2001 - 2018 Avifaunal Advisor and Education Officer for Oolong Sanctuary, Dalton.

1997 - 2010 Project Manager for Atlas of Birds of the County of Cumberland.

2010 - 2018 Technical advisor to the Cumberland Bird Observer's Club's Atlas Databasae Management Committee.

1996 - 2009 Committee Member - CBOC (Cumberland Bird Observers Club Inc.).

1998 – 2014 CBOC representative to Bird Interest Group Network (BIGnet).

1997 - 2002 Faunal Advisor for the Hawkesbury Rainforest Network.

1999 - 2002 Member of Steering Committee of Birds in Backyards for Birds Australia.

1998 - 1999 Consultant to Birds Australia Birds for Birds in Backyards Project.

1998 - 2003 Regional Organiser for Sydney and the Blue Mountains, NSW facilitator and NSW/ACT representative on the Steering Committee for the National Bird Atlas for Birds Australia.

2002 Representative on NSW NPWS Wildlife Issues Advisory Panel for Birds Australia.

Relevant experience:

Co-ordination, facilitation and organization of exhibits and presentations at field-day events and indoor venues. This has involved allocating space, providing necessary facilities and setting-up audio-visual equipment for exhibitors and presenters (18 years)

Co-ordinator of volunteers for the CBOC Inc. and the Birds Australia national birds atlas. (13 years)

Facilitated the BIGnet data exchange agreement between Birds Australia, NSW Bird Atlassers, Canberra Ornithologists Group and the Cumberland Bird Observers Club. Facilitated bird data exchanges between Birds Australia, NSW State Forests and NSW DECC. (4 years)

Presenter at seminars for Bushcare, Landcare, Greening Australia, Wires and local councils, conservation societies and garden clubs on habitat management for birds and bird survey techniques. (32 years)

Educator at public, tertiary and secondary levels in the area of bird habitat management and bird survey methodology. (23 years)

Ecotourism and bird guiding (19 years).

Undertaking avifauna surveys of sites for development applications and assessment of status of threatened bird species on sites and making recommendations for minimising impact of development on these species.

Bird habitat assessment of managed landscapes and natural habitat areas and recommendations for habitat enhancement and rehabilitation for birds. (21 years)

Design, building and management of the bird database for the birds of the County of Cumberland on behalf of CBOC Inc. (16years)

Membership and professional affiliations:

Australian Bird Study Association
Australian Bush Heritage
Birdlife Australia
Crookwell Native Flora and Fauna Society
Cumberland Bird Observers Club
Ecological Consultants Association of NSW
Grabine/Foggs Crossing Landcare Group
Greening Australia
NSW Bird Atlassers
Royal Zoological Society (Scientific member)
Wildlife Preservation Society of Queensland

Saunders, T. 2018 *Bird surveys, likelihhood for threatened birds and habitat description for Maxwell Mine Project, Jerrys Plains,* Unpublished Report.

Saunders, T. in prep. Trends in woodland bird populations on the Cumberland Plain.

Thesis:

Saunders, A.S.J. 2006 Comparative Foraging Ecology of the Noisy Friarbird *Philemon corniculatus* and the Red Wattlebird *Anthochaera carunculata* in central eastern New South Wales.

Dr Stephen Debus

Abridged CV: Stephen John Stewart DEBUS

BA (Biol./Behav. Sc.), Dip. Natural Resources (Wildlife), Dip. Ed. (Sci.), MSc. (Zool.), PhD (Zool.)

Contact details:

Ph: 02 6773 2510 (BH), 02 6772 1710 (AH), mobile: 0409 779 766

Addresses: Zoology, University of New England, Armidale NSW 2351 (business)
PO Box 1015 (6 Holloway St), Armidale NSW 2350 (private)

Website www.une.edu.au/staff-profiles/ers/sdebus

Professional capacities:

Vertebrate fauna surveys. Research and survey of threatened forest and woodland birds, particularly raptors and owls. Ecology/biology/behaviour of birds, especially predatory species. Conservation and management of threatened bird species. Distribution, status and biology/ecology of NSW birds. Reviews and biological profiles of bird species. Editing ornithological papers. Peer review of ornithological documents/EISs/species impact statements. Impact assessment (avifauna). Review of conservation status of NSW fauna.

Computer skills:

Proficient in Word and Excel, limited experience with GIS and ArcView

Employment:

Eco Logical Australia 2011-18 (casual; senior ecologist: fauna survey and report)

EA Systems (now EnviroAg Australia) 2000-14 (casual; ecologist: fauna survey and assessment)

Research assistant, Zoology, UNE, casual 1984-2014 (field ornithology: bird banding, bird surveys/censusing, ecological studies)

Tutor/demonstrator, Zoology UNE (casual), 2007-13

NSW Dept Environment & Climate Change, 2008-09 (temporary) (threatened species officer: Project Officer, NSW Scientific Committee)

Research Assistant, Ecosystem Management UNE (casual), 2008-09 (bird survey)

Post-doctoral research fellow, Zoology, UNE, 2005-07 (ecology of woodland birds)

Junior research fellow, Zoology, University of New England, 1990-1993, 1998-2004 (ecology of rare forest owls in relation to habitat and forest management; ecology and management of birds)

Technical officer, University Partnerships Pty Ltd (UNE), 1995-1996 (fauna survey and report, Eastlink EIS)

Casual assistant demonstrator, Depts Zoology and Ecosystem Management, UNE, 1988-2002 (field practical classes on population ecology and behavioural ecology of birds)

Casual teacher, New England Institute of TAFE, 1987-1993 (bird biology: including laboratory and field practical classes on classification, identification and ecology)

Field technician, National Parks & Wildlife Service Armidale, 1986 (fauna inventory, vegetation sampling and analysis)

Research assistant, Department of Ecosystem Management, University of New England, casual 1986-1987 (field survey of vegetation and fauna)

Honorary position:

Adjunct associate lecturer/research associate, Zoology UNE, 2004-2017 (includes collaborative research and publication, co-supervision of Honours/Masters/PhD students)

Consultant biologist:

Whitehaven Coal 2018 (field survey, assessment and report on potential BioBank site for Regent Honeyeater)

Northern Tablelands Local land Services 2017-18 (Birds of Prey Monitoring project: nest sites and productivity of threatened raptors on the tablelands – field survey and report)

North West Local Land Services 2015-18 (Regent Honeyeater, Swift Parrot, raptor and woodland bird surveys and reporting)

28 South Environmental 2013-2018 (threatened fauna survey/assessment and report)

Fenner School of Environment and Society, Australian National, University 2016-17 (Regent Honeyeater surveys and data submission)

3E Environmental 2012-17 (flora & fauna survey and reporting)

BirdLife Australia – Northern NSW (for Bundarra-Barraba Operations Group of the Regent Honeyeater Recovery Team), 2007-17 (Regent Honeyeater/woodland bird survey and monitoring)

Southern New England Landcare 2014-16 (fauna surveys on farms, data submission, landholder workshop, report review)

James Warren & Associates 1997-2016 (fauna survey and reporting)

Conacher Environmental Group 2008, 2015 (fauna survey and report)

Ecotone Environmental Services 2012-13 (peer review of threatened fauna assessment; targeted fauna survey: federally listed birds)

NSW National Parks & Wildlife Service/Dept Environment & Conservation/DECC 1987-2013 (fauna survey, review of avifaunal component of environmental impact statements/ fauna impact statements/fauna reports, preparation of recovery plans and species profiles for threatened species)

Australian Museum, 1995, 2012 (review of fauna impact statement, avifauna; feather sampling of wild-caught birds for DNA analysis)

Cumberland Ecology 2004-2012 (fauna survey and report)

Arnhem Environmental 1996-2012 (fauna survey)

Eco Logical Australia 2010-2011 (threatened bird research, fauna database compilation)

Warkworth Mining Ltd 2008, 2011 (avifauna survey and report)

Terra Consulting/Geolyse/Orogen 2004-11 (fauna survey and assessment)

State Forests of NSW 1987-2009 (fauna survey, review of avifaunal component of environmental impact statements/fauna impact statements/fauna reports, fauna survey worskhop)

TransGrid 2009 (investigation and report: bird-related outages on 500 kV transmission lines)

Earth Services 2007-08 (fauna survey and report)

Armidale Dumaresq Council 2006-08 (fauna assessment)

Tamworth Regional Council 2007-08 (starling control/raptor assessment)

PLACE Environmental 2006-07 (fauna assessment)

ACT Planning & Land Authority 2005-06 (fauna survey and assessment)

Greenloaning Biostudies 1996-2004 (fauna survey)

Burnett Shire Council 2003 (fauna survey and assessment)

Inverell Shire Council 2003 (fauna assessment)

HWR Ecological 2003 (fauna survey)

WBM Oceanics 1999-2002 (fauna survey)

Resource Strategies 1999 (fauna survey)

Network Design & Construction Ltd, 1999 (fauna survey)

Woodward-Clyde Pty Ltd, 1994-1999 (fauna survey)

Telstra Environmental Evaluation Team 1998 (fauna survey and report)

Maunsell Pty Ltd, 1995-97 (fauna survey, review of environmental assessment)

Austeco Pty Ltd, 1990-1997 (fauna survey)

North-west Ecological Services 1997 (fauna survey)

ANCA 1995-1996 (fauna survey, Jervis Bay National Park)

SA National Parks & Wildlife Service, 1995 (fauna survey)

Grants and awards:

Search for Red Goshawk in NSW: $1,000 from the Australian Bird Environment Fund (Bird Observers Club of Aust.), 1987.

Distribution, status and habitat requirements of the Sooty Owl in northern NSW: $2,000 as a Cayley Memorial Scholarship (Gould League of NSW) 1990-93; with Associate Professors Hugh Ford & Harry Recher (UNE), $34,280 from WWF Australia and $64,835 from ANPWS (Endangered Species Program) 1990-93.

Will wildlife corridors work for sedentary birds?: with Professor Hugh Ford, $42,565 from the NSW Environmental Trust 2005, $43,359 in 2006-07.

Bird Observers Club of Australia: Distinguished Service Award, 2005 (editing the *Australian Bird Watcher*/*Australian Field Ornithology* for 21 years 1984-2005).

Royal Zoological Society of NSW Whitley Award, 2013 (*Birds of Prey of Australia: A Field Guide*, 2nd edn, best vertebrate guide in 2012)

BirdLife Australia's D.L. Serventy Medal for publication in ornithology, 2015

Voluntary work:

Editor: *Australasian Raptor Association News* 1980-1989 and *Boobook* (re-named) 2004-17 (biannual journal for bird-of-prey enthusiasts); *Australian Field Ornithology* 1984-2015 (quarterly journal)

Sub-editor: *Corella* Wedge-tailed Eagle special issue, 2007; White-bellied Sea-Eagle special issue, 2009; rare raptors special issue, 2011

Committee member: Australian Bird Study Association 1981-1988, 2005-17; Birds Australia Northern NSW Group 1996-99, 2004-12, 2015-17; Australasian Ornithological Conference 2009 organising committee 2008-09; ABSA/BirdLife Southern NSW conference organising committee 2013-14

Regent Honeyeater Recovery Team: Bundarra-Barraba Operations Group rep, 2008-18

Red Goshawk National Recovery Team 2014-18

Publications:

~130 refereed papers (selection appended), books and book contributions, theses: see appended list

Review of updates to the development footprints of the Greater Macarthur and Wilton urban growth areas in relation to strategic assessments on the Little Eagle and the Square-tailed Kite

This supplementary report has been requested by Biosis Pty Ltd in order to examine how changes in the development footprint of the growth areas may affect some of the conclusions made in the strategic assessments for the Little Eagle and the Square-tailed Kite done by Merops Services Pty Ltd in 2018.

This has involved comparisons between the maps of the development footprints from 2018 to 2020 and in particular whether there are changes to the potential breeding habitat for both bird species.

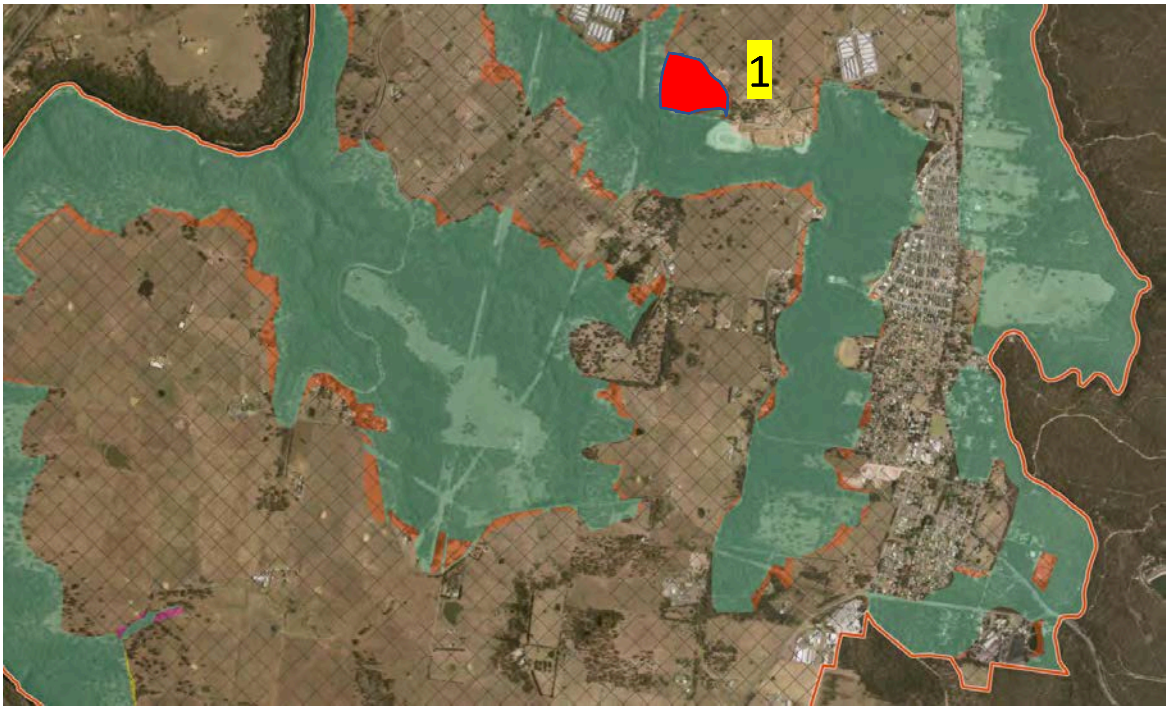
As described in the 2018 strategic assessments, there was no evidence found for breeding for either bird species within the development footprints. As a result, habitat structure, plant species composition and presence of prey species was used to assess whether potential breeding habitat areas existed for either species within the development footprint. The timing of the survey work (late May and June) was outside the breeding period for both raptor species. Although the Little Eagle is present for most of the year the Square-tailed Kite is mostly absent from south-eastern New South Wales during the non-breeding season. In addition, access to much of the area was restricted and often many of the potential areas were examined only from the edges. This was sufficient to describe habitat structure, confirm PCTs and detect potential prey species, but we were not able to check for nests that may have suggested that either species could be using the area. The habitat criteria were used as a surrogate for actual sightings of either species, detection of nests and breeding activity.

The maps created for the 2018 reports indicated potential breeding habitat and potential foraging habitat. The Square-tailed Kite will forage along forest and woodland edges and is somewhat tolerant of nearby human activity. However, the Little Eagle requires a greater buffer between urban areas and breeding habitat. Many of the areas suitable for the Little Eagle have been mapped to show foraging areas working as buffers for potential breeding areas for the Little Eagle. This species requires foraging areas to be adjacent to breeding areas and the more open areas adjacent to the woodland remnants provide these. The Little Eagle will often forage along the edges of timbered habitat and also nest close to edges of more open foraging habitat. The red polygons indicating breeding and foraging habitat represent these areas. The areas shown as orange polygons represent foraging habitat areas that are sufficiently close to potential breeding areas and the areas marked as yellow polygons indicate the same type of habitat, except that such areas overlap the development footprint. Both types of areas would also provide a buffer zone to any development.

The differences in mapping between 2018 and 2020 are considered under two headings. The first looks at potential differences in polygons from the 2018 reports and the 2018 footprint maps supplied to us in 2020. The second looks at whether changes to the development footprints between 2018 and 2020 have meant that changes to the conclusions in the 2018 reports are likely to be required.

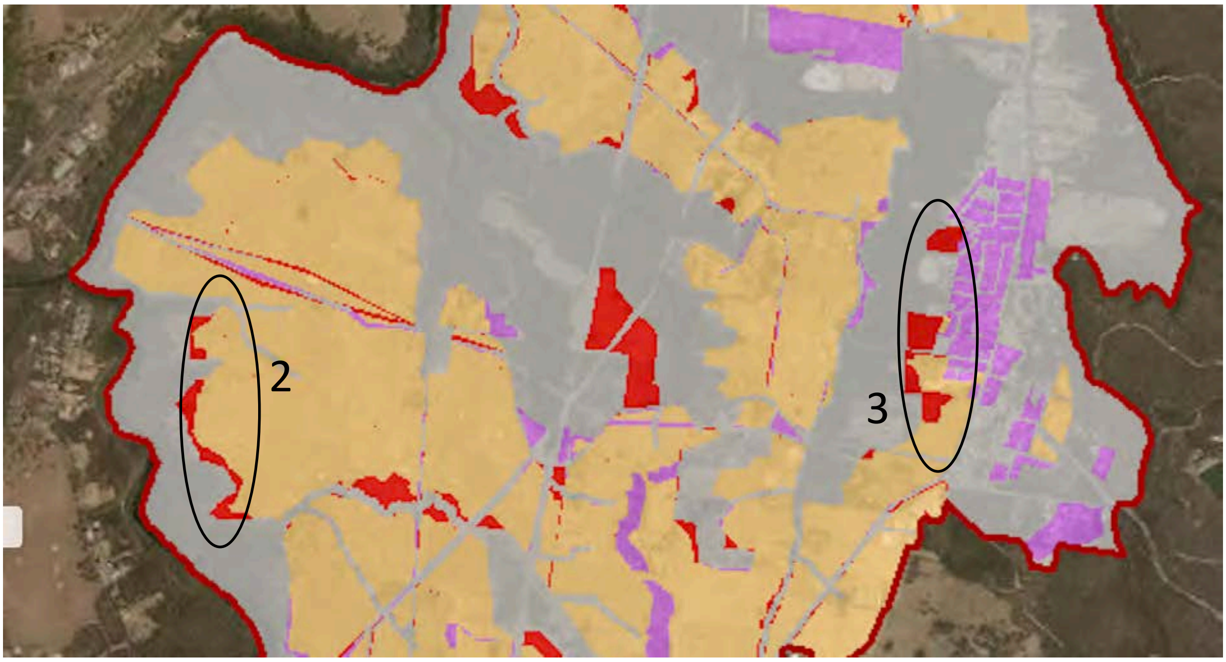
The original vegetation maps supplied to us in 2018 have large areas of PCT 1395 colour coded dark blue. Unfortunately, it was difficult to delineate between the development footprint and areas excluded from the footprint in the margins of these areas. The red polygons in the 2018 reports indicated potential breeding and foraging habitat and some edges of these polygons overlapped the development footprint. Most of these edges will need to be corrected to show foraging habitat overlapping the development footprint. Where there are exceptions to this, maps have been copied and areas of concern are labelled with a number (see sites 1, 2 and 3 on the following maps) and any concerns are discussed in the text for the area with that number.

There were three maps provided for the 2018 footprint for the Macarthur growth area. All impacted margins on the northern and middle maps will need to be changed to yellow polygons. Most of the impacted areas on the southern map will need to be changed to yellow polygons. However, it was noted that the area labelled '1' in the small section of this map inserted below was not shown as being in the original 2018 maps supplied to me. I don't think this is a problem because I also notice that the area and the adjacent area to the east have now been removed from the 2020 footprint. The two maps for the Wilton growth area can also have all impacted margin errors corrected to show yellow polygons. Hopefully this removes any problems with discrepancies between maps for the 2018 development footprints.



The change in footprint maps supplied for this report indicated areas that were not to be developed in both the 2018 and 2020 footprints, areas that were to be developed in both the 2018 and 2020 footprints, development areas that were in the 2018 footprint but which have since been removed and areas that have been added to the development footprint since the 2018 surveys.

Only the changes in footprint are considered here. We have no problems with the areas that have been removed from the development footprint unless there are substantial changes in land-use practices somewhere in the future. At present we see that these changes reduce some of the pressures on local populations of both raptor species. From the maps it appears that most extensions to the development footprint are in areas that have been mostly already cleared of woodland. They are mostly pastureland with some areas where substantial tree thinning has occurred. We can see no problems with these extensions for either raptor species. There are only two areas that may be of concern and these are in the southern section of the Macarthur growth area (see sites 2 and 3 in the section of map shown below). In area 2 the development footprint has been extended into the open woodland buffer zone adjacent to potential breeding habitat and is likely to impact on potential breeding. In area 3 the changes in the development footprint further fragment PCT 1395 habitat which is part of a north-south trending tongue of habitat area. The edge effect of urban development in this area is likely to reduce the area of habitat available to either species, particularly the Little Eagle.



It is suggested that the development footprint within area 2 be moved back to the 2018 position to protect the buffer area and provide more foraging area adjacent to the potential breeding area. Without this suggested change, area 2 should be labelled with yellow polygons as under this development footprint the urban area will overlap foraging habitat. It is difficult to tell from the maps what the habitat quality is like in areas where the development footprint has been extended in area 3 and it may be necessary to examine the site to further assess possible impacts.

In summary, most of the red areas that are margins to potential breeding habitat can be removed as this was due to not being able to see where the development footprint extended into PCT 1395, and the new development footprint appears to be fine except for areas 2 and 3 as described above.

