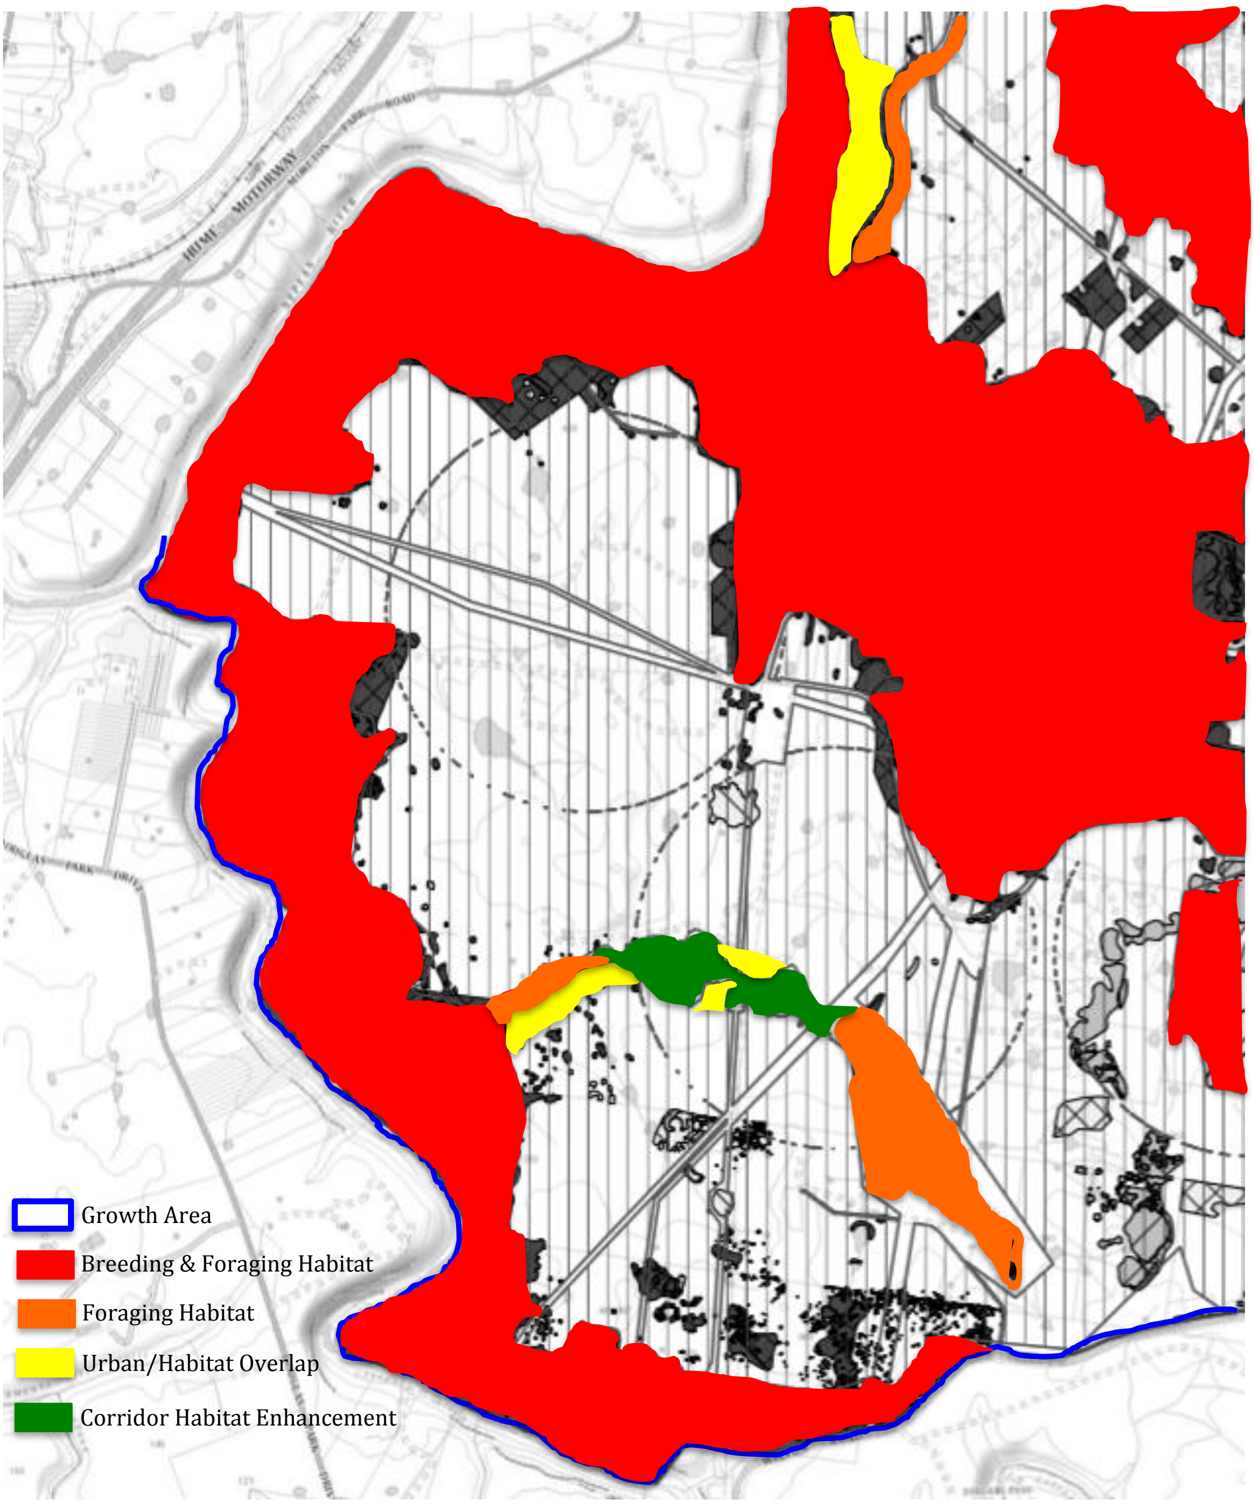

Figure 3. Potential breeding and potential foraging habitat for the Square-tailed Kite in the Greater Macarthur growth area (Map 6). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

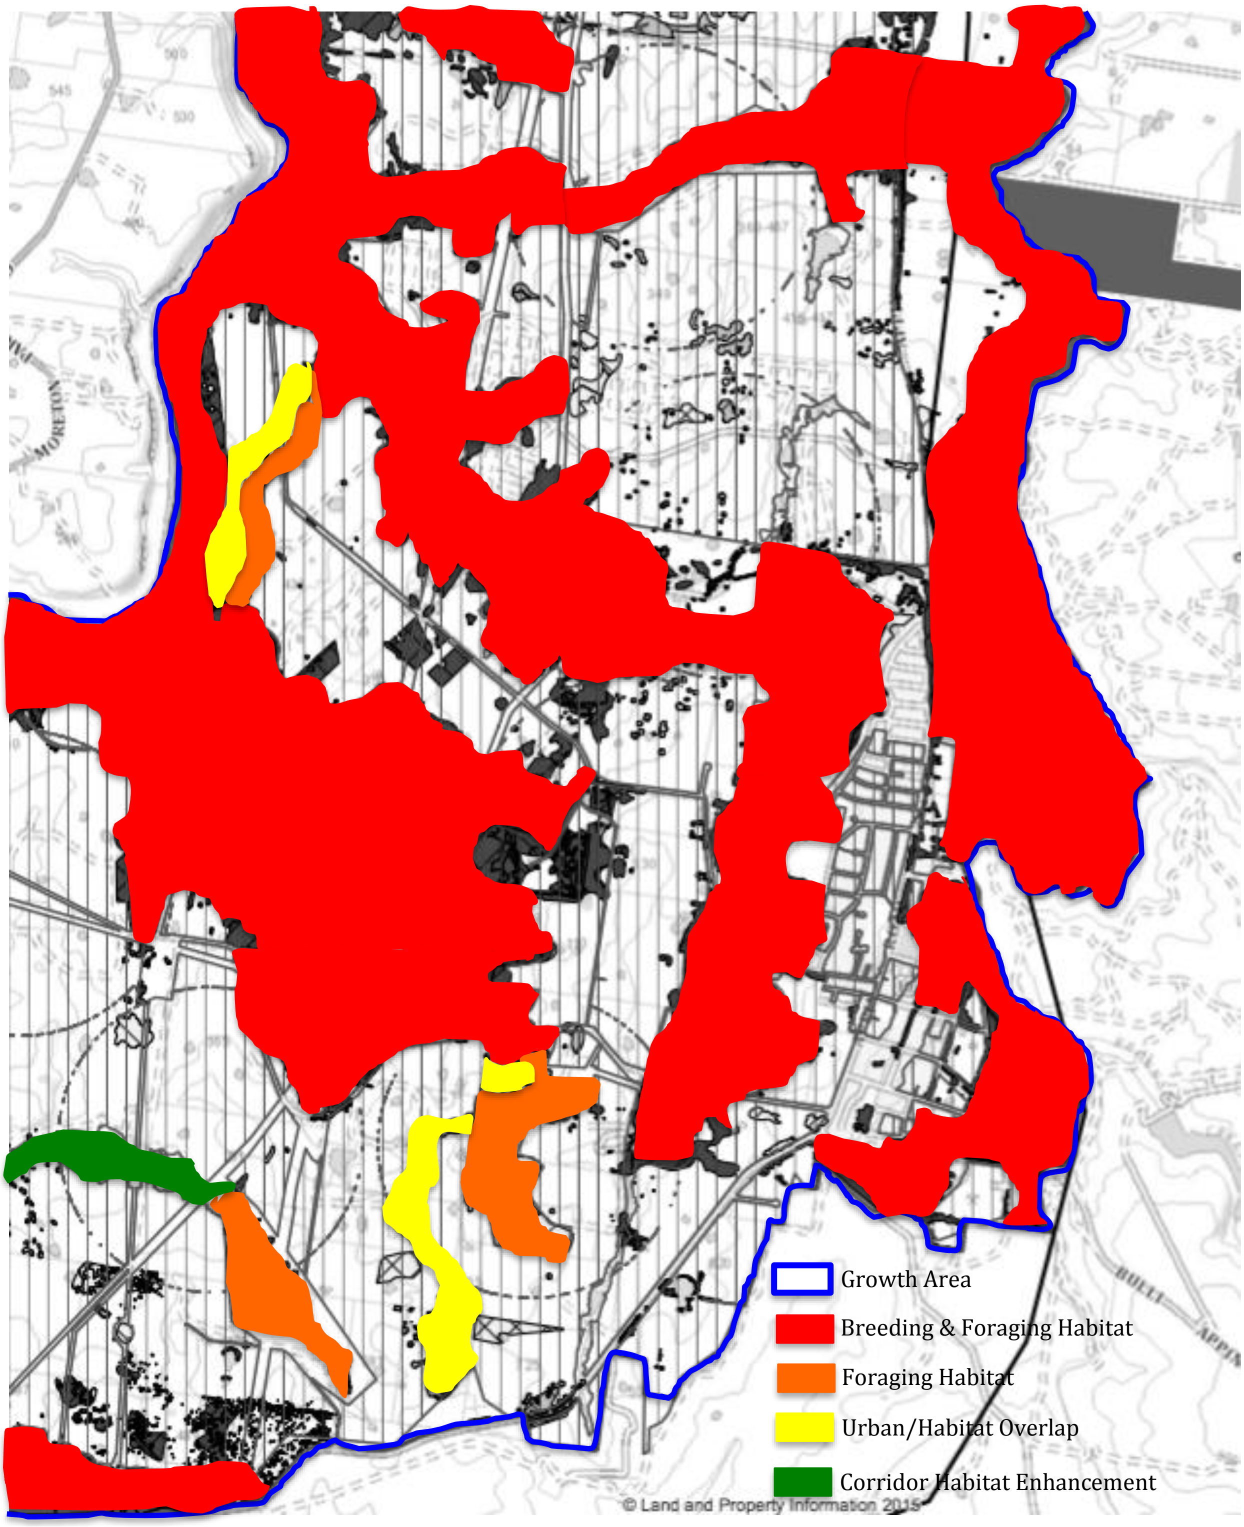

Figure 3. Potential breeding and potential foraging habitat for the Square-tailed Kite in the Greater Macarthur growth area (Map 7). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