1. Introduction

1.1 Purpose of the Expert Report

An Expert Report may be prepared under s.6.5 of the Biodiversity Assessment Method (BAM) in place of undertaking a threatened species survey of sufficient extent, intensity and duration as would otherwise be necessary to comply with the BAM. Use of an Expert Report may be beneficial where it is highly unlikely that a species may occur within a study area; where survey cannot meet BAM specifications; and/or the reliability of detecting the species is low. In respect of *Melaleuca deanei*, insufficient survey extent; constraints on the effectiveness of survey; and unreliability of detection due to aspects of the species' ecology are the primary reasons for preparing an Expert Report.

The purpose of this Report is to provide an assessment of the current status and conservation requirements of *Melaleuca deanei* within the four priority growth areas of Greater Macarthur (GMGA); Wilton (WGA); Greater Penrith to Eastern Creek (GPECGA); and Western Sydney Aerotropolis (WSAGA)to determine whether:

a) The species is unlikely to be present and would thus require no further assessment; or
b) The species is known or likely to be present, and the Expert Report must provide estimates of potential habitat within growth areas and development footprints as part of the biocertification process.

1.2 Project context

The NSW Government is identifying areas for future urban land use and associated infrastructure in western Sydney. The four priority growth areas are all located in the Cumberland Subregion under the Interim Biogeographic Regionalisation for Australia (IBRA) (SEWPaC, 2012).

As part of the planning for these areas, the Department of Planning and Environment (DPE) will prepare the Cumberland Plain Conservation Plan to identify land use outcomes. A strategic assessment of this Plan is underway, and this Expert Report will assist in determining the extent and quantum of impacts of the proposed urban growth on *Melaleuca deanei*.

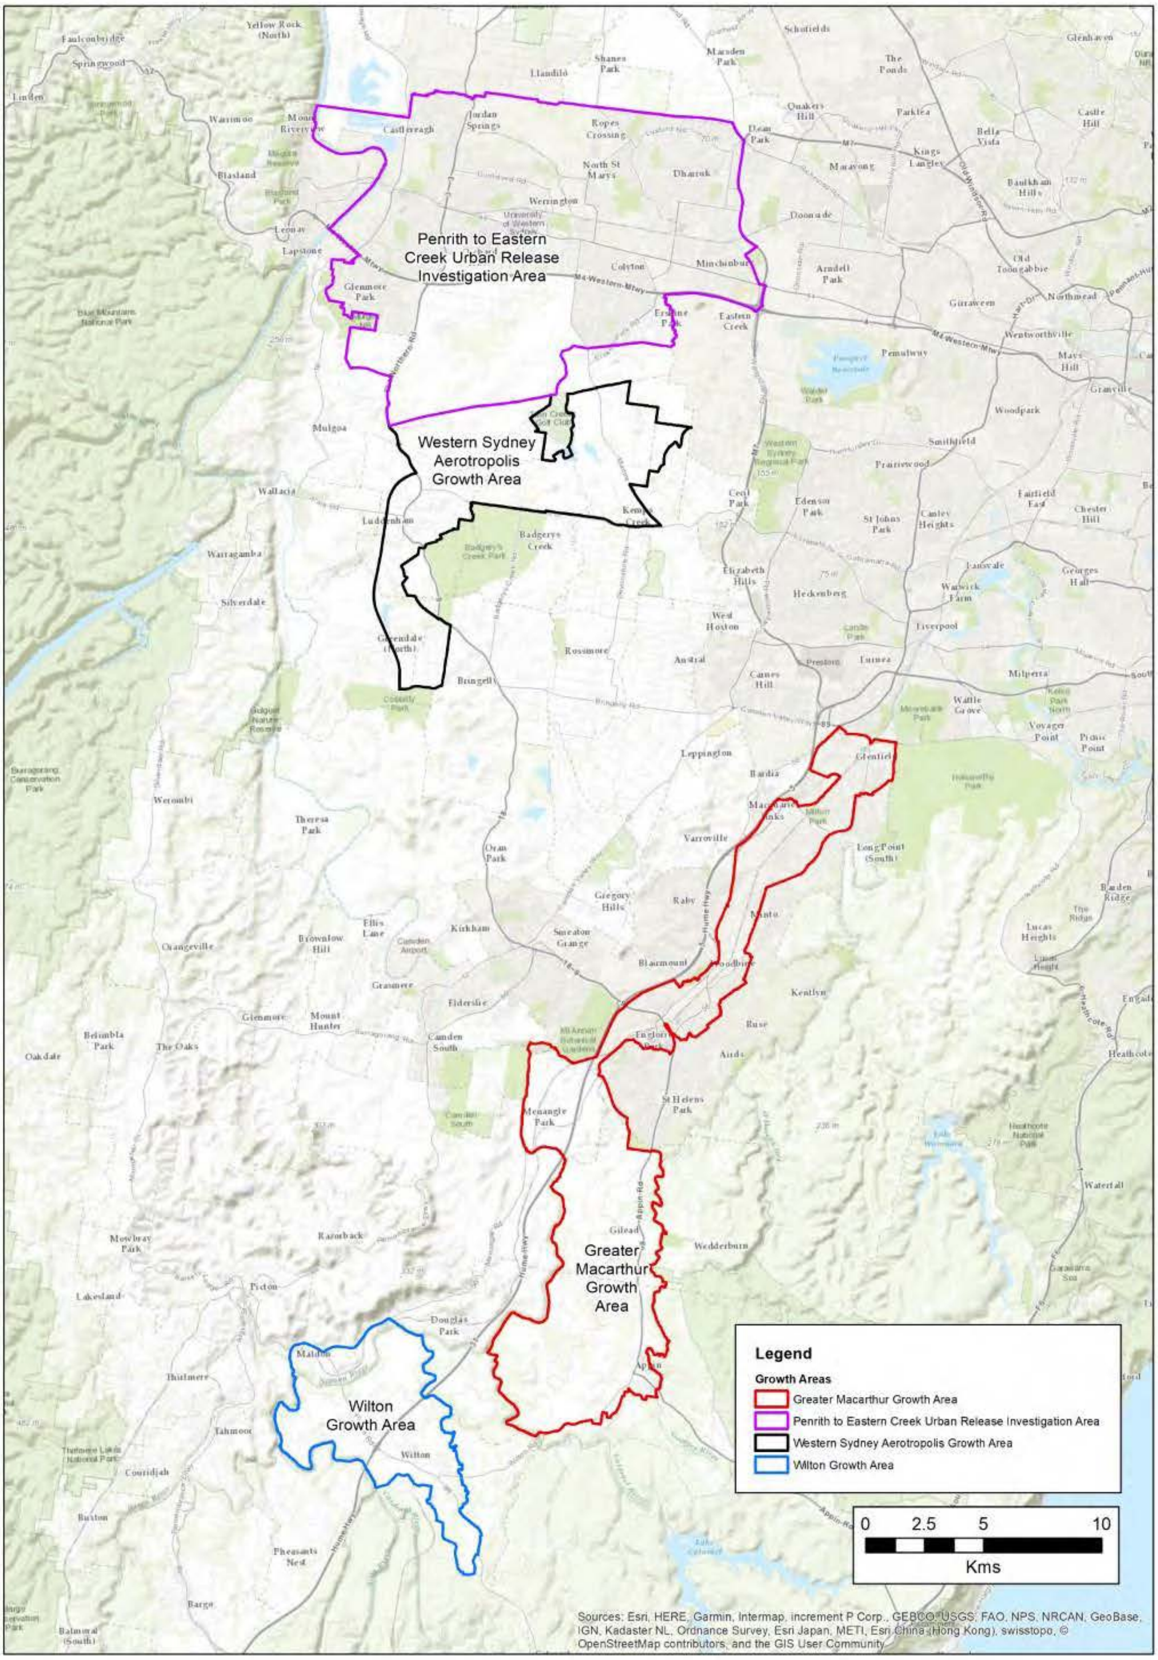
1.3 Study area



Map 1. Growth Areas subject to this Expert Report

Greater Penrith & Eastern Creek Growth Area (GPECGA)

A large portion of this Growth Area is already urbanised, with several areas of industrial land use. Significant rural and peri-urban areas remain in the central north, the centre, and the southwest. Large areas of remnant vegetation are present in the far north (former Australian Defence Industries site, now in part Wianamatta Regional Park), and the Orchard Hills Defence facility. Mining of alluvium for sand and soil continues in the far northwest of the area in the Penrith Lakes locality.

The area has been extensively cleared because of its relatively arable terrain, based mainly on shale and alluvium. Some of the remaining vegetation is associated with the much less arable to infertile Castlereagh Woodlands and its older, leached and mineralised alluvium and shale-derived soils. Strips of remnant vegetation are present along some of the larger watercourses such as Eastern and South Creeks. Significant parts of the study area are or were flood-prone, and this has influenced the retention of vegetation in some affected areas.

Western Sydney Aerotropolis Growth Area (WSAGA)

This Growth Area adjoins the Greater Penrith to Eastern Creek area, extending south to the locality of Greendale, west of Bringelly. It is currently largely rural, with villages at Luddenham and Kemps Creek. Most rural areas are pastoral, but there are significant areas of more intensive rural use, including poultry and egg production, a large dairy and associated fodder cropping, and some market gardens and enclosed fruit and vegetable production. Quarrying occurs at the localities of Badgerys Creek and Kemps Creek.

This Growth Area is extensively cleared but retains native vegetation in areas where rural uses were constrained by steeper terrain, flooding along streams, or unsuitable soils.

Greater Macarthur Growth Area (GMGA)

The GMGA occurs in southwestern Sydney on predominantly shale soils that have been heavily cleared for agriculture and urban or industrial use. The northernmost section has long-established urban and commercial / industrial land use, while the southern section is largely rural (pastoral, minor cropping), with some villages and primarily subsurface mining (e.g. coal and coal seam gas). It extends from urban Glenfield in the north, to the rural village of Appin in the south.

In the southernmost section, geological uplift and erosion have exposed infertile sandstone terrain along gullies and valleys. Much of that terrain remains naturally vegetated because it is unsuited to agriculture, however it occupies only a small percentage of the total area of this heavily-cleared region. Between the infertile sandstone valleys and the relatively arable shale plateau and hills is a geological and ecological transition zone. Whilst much of the vegetation of the shale terrain has been cleared, a greater area of vegetation remains on the transition zone, primarily in the south. Both the shale and transition zones support Critically Endangered ecological communities that are potential habitat for some threatened plant and animal species.

Wilton Growth Area (WGA)

The Wilton Growth Area is the most southerly of the four Western Sydney Growth Areas dealt with in this Report. It extends from the village of Douglas Park in the north, to the village of Wilton in the south. It is primarily rural (pastoral) area with some more intensive agriculture, significant but mostly underground mining (primarily coal), and some long-established villages. The Hume Motorway dissects this Growth Area.

The pattern of clearing and vegetation retention is broadly similar to that of Greater Macarthur, with the majority of remnant vegetation associated with infertile but biodiverse sandstone gullies and the Nepean River gorge, and with associated transition into the heavily cleared shale landscapes.

1.4 Justification for the use of an Expert Report

An Expert Report for *Melaleuca deanei* is required as part of the threatened biota assessment for the Cumberland Plain Conservation Plan because:

1) Survey effort for this species did not meet the recommendations in the OEH threatened species guidelines (OEH, 2016) for field traverses due to limitations on land access, particularly in the GMGA;
2) Survey quality was constrained by drought conditions. Whilst this species is perennial, under sufficiently severe drought and associated total grazing pressure (livestock, if relevant; native species; feral species), it can be suppressed such that it only remains apparent (but likely undetectable) as rootstock and as seed bank;
3) Survey effectiveness was further constrained by parts of the study area having been long-unburnt. This can create an unnaturally dense shrub layer that limits access.

Surveys associated with biocertification of the study areas and earlier projects in those areas have been insufficient to reliably determine the presence and extent of the species. An Expert Report is required to provide an assessment of the likely presence, location, and significance of occurrences of the species in those areas.

1.5 Credentials of expert

I have worked as an ecologist since the mid-1990s, primarily in the Greater Sydney region, but also in the ACT, Central Coast, southern NSW (coast, tablelands and slopes), throughout Victoria and into eastern South Australia. I have primarily been self-employed, with a mix of government, private, and corporate clients, and have also worked as a subconsultant to larger firms, including two university-based consultancies. I have also worked directly for the NSW NPWS, and more recently for OEH (Native Vegetation Information Science). A summary of my credentials as required under the BAM is provided below as Table 1. I was approved by OEH as a species expert for *Melaleuca deanei* under s.6.5 of the BAM in November 2018.

Table 1. Credentials of Dr Steven Douglas as Expert in relation to *Melaleuca deanei*

BAM section	BAM requirement	Details
s.6.5.2.8 (g)	Name of expert	Dr Steven Douglas
s.6.5.2.3 (a)	Expert's qualifications	Bachelor of Science (Plant Ecology, Land Management, Resource & Environmental Management), Macquarie University, 1993. Master of Environmental Planning, Graduate School of Environment, Macquarie University, 1996. Doctor of Philosophy, Australian National University, 2008. Graduate Certificate of Information Literacy, ANU, 2006. BAM Accredited Ecologist, 2018.
s.6.5.2.3 (b)	History of experience in ecological research and survey method for the relevant entity	Partial review of BioNet and incorporated NSW Herbarium database records of *Melaleuca deanei* in the Cumberland Subregion and immediately adjoining areas (DPE, 2018). Discovery and documentation of new populations of *Melaleuca deanei* in The Hills Shire (former Maroota State Forest, 1994 and 2001). Contributor to National Recovery Plan for *Melaleuca deanei* (2010). Preparation of species management profile for Hornsby and later Gosford LGA Threatened Biota Management Plans (1999, 2001). Surveys, documentation and recommendations for threatened species including *Melaleuca deanei* as part of the Landcom ESD report (Total Environment Centre, 1999). Successfully nominated species for listing as Vulnerable under Threatened Species Conservation Act 1995 (1998-99). Numerous historic surveys in northwest and western Sydney including Hills Shire, Hornsby Shire, Blue Mountains City and Hawkesbury LGAs (1994-2000). Most records lodged are from Berowra Valley NP. Most surveys were opportunistic or if targeted, specified impact areas to be searched, e.g. road verges.
s.6.5.2.3 (c)	Resumé detailing projects pertaining to the survey of the relevant entity	See Appendix 1. Relevant surveys and works listed above.
s. 6.5.2.3 (d)	Employer's name and period of employment (if relevant)	Self-employed ecological consultant, 1996 to present (continuous other than for periods of study). Employed by OEH as contracted staff from November 2015 to July 2018 (Wingecarribee Shire vegetation map, South Coast Regional vegetation map, Review of mapping issues for TECs).
s.6.5.2.3 (f)	Evidence that the person is a well-known authority on the relevant entity	Profiles prepared for this species in threatened biota management plans for Hornsby and Gosford Councils. Successful nomination to NSW Scientific Committee required preparing of a review of the species' conservation status. Consulted by DECCW on this and other threatened flora species of the region as part of a data review for the purposes of the BioBanking Tool (2006). Approved by OEH as a species expert for *Melaleuca deanei* under s.6.5 of the BAM in November 2018.

2. Species information

2.1 Description

Melaleuca deanei is a shrub to 3 metres high with fibrous-flaky bark. Leaves are alternate, narrow-elliptic to lance-shaped and 12-25 mm long and up to 6 mm wide. The smooth leaves are not paired. The leaves are moderately dark green in colour and twisted so the edges turn towards the stem, while the leaf tip ends in a sharp point. The mature plant is hairless, however new shoots are covered in white hairs. Flowers are creamy-yellow and arranged in a typical 'bottlebrush' spike, up to 6 cm long. Within each flower, groups of stamens (17-28) are fused together at the base. Fruit is barrel-shaped, 3-7 mm in diameter, and the opening to the fruit is 3 mm in diameter (DECCW, 2010; OEH, 2017).

Melaleuca deanei (Maroota) © S. Douglas

2.2 Ecology

"The longevity of individuals is reported to be greater than 100 years (Benson & McDougall 1998). As a clonal species, *M. deanei* has the ability to re-sprout from a swollen rootstock (lignotuber) to produce coppiced growth, and it can also sucker from its rootstock (Felton 1993).

The exact age at which *M. deanei* starts to produce flowers and seed is unknown. Some observers estimate this age as 3-4 years (Wrigley pers. comm. cited in Maryott-Brown & Wilks 1993), while others claim that it may take as long as 10 years (Ross Doig, Australian Plant Society, pers. comm.). *Melaleuca* seedlings, in general, take between 7 and 20 years to start flowering (Holiday 1999, cited in Virtue 1991).

It is not known how *M. deanei* is pollinated, though insects are the most likely group of pollinators (Turnbull & Doran 1997 cited in Virtue 1991). Self-fertilisation of *M. deanei* should also not be ruled out (Virtue 1991). Clonal plants, such as *M. deanei*, are known to produce flowers and seed infrequently and at irregular periods of time (Benson & McDougall 1998). Flowering has been observed in spring (Fairley & Moore 1989; Wrigley & Fagg, 1993) and summer (Beadle *et al*., 1983; Maryott-Brown & Wilks 1993; [Hewitt *et al*., 2014a, b]).

Infrequent flowering was evident when some populations did not flower for more than 4-5 years (Benson & McDougall 1998), for 15 years (R. Payne pers. comm., cited in Benson & McDougall 1998), or for many years (Doig & Thumm, pers. obs.). In contrast, one population in Royal National Park has flowered annually for a number of years (Felton 1993). In the populations surveyed for the present Recovery Plan, only approximately half (20 of 43 surveyed) showed evidence of flowering (including the presence of fruit). Low levels of flowering are apparently common in many other *Melaleuca* species (Travers Morgan 1990; Virtue 1991). Felton (1993) suggests that in *M. deanei*, this may be a result of the following two factors: first, this species can re-sprout and hence often invests energy in vegetative reproduction rather than flower and seed production. Second, a specific stimulus (or set of stimuli) may need to trigger flowering in the species, e.g. fire or high/prolonged rainfall. However, Felton also observed that time since last fire did not influence flowering of *M. deanei*, nor did other variables, such as plant height.

Seed production is described as poor and infrequent by several authors (Virtue 1991; Travers Morgan 1990). For example, only 5 of 28 populations surveyed were carrying seed capsules (Felton 1993).

The only variable of importance in Felton's study was the size of *M. deanei* populations, as low density stands appeared less likely to flower than high density stands. The important role of population size is supported by Virtue (1991) who observed that seed set appeared to be greater in large populations. It is also supported by the data in the Recovery Plan: all populations with more than 100 ramets produced seed, and populations with less than 10 ramets were most likely to contain no seed. The relationship between population size and fruit or seed production may be explained by crossbreeding. Virtue (1991) suggests a requirement for crossbreeding in the species, that is, for breeding between different individuals" (DECCW, 2010).

Recent research on *M. deanei* (Hewitt *et al*., 2014b) confirmed that this species "had a low incidence of flowering within the small populations, significantly fewer fruiting plants per population and significantly lower numbers of viable seeds per square metre, most likely compounding its limited recruitment. Flowering, when it occurred in *M. deanei*, was from mid to late October through to late November–early December with increased flowering in response to fire and along road edges" "Results suggest that seed production within smaller populations of *M. deanei* is poor because of a low frequency of flowering and a low proportion of flowering plants per population, rather than plant-level pollination, fruit- or seed-set barriers" (Hewitt *et al*., 2014a).

Seed dispersal and seed bank dynamics

"Seed in *M. deanei* is produced in barrel shaped woody capsules that contain 500-600 seeds (Felton 1993). It is held in the canopy of the plant for several years (possibly up to 15 years) until dehydration allows the capsules to open (Benson & McDougall 1998). Seed release is triggered by fire, occasionally also by drought or frost (Virtue 1991; Felton 1993).

Melaleuca deanei seed is wind dispersed. Light winds are sufficient to empty most capsules of *M. quinquenervia*, which has similar sized seed (Virtue 1991). It is unknown whether *M. deanei* possesses a persistent soil seedbank. Its seeds remain viable for at least nine weeks following release from the capsules, but their viability after this period is unknown (Felton 1993). Felton suggests that the species does not require a persistent soil seedbank as the requirements for germination are provided by fire, which also triggers the release of the seed from its capsule.

Under laboratory conditions, seeds germinated readily and had high levels of viability (Virtue 1991; Felton 1993). Germination seems to be greatest in seeds that are sourced from large populations (Virtue 1991). However, in the wild, no seedlings have been observed during the field work associated with the preparation of this recovery plan, or in previous studies (Travers Morgan 1990; Virtue 1991; Felton 1993). Doig (pers. comm.) notes that despite setting lots of potentially viable seed, germination in the wild is poor and many seedlings do not survive. Seedling establishment is most likely also dependent on prolonged moisture availability (Virtue 1991). It appears that overall, this species relies predominantly on clonal reproduction and produces seed infrequently" (DECCW, 2010). These findings were validated by Hewitt *et al*. (2014a, b).

Disturbance ecology

"*Melaleuca deanei* frequently produces coppiced growth and suckers from its roots, particularly after fire or the disturbance and death of a major stem (Travers Morgan 1990). The species has also been observed to regenerate from epicormic buds that are protected from fire by thick, papery bark (Felton 1993).

It has been suggested that fire is required to provide the right conditions for germination and seedling growth and that seedlings very rarely establish at any time other than after fire (Felton 1993). It has also been suggested that fire may be required to stimulate flowering of *M. deanei* (L. McDougall pers. comm. cited in Benson & McDougall 1998), however Felton (1993) states that some populations flower annually regardless of time since the last fire.

Melaleuca deanei has been observed growing most commonly and vigorously in sites exposed to direct sunlight, or in places where light penetration has been increased by disturbance, such as the edge of fire trails (Travers Morgan 1990; S. Douglas, pers. comm.). The species' preference for light may explain its habitat preference for open ridgetop vegetation (Felton 1993). Shaded plants seem to have fewer and shorter new stems and leaves, and a shorter internodal distance (Travers Morgan 1990).

It is therefore likely that fire, and possibly other physical disturbances that increase light levels without impacting upon the soil, play a role in providing for the recruitment and long-term persistence of the species" (DECCW, 2010).

"The size of the minimum viable population is unknown, however, some of the small sites such as those in Pennant Hills Park (now part of Lane Cove National Park) are unlikely to survive in the long-term due to (apparent) inbreeding depression" (ESP Ecological Surveys & Planning, 1999). This view has been partially substantiated by Hewitt *et al*. (2014a, b; 2019). Without supportive intervention, it seems likely that these particularly small populations will be increasingly restricted to vegetative growth. This may undermine their long-term viability because it does not permit recombination of DNA as might allow adaptation to changing circumstances.

2.3 Distribution and abundance

Melaleuca deanei is endemic to the Sydney Basin Bioregion. The currently accepted distribution of the species extends from Colo Heights and St. Albans in the northwest and west; to Faulconbridge in the lower Blue Mountains in the west; to Brisbane Water National Park in the northeast, through several peri-coastal areas of the lower Hornsby Plateau in metropolitan Sydney, southward through Royal National Park and numerous locations on the Woronora Plateau and the Upper Nepean catchment; an unconfirmed record from Hill Top in the Southern Highlands; then a significant gap before reaching the southern limit in Colymea State Conservation Area west of Nowra; and to Tallowa Dam in the southwest (*sensu* DECC, 2010, augmented by review of BioNet records).

The species' distribution can be divided into a northern and a southern range. "The northern range extends north from Ryde LGA, including the Blue Mountains (48 populations), whereas the southern range extends south from Sutherland LGA (46 populations). The two ranges are separated by a distance of approximately 28 km. This is partly a consequence of unsuitable habitat for the species occurring on the Cumberland Plain in Western Sydney but is also the result of the loss of habitat in northern, southern, and inner western Sydney to urban development" (DECCW, 2010). The southernmost occurrence is ~ 68 km south of the nearest record to the north on the Woronora Plateau. Additionally, the southernmost records are on older, Permian geology rather than Triassic geologies typical of all of the other records.

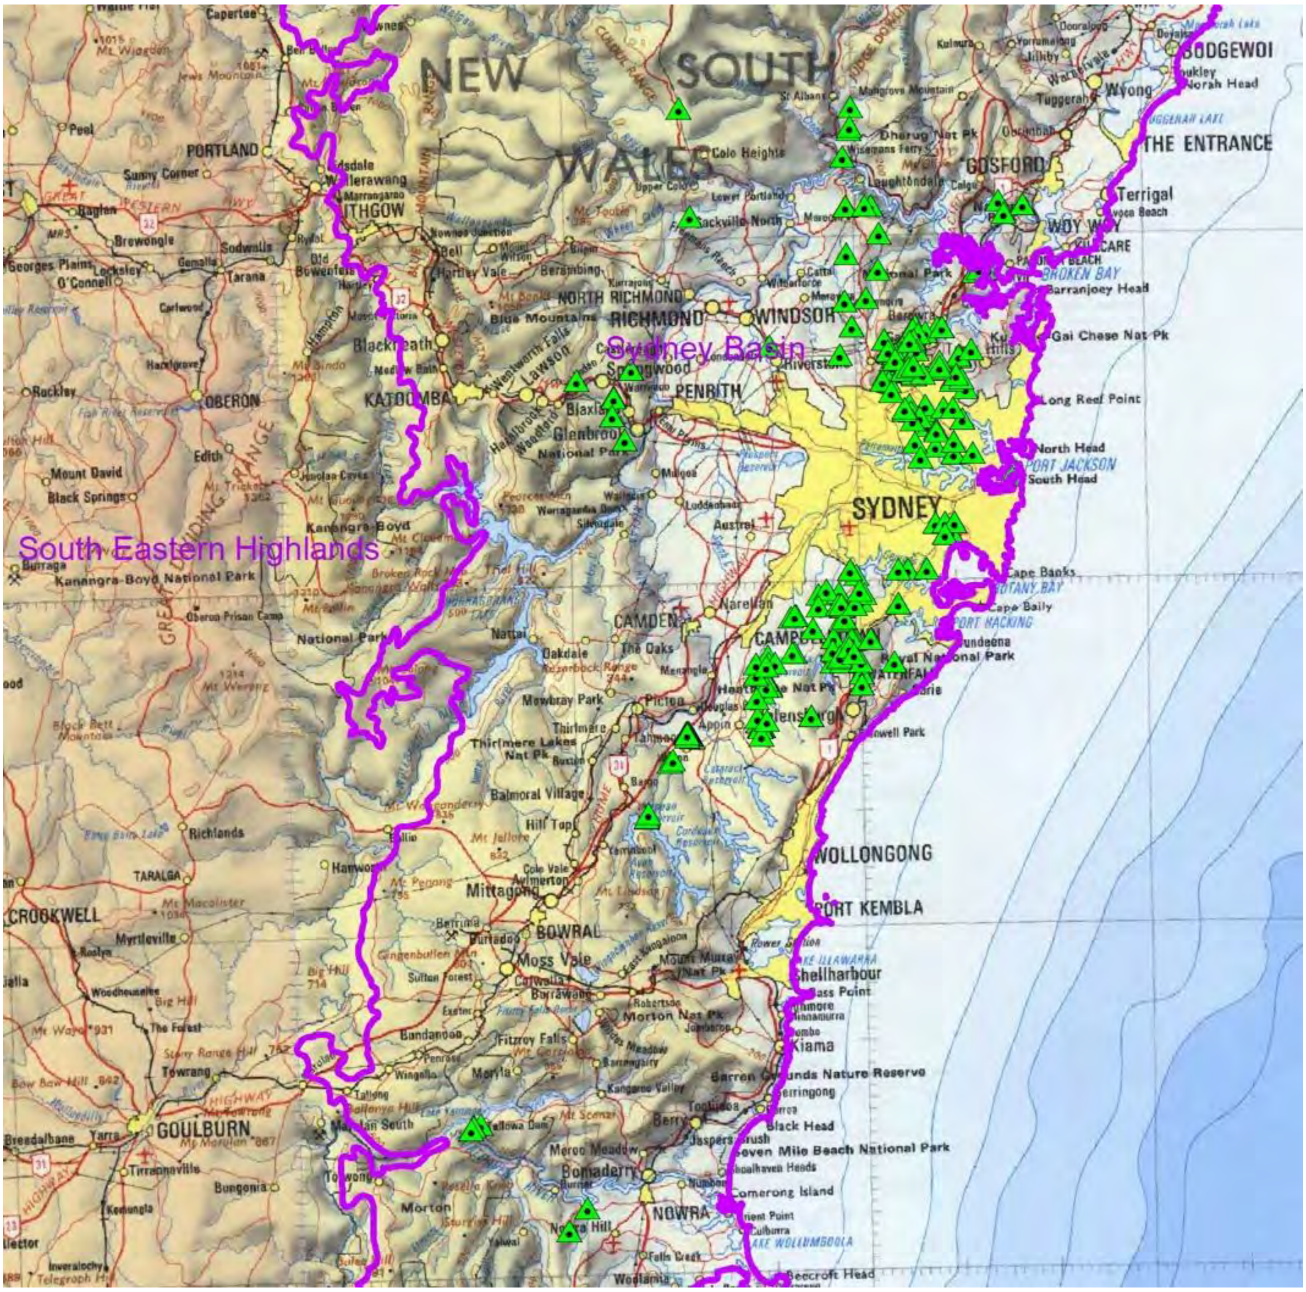
"It is likely that our understanding of the distribution of *M. deanei* is incomplete" (DECCW, 2010). It is feasible that populations are yet to be documented between the Upper Nepean record and the Shoalhaven hinterland records, however, similar to the situation in metropolitan Sydney, these populations will still be separated by the substantial area of unsuitable and largely cleared habitat of the Wingecarribee Plateau between Morton National Park, Meryla State Forest (now largely a Flora Reserve) and Budderoo National Park in the south, and Macquarie Pass National Park and Upper Nepean State Conservation Area to the north. The prospective record at Hill Top may indicate that the species could occur in Nattai National Park, which may provide a link to the Lower Blue Mountains populations.

Several of the early collections of *M. deanei* were made from now-suburban areas where the species is considered locally extinct. These include Kogarah (1884), Arncliffe (1897), Tempe (1898), Oatley (1899), Cooks River (1901), and Earlwood (1912) (Fairley, 2004; DECCW, 2010). "In the last ten years, sites have also been lost to residential development and road construction in Hornsby Heights (J. Slaven, Hornsby Council, pers. comm.), Bangor, and Menai (I. Drinnan, Sutherland Council, pers. comm.)" (DECCW, 2010).

"The available habitat for *M. deanei* has been severely reduced and fragmented by urban development, quarrying, and associated disturbances. This is primarily a consequence of the species' distributional range being centred upon the Sydney region, and its apparent preference for ridge-top locations and sites with lateritic soils… Ongoing urban consolidation and expansion continues to threaten a number of populations. For example, undetected, though probably small, populations may be present in the rural-residential areas of Baulkham Hills (now The Hills) and Hornsby LGAs where the threat of clearing is substantial (S. Douglas, pers. comm.)" (DECCW, 2010). Hewitt et al. (2014b) also notes, "The species' naturally restricted distribution has been markedly reduced by urban development in the Sydney area, and many sites where it was previously recorded (Australia's Virtual Herbarium 2013) were visited and found to have been lost in the years since the records were made" (DECCW, 2010).

In the species' Recovery Plan, "*M. deanei* records within 500 metres of each other have been defined as belonging to the same population, as dispersal of the species is unlikely to exceed this distance (Felton 1993). Populations may consist of a number of sites, as sites have been determined on the basis of tenure… It is difficult to count individual plants within populations, because *M. deanei* is a clonal species. This means that an individual (or genet) may occur as a number of stem clumps (or ramets), which may appear as different plants (Myerscough 1998)... Research by Felton (1993) suggests that for every 10-15 *M. deanei* ramets counted, two to three individuals may be present, while the NSW Scientific Committee (1999) notes that for this species 'ramet counts may overestimate population size by two or three times'. This difficulty with identifying genetically distinct plants needs to be considered when discussing the size of populations based on ramet counts. It also explains why no attempt has been made to determine the size of 28% of all populations. Generally, it is likely that the number of genetically distinct plants is lower than the number of ramets counted… At least 52% of the populations contain less than 50 ramets, and thus most likely even less (*sic*) individual plants. Only four populations contain more than 500 ramets. Of these four, only one occurs in the northern part of the species' range, the other three are in the southern part" (DECCW, 2010).

The latest research in this field is bey Hewitt *et al*. (2019) who undertook genetic analysis of selected *M. deanei* populations and determined that "Multiple stems were found to comprise single genets up to ~10m diameter on the ground, and (that) molecular evidence points to an outcrossing breeding system. Genetic diversity was positively correlated with population size, and significant genetic differentiation was shown between northern and southern regions using clustering analyses." Of particular importance is that they also found that estimates of population size given in DECCW (2010) are likely to be a least 6 times higher than what is now supported by molecular analysis.



Map 2. BioNet records (26/11/18) for whole of species' range

The above map was generated from BioNet data and gives a generally accurate indication of the species' known range, but not the extent of potential habitat. Large areas of NPWS estate and Water NSW catchment lands have not been subject to the same level of survey effort as areas where pressure for land clearing is high or where activities such as mining have funded surveys. The map shows an absence of records of the species between the lower Blue Mountains and the Southern Highlands, despite there being extensive areas of potential habitat present. Similarly, there are very few records north from the Blue Mountains villages through to those north of Colo Heights and near St. Albans. Again, that area contains significant areas of potential habitat.

2.3.1 Reservation status

As of 2010, more than 50% of all 'sites' of the species were known to occur in NPWS reserves (DECCW, 2010). "Holsworthy Military Reserve, contains 17 % of the known *M. deanei* population, including large populations that extend along the ridgelines in the central and western section of the area" (DECCW, 2010). That area is largely naturally vegetated but is subject to clearing and detrimental disturbance for military purposes and is not conservation estate. Two large populations occur on land managed by Water NSW for potable water catchment protection within the Nepean and Avon Dam catchments. Since the 2010 Recovery Plan, these populations have received additional protection through the gazettal of the large Upper Nepean State Conservation Area. Whilst this reserve permits subsurface mining and some surface infrastructure for mining and water management purposes, the two populations are close to dams, and unlikely to be threatened by mining activities. Additionally, gazettal of Dharawal National Park in place of and beyond the scope of most of the former Dharawal State Conservation Area has protected numerous occurrences of the species. The now much smaller portion that remains a State Conservation Area does not contain records of this species, based on BioNet data.

Berowra Valley Regional Park, which according to DECCW (2010) was known to contain 17% of the sites of *M. deanei* at that time, has since been gazetted as a National Park, increasing the emphasis on conservation in this area, and affording the species some additional protection, subject to resourcing.

The north-western populations on the fringes of metropolitan Sydney, primarily in The Hills Shire, remain unreserved in terms of NPWS estate. These extend from Kenthurst through Middle Dural, Glenorie, the former Maroota State Forest, to north-nor-west of the locality of Maroota. Most are on Crown land or former Crown land where there are conflicts between grants or claims under the NSW Aboriginal Land Rights Act and competing claims under the Commonwealth Native Title Act. These areas are not known to be actively managed for conservation but may be increasingly protected through biodiversity stewardship agreements / biobanking.

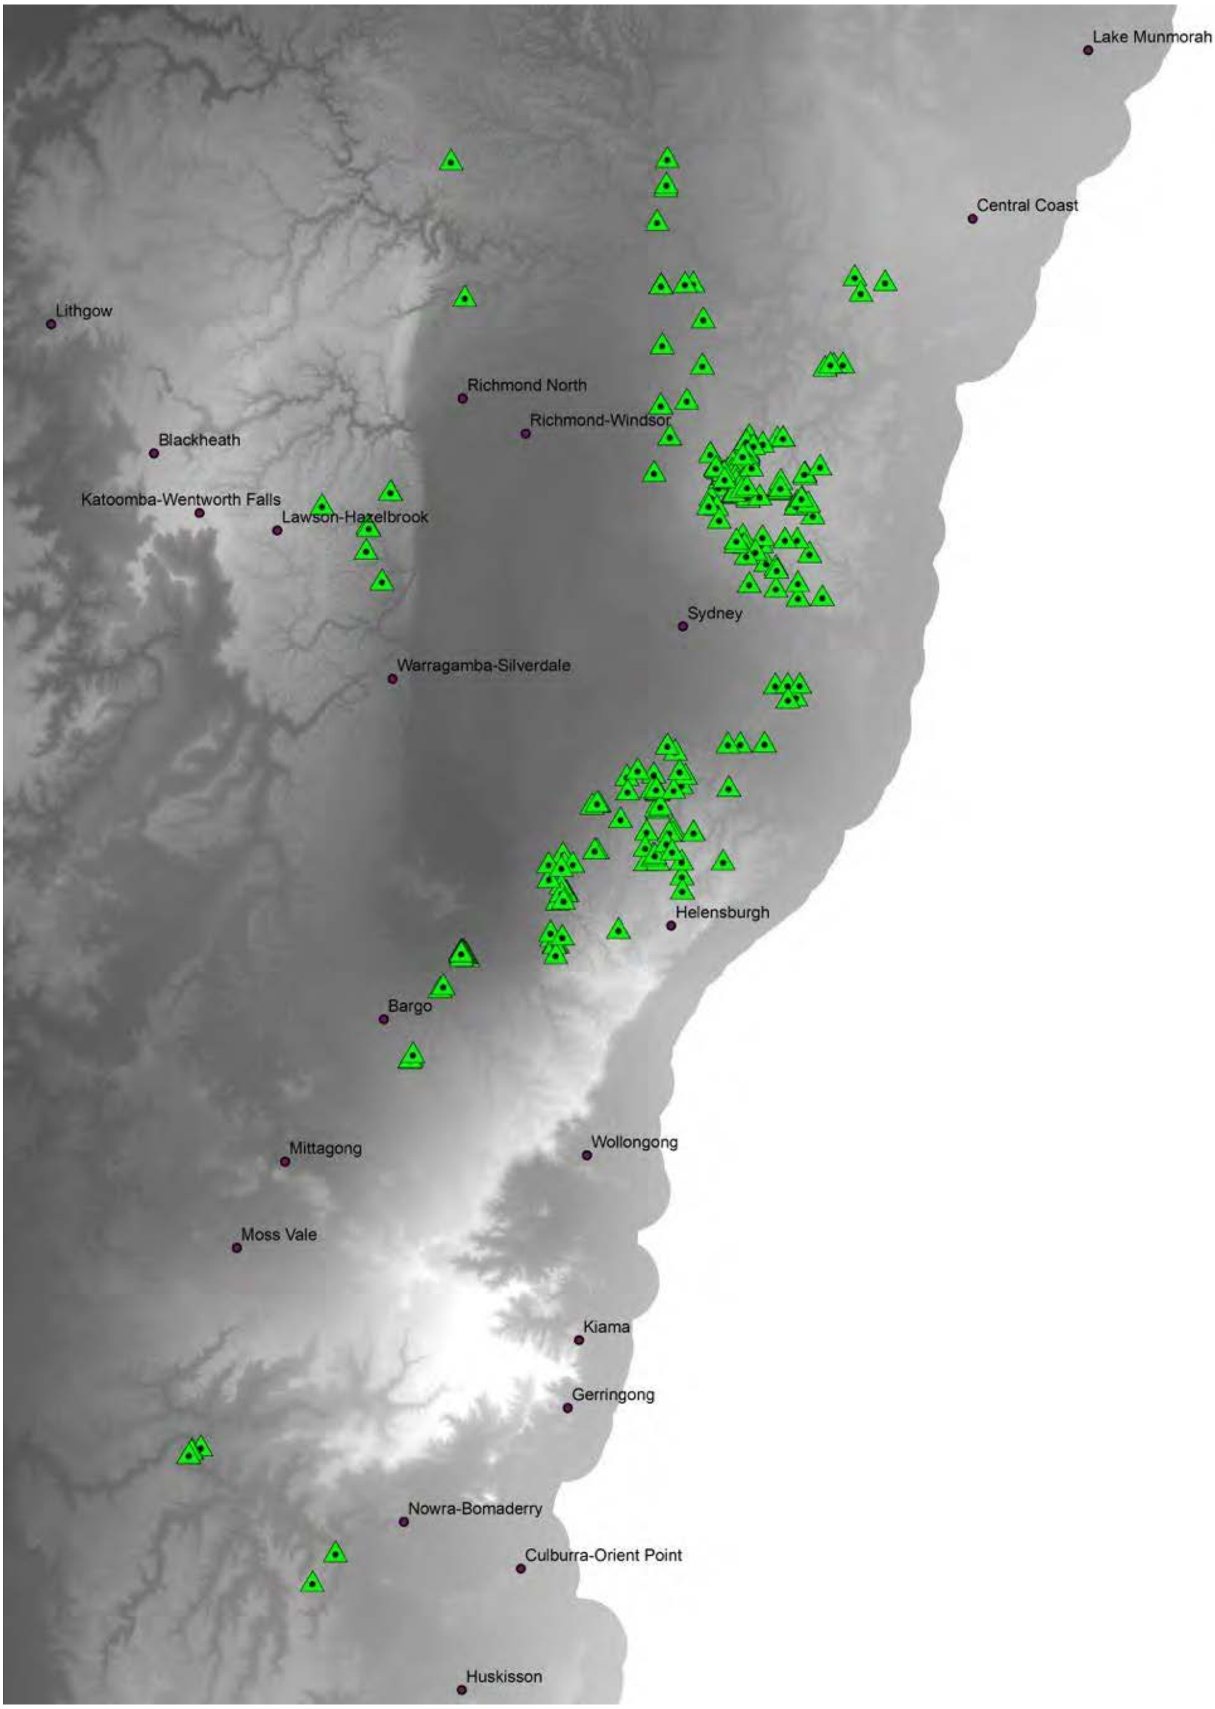
The outer northernmost populations are within Parr State Conservation Area and Yengo National Park. A 1933 record 'near Hawkesbury Punt' (ferry) plots in unsuitable habitat can could be in Dharug National Park north of the River, in Wisemans Ferry Historic Site south of the River, or on unreserved freehold nearby.

2.4 Habitat

2.4.1 Geology, soil, climate

"*Melaleuca deanei* mostly occupies broad flat ridgetops, dry ridges and slopes (Benson & McDougall 1998). In southern Sydney, the species is most often found on flat broad ridge tops more than 100 metres wide (Travers Morgan 1990). The altitudinal range of *M. deanei* is between 20 and 410 metres above sea level, and annual rainfall in the species' distribution ranges from 1,000 to 1,400 mm (Benson & McDougall 1998)" (DECCW, 2010). However, more recent distribution and rainfall data obtained from OEH indicates that the species' minimum average annual rainfall tolerance is considerably lower: ~830 mm (Wilton), with several occurrences in areas with 900 -950 mm in western and north-western Sydney and environs. Notably, the species has a very narrow range of annual average temperature tolerance based on current BioNet distribution data: ~14 to ~16 C.

"*Melaleuca deanei* is strongly associated with sandy loam soils that are low in nutrients, sometimes with ironstone present (Benson & McDougall 1998). In a study of ten populations in southern Sydney, Travers Morgan (1990) found that the species most frequently occurred on deep and well-developed lateritic soils, i.e. soils where an indurated iron-rich layer usually overlies a mottled clay and a pallid clay (Murphy 1993)." (DECCW, 2010).