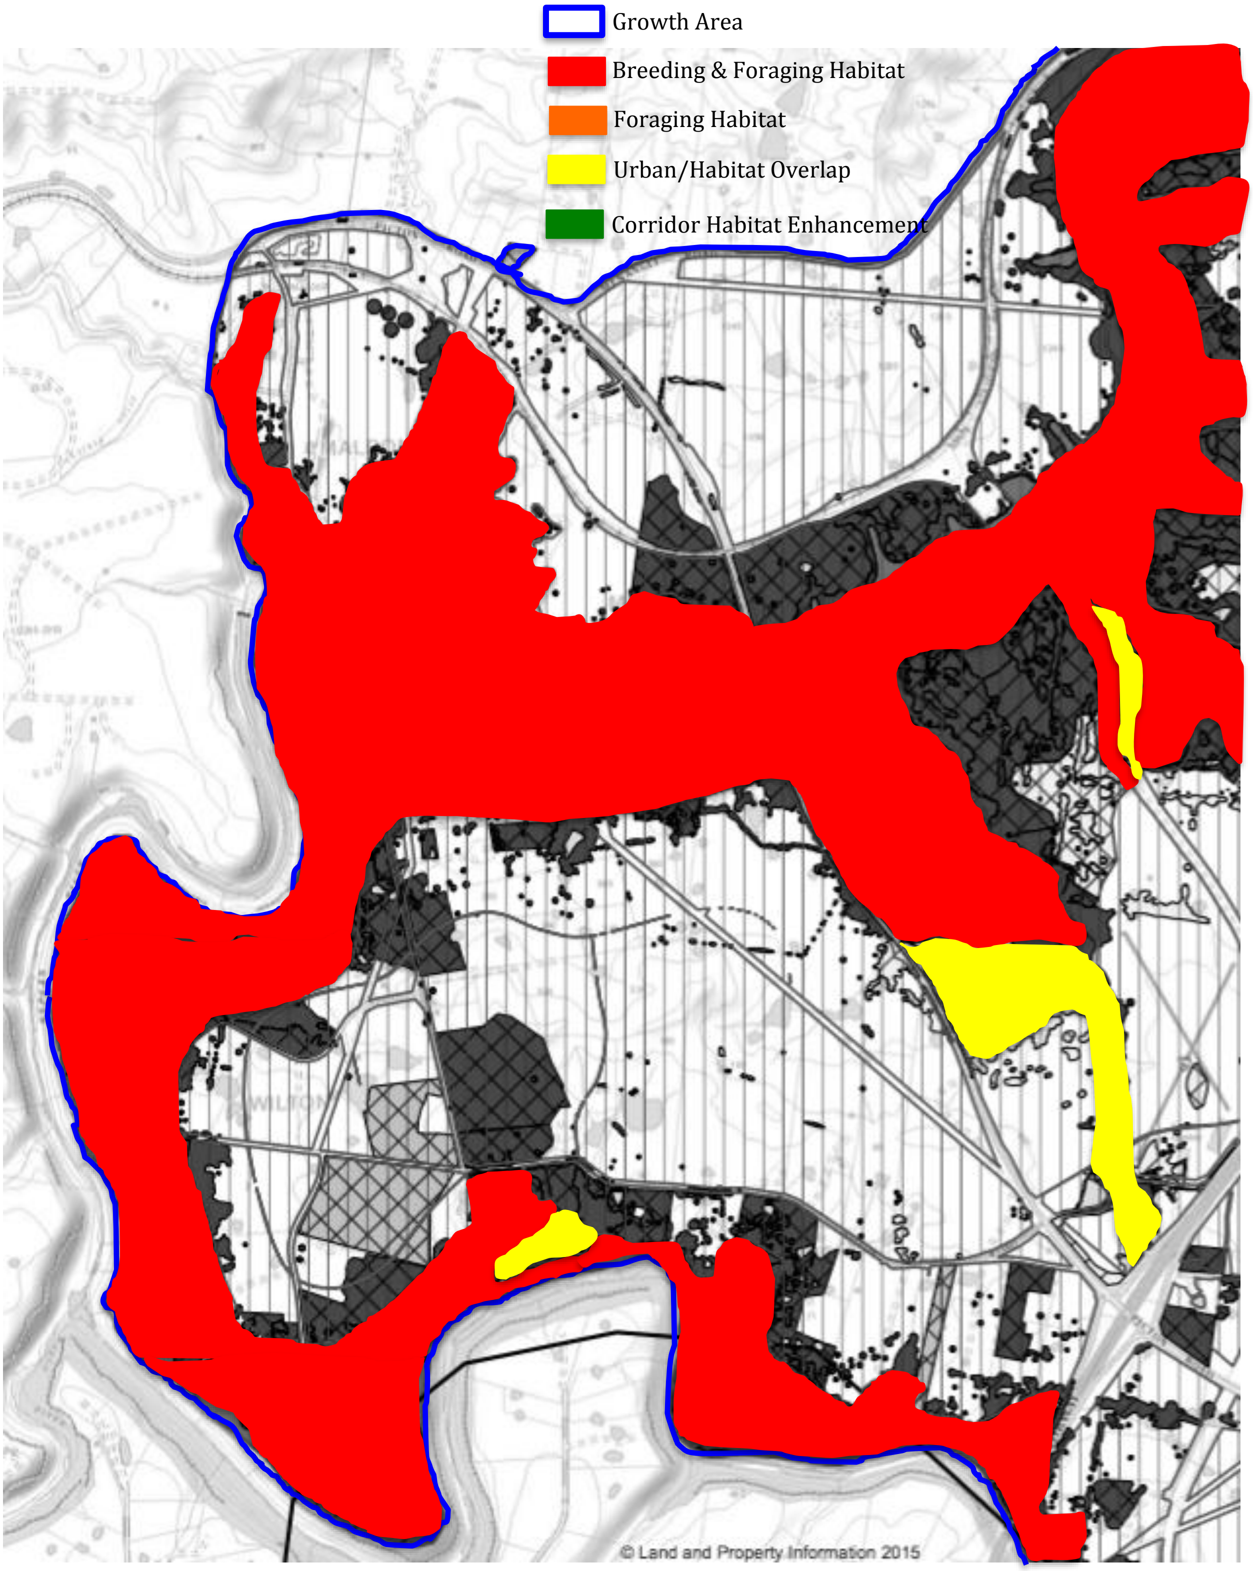

Figure 4. Potential breeding and potential foraging habitat for the Square-tailed Kite in the Wilton growth area (Map 1). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