Map 3. *M. deanei* locations shown over average annual rainfall (lightest shading shows highest rainfall)

Analysis of BioNet records and mapped Soil Landscapes indicates that the species is strongly associated with the Lucas Heights Soil Landscape, especially south of metropolitan Sydney. The northern Sydney records are mainly associated with Hawkesbury and Lucas Heights Soil Landscapes, with some occurring on Gymea and Lambert Soil Landscapes. Most of these are associated with the upper Hawkesbury Group, principally Hawkesbury Sandstone, though the Lucas Heights Soil Landscape is associated with the Mittagong Formation. This is a transitional bed between the Wianamatta Group (mostly shale) and the Hawkesbury Group (mostly sandstone) (*sensu* Martyn, 2018) and is very strongly associated with several threatened plant species, and at least one threatened ecological community.

A very small number of records occur on the Glenorie and Blacktown Soil Landscapes, which are derived from Wianamatta Shale. When reviewed, most of these records were very vaguely located, with very low spatial Accuracy scores. The exception is recent, spatially accurate records near Wilton, which plot on the Blacktown Soil Landscape. The apparent explanation in this case is that the Soil Landscape mapping is very coarse on the Wollongong 1:100,000 sheet, and that the Lucas Heights Soil Landscape is under-mapped. This is supported by recent vegetation mapping. In this area, the map shows the Blacktown landscape directly adjoining the Hawkesbury landscape – a situation that effectively does not occur in Nature, as there is almost always some transition between the purely shale terrain and the purely sandstone terrain.

2.4.2 Associated vegetation communities and NSW TECs

"M. deanei occurs in a wide range of vegetation communities but is most often found in Coastal Sandstone Ridgetop Woodland (Tindall *et al.* 2004). Several authors state that there seems to be no obvious association between *M. deanei* and any particular components of the ridgetop flora (Specht 1981; Travers Morgan 1990; Felton 1993; Benson & McDougall 1998)" (DECCW, 2010).

The OEH Threatened Biodiversity Data Collection lists the following Keith Vegetation Classes as being associated with *M. deanei*:

- Coastal Valley Grassy Woodlands;
- South East Dry Sclerophyll Forests;
- Sydney Coastal Dry Sclerophyll Forests;
- Sydney Coastal Heaths;
- Sydney Hinterland Dry Sclerophyll Forests; and
- Sydney Montane Dry Sclerophyll Forests.

The Threatened Biodiversity Data Collection indicates that *M. deanei* is potentially associated with 20 Plant Community Types (PCTs) across its range. Two of these are also associated with State and/or Commonwealth-listed Threatened Ecological Communities (TECs). Within the Growth Areas, relevant communities and NSW-listed TECs, excluding apparent errors, are shown in Table 4. The associated PCTs are treated by OEH as *potential* habitat, and the species may not actually occur in all of those communities.

Associations between a species and Vegetation Classes and PCTs in the Threatened Biodiversity Data Collection represent *potential* habitat, not actual habit. Given the limitations of vegetation mapping and that in most cases, survey effort for threatened species is incomplete across their range, such an approach is understandable.

The listed association between *M. deanei* and Coastal Valley Grassy Woodland is a consequence of the association with PCT 1395. Ordinarily, *M. deanei* would not be considered to be associated with this Vegetation Class as the vast majority of occurrences are in heathy/shrubby habitats. However, PCT 1395 is legitimately associated with this species, even though such occurrences are atypical across the species' range.

An assessment of the association between *M. deanei* and PCTs was undertaken to better understand the potential habitat for this species in terms of plant communities. The information is used to generate 'species polygons' (maps of potential habitat) as required under the BAM. Whilst DPE required habitat associations to be graded i.e. strong to weak association with particular PCTs, only ungraded PCT association data was used to generate the 'species polygons'. The assessment is constrained by limitations of BioNet data and available vegetation maps. The assessment of the species' relationship with PCTs in and near the Cumberland Subregion used publicly available OEH vegetation maps and did not use the updated vegetation maps produced by Biosis within the Growth Areas. There are now known to be significant differences between Biosis' updated and finer-scale map and OEHs earlier maps. These have a bearing on the results presented in Table 2. However, the effect on the modelling of habitat for *M. deanei* is likely to be far smaller for *M. deanei* than for species that are strongly associated with the Cumberland Subregion.

Some of the records of the species are not spatially associated with a PCT. This may be because:

- the record occurs in a site now cleared of native vegetation or too degraded to be captured by mapping;
- because the record is too spatially uncertain, so has been assigned generic co-ordinates, usually in a named town or suburb, and such settled areas often lack native vegetation; and/or
- the record plots just outside an area of mapped vegetation because it is on a road verge, and even most GPS records are only accurate to 5m, meaning it could plot on the road, not on the verge.

To overcome this latter problem, those records were assigned a 10m buffer so that they would associate with the nearest mapped vegetation polygon up to 10m from the plotted location.

A further consideration is that survey effort for the species is not evenly distributed across the area subject to analysis. Some sites of potential habitat have had very little or no effort, often due to tenure constraints, yet others have had every apparent plant recorded (mostly in reserves or as part of ecological impact assessments). This creates very substantial biases in the data, which can create misleading weightings of association between the species and particular PCTs. Furthermore, most records do not include population data, such that a record might be for one plant or many. In short, this analysis is best used only for presence/absence i.e. whether the species has been recorded at a point that is mapped as a particular PCT, or not. Analysis beyond that is very constrained by deficiencies and biases in the datasets, especially in BioNet data.

The analysis of association with PCT in Table 2 below deals only with records in the Cumberland Subregion plus a 10 km buffer. Records that associate with a PCT when a 10 m buffer is used are included in the counts of sightings below and are not shown separately. Two analyses were undertaken: All records in the target area without regard to spatial Accuracy score; and only records in that area with Accuracy score of 100 m or better. The latter analysis is considered more reliable, but both sets of figures are provided. Sightings with Accuracy <=100 m are shown in square brackets **[ ]** and in bold text. Where available, the combined count of individuals associated with the records is provided in parentheses { }. Those counts relate only to records with Accuracy <=100 m. Where a record doesn't contain population data, it is assumed to relate to a single plant.

Only PCTs mapped in the Growth Areas are dealt with in the table below. For PCTs outside the Growth Areas but within the 10 km buffer, 1777 (63 **[49]** {1641}) and 1787 (24 **[11]** {14}) are significantly associated with *M. deanei*. Those PCTs are more typical of the species' habitat across its range.

Because there are very few records of *M. deanei* from the Cumberland Subregion, a 10 km buffer (which mostly comprises incompatible geology and soils for this species) has been used to broaden the dataset. Even with this buffer, the analysis in Table 2 is unrepresentative of the species' association with PCTs across its range, as the species primarily occurs outside the Cumberland Subregion. Additionally, the recent records of the species from the Bingara Gorge housing development skew the analysis in favour of PCT 1395 because it is over-mapped by OEH where this population occurs. The more recent and accurate map by Biosis designated as 1181 much of what OEH maps at that site as 1395. The boundary between these communities is unlikely to be as clear as either map indicates, and it is likely that unmapped, transitional areas related to PCT 1081 are present.

A pattern of PCT 849 on shale, 1395 on the high-shale part of the transition, 1081 on the low-shale part of the transition, then 1181 on the predominantly sandstone terrain is evident just to the north of the Bingara Gorge site but 1081 is not mapped at this latter location. It is likely that 1081 is a more strongly associated PCT for this species than is 1181, despite what the basic analysis of association suggests. It is also very likely that the apparently Very High association with 1395 is primarily an artefact of the dataset and is unrepresentative. All such biases are dealt with in the column, Adjusted relative significance.

In my Expert Report for *Persoonia nutans*, I compensated for the fact that vegetation mapping of the Growth Areas is arguably affected by the fact that two different OEH PCT maps cover this area, and they don't seem to be as aligned as they might be in terms of PCT allocations – at least not where they adjoin in some cases. For *P. nutans*, two PCTs that are clearly very similar to PCT 1081 but that do not occur in the Growth Areas were treated as 1081 for the purpose of analysing the association of that species with PCTs. Were a similar approach taken in relation to *M. deanei*, the number of sightings and the population sizes associated with PCT 1081 would significantly increase because most of the records of this species in the 10 km buffer come from PCTs that are similar to or at least closest to 1081. That PCT is present in parts of the Wilton and Greater Macarthur Growth Areas but absent further east.

It is important to note that the ranking of relative significance of PCTs for this species does not infer that the species will occur where any of these PCTs are present in the two relevant Growth Areas. It only indicates the relative probability of occurrence and of associated population size in the context of this limited analysis.

TABLE 2. Species records relative to mapped PCTs and their relative significance for the species in the Growth Areas

PCT	PCT Name	Associated TECs (NSW BC Act)	% Cleared (VCD)	Sightings & Population	Relative association	Adjusted relative association#
1081	Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain	Not a TEC but some areas may be within Shale Sandstone Transition Forest (CE)	40	20 **[13]** {561}	Moderate	High
1181	Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney	Not a TEC	20	23 **[16]** {587}	Moderate	Moderate
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain	Shale Sandstone Transition Forest (CE)	80	41 **[40]** {1192}	Very High	Moderate

Figures for the % Cleared column were obtained from the OEH BioNet Vegetation Classification Database (VCD).

2.4.1 Description of PCTs associated with *Melaleuca deanei* in each Growth Area

PCT 1081

This community is a form of 'shale/sandstone transition forest' that was previously within the scope of the now circumscribed Shale/Sandstone Transition Forest TEC. It has been independently assessed as a prospective threatened community, that whilst significantly reserved, is suffering on-going losses around Sydney, largely due to urban and peri-urban land use. It is a very significant habitat for *M. deanei* and several other threatened plant species.

This PCT is absent from GPECGA and WSAGA due to the lack of suitable geology. It is a present but as a very minor component of the GMGA (one site and three polygons) and as a moderate component of the WGA. It is likely to have been naturally uncommon to rare in those areas and has probably not been heavily cleared there. It is not readily mapped with high reliability because of the broad ecotone with PCT 1395. Consequently, a precautionary approach is particularly necessary when dealing with areas mapped as PCT 1081, as some may be better classified as 1395 and therefore a Critically Endangered Ecological Community. It is also highly likely that 1081 is present but unmapped in areas that show 1395 immediately adjoining 1181, as the transition zone between the associated geologies is rarely as simple as most maps indicate.

No areas mapped as PCT 1081 are within the proposed urban footprint in either of the two relevant Growth Areas.

PCT 1181

This community is mapped within the WGA and GMGA, but is largely outside the proposed areas of urbanisation, being associated with sandstone soils in gullies, valleys and slopes. It is associated with often-protected habitat along watercourses, and with relatively high bushfire risk and with steep, often rocky terrain.

This PCT is highly associated with *M. deanei* habitat within the study area but this is probably amplified by limitations of the vegetation mapping, which tend to simplify the shale/sandstone transition and over-map PCTs 1395 and 1181 by under-mapping PCT 1081. This PCT is not present in the GPECGA or the WSAGA due to the absence of associated geology.

PCT 1395

This community is the principal PCT of the Shale Sandstone Transition Forest TEC and has a significant though atypical association with *M. deanei* in and beyond the study area. This community occurs on flat to gently sloping terrain, usually bordering cleared or highly modified rural land. This PCT is absent from the GPECGA and the WSAGA due to the lack of associated geology.

Most mapped occurrences are excluded from the proposed urban footprint in the two relevant Growth Areas. However, even where proposed urbanisation does not involve clearing, habitat can be increasingly threatened by urban encroachment in the form of bushfire hazard reduction works, recreational pressures, urban pollution e.g. nutrient-laden runoff, increased weed invasion from inappropriate landscaping/gardening, and increased predation of fauna by domestic pets.

2.4.2 Associated Commonwealth TECs

As of November 2018, there was not an Approved Conservation Advice for this species. The Commonwealth Department of Environment & Energy appears to defer to the Recovery Plan (DECCW, 2010) in this regard.

GIS analysis indicates that *M. deanei* is associated with the nationally listed Shale Sandstone Transition Forest (this is essentially the same entity as the NSW TEC of the same name, though it permits greater inclusion of PCT 1081 / DSFp146 of Tozer *et al*., 2010).

2.4.3 Habitat condition

Degraded and significantly modified areas of the above-described PCTs can still be habitat for this species due to its ability to persist as woody rootstock and in the soil seed bank. Such modified sites may have reduced or no canopy and/or midstorey, and/or reduced understorey and some weed invasion. The species could persist in highly modified sites such as slashed bushfire Asset Protection Zones, and road and trail verges. Some forms of disturbance, even relatively severe forms that would be considered clearing of vegetation, could be beneficial to this species, within limits. This situation is recognised for numerous threatened plant species in and beyond the Sydney Basin Bioregion. It is believed to be related to the fact that modern fire regimes are likely to be significantly different to those prior to 1788. *M. deanei* is known to be disadvantaged by prolonged absence of fire because reproduction is promoted by, though not dependent on plants and habitat being burnt. Conversely, too frequent fire would be detrimental because seedlings would not have sufficient time to develop post-fire recovery functions such as a lignotuber and epicormic buds, so would likely be killed.

The condition of potential habitat for this species is not, in itself, a reliable indicator of the species' presence, and accordingly, **all condition states except derived grassland are considered in determining suitable habitat** i.e. intact, thinned, scattered, and derived shrubland.

3. Description of the study area

3.1 Landscape context and land use history

All of the Growth Areas have been significantly cleared for earlier activities, primarily timber production associated with opening areas for agriculture and pastoralism, minor areas of surface resource mining, and to varying degrees, for urban and commercial/industrial use. They are proposed to accommodate phased increases in urban land use, primarily within existing cleared or highly modified lands. Increased urban use is planned as a response to population growth.

3.1.1. Greater Macarthur Growth Area (GMGA)

The GMGA extends from Glenfield in the north to Appin in the south. It is largely within the Campbelltown LGA with the southernmost section within the Wollondilly LGA. The northern half comprises an urban renewal corridor centred on the Sydney to Main Southern railway line. It encompasses the existing industrial and residential suburbs of Glenfield, Macquarie Fields, Minto, Leumeah and Campbelltown. The GMGA is associated with extensively cleared, gently undulating shale terrain typical of the Cumberland Plain, and contrasts the sandstone gorges of the Woronora Plateaus across the Georges River to the east. The northern portion of the GMGA is already substantially urbanised, with remnant vegetation largely restricted to creek-lines or small patches associated with designated open space. Vegetated creek-lines include Bunbury Curran Creek, Bow Bowing Creek, Leumeah Creek, Fishers Ghost Creek and Spring Creek.

The more extensive southern half of the GMGA, south of Rosemeadow, comprises proposed urban land releases at Menangle Park, Mount Gilead and Appin. Menangle Park and Mount Gilead are subject to separate planning processes, so are not within the scope of this biocertification. In the north-west, Mount Sugarloaf (213 m AHD) forms the southern end of a hilly ridge on the Luddenham Soil Landscape above the Menangle floodplain that extends north to Denham Court, then to Cecil Hills and Prospect Hill. Some native vegetation persists, although it is often invaded by African Olive. The floodplain is dissected by Menangle Creek and its tributaries, including Nepean Creek, Woodhouse Creek and Leafs Gully.

The southern GMGA is primarily semi-rural and agricultural land, with creek corridors and some larger patches of remnant vegetation located between the Nepean and Georges Rivers. Geologically, the area comprises gently undulating hills on Wianamatta Shale intergrading via a shale sandstone transitional zone (can include the Mittagong Formation) with steeper and infertile terrain on Hawkesbury Sandstone along the rivers. Transitional and sandstone geologies are sometimes exposed along the smaller creek lines.

3.1.2. Wilton Growth Area (WGA)

The WGA is a relatively smaller area that occurs to the south of the GMGA, extending from the vicinity of Douglas Park in the north, Maldon in the north-west, and beyond Wilton in the southeast. The boundaries closely follow the Nepean River in the north and west, a tributary Allens Creek in the east, and the Cordeaux River in the south. Away from the Nepean River and gullies, a higher, gently undulating zone has been largely cleared for agriculture. The Woronora Plateau forms the southern boundary and includes the northernmost section of the large Upper Nepean State Conservation Area, with unreserved but closed areas of the Water NSW Special Area (Sydney water supply catchment) extending to the east and southeast. The Hume Highway dissects the WGA roughly north to south, and Picton Road traverses it roughly northwest to southeast.

The WGA includes both shale, shale sandstone transition and sandstone environments. Remnant vegetation occurs predominantly along the watercourses and on associated slopes. The flatter shale terrain has soils of the Blacktown Soil Landscape, which is derived from Ashfield Shale (a member of the Wianamatta Group), and typically supported the now Critically Endangered Cumberland Plain Woodlands. Much of this area is cleared or modified for agriculture and hobby farms. It comprises native/exotic grassland with smaller areas of Derived Native Grasslands in relatively better condition. Areas above the gullies feature soils of the Lucas Heights Soil Landscape derived from the Mittagong Formation (a transitional bed between the Wianamatta and Hawkesbury Groups). These support variable shale sandstone transition woodlands and forest, some of which are also Critically Endangered. In the steeper gullies, the Hawkesbury Soil Landscape dominates, and supports Hawkesbury Sandstone Gully Forest types with Ridgetop Woodlands on some of the upper slopes.

3.1.3. Penrith to Eastern Creek Growth Area (GPECGA)

The GPECGA is a relatively large area that extends from Rooty Hill, Minchinbury and Hassell Grove in the east, across the Cumberland Plain to the Hawkesbury-Nepean River in the northwest, then south through Jamisontown, Glenmore Park, to the intersection between The Northern Road and the Warragamba Water Supply Pipelines in the far south-west. The predominant geology is Wianamatta Shale on flat to gently undulating terrain that has been extensively cleared for agriculture, and later for housing and industrial use, with some remnant vegetation on current and former Defence holdings. The shale soils support(ed) Cumberland Plain Woodlands. Overlying the extensive shale deposits are small areas of weathered Paleogene-Neogene alluvium e.g. Shalvey and Willmot, that are much more common to the north. These support(ed) the Castlereagh Forests & Woodlands complex of vegetation types, which is strongly associated with several threatened plant species. More common are broadly linear deposits of Quaternary alluvium along watercourses such as South Creek and Eastern Creek, and on the flood terraces of the Hawkesbury-Nepean River. Other lithologies occur but are very rare and of very small extent.

Very little of the GPECGA is reserved in NPWS estate. Wianamatta Regional Park (which emphasises recreational uses) encloses small areas of former Defence land in the far north. Adjacent to the southwestern boundary is the small Mulgoa Nature Reserve (emphasises biodiversity values). Two Biobanking sites adjacent to the Nature Reserve have increased the area under conservation.

3.1.4. Western Sydney Aerotropolis Growth Area (WSAGA)

The WSAGA abuts the GPECGA's southernmost border near the locality of Sovereign (east of Mulgoa), then extends south past Greendale, northeast to the locality of Badgerys Creek, east to Kemps Creek, and northward to the vicinity of Mount Vernon, excluding Twin Creeks Golf Course and associated settlement.

The lithology and soils are broadly similar to that of the GPECGA, being effectively just an extension of that area to the south to incorporate the developing Badgerys Creek Airport and environs. The area is even more severely cleared of native vegetation, except along some streams and on rare occurrences of steeper terrain. It contains no NPWS reserves, with the nearest being the small Kemps Creek Nature Reserve, outside the Area to the southeast. Gulguer Nature Reserve and Bents Basin State Conservation Area occur to the southwest of Greendale.

3.2 Geology and remnant vegetation

All of the Growth Areas are within the Cumberland Subregion. The dominant lithology across all of the Growth Areas is Wianamatta Shale (Ashfield and Bringelly Shales), with much smaller areas of Paleogene-Neogene alluvium occurring largely outside these boundaries, and much larger areas of Quaternary alluvium associated with floodplains of the many watercourses (*sensu* Martyn, 2018).

The terrain varies from almost flat through to steeply hilly areas associated with minor volcanism and more often, in association with shale ranges. In the far south, the more elevated shale landscapes have been eroded down to the underlying Hawkesbury Sandstone in a series of gullies and gorges. A transition zone between the shale and the sandstone is discernible in some areas.

On the dominant shale geology, the associated Critically Endangered Cumberland Plain Woodlands are still present in all of the four Growth Areas but have been disproportionately cleared for rural and later urban and allied uses. Much of what remains of this ecological community occurs as paddock trees and areas of remnant native ground-layer vegetation in pastoral and other contexts, with the exception of some substantial, though fragmented and isolated remnants. Remnant vegetation in these relatively fertile and arable landscapes is often in poor condition. In the most heavily cleared areas, it can be restricted to strips along watercourses. Some forms are dominated by *Casuarina* species. Weeds are common and sometimes severe in the moister situations. Weeds often extend into higher and drier terrain, especially in the form of African Olive and African Love Grass, both of which can occur on a landscape scale.

Small areas of the biodiverse Castlereagh Forests and Woodlands persist in all but the Wilton Growth Area on often-laterised Paleogene-Neogene alluvium. These variable woodlands and open forests support a particularly high number of threatened plant species, and because their soils are less suitable for agriculture and grazing, are better conserved than the Cumberland Plain Woodlands. Nonetheless, they are all listed as threatened ecological communities.

In the two southern Growth Areas, vegetation of the shale sandstone transition zone is relatively common and tends to remain in less arable areas adjoining the largely cleared former Cumberland Plain Woodlands. It is often found fringing the largely uncleared sandstone-based terrain, and ranges from highly intact to significantly modified and degraded, largely due to grazing and weed invasion. The associated Shale Sandstone Transition Forest is recognised as Critically Endangered due to extensive clearing across its substantial range, and because of the severity of other threats. Very little is present in formal conservation areas.

In the two southern Growth Areas, diverse, sandstone-based vegetation persists in association with most of the many incised watercourses. This vegetation is broadly the same as what occurs in extensive conservation estate around urban Sydney, but some communities adjoining current or former Shale Sandstone Transition Forest are not well-conserved and are threatened by further clearing and degradation.

3.2.1 Plant Community Types

The following section lists the Plant Community Types mapped in each Growth Area with brief notes about their distribution in those Areas. The list is not restricted to PCTs associated with *M. deanei*.

3.2.1.1 Greater Macarthur Growth Area (GMGA)

The predominant ecological communities in the GMGA are or were Cumberland Plain Woodland (CPW), Shale Sandstone Transition Forest (SSTF) and River-flat Eucalypt Forest (RFEF), all of which are Threatened Ecological Communities. All have been extensively cleared and degraded, primarily by agriculture and weed invasion, but also by urban and allied uses. There are no NPWS reserves in this Growth Area. However, the very small Leacock, Edmondson and William Howe Regional Parks occur just outside the border and are managed primarily for recreation rather than conservation. Dharawal State Conservation Area and National Park border the southern portion of the Growth Area to the east.

A summary of the mapped ecological communities is found in Table 3. The maps are based on OEH products that have been updated by Biosis for DPE.

Table 3. Summary of all ecological communities within the Greater Macarthur Growth Area

PCT	PCT Name	Distribution & notes
830	Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain	Small patch at Menangle Sugarloaf on SE slopes.
835	Forest Red Gum – Rough- barked Apple grassy woodland on alluvial flats of the Cumberland Plain	Along creek lines in shale areas in northern and central parts of GMGA.
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	Small patches on shale soils throughout GMGA but mostly in northern and central parts.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	Very small patches on shale soils throughout GMGA, more common in southern parts on steeper terrain.
883	Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain	4 polygons, Macquarie Fields, most of which have long been historically mown (Milton Park Softball Complex). They are now subject to regeneration.
1081	Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain	One small occurrence mapped around the margins of bushland associated with Smiths Creek at Leumeah.
1105	River Oak open forest of major streams, Sydney Basin Bioregion and South East Corner Bioregion	Only mapped along the Nepean River north from Menangle Bridge.
1181	Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of west & south Sydney	Narrow zone along Nepean & Georges Rivers and tributary gullies and a small zone along Smiths Creek at Leumeah.
1292	Water Gum - Coachwood riparian scrub along sandstone streams, Sydney Basin Bioregion	Restricted to parts of the riparian zones of the more incised and larger watercourses. Very restricted extent in this Area.
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain	Relatively small remnants extend from Glenfield into the far south where it is extensive on transitional soils mostly south from Rosemeadow. Can intergrade with 849 and 1081.
1800	Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley	Only mapped to a very minor extent as highly linear remnants between Glenfield and Macquarie Fields (along the railway) and at Ingleburn (adjoining roads).

3.2.1.2 Wilton Growth Area (WGA)

The predominant ecological communities in the WGA are or were Cumberland Plain Woodland (CPW) and Shale Sandstone Transition Forest (SSTF) both of which are Threatened Ecological Communities. Sandstone-based communities occur in and surrounding the more incised watercourses. There are no NPWS reserves in this Growth Area, though Upper Nepean State Conservation Area occurs immediately to the south. There is a Biobanking site on the northern side of the river near Douglas Park (within the WGA), and three more such properties to the immediate north (including St Marys Towers) and those associated with coal mines (Steenbeeke, pers. comm.).

Table 4. Summary of all ecological communities within the Wilton Growth Area

PCT	PCT Name	Distribution & notes
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	On shale soils of higher, gently undulating terrain of northern and central areas. Small patches with scattered trees (farming properties) adjoining more extensive exotic and native grasslands.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	One patch in a derived grassland (treeless) condition in the west, and a much larger portion in the far north.
1081	Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain	Limited to a few patches in the north between 1395 on plateau edges and 1181 in sandstone gullies.
1181	Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of west & south Sydney	Common on slopes and plateau edges above and around incised sandstone-based watercourses that surround most of the Area.
1292	Water Gum – Coachwood riparian scrub along sandstone streams	Restricted to a very narrow riparian strip along the Nepean River.
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain	The most extensive community on shale sandstone transition soils between 849/850 and sandstone communities along gullies. Variable floristics.

3.2.1.3 Greater Penrith to Eastern Creek Growth Area (GPECGA)

The native vegetation of this Growth Area has been extensively cleared, with what remains classified as Threatened Ecological Communities. The majority of the Area formerly supported Cumberland Plain Woodlands, with a much smaller area supporting Shale Gravel Transition Forest and Castlereagh Forests & Woodlands. River-flat Eucalypt Forest was previously much more extensive along the Hawkesbury-Nepean River and adjoining primary floodplain, and it remains to varying degrees along many watercourses such as Eastern Creek, though frequently in poor condition, due largely to extensive weed invasion and a long interface with unsympathetic land uses. There is one NPWS reserve in this Growth Area: Wianamatta Regional Park, however it is already significantly fragmented and may be required to potentially accommodate a large transport corridor. The small Mulgoa Nature Reserve and associated Biobanking sites occur near the south-western border of this Growth Area. Yarramundi SCA occurs on the western boundary but across the Nepean River, and Wianamatta NR occurs near the NW corner.

Table 5. Summary of all ecological communities within the GPECGA

PCT	PCT Name	Distribution & notes
724	Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain	Scattered as small remnants and one larger remnant in the central portion, but with greater extent in the central north, mainly in the western ungazetted portion of Wianamatta Regional Park.
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain	A few very small remnants present south of the M4, with larger remnants within and near the gazetted and ungazetted portions of Wianamatta Regional Park.
781	Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion	Very limited extent, primarily in the far northwest, with some small remnants in the southwest, often associated with watercourses.
830	Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain	Present to a very minor extent on the southwestern edge adjoining Mulgoa Nature Reserve
835	Forest Red Gum – Rough- barked Apple grassy woodland on alluvial flats of the Cumberland Plain	Common along creek lines and associated floodplains through the south and central areas.
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	Common in and near Orchard Hills in the south, and former ADI lands in the central north, with some areas in the ungazetted portion of Wianamatta Regional Park. Other scattered remnants, particularly in the east.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	Very small patches in the south west, primarily in pastoral settings and on steeper terrain.
883	Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain	Restricted to one linear polygon in the eastern portion of Wianamatta Regional Park.
1105	River Oak open forest of major streams, Sydney Basin Bioregion and South East Corner Bioregion	Only mapped along the Hawkesbury-Nepean River, primarily near Penrith Lakes.
1800	Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley	Present as mostly-linear remnants along South Creek and Eastern Creek and tributaries, with some scattered occurrences, including along the M4.

3.2.1.4 Western Sydney Aerotropolis Growth Area (WSAGA)

The native vegetation of this Growth Area has been extensively cleared, with what remains classified as Threatened Ecological Communities. The majority of the Area formerly supported Cumberland Plain Woodlands, with a much smaller area supporting Castlereagh Forests & Woodlands near the localities of Kemps and Badgerys Creeks, and potentially in the vicinity of the water pipeline crossing of Luddenham Road. Riverflat Eucalypt Forest remains to varying degrees along most watercourses, though frequently in poor condition, due largely to extensive weed invasion and a long interface with unsympathetic land uses. Swamp Oak Forest occurs mainly along South Creek and some tributaries. There are currently no NPWS reserves in this Growth Area. The small Kemps Creek Nature Reserve occurs just outside the south-eastern corner and Gulguer Nature Reserve and Bents Basin State Conservation Area are near the south-western corner.

Table 6. Summary of all ecological communities within the WSAGA

PCT	PCT Name	Distribution & notes
724	Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain	Restricted to the Kemps and Badgerys Creek area as three patches of remnants.
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain	As above: two patches with smaller remnants nearby and on slightly higher ground than 724.
781	Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion	Very limited extent, primarily in the far northeast, with one remnant in the centre.
835	Forest Red Gum – Rough- barked Apple grassy woodland on alluvial flats of the Cumberland Plain	Common along creek lines and associated floodplains but very little remains, and most occurrences are linear.
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	The most common PCT in this Area, with remnants throughout on the dominant shale terrain.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	Only very small patches in the far south.
1800	Swamp Oak open forest on river-flats of the Cumberland Plain and Hunter valley	Present as mainly very linear remnants along most watercourses but largely absent from the southernmost portion.

4. Assessment of species' presence and suitable habitat

4.1 Existing records and surveys

The principal source of threatened flora records in NSW is the OEH BioNet database, which includes most records held by the NSW Herbarium (specimen-based), as well as sightings, including those associated with vegetation sampling for the purposes of mapping. Other databases, such as Atlas of Living Australia, largely mirror BioNet data within NSW, but are not used in this Report due to their having lower data quality control, and because they do not allow even a registered user to access data that may not have been generalised to obscure the exact location of a record. Very few flora records that are in ALA but not in BioNet are original – most are simply replicate records based on specimens held in other herbaria.

The preliminary assessment of threatened species records undertaken for the preparation of this Expert Report reiterated the merit of reviewing BioNet data and resolving a range of errors, rather than simply using data 'as held'. *Melaleuca deanei* records within BioNet were reviewed, and numerous corrections were made, though the majority of these relate to the assigned spatial accuracy scores and to clarifying or correcting location placements and descriptions. Not all records were able to be checked in that stage, and a second review for records in or near the Growth Areas was conducted to further improve data quality. The reviews eliminated a range of errors and allowed many records that were otherwise too spatially vague, to be refined such that they were suitable for habitat modelling and for general reference. Not all records were reviewed, and inaccuracies remain in the dataset, but records within the Cumberland Subregion are now far more accurate in terms of their identification of the species, their location, and their spatial accuracy score.

BioNet data should only be treated as indicative, not least because there has not been comprehensive survey of all of the Growth Areas or environs, and surveys have been variously constrained. The absence of records from an area does not necessarily mean the species is absent, as it may not have been surveyed there, or survey conditions and methods may have been inadequate.

Field survey undertaken by consultancy firms engaged by DPE (Biosis and Ecoplanning) did not add any records of *M. deanei*.

The preliminary assessment of threatened species records undertaken for the preparation of this and three other Expert Reports reiterated the merit of reviewing BioNet data and resolving a range of errors, rather than simply using data 'as held'.

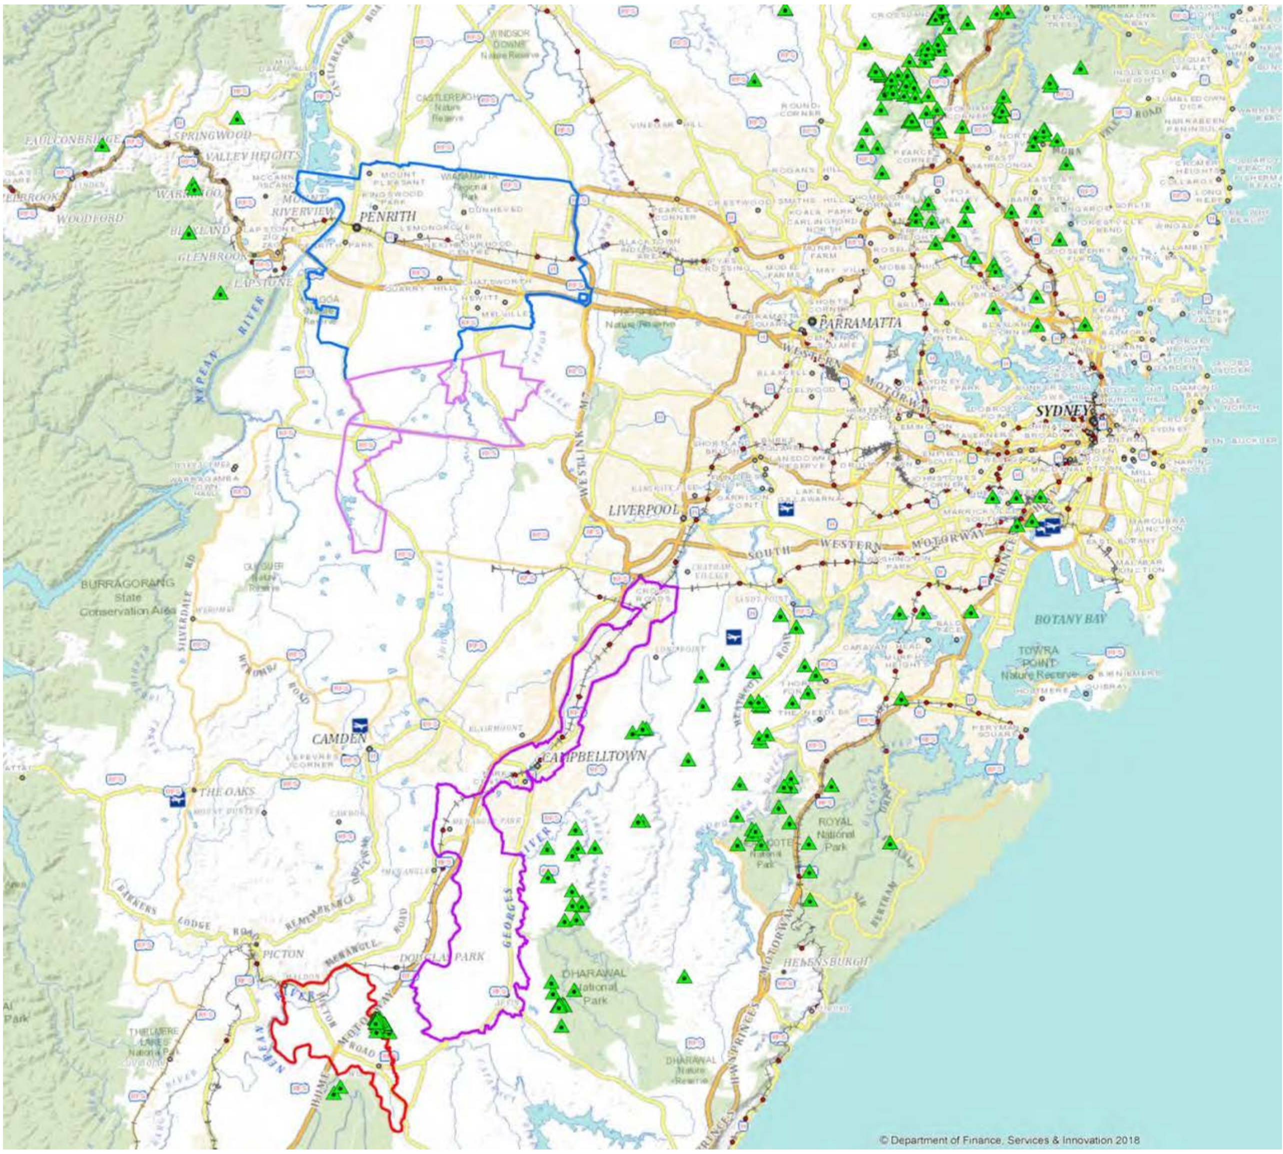
The preparation of this Report entailed detecting and notifying OEH about the correction of several records of *M. deanei* that were errors of some form. One record from the Cumberland Plain near Vineyard was determined to be a data entry error (wrong species). Another record plotted in the GMGA from an experienced botanist had a 1 km spatial accuracy and sparse notes: "north of Appin" and "in swampy area". The plotted location of the record was highly arbitrary and in a cleared paddock in the southern half of Appin village on unsuitable geology. The observer of the record was contacted about the inconsistency and was able to supply information confirming its proper location. BioNet staff have since moved this record. There is no longer a record of this species from the GMGA.

4.1.1 Existing records by Growth Area

There are no BioNet records of *M. deanei* from either the GPECGA or the WSAGA. There is no suitable habitat for this species in those areas.

There are no records of *M. deanei* in the GMGA, but there are numerous valid records to the east on the Woronora Plateau. Equivalent habitat extends into the GMGA and is identified in this Report.

M. deanei is known from numerous spatially accurate records of a population within and just outside the WGA. Other threatened flora species are present in the same area e.g. *Epacris purpurascens* var. *purpurascens*, *Acacia bynoeana*, *Persoonia bargoensis*, *Grevillea parviflora* ssp. *parviflora*. The records are dated 2015 and are from flora assessments for the Bingara Gorge housing project, which is outside the scope of the WGA.



Map 4. BioNet records (as of 26/11/18) relative to Growth Areas

Each point on Map 3 may not designate a collection or observation at that location, as most very old records lacked any co-ordinates, or only supplied coarse co-ordinates, and may only have mentioned a town or locality. Such records will generally have a relatively poor Accuracy score (10-25 km) to indicate that the actual location of the species could be within a considerable distance of the designated point. Many such records are assigned the same indicative co-ordinates such that one point on a map may relate to several old records that were supplied with very little locational information.

4.1.2 Prior surveys within each Growth Area

There is no central or local registry of surveys and survey effort for threatened biota, and a large proportion of survey reports are not made public or only made public when lodged with a planning consent authority. This makes it extremely difficult, if not impossible to compile a list of surveys, methods and findings across the study area.

The OEH Authorised Officer for *M. deanei* was contacted in this regard. She provided information in the form of two 2014 publications by Alison Hewitt *et al*. (Western Sydney University) and mentioned a site in Sutherland Council area (outside the Growth Areas) that may have been subject to rehabilitation. She also mentioned a report that was seen to be of potential relevance (c.f. Cumberland Ecology, 2011).

The aforementioned surveys associated with the Bingara Gorge housing project have been considered in the preparation of this report.

4.2 Summary of survey work undertaken for the biocertification assessment

4.2.1 Vegetation mapping

Vegetation mapping of the Cumberland Subregion was completed in stages by OEH in 2013 and 2016. These two vegetation layers have been used as the base to compile an updated vegetation community layer for each of the Growth Areas. This updated work has been completed by Biosis under contract to DPE. The mapping update includes checking plant community types and confirming the accuracy of boundaries to account for clearing or regrowth that may have occurred since the original mapping was completed. Field verification of the mapping was undertaken by Biosis and Ecoplanning, both of whom undertook vegetation surveys where access was permitted.

Vegetation in the Growth Areas was mapped and assessed based on five vegetation condition classes:

- Intact;
- Non-offsettable Grassland;
- Offsettable Grassland;
- Scattered Trees;
- Thinned.

4.2.2 Field survey effort

The information in section 4.2.2 has been provided by DPE but has been edited here to only deal with threatened flora where feasible. Further details are provided separately by DPE:

An initial 726 letters were sent to landholders within the Wilton and Greater Macarthur Growth Areas in late 2017 with a second letter following in March 2018. To increase the response rate, Biosis commenced targeted door-knocking in May 2018. From this, just under 20% of landholders within these Growth Areas allowed access to their property. However, this included access to large parcels of land owned by major developers, which allowed a reasonable amount of access, particularly for the Wilton Growth Area.

Floristic plot data collected:

- Wilton (86 plots across 6 PCTs)
- Greater Macarthur (82 plots across 9 PCTs)

Approximately 150 of the plots required to meet BAM requirements were obtained by supplementing Biometric plots from various recent assessments. This involved locating the previous plots and collecting additional data on stem classes, number of large trees, and litter cover to meet BAM requirements. The ecologists had no trouble locating the original survey sites and found that the additional data was quick and easy to collect (approximately 30 minutes per site).

The remaining plots in Wilton and Greater Macarthur, and all of the plots in Western Sydney Aerotropolis and Greater Penrith to Eastern Creek consisted of new plots surveyed for this project. All plots were sampled according to the methods prescribed by the BAM Manual (OEH 2017). This includes collecting information on species cover and abundance from 20 x 20 m or equivalent configuration plots within each vegetation zone.

A total of 432 letters were sent to landholders across the Western Sydney Aerotropolis Growth Area between November 2017 and August 2018 with 84 landholders responding positively to provide access. A further seven properties were accessed after doorknocking resulting in a response rate of 21%.

A small number of targeted letters were sent to landholders in the Greater Penrith to Eastern Creek Growth Area from November 2017. However, most letters (more than 1500) were sent in August 2018, which included many urban and small acreage landholders. From this, 177 landholders provided access to their properties and an additional three landholders provided permission via doorknocking (12% response rate). Not all of these properties were surveyed as some did not support vegetation patches of interest. In addition, the Open Spaces Team at Penrith Council facilitated access to 64 lots owned by Council.