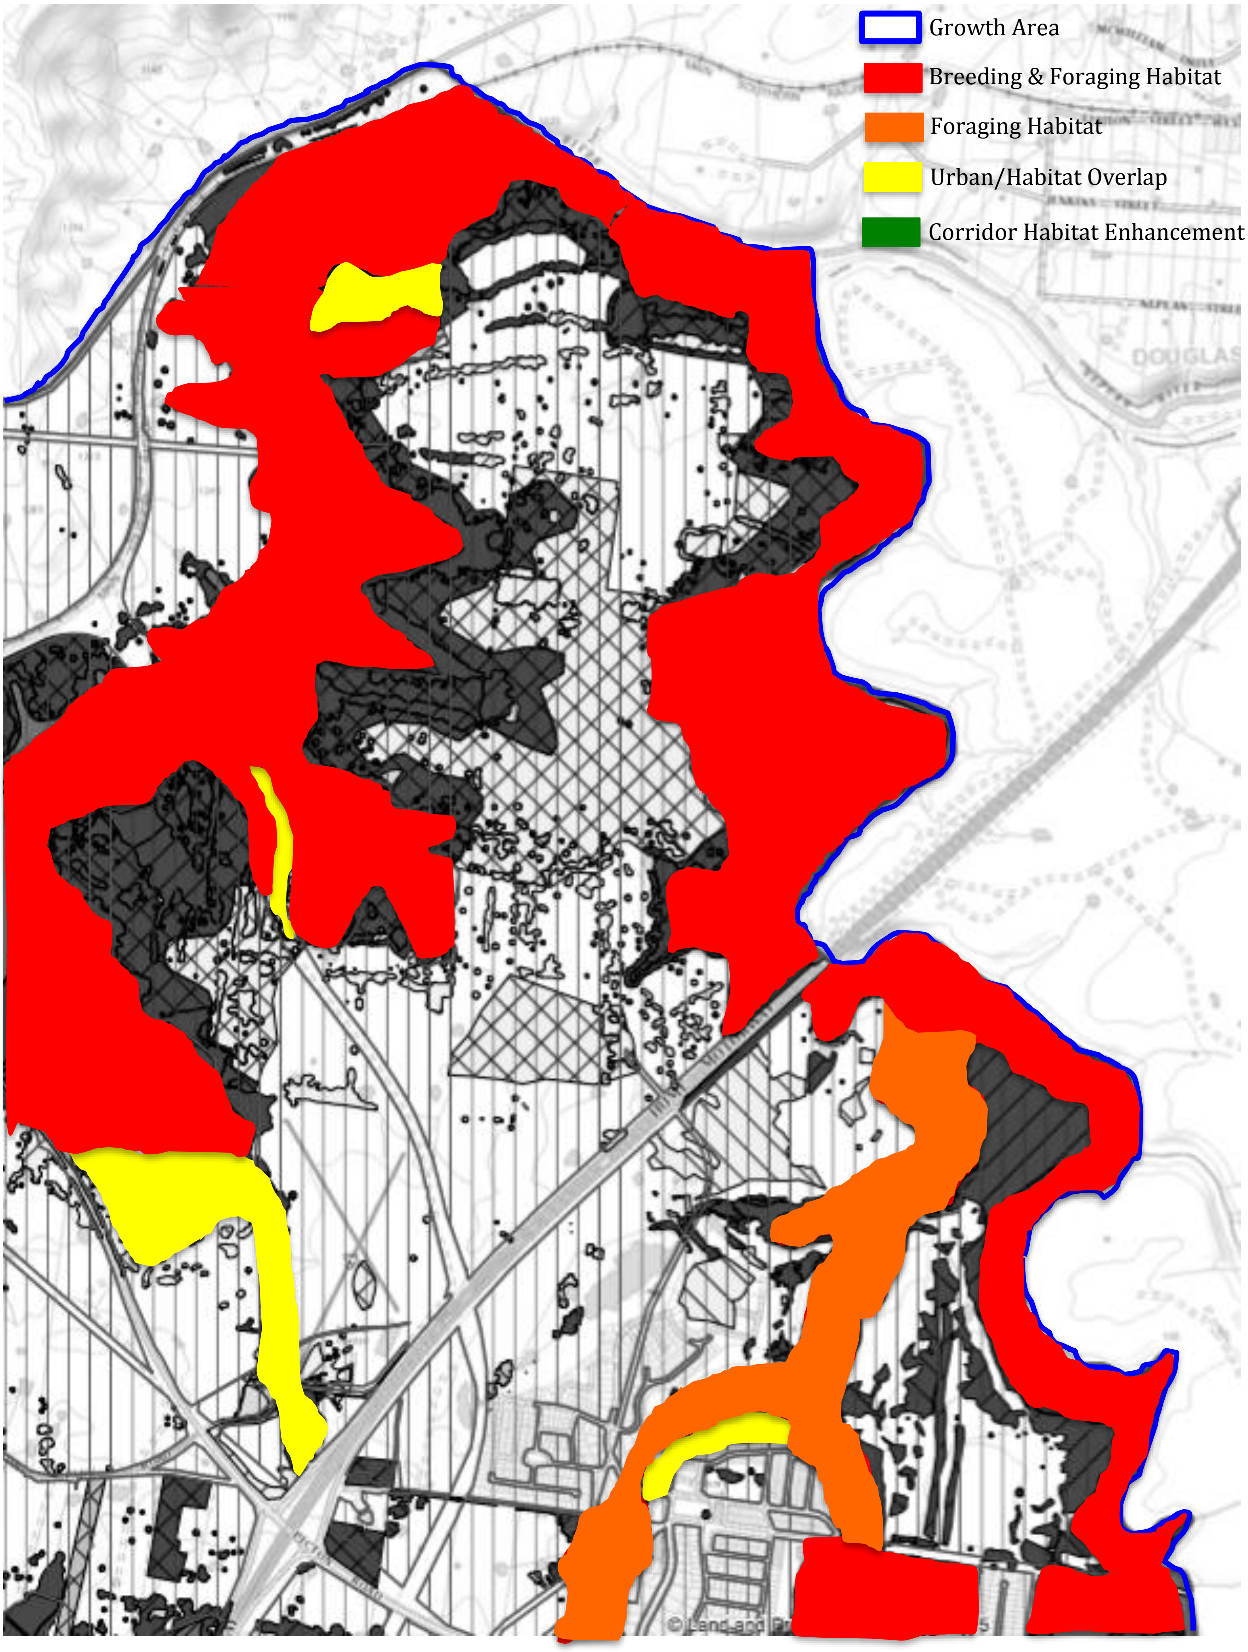

Figure 4. Potential breeding and potential foraging habitat for the Square-tailed Kite in the Wilton growth area (Map 2). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