Floristic plot data collected:

- Western Sydney Aerotropolis (53 plots across 6 PCTs)
- Greater Penrith to Eastern Creek (26 plots across 7 PCTs)

Targeted survey for threatened species

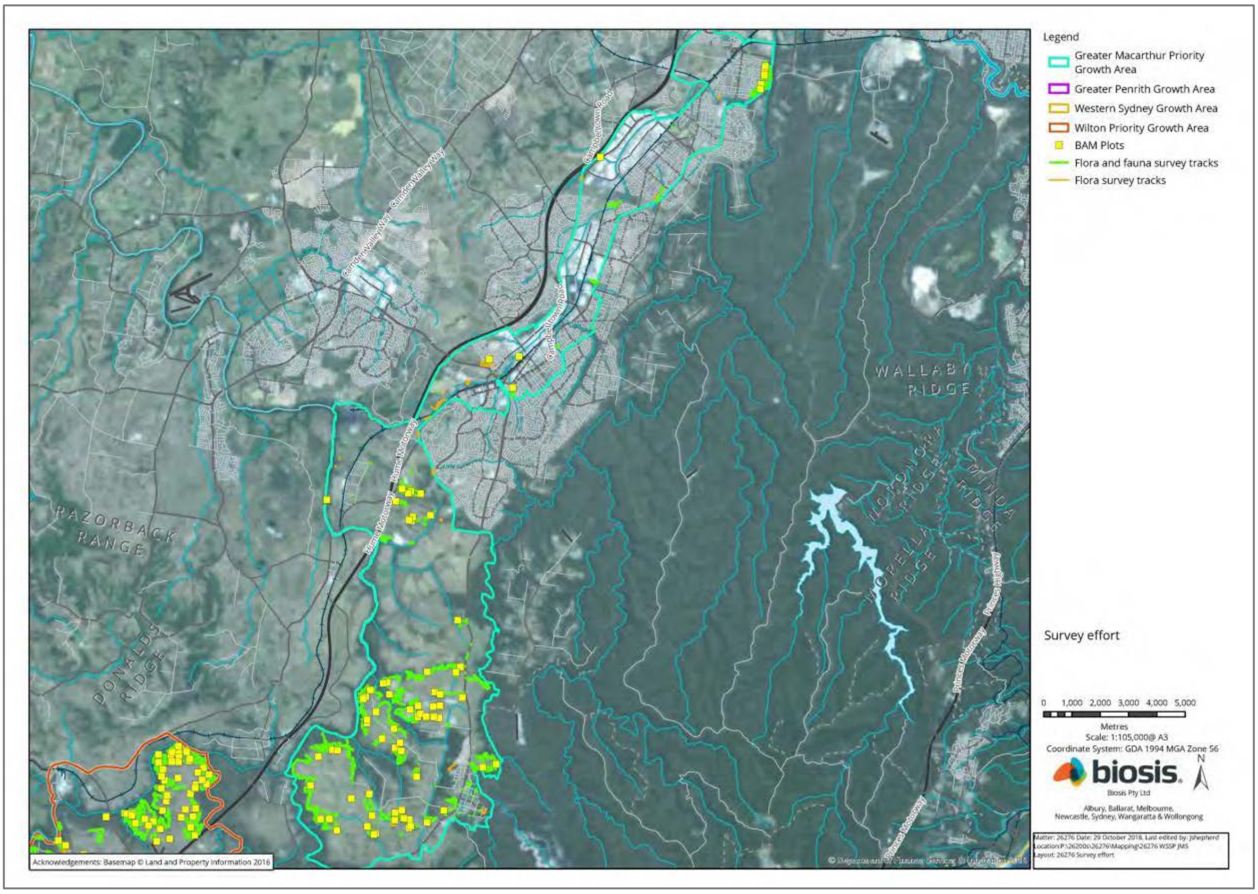
Targeted survey for threatened plant species has been conducted on lands where access has been granted. Vegetation transects and random meanders for threatened flora was conducted by Ecoplanning and Biosis in accessible areas proposed for certification, with particular attention to areas of likely habitat. The survey has included effort through each PCT and vegetation zone and has extended into suitable habitat adjacent to the edge of the future urban area where potential indirect impacts to high quality habitat may occur (up to ~50m).

Likely habitat for most threatened flora species comprised areas of lower disturbance. This includes areas with a predominantly native understorey (with or without a canopy), the base of scattered trees in paddocks, paddocks with an apparent low grazing pressure, and known topographic/habitat preferences for certain flora.

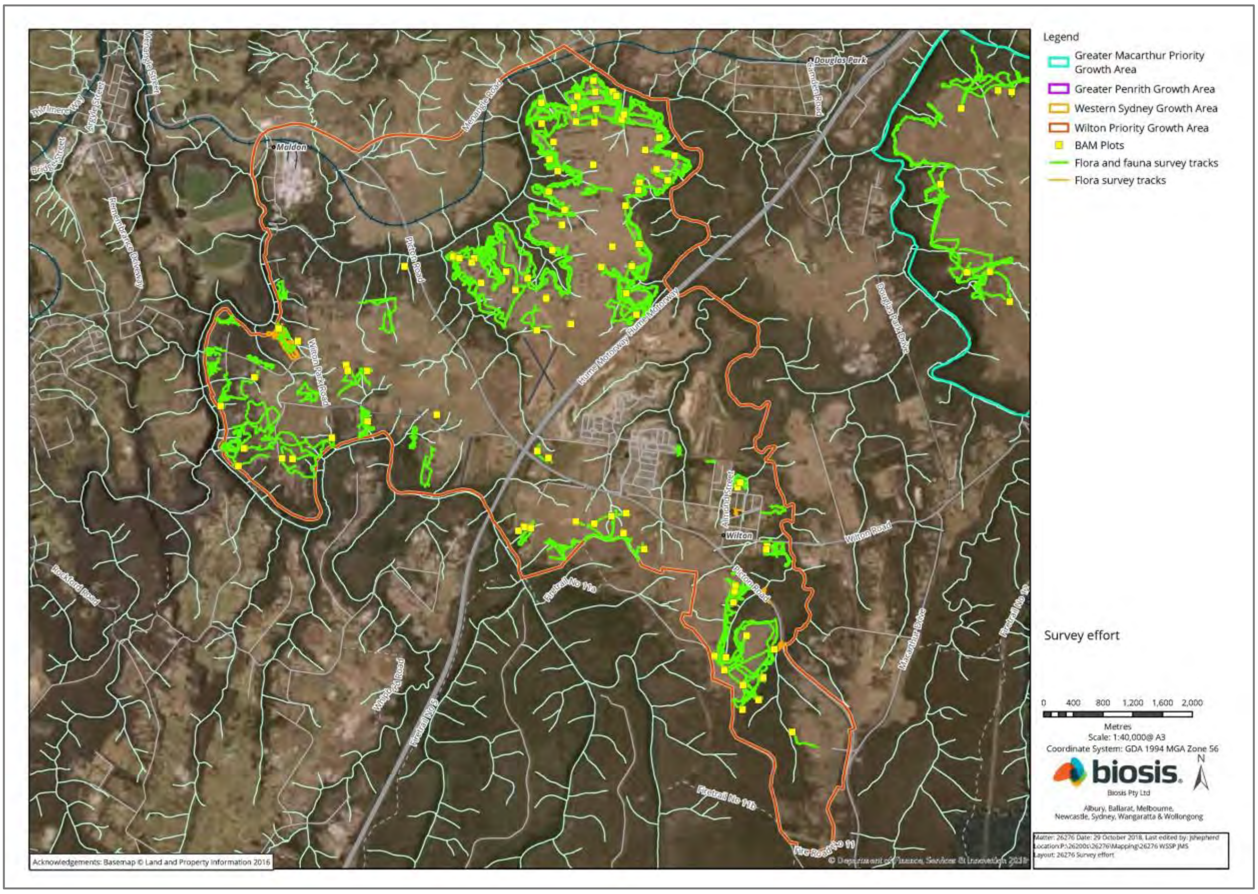
Table 9. Survey effort for threatened plant species *and* fauna habitat by PCT

PCT No.	Area of PCT in Growth Area (ha)	Area of PCT in urban zone (ha)	Field survey area (ha)	Percent of PCT surveyed within Growth Area (%)	Percent of PCT surveyed relative to urban zone (%)
724	191.3	57.0	12.1	6.3%	21.2%
725	167.4	51.4	6.9	4.1%	13.4%
781	68.9	5.6	0.9	1.4%	16.8%
830	21.6	0.8	1.7	7.8%	206.5%
835	1175.8	287.3	30.5	2.6%	10.6%
849	3078.3	637.6	125.0	4.1%	19.6%
850	522.9	294.3	36.1	6.9%	12.3%
883	7.4	0.0	0.5	6.8%	
1081	74.2	0.0	0.2	0.3%	
1105	138.6	0.0	0.0	0.0%	
1181	780.7	0.2	39.6	5.1%	19794.4%
1292	39.8	0.0	0.3	0.7%	
1395	3326.6	486.9	483.4	14.5%	99.3%
1800	232.6	20.2	7.3	3.1%	36.2%
TOTAL	**9826.1**	**1841.3**	**744.5**	**7.6%**	**40.4%**

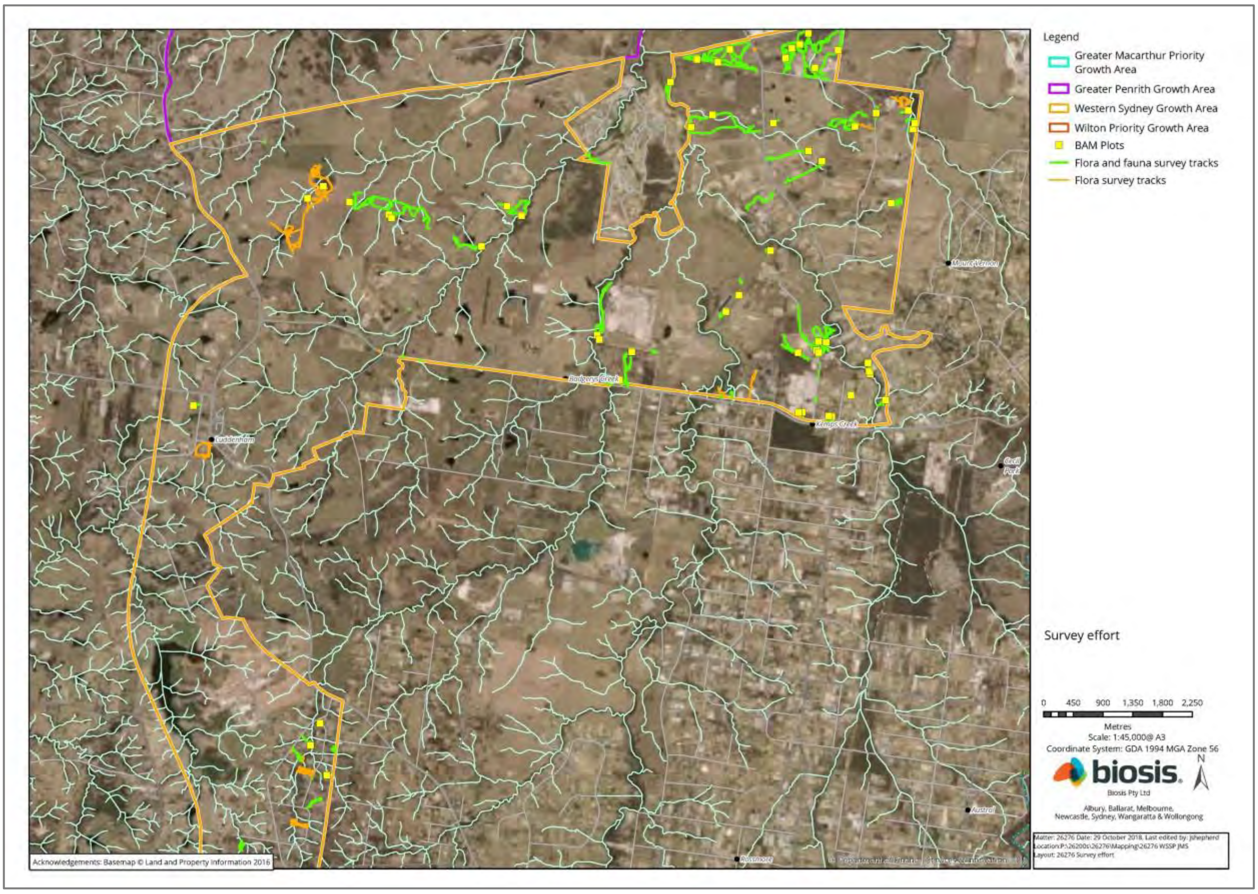
Field survey effort was not confined to the urban zone. Surveys occurred into nearby vegetation zoned for conservation. The urban zone has been revised over time and some areas where survey had already occurred were later removed. For these reasons, comparison of the survey area to the urban zone is indicative only. Survey effort has been calculated using a 20-metre buffer either side of GPS survey tracks. For the purposes of this analysis, the urban zone includes land zoned for future urban development plus transport corridors within the growth areas. It does not include any transport corridors outside the growth areas.



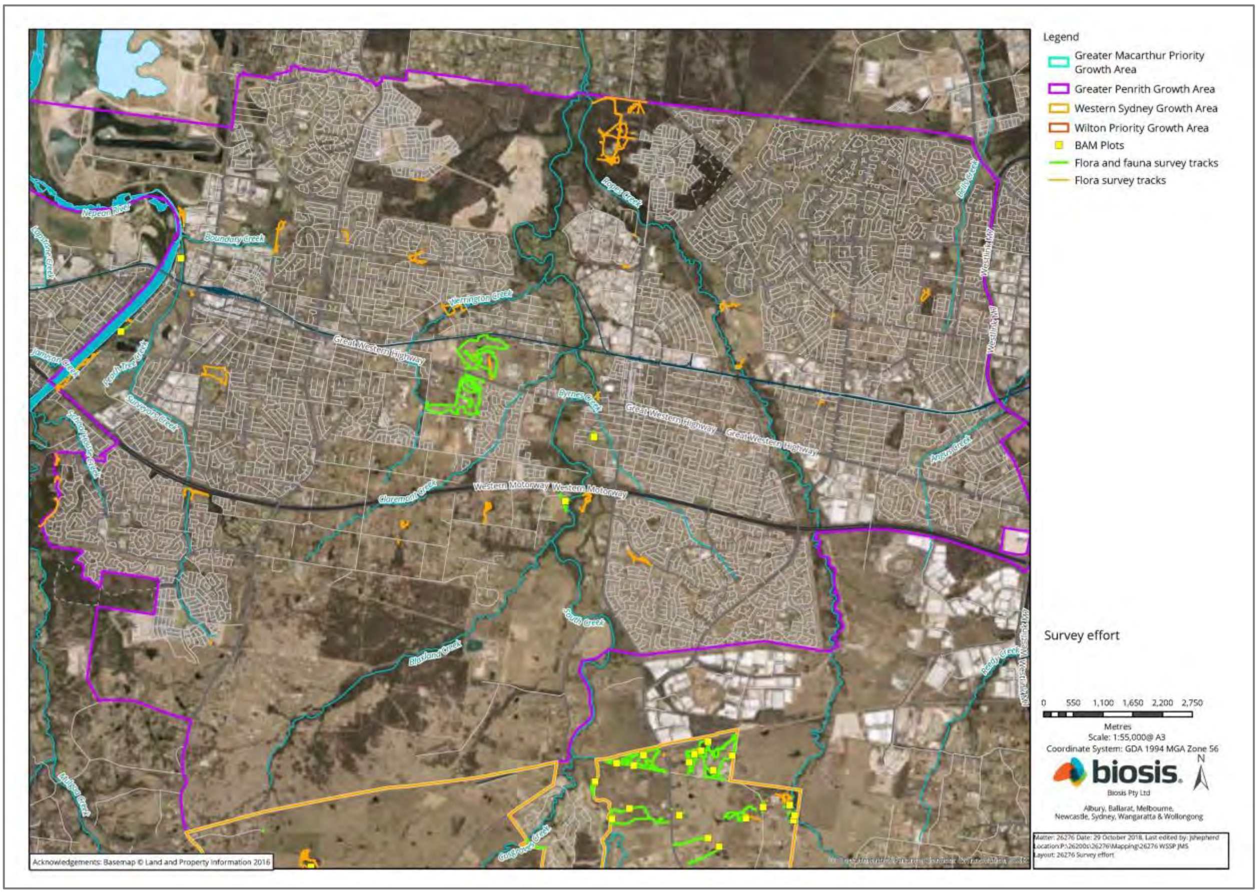
Map 5. GMGA survey effort (Biosis & Ecoplanning)



Map 6. WGA survey effort (Biosis and Ecoplanning)



Map 7. WSAGA ('Western Sydney') survey effort (Biosis and Ecoplanning)



Map 8. GPECGA survey effort (Biosis and Ecoplanning)

4.2.3 Survey constraints –timing / site conditions

As noted earlier, severe drought affected all of the study areas for some or all of the survey period. The Wilton and Greater Macarthur GAs were only surveyed during drought, whereas the Penrith & Eastern Creek and the Aerotropolis GAs were surveyed both during intense drought and the subsequently slightly wetter conditions that followed in the Spring of 2018. Whilst wetter, drought remained present, and fellow Expert, Robert Miller, reported that vegetation was evidently drought-affected across all of the Growth Areas into November.

Drought, combined with increased intensity and extent of total grazing pressure, meant that affected surveys may have under-recorded the target species compared to normal conditions. Whilst drought alone is unlikely to cause *M. deanei* to die back to rootstock or die and only remain as seedbank, when combined with increased herbivory due to drought, this is a far more likely outcome. The extent to which herbivory of any kind affects this species is unknown. It is unlikely to be palatable to livestock because of the high volatile oil content, and that it is not likely to be nutritious, but native browsers may consume it e.g. Swamp / Black Wallaby or Brushtail Possum under harsh conditions.

Irrespective of drought, surveys for this species are constrained by consideration of fire ecology, in that this species can be suppressed and potentially rendered apparently extinct at a site if the area has not been burnt for many years and shrub growth is thick. Prolonged absence of fire is a constraint in some of the surveyed areas. Conversely, the species could be undetectable or not readily distinguished and identified in areas burnt very recently.

4.2.4 Survey constraint – surveys undertaken by generalists / non-experts

M. deanei is not a cryptic species and it is not easily missed when suitable conditions are present. However, it is more likely to be present but not recorded when surveyed by personnel not very familiar with the species, and more so in situations such as restricted visibility and access due to dense scrub cover as a result of prolonged absence of fire and/or regrowth after earlier clearing or intense grazing etc. Those situations are more likely in some of the areas surveyed i.e. between grazed lands and ungrazed bushland.

4.3 Surveys completed specifically for this Report

I did not undertake any surveys for this species in either of the two Growth Areas in which it is either known or likely to occur. Reasons for this include:

- Consultants who detected the Bingara Gorge population had earlier surveyed some of the nearby equivalent habitats, but did not detect this species or the other associated threatened plant species present at that site (G. Steenbeeke, pers. comm.);
- Surveys by other consultants on behalf of DPE traversed some additional areas of potential habitat, and also did not detect the species;
- There were constraints in terms of ready access to properties other than those that DPE's consultants had already surveyed or were scheduled to survey, and some sites of potential habitat were inaccessible due to the land owner not providing permission to enter;
- Relatively little time was available given the timeframes that had been specified for the provision of the four Expert Reports that I was commissioned to complete;
- *M. deanei* is naturally rare and patchily distributed, and the species appears to be at its low rainfall limit of distribution in the WGA and GMGA. Most of the more westerly populations are at higher elevations with greater orographic rainfall and/or less rain-shadow than the WGA and GMGA (both of these Areas experience rain-shadow from the Woronora Plateau to the east, and the Greater Blue Mountains to the west);

Having regard to the above, there seemed to be relatively little merit in my undertaking additional surveys, especially given that my work in this Expert Report is intended to cover gaps in survey effort, so would necessarily take a precautionary approach when dealing with the prediction of potential habitat. This decision has been further supported by the fact that the majority of potential habitat for this species has been excluded from the proposed urban footprint.

4.4 Assessment of species' presence

The following section deals with known occurrences of the species in the context of the four Growth Areas.

4.4.1 Greater Macarthur Growth Area

Most of the northern half of the GMGA is not likely to support the species based on the extent of land clearing and/or the scarcity of suitable habitat parameters such as plant communities and soil types. Were the species found in the highly urbanised northern GMGA, it is likely that unless on public land able to be managed for conservation, any such occurrence may not be viable in the long-term terms because of threats including fragmentation / isolation of habitat, and ability to maintain ecological processes.

In contrast, the southern half of the GMGA contains significant areas of potential habitat. This habitat mainly occurs around the upper slopes and ridges associated with gullies and valleys of incised watercourses, and some other remnants that appear to have escaped clearing and grazing due to their relative infertility or other constraints. Some potential habitat is present within and on some edges of the biocertification area (urban footprint). However, potential habitat within the proposed urban footprint is likely to be of lower condition and less viable due to historic and current land uses.

4.2.2 Wilton Growth Area

The species is known to be present in this Growth Area, and nearby to the south, with both populations being substantial in extent and the number of apparent individuals. The only occurrences in the Growth Area are on a site outside the proposed urban footprint, within the separately approved Bingara Gorge housing project. A significant area of similar habitat occurs largely outside but occasionally on the margins of or adjoining the proposed urban footprint. However, surveys of some nearby sites supporting apparently suitable habitat by the same personnel who found the documented population did not detect any further occurrences. This may be a result of the areas having different disturbance histories, particularly in terms of fire. This situation does not preclude the species being present in those sites, as it may be restricted to the seed bank or to rootstock, or in areas with thick scrub cover.

The species is unlikely to occur within the majority of the proposed urban footprint as it is not suitable habitat or has been too heavily modified. Potential habitat within the proposed urban footprint is likely to be of lower condition and less viable due to historic and current land uses.

4.2.3 Greater Penrith & Eastern Creek Growth Area

The species is not known to be present in this Growth Area, nor immediately nearby. This Area does not contain suitable habitat for this species.

4.2.4 Western Sydney Aerotropolis Growth Area

The species is not known to be present in this Growth Area, nor nearby. This Area does not contain suitable habitat for this species.

4.5 Assessment of suitable habitat for *Melaleuca deanei*

4.5.1 Description and relative significance of potential habitat

The species' ecology and distribution are now sufficiently known to be confident in predicting the Plant Community Types, associated Threatened Ecological Communities and landscapes in which it is likely to occur, both in general, and within the Growth Areas. DECCW (2010) indicates that there is not a clear association between the species and particular habitat. However, this may refer to the fact that the species is not specific to a *single* habitat. At that time, vegetation maps were not as developed as they are now over much of the species' range, which likely constrained DECCW's ability to perceive and describe habitat associations.

Potential habitat for *M. deanei* has been determined based on the species' known affinity with particular geology, soils, and vegetation communities, with some regard to habitat condition. Additionally, the species is not associated with watercourses, so graded riparian exclusion buffers have been applied in the creation of the required 'species polygons' that map potential habitat. All vegetation condition classes are included except Derived Native Grassland.

As per the findings presented earlier, combined with expert knowledge, the following vegetation communities are regarded as potential habitat for *M. deanei* across the **two southern Growth Areas** in which it is either known or considered likely to occur:

Table 8.

PCT	PCT Name	Relative significance
1081	Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain	High to potentially Very High when compensating for limitations of datasets
1181	Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney	Moderate to Low when compensating for limitations of datasets
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion	Very High to High when compensating for limitations of datasets

Again, it is important to note that the relative significance of these PCTs for this species should only be seen in the context of the Greater Macarthur and Wilton Growth Areas. Across the species' range, the relative strength of association for these PCTs will likely drop, not least because other PCTs, particularly more coastal heathy woodlands, are strongly associated with this species.

Greater Macarthur Growth Area

The vegetation mapping provided for use in the project indicates that there are **1645.0 ha** of potential habitat for this species in this Growth Area based only on the extent of relevant PCTs. However, significant portions of some components are of lesser habitat significance due to persistent disturbance, particularly intensive pastoralism (sewing of introduced pasture species, addition of fertiliser, commercial stocking rates), and are less likely to retain this species in any form. This is particularly the case for PCT 1395, which is the most likely to be directly degraded by rural land uses. PCT 1181 is more likely to be compromised by rural and urban run-off and associated weed invasion but only along riparian zones in which *M. deanei* does not occur.

Table 9. Potential habitat in the GMGA

PCT	Distribution	Relative habitat value of local occurrences
1081	Very rare in this GA – just one site and three polygons above a drainage line in an established urban area.	Moderate to high depending on condition (mapped as Intact but likely to suffer from urban pressures, particularly weeds and altered fire regime). Site has very high edge to area ratio, further reducing general habitat value.
1181	Common within sandstone gullies and gorges, mainly on or near WGA boundaries, primarily in the southern portion. Only one small example in the northern portion (urban bushland).	Low to moderate depending on sandstone influence – high sandstone and no shale influence is of lower habitat value. Not suitable habitat close to watercourses. Areas degraded by adjoining rural and urban land uses are likely to be of less habitat value.
1395	Common in the far south from around Menangle Park through Gilead to Appin area; between cleared shale landscapes and sandstone gullies	High to moderate depending on shale content: high shale content is of lower habitat value. Unlikely habitat when near other than low order watercourses

Wilton Growth Area

There is a substantial area of potential habitat in the WGA, with several recent records within one population mapped as part of the Bingara Gorge housing project. Similar habitat extends along the upper slopes of many remnant vegetation areas associated with larger watercourses. The updated vegetation map indicates that there are **1162.2 ha** of potential habitat for this species in this Growth Area.

Table 10. Potential habitat in the WGA

PCT	Distribution	Relative habitat value of local occurrences
1081	Uncommon and restricted to three substantial patches above sandstone gorges, mainly on or near edges of WGA.	High to moderate even when considering that the nearby records are not mapped in this PCT (likely due to limitations of that mapping).
1181	Common within sandstone gullies and gorges, mainly on or near WGA boundaries.	Low to moderate depending on sandstone influence – high sandstone and no shale influence is of lower habitat value. Not suitable habitat close to watercourses.
1395	Common in the far south from around Menangle Park through Gilead to Appin area; between cleared shale landscapes and the upper margins of sandstone gullies	High to moderate depending on shale content and site condition: high shale content is of lower habitat value. Unlikely habitat when near anything other than low order watercourses

4.5.2 Species habitat polygons

Species habitat polygons generated by this report relate to the extent of potential habitat that is proposed to be cleared for urbanisation or related purposes, such as transport corridors. The polygons were generated to inform biodiversity offset assessments. The data presented in this section does not deal with species habitat outside proposed urban zones as those areas are treated as conservation zones or are excluded from urban and associated transport zones for a range of reasons.

The habitat polygons include all relevant condition classes of relevant PCTs as identified in this Report. In this case, all condition classes are included except Derived Native Grassland. However, that class was apparently accidentally included in the calculations, but the effect of this is trivial.

Species habitat polygons have been generated based on DPE's project-specific PCT maps and the application of graded riparian buffers. The riparian buffer distances used to generate the polygons increase with the Strahler stream order as shown below. The buffer is applied either side of the mapped stream centreline. The distances have been determined based on observations of spatially accurate records of the species in relation to relevant stream orders. Riparian exclusion buffers are used for this species as *M. deanei* is primarily associated with ridge tops, plateau margins, spurs, and upper slopes with relatively exposed aspects. It is not associated with lower slopes or sheltered aspects, and not with riparian habitats. Note that these riparian buffer distances are a different concept and serve a different purpose to those applied by DPE for the purposes of protecting streamside vegetation and watercourses in its planning within the Growth Areas.

Spatially reliable records of this species do not occur near streams, but can occur closer than would otherwise be expected, simply because of steep terrain. This factor is partly why a simplistic linear GIS-based assessment has not been used to determine the optimal buffer distances. The distances used here err in accordance with the precautionary principle. Many spatially reliable records occur considerably more than 20 m from first order streams. A simple linear relationship between stream order and buffer distance was not evident because higher order streams in elevated areas tend to be deeply incised such that ridgetop habitat can be relatively close to the stream but over very steep, sometimes vertical terrain. The distance can be relatively short, but the altitude difference can be dramatic.

Table 11.

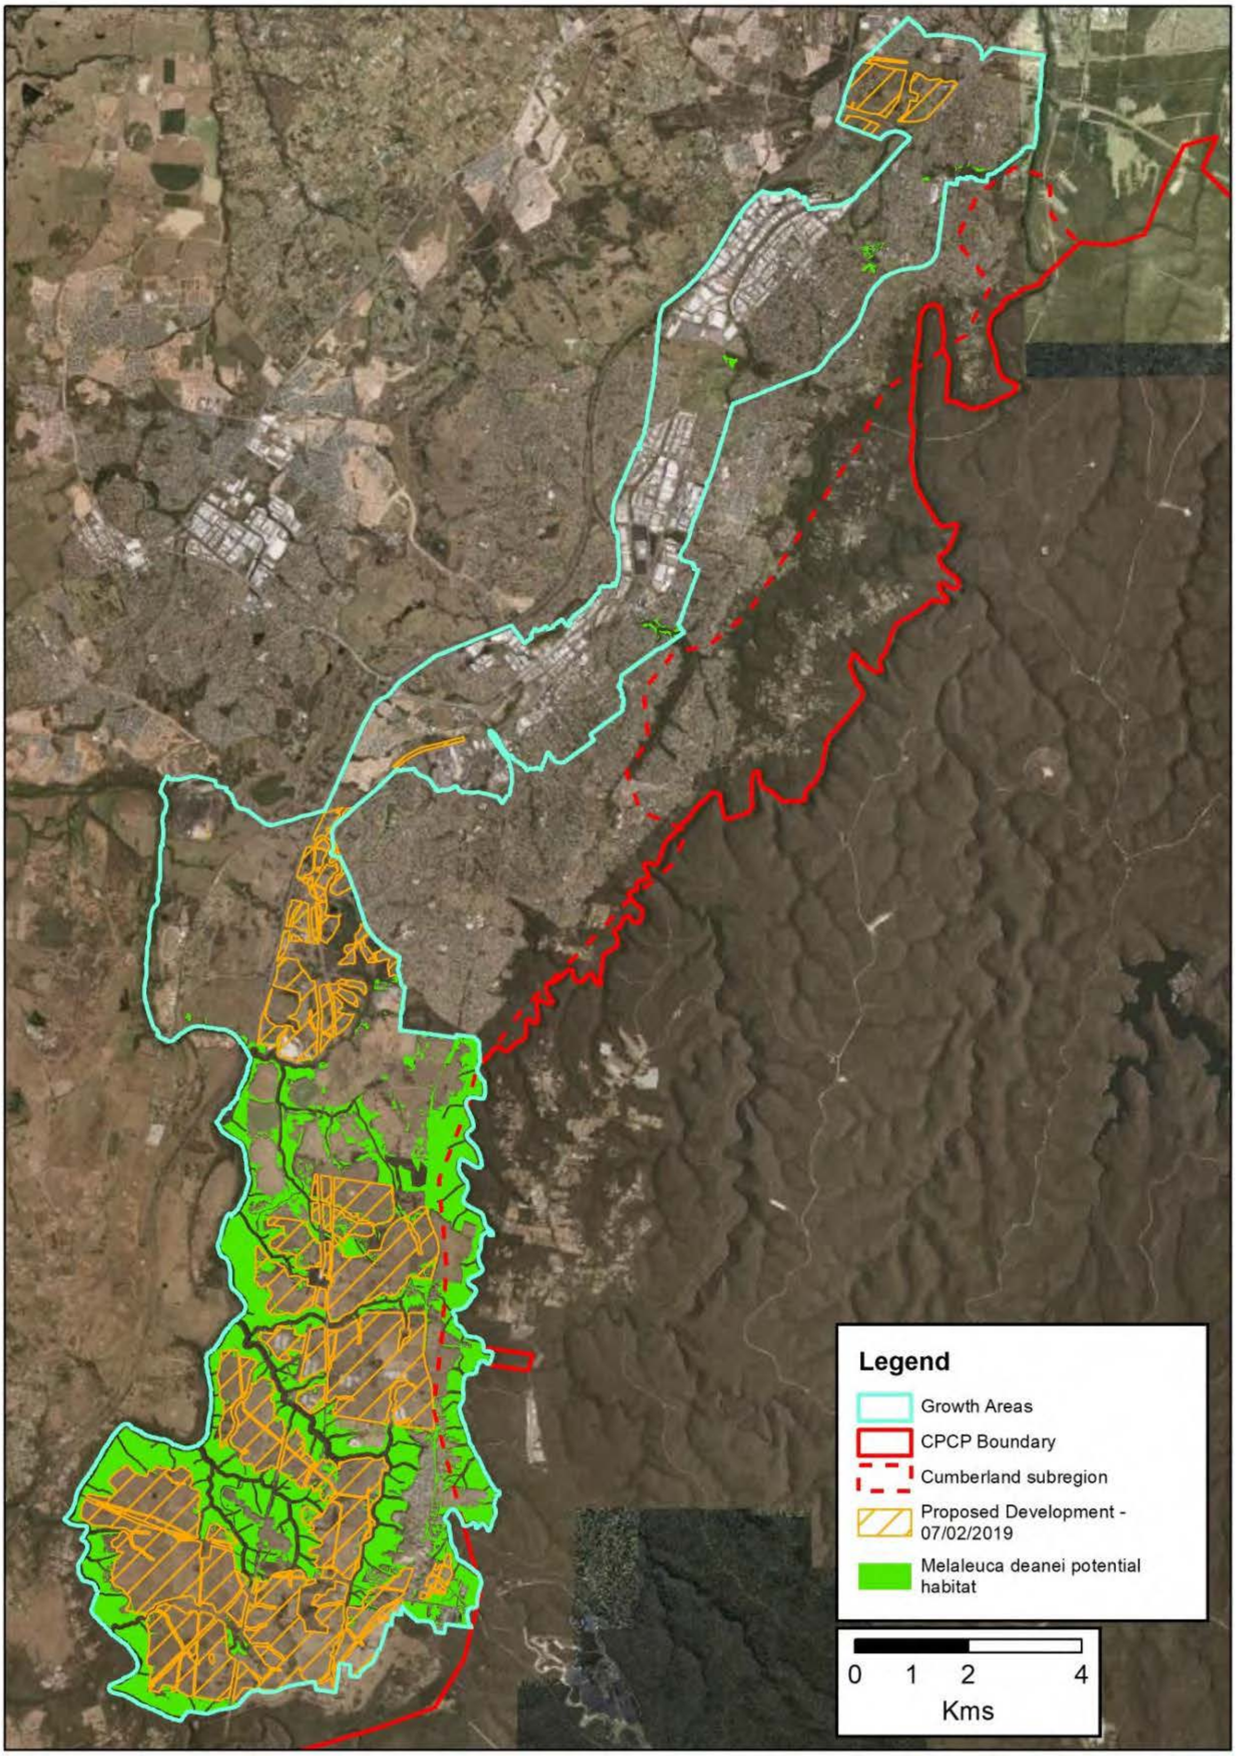
Stream order	Buffer distance (m)
1	20
2	30
3	40
4	60
5	70
6	80
7	90

Species polygons in the form of GIS shape files were provided to the Biodiversity and Sustainability Branch of DPE in November 2018. A summary of the analysis of these shape files is presented in Table 12. These figures are based on precautionarily modelled *potential* habitat, and do not necessarily equate with *actual* habitat, nor do they provide any information of potential population sizes or population viability. It is unlikely that a large percentage of the potential habitat identified in this Report would actually support *M. deanei* because this species is naturally rare and patchily distributed, even though it can be locally abundant in favourable conditions.

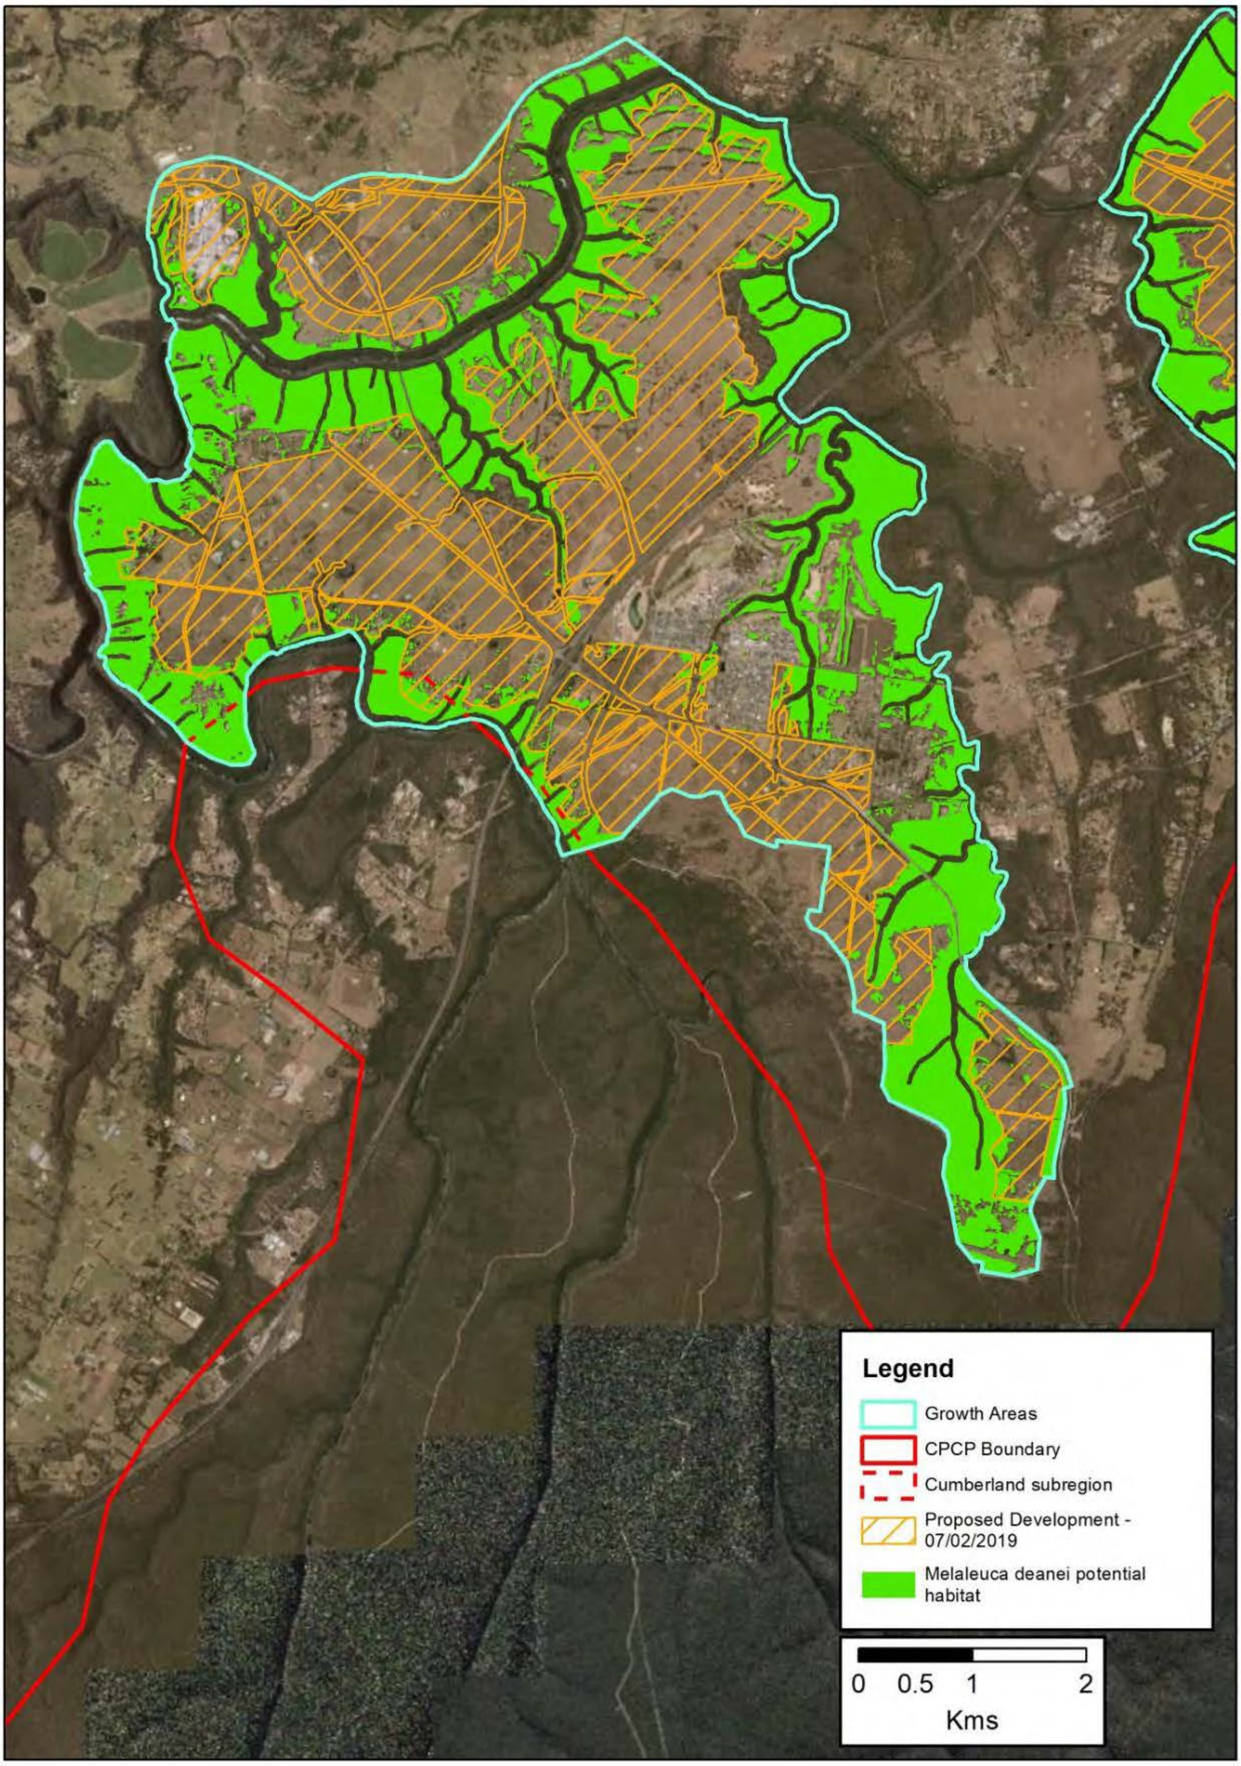
Table 12. Area of PCT-based potential habitat proposed for removal in each Growth Area

Growth Area	Area of potential habitat (ha)	Area of potential habitat removal (ha)	% area of potential habitat removal by GA
Greater Macarthur	1645.0	102.3	6.2
Wilton	1162.2	114.6	9.9
Transport corridors **(all GAs)**	-	0.0	0.0
TOTAL	**2807.2**	**216.9**	**7.7**

Map 9 Greater Macarthur - Potential habitat and proposed urban/transport habitat removal



Map 10 Wilton - Potential habitat and proposed urban/transport habitat removal



5. Summary and conclusion

Within the four Growth Areas, *Melaleuca deanei* is currently only known from the Wilton Growth Area, and that occurrence is outside the biocertification area. Potential habitat for this species exists in other parts of the WGA and in the GMGA, though in the latter case, the vast majority of that habitat is in the southern section. The species is not known or likely to occur in the GPECGA or WSAGA, and no potential habitat is identified in those Growth Areas in this Report.

Based on current information, the proposed urban footprint and associated transport corridors across the two relevant Growth Area would destroy 216.9 hectares of potential habitat for *M. deanei*. This equates to 7.7% of the area of potential habitat as defined in this Report. The actual extent of conflict between habitat for the species and proposed clearing for urbanisation is likely to be much smaller as the species is naturally rare and patchily distributed. Not all of the area proposed for removal is of equal value as potential habitat, and different PCTs and condition classes have different probabilities of supporting *M. deanei*.

Because this species is relatively tolerant of some types of disturbance, and it can persist in the soil seedbank, as well as surviving for some time as rootstock, it may occur in areas that might otherwise be disregarded as habitat. It may even persist in areas not mapped as native vegetation. It is likely that some modified sites might support the species in some form, but in general, these are of relatively low significance in the context of the much larger areas of more intact potential habitat that is excluded from urbanisation and associated clearing. It is also feasible that some forms of disturbance associated with urbanisation, particularly the creation of bushfire Asset Protection Zones (APZs) between bushland conservation areas and housing, could advantage this species, especially where the habitat has not burnt for many years. Thinning of the shrub layer by fire or mechanical means could favour the species. More frequent, moderate intensity burning of bushland that represents known or likely habitat for this species, may, within limits, also advantage it compared to low frequency and/or very cool burning.