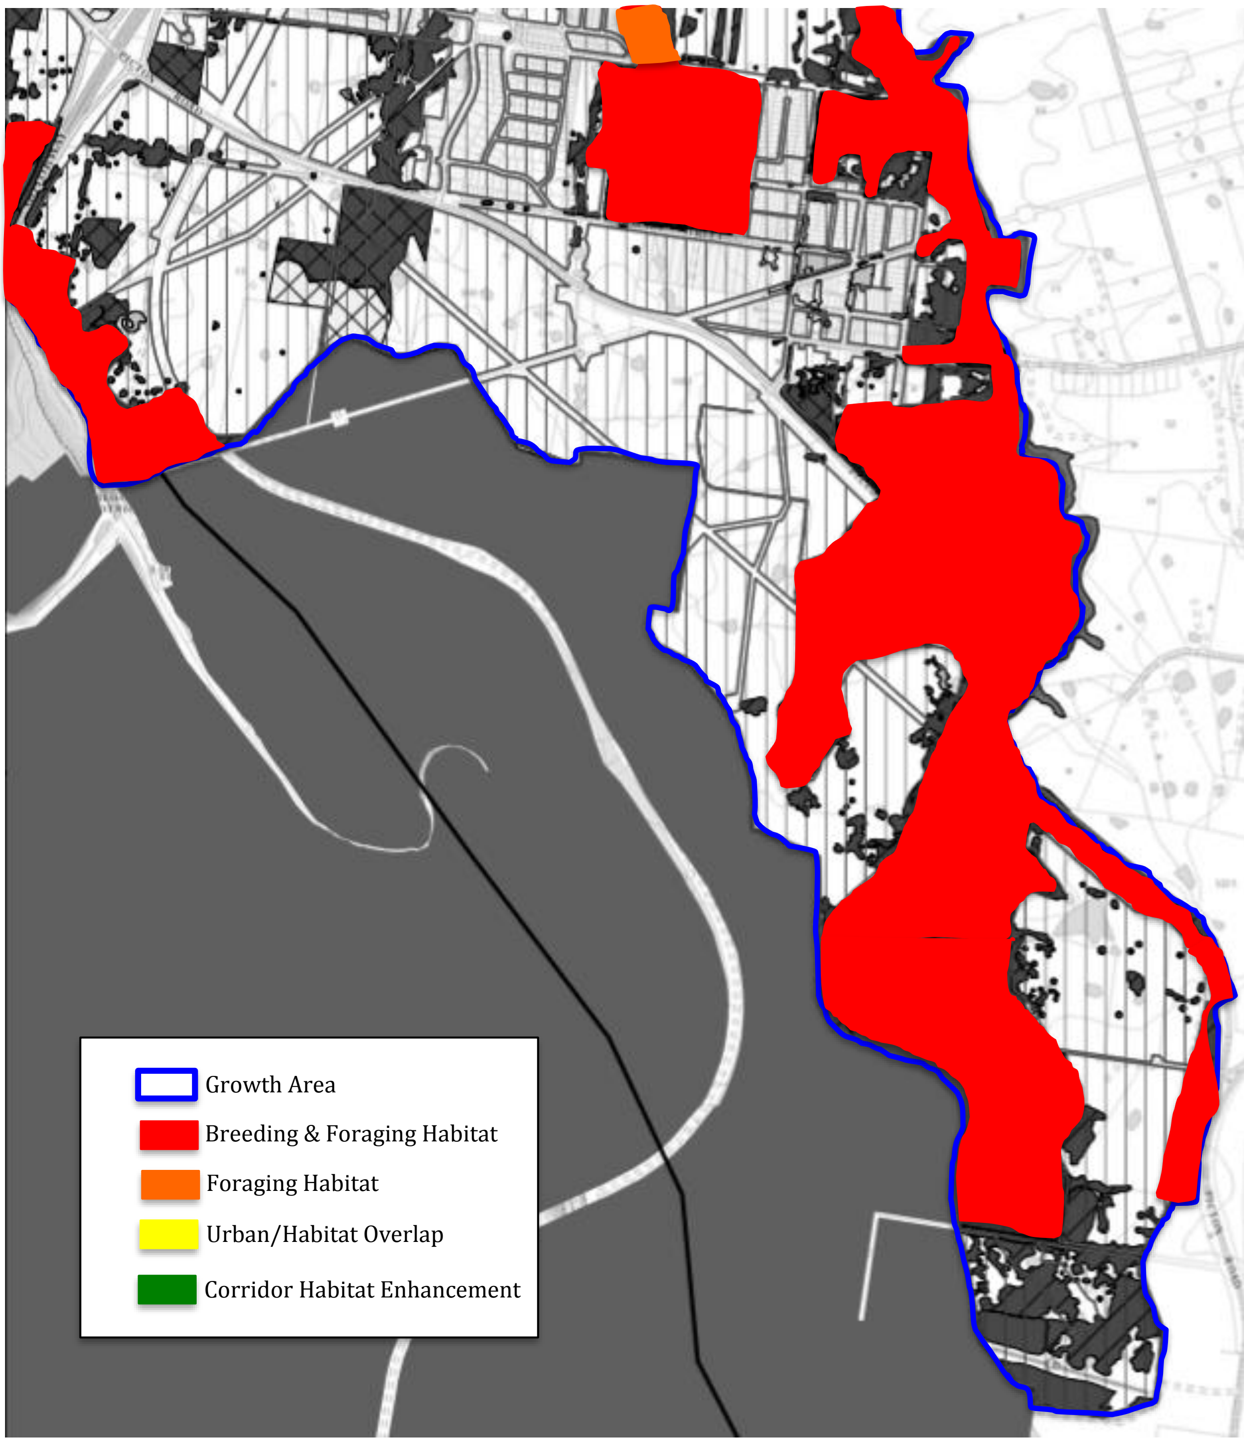

Figure 4. Potential breeding and potential foraging habitat for the Square-tailed Kite in the Greater Macarthur growth area (Map 3). Potential breeding and foraging habitat areas are shown in red, potential foraging areas are shown in orange, potential foraging areas that overlap urban development footprint shown in yellow and potential areas for habitat enhancement and improved connectivity shown in green.

Assessment of the Likelihood of Species Presence in the Growth Areas, Distribution, Population Estimate and Justification for Determination

There is a very high likelihood of Square-tailed Kites occurring within the growth areas during the breeding season. Although breeding has not been observed within the growth areas it is very likely that they will forage in the area while breeding. However, the Kite has nested in similar situations elsewhere and nesting within the growth areas would also be possible. This is supported by the occurrence of records for the Kite within and around the growth areas in October to December. The habitat remnants within the growth areas are tall open forests and woodland, are mostly along watercourses and have abundant edges. These factors provide good foraging habitat for the Kite. The Kite has also been recorded in most of the plant community types that occur within the growth areas, and again this supports a high likelihood of Square-tailed Kites occurring there.

It would appear from the distribution of records that there are likely to be 2 to 3 breeding pairs in the area that will use the site for foraging during the breeding season. Although the distance between adjacent nests in published data on nesting Kites exceeds the total length from north to south through the growth areas, there is connectivity to several larger areas of suitable habitat around the growth areas. This means that each pair's breeding territory could extend into the site from a larger area outside the growth areas. The distribution of records suggests that there may be a pair centred along the Georges River along the eastern edge of the northern half of the Greater Macarthur growth area. Another pair is likely to occur along the Appin Road area that extends into contiguous forest to the east of the southern section of the Greater Macarthur growth area. It is also possible that another pair occupies the area around the southern section of the Wilton growth area.

However, no nests have ever been recorded in the growth areas. Breeding was not observed during the surveys undertaken by Biosis or by us during our surveys. As other bird species build similar stick nests it is difficult to identify a Square-tailed Kite nest without the bird being in attendance, which would be required to confirm breeding within the growth areas. The breeding habitat areas indicated in Figures 3 and 4 are based on the minimum criteria presented in Tables 1 and 2. Although, there is much potential breeding habitat within the growth areas no breeding habitat, as defined by BAM requirements, was observed.

In summary, the evidence suggests that the Square-tailed Kite is found within the growth areas of Greater Macarthur and Wilton and that are likely to be 2 or 3 pairs occurring during the breeding season. The presence of suitable foraging habitat and potential breeding habitat within these growth areas means that protection of habitat within them may be critical to the continued presence of the Kite in the area.

5. Information Used in the Assessment

Data:

Atlas of Living Australia - occurrences of Little Eagle and Square-tailed Kite in Liverpool, Campbelltown and Wollondilly LGAs. (accessed 29-06-2018). <https://biocache.ala.org.au/occurrences/search>

6. Curriculum Vitae

Dr Tony Saunders

Name: Anthony Stephen John Saunders

Contact Details: 1878 Taralga Road Laggan NSW 2583 0409 399 849

Academic Qualifications:

BSc University of Sydney 1976
Dip Ed Sydney Teachers College 1977
PhD University of Western Sydney 2005

Other Qualifications:

LR Drivers Licence
Public Vehicle Driver Authority
Work Health & Safety General Construction Induction (White Card)
Chemical Use and Handling Certificate
Resuscitation Certificate
Emergency Care Certificate
Anaphylaxis Training Certificate
Drone Essentials Certificate

Fields of expertise:

Bird habitat assessment on reserves, lands in production and potential offset property.
Bird monitoring in natural, modified and managed habitats.
Assessment of likelihood of threatened woodland bird species occurrence on development sites.
Coordinating projects between government and non-government organisations.
Coordination of volunteers collecting wildlife data.
Ecotourism: guiding general interest and specialists groups in flora and fauna.
Environmental and science education at high school, TAFE, and university levels.
Habitat management for terrestrial woodland birds and other wildlife.
Presentations on ecology to public interest groups and at professional workshops.
Remote area wildlife atlassing.
Wildlife database design and management.
Land for Wildlife assessments and habitat enhancement planning.

Professional positions held:

2010 - 2018 Merops Services Pty Ltd (director, avifaunal ecologist). Environmental and landscape consultant and contractor, flora and fauna surveys, habitat enhancement plans.

2013 - 2018 Land for Wildlife Assessor for Community Environment Network

1995 - 2010 Merops Services (avifaunal ecologist). Environmental and landscape consultant and contractor.

2006 - 2018 Part-time teacher, mainly science, but also industrial arts, English and maths, Crookwell High School, Goulburn High School and Trinity Grammar School.

1997 - 2005 Part-time bird guide and ecotourism bus driver.

1993 - 2004 Part-time lecturer, supervisor and demonstrator, University of Western Sydney (biology, ecology and field survey techniques).

2001 - 2004 Atlas Facilitator, Birds Australia (organising remote atlassing, facilitating data exchange and communication between Birds Australia, state government organizations and other non-government organisations).

1997 Field Technical Officer, Birds Australia (monitoring breeding success of endangered bird species).

1996 Field Technical Officer, University of Western Sydney (reptile, bird and plant survey techniques and data analysis).

1978 - 1994 High School Science Teacher at Marsden, Heathcote, Penrith and Kingswood High Schools.

Other volunteer positions held:

2014 - 2017 Assistant to Co-ordinator of the Sydney Bird Fair.

2009 – 2018 President - Crookwell Native Flora and Fauna Club.

2013 - 2018 Secretary - Grabine/Foggs Crossing Landcare Group