The positioning of the bushland / urban interface and associated infrastructure such as APZs, should have appropriate regards to this species' habitat and ecology. Appropriate buffers and other strategies are required to prevent direct and indirect harm to this species as a result of the urbanisation of adjoining lands. For example, potential habitat should not be compromised by the placement of housing nearby as might prevent that habitat being managed for conservation, especially in terms of bushfire risk management. DPE has informed me that the intention is for APZs to be accommodated within the proposed urban footprint, not in the non-biocertified bushland areas that may adjoin it.

The absence of records of this species from areas of potential habitat does not mean it could not be present. This is because:

- not all areas have been surveyed historically or recently;
- all surveys have a range of limitations;
- not all discoveries of threatened species are disclosed; and
- large areas of potential habitat are highly likely to have fire regimes that do not favour this species, meaning it may currently occur in very low numbers or as seedbank, yet could appear in substantial numbers after an appropriate fire or equivalent disturbance.

These factors have been considered in the preparation of the species habitat polygons that will inform DPE in relation to biodiversity offset obligations.

6. Information used in the assessment

6.1 DPE or OEH resources

- BioNet data (internal access provided under license for use in this Expert Report and associated dataset cleaning for the purposes of species habitat modelling to meet EPBC Act requirements)
- Atlas of Living Australia on-line (partial use to check for records not in BioNet)
- EMU data (NSW Herbarium specimen database, provided by OEH)
- OEH on-line threatened species profile
- OEH Threatened Species Data Collection on-line
- OEH BioNet Vegetation Classification Database (previously known as VIS)
- EPBC Act Listing/Conservation Advice
- OEH PCT (vegetation) maps for Sydney Metropolitan and Cumberland Plain
- Field data from Biosis and Ecoplanning consultancies engaged by DPE
- GIS layers and maps provided by DPE and its contractors, or by OEH

7. Acknowledgements

I acknowledge the contributions of DPE staff, particularly Dayle Green, Greg Steenbeeke and Christian Marando (GIS), and DPE contractor Darren James (GIS) in the preparation and refinement of this document and associated maps. My contractor, Rhys Grogan, also assisted with GIS output in the form of drafts of the 'species polygons'.

Consultant botanist, Robert Miller assisted with fieldwork at Kemps Creek, and provided information about field observations associated with searches for his target species and with opportunistic sitings of my target species.

OEH staff assisted with some aspects of data availability and with the processing of many amendments to BioNet records.

8. Statement of professional independence

Whilst I was engaged and funded by DPE to prepare this Expert Report, and series of draft reports and maps were reviewed by DPE staff, I was not coerced by DPE to amend my work in any manner that I did not otherwise agree with. I believe that I had appropriate professional independence in the preparation of this document and associated maps.

I also declare that I do not have any personal or commercial conflict of interest in the preparation of this Report. I do not own real estate or businesses with property in the Growth Areas, nor do I have other active clients with real estate or associated commercial interests in the Growth Areas.

9. Appendix 1. Author's *Curriculum Vitae*

Dr Steven Douglas (BSc., MEnv. Plan., PhD.)

I have over twenty years of experience as an ecologist and environmental planner, primarily in New South Wales, with some experience in the ACT, Victoria and South Australia. I have worked for all levels of government, for environmentalist non-government organisations (NGOs), and for a large number of private clients ranging from individuals to multinational firms, directly and as a subcontractor. I have often worked as a sole consultant but have also collaborated with other specialists and have sometimes been part of large teams involved in large-scale, even interstate projects.

I specialise in the detection, management and conservation of rare and threatened flora species and communities, and in associated ecological impact assessment and mitigation.

I have qualifications and experience in a range of general and specific ecological, social, organisational and 'sustainability' fields.

I have served on environment-related ministerial committees and have held other ministerial appointments in NSW, including those dealing with bushfire management.

I have published in journals dealing with plant conservation, environmental law and policy, social science, and ecological ethics. Aspects of my work have been published by government, prominent NGOs, and in the popular press and other media.

This CV only contains content directly related to my botanical expertise.

Employment summary

1996 to present:

Self-employed, trading as *Ecological Surveys & Planning* (www.ecologicalsurveys.net)

Through this enterprise, I have undertaken a large number of consultancies for public and private sector clients including environmental impact assessment and mitigation; threatened biota research, profiling and management; vegetation mapping; preparing management plans for conservation estate; providing environmental planning and catchment management advice; advising on bushfire risk management; acting as an expert witness in Land & Environment Court proceedings; and developing organisational sustainability policies and practices.

July 2017 to July 2018:

Senior Ecologist, NSW Office of Environment & Heritage (NVIS, Science Division)

My work on the project below led to OEH retaining my services to research and document problems with the description, interpretation and mapping of Threatened Ecological Communities (TECs) statewide. This project provides advice to OEH, the NSW Threatened Species Scientific Committee, and through those agencies, to the Commonwealth Threatened Species Scientific Committee. It identifies technical issues with the description of TECs and their mapping, as well as wider problems of how TECs are defined. It draws on a major project undertaken by OEH for the NSW EPA and Forestry Corporation, in which TECs of the east coast and ranges were assessed and mapped for regulatory purposes on forestry estate. However, my work includes many more TECs and recent information emerging from Save Our Species project panels.

November 2015 to July 2017:

Team Leader, NSW Office of Environment & Heritage (NVIS, Science Division)

This project in Wingecarribee Shire is the first in which OEH's vegetation mapping team has worked at a very fine scale for a single local government area. The project entails auto-segmentation of digital aerial photography; supervising contract vegetation sampling; conducting strategic sampling; modelling of most vegetation communities; describing new communities; and extensive remote and on-ground map validation. I was hired partly because of my extensive familiarity with much of the vegetation of this geodiverse and biodiverse region. The role included supervision of two staff; liaison with consultants; and substantial networking with OEH and Wingecarribee Council staff. An update of vegetation classification will occur from mid 2019 onwards, and I have drafted a peer-reviewed journal article about the project that will be submitted for publication.

1995/6:

Project consultant, then Project Manager, Urban Bushland Biodiversity Survey (NPWS)

The Urban Bushland Biodiversity Survey was undertaken by the NPWS to compile comprehensive data on indigenous flora and fauna in twelve local government areas in Western Sydney. Contracted initially as a consultant to design and scope the project, I was later employed as Project Manager. Responsibilities involved an extensive literature review, preparation of a project plan and a background paper for the Survey and the overall management of the project including up to twelve staff and several consultants. The major focus was on coordinating research work, fauna and flora field surveys, and a community liaison and media campaign. Extensive flora survey work and scientific data analysis was undertaken. I provided a tour of important vegetation sites for the South Creek Catchment Management Committee. I also wrote media releases and conducted various media events including a live-to-air interview on ABC Radio National, and filming of a story in the field for the Totally Wild program.

1994:

Catchment Environment Officer (*Hawkesbury City Council*).

The project was funded by a grant from the former Hawkesbury-Nepean Catchment Management Trust and had the objective of identifying land uses on riverside properties to assess their potential to generate water pollution. The information on land use and riparian vegetation was primarily gained from aerial photo interpretation, limited land-based inspections and several water-based inspections, and was recorded in a GIS. Work site inspections, pollution control on agricultural lands, community meetings, site visits with landowners, and facilitating the formation of a Landcare group in the Sackville area.

1993/4:

Technical Officer (*Hawkesbury-Nepean Catchment Management Trust*).

Work included assisting with the preparation of a vegetation management strategy for the Trust and the outline of a revegetation strategy for South Creek. Other responsibilities involved providing scientific advice for development assessments, the preparation of hard copy and computer-based catchment maps, and advising on the implementation of revegetation projects in the catchment.

Ministerial appointments

- Appointed a member of the **National Parks & Wildlife Service Regional Advisory Committee** (South Coast) (2010-mid 2018). I opted not to reapply for this role after serving two terms. The restructure of the NPWS meant that the Committee would operate from Wollongong to the Victoria border and inland to the Tablelands. This was logistically fraught, and the role of RACs was evidently being diminished, with larger areas to manage but less meetings held.
- Appointed a member of the **NSW Sustainability Network** (2001), part of the Sustainability Advisory Council reporting to the Minister for Planning. I did not take up this position due to my relocating to Victoria.
- Nature Conservation Council representative on the former NSW **Native Vegetation Advisory Council** (1999-2001) reporting to the Minister for Land & Water Conservation under the Native Vegetation Conservation Act. I served as a member of the Regional Vegetation Planning Subcommittee, which amongst other matters, reviewed draft Regional Vegetation Management Plans and Codes of Practice for activities such as native forestry and timber plantations. I was particularly involved in reviewing and recommending amendments to the Code of Practice for plantation forestry. I resigned due to my relocating to Victoria.
- Nature Conservation Council representative on the former **Southern Catchment Management Board** (June 2000 - March 2001). I resigned due to relocating to Victoria. I expressed my dissatisfaction with the design of the catchment boards and recommended to the Minister that they be replaced with the Catchment Management Authority model used in Victoria. The Boards were later replaced with such Authorities.
- Nature Conservation Council representative on Baulkham Hills and Hornsby-Ku-ring-gai **District Bushfire Management Committees** (1995-2001).
- Australian Conservation Foundation representative on the former **Environmental Works Community Audit Committee** reporting to the Minister for Environment in relation to the Special Environment Levy imposed by the then Water Board (1993-5). I completed my term when the Committee concluded its business and dissolved upon acceptance of its final report by the Minister.

Tertiary qualifications & titles

Adjunct Research Fellow

School of Philosophical, Historical & International Studies, Monash University, 2014-16

Doctor of Philosophy

Fenner School of Environment & Society, The Australian National University, 2004-7

The research was undertaken in the transdisciplinary Human Ecology Program and covered fields such as ecological philosophy, ecotheology, environmental policy-making, policy evaluation, organisational change, and critical systemic analysis. My thesis was passed unanimously and unamended by one Australian and two USA-based professors. I was awarded a $10,000 Publication Fellowship by the Fenner School and have since published aspects of my research.

Master of Environmental Planning

Macquarie University Grad. Sch. Env., 1994-96

This course included environmental law and politics, community involvement in planning, environmental education, development approval processes, urban planning, EIA, environmental science/fieldwork and heritage management. The dissertation component involved a pioneering report on the significant flora of the Greater Cattai Region (Cattai subcatchment) in north-western Sydney and led to my being offered employment with the NSW NPWS to design and manage a biodiversity survey of western Sydney.

Bachelor of Science

Macquarie University, 1990-93

My degree majors are Resource and Environmental Management, Land Management, and Plant Biology/Ecology.

Graduate Certificate of Research Information Literacy

The Australian National University, 2004-7

This course included advanced word processing, citation management, literature gathering (including on-line literary databases and other Internet sources), on-line publishing, presentation software, and thesis production.

Professional memberships

- Founding member of the Ecological Consultants Association of New South Wales (did not renew due to my relocating to Victoria and later to the ACT).
- Member of the NSW Environmental Defenders Office (EDO) Scientific Advisory Service (continuing).

Threatened biota experience

The following threatened plant species and populations and threatened ecological communities (TECs) have been engaged with in the various forms and processes listed below. The list is not complete, and some processes are on-going. I also successfully nominated three Key Threatening Processes under the TSC Act: Bushrock Removal; Clearing of Native Vegetation; Competition from European Honey Bee.

Species / population	Work conducted
Acacia bynoeana	Fieldwork, research, successful nomination, monitoring, advice to authorities, expert witness, rediscovered lost population, documented new population near range limit, PAS2 review, SOS review panel, review and amendment of BioNet dataset. Nominated by DPE and recognised by OEH as a species expert under BC Act (Nov 2018).
A. gordonii	Fieldwork, successful nomination, advice to NPWS, PAS2 review, SOS research and monitoring program (fire ecology, BMtns NP), review and amendment of BioNet dataset.
A. prominens	Successful nomination of Endangered Population
A. pubescens	Fieldwork, contribution to Recovery Plan, confirmed disjunct southern populations, nominated population, PAS2 review, review and amendment of BioNet dataset. Nominated by DPE and recognised by OEH as a species expert under BC Act (Nov 2018).
Ancistrachne maidenii	Fieldwork, research, successful nomination, advice to NPWS, CAM review
Asterolasia elegans	Fieldwork, species profile, advice to Council and NPWS
Baloskion longipes	Research linked to *Carex klaphakei*, review of BioNet records, advice to OEH
Boronia deanei	Research, SOS review, CAM review, advice to OEH
Bossiaea oligosperma	SOS fieldwork, review of records (NW population), report to OEH, establishment of monitoring plots in Yerranderie SCA
Callistemon linearifolius	Fieldwork, research, successful nomination, advice to RMS and NPWS, PAS2 review
Callistemon megalongensis	Co-described new species, successful nominations (listing then upgrade), fieldwork, advice to Council and OEH, PAS2 review, SOS monitoring program (OEH, BMCC, on-going)
Callistemon purpurascens	Described new species, fieldwork, successful nominations, advice to Council and OEH, SOS monitoring project (2018 on-going)
Calotis glandulosa	Fieldwork (new and extended populations, Kosci NP), CAM review
Calotis pubescens	Fieldwork (new population, Kosci NP), CAM review
Carex klaphakei	SOS research project and recommendation for monitoring; resolved errors in BioNet records

Species / population	Work conducted
Commersonia prostrata	PAS2 / PKF research, fieldwork, advice to NPWS and OEH, documentation and monitoring of new and known populations for Forestry Corp, designed recovery actions for populations in Wingello and Penrose SFs
Cullen parvum	Fieldwork, located new NE population, report to NPWS
Dampiera fusca	Research, fieldwork, successful nominations, monitoring program for ACT Parks & Conservation, advice to NPWS and OEH, CAM review
Darwinia biflora	Fieldwork, research, contributor to Recovery Plan, PAS2 review, review and amendment of BioNet dataset.
Darwinia glaucophylla	Fieldwork, research, successful nomination, advice to NPWS, PAS2 review
Darwinia fascicularis ssp. *oligantha*	Fieldwork, research, successful nomination of population
Darwinia peduncularis	Research, successful nomination, CAM review
Dillwynia tenuifolia	Fieldwork, research, successful population nominations, advice to OEH
Epacris purpurascens var. *purpurascens*	Fieldwork, research, nomination, new SW range limit (Nattai NP), advice to NPWS/OEH
Eucalyptus aggregata	Research, successful nomination of species and population, fieldwork (Wingecarribee Shire) and advice to Council and OEH, CAM reviews
E. aquatica	Fieldwork, advice to Council and Forestry Corporation
E. sp. *Cattai*	Successfully argued for recognition of this entity as a new species, successful nomination, fieldwork, PAS2 review, advice to OEH, SOS project panel
E. kartzoffiana	Fieldwork, research, expert witness
E. macarthurii	Fieldwork, research, successful nominations, advice to Council and OEH
E. parvula	Fieldwork (Wadbilliga NP), CAM review
E. pulverulenta	Fieldwork (Bredbo Hills), CAM review
Galium australe	PAS2 research, recommended taxonomic review of most records in NSW based on Herbarium assessment, advice to OEH, CAM review
Grevillea juniperina ssp. *juniperina*	Fieldwork, research, advice to OEH (Colebee NR offset site)
Grevillea molyneuxii	Fieldwork, advice to OEH for CAM review
Grevillea parviflora ssp. *parviflora*	Fieldwork, research, expert witness, review and amendment of BioNet dataset.
Grevillea parviflora ssp. *supplicans*	Fieldwork, research, nomination, advice to NPWS
Grevillea raybrownii	Fieldwork, research, nomination and advice to NSWSC – listing pending
Gyrostemon thesioides	Successful nomination
Helichrysum calvertianum	Fieldwork, research, nomination, advice to NSWSC – listing pending
Hibbertia fumana	Research, minor fieldwork, expert witness
*H. incana (*syn. *superans)*	Successful nomination of population then species
H. praemorsa	ROTAP, researched, fieldwork (informal)
H. puberula ssp. *furcatula*	Fieldwork (incidental) documenting new occurrence, advice to OEH/NPWS
H. puberula ssp. *puberula*	Research, minor fieldwork with R. Miller, expert witness
Homoranthus binghiensis	CAM review (recommended changing to CE)
Keraudrenia corrolata var. *denticulata*	Successful nomination of population
Lasiopetalum joyceae	Fieldwork, research, successful nomination, species profiling for Council and NPWS, PAS2 review

Species / population	Work conducted
Leptospermum deanei	Fieldwork, research into hybridization with *L. trinervium*, advice to RBG, Council, OEH
Leucopogon fletcheri ssp. *fletcheri*	Fieldwork, research, successful nomination, advice to OEH and NPWS
Melaleuca deanei	Research, fieldwork, successful nominations, advice to NPWS/OEH and species profile for Council, review and amendment of BioNet dataset. Nominated by DPE and recognised by OEH as a species expert under BC Act (Nov 2018).
Olearia cordata	Fieldwork and report to NPWS, PAS2 review
Persoonia acerosa	Fieldwork, PAS2 review, SOS monitoring plots, advice to Council and OEH
Persoonia bargoensis	Fieldwork, research, successful nomination, PAS2 review, CAM review, review and amendment of BioNet dataset.
Persoonia hirsuta	Fieldwork, research, nominations of species and population, PAS2 review, review and amendment of BioNet dataset.
Persoonia glaucescens	Fieldwork, nomination, report to NPWS, PAS 2 review, CAM review, review and amendment of BioNet dataset.
Persoonia marginata	Fieldwork and report to OEH, CAM review
Persoonia mollis ssp. *revoluta*	Fieldwork, research, advice to OEH and Forestry Corp., nomination as Vulnerable - listing pending
Persoonia nutans	Fieldwork, nomination, advice to OEH, review and amendment of BioNet dataset. Nominated by DPE and recognised by OEH as a species expert under BC Act (Nov 2018).
Phyllota humifusa	PAS2 fieldwork and research; advice to NPWS, OEH, Council, Forestry Corp (monitoring plots, reduced APZ width), review of BioNet dataset.
Pimelea curviflora var. *curviflora*	Fieldwork, research, successful nomination, advice to OEH
Pomaderris brunnea	Incidental fieldwork and documentation of new populations and range extension; review and amendment of BioNet dataset.
P. cotoneaster	Fieldwork, research, advice to Council, NPWS, OEH, liaise with ANBG seed collectors, CAM review
P. sericea	PAS2 research (review of records and habitat), recommended consideration of Presumed Extinct or at least CE
Pultenaea elusa	PAS2 research (review of records and habitat), recommended Presumed Extinct
P. glabra	SOS fieldwork and monitoring plots. Review of Mts Wilson/Irvine records resulted in these being reallocated to an undescribed species given the interim name, *P. monticola*.
P. parviflora	SOS fieldwork and report to OEH (Colebee NR offset site); review and amendment of BioNet dataset.
P. pedunculata	Fieldwork, research, expert witness, CAM review
Solanum armourense	PAS2 fieldwork, research, report, advice to OEH, CAM review
S. celatum	Fieldwork, research, new populations (new range limit and habitat), advice to OEH, CAM review
Tetratheca glandulosa	Fieldwork, PAS2 review, advice to OEH and Cwlth DEE re conservation status
Triplarina nowraensis	SOS fieldwork, review of BioNet records, advice to OEH/NPWS, establishment of monitoring plots
Zieria involucrata	Fieldwork, input to Recovery Plan, CAM review
Zieria murphyi	Liaise with ANBG, fieldwork, advice to OEH

Threatened Ecological Communities (TECs)

My work for OEH in reviewing all NSW and EPBC Act TECs in the State has given me at least some familiarity with most of these entities and builds on already-strong knowledge of some. I have also been an expert witness in cases involving some of these communities – some entailing basic reviews and advice, and others involving in-depth considerations. All of the EPBC Act parallel listings are not included here unless I was involved in a particular nomination:

Ecological community	Nature of engagement
Blue Gum High Forest	Successful nomination, expert witness
Blue Mountains Basalt Cap Forest	SOS panel
Blue Mountains Shale Cap Forest	Successful nomination, SOS panel
Blue Mountains Swamps	Fieldwork, mapping, advice to BMtns Council, modelling
Castlereagh Scribbly Gum Woodland	Successful nomination, advice to DEE re Cwlth listing, expert witness
Cooks River / Castlereagh Ironbark Forest	Advice to DEE for EPBC Act listing
Cumberland Plain Woodland	Correction of OEH mapping, fieldwork, assessments, advice to Councils and NPWS
Eastern Suburbs Banksia Scrub	Major review for DEE Recovery Plan update, advice to OEH
Elderslie Banksia Scrub Forest	Major review for DEE Recovery Plan, SOS panel
Illawarra Lowlands Grassy Woodland	DEE review panel for EPBC Act listing
Lowland Grassy Woodland & Forest of SE Corner Bioregion	Successful nomination
Maroota Sands Swamp Forest	Successful nomination, SOS panel
Melaleuca armillaris Tall Shrubland	fieldwork, mapping, advice to OEH
Montane Peatlands & Swamps	Fieldwork, modelling and mapping, advice to OEH
Mount Gibraltar Forest	Detailed review for modelling and mapping, and advice about revised listing, advice to DEE re Upland Basalt Eucalypt Forest inclusion of NSW TECs
O'Hares Creek Shale Forest	Research and review for modelling and mapping
Pittwater & Wagstaffe Spotted Gum Forest	Successful nomination
Riverflat Eucalypts Forest on Coastal Floodplains	Successful nomination (component), research, modelling and mapping (limited extent)
Robertson Basalt Tall Open-forest	Modelling and mapping, advice to NSW SC
Robertson Rainforest	Modelling and mapping
Shale/Gravel Transition Forest	Mapping, TEC review
Shale/Sandstone Transition Forest	First to describe this concept c. 1996 based on Masters research. Formally published as a concept in NPWS (1997, UBBS). Successful nomination, research, major review and advice to DEE for EPBC Act listing, modelling and mapping
Southern Highlands Shale (Forest &) Woodland	Major contributor to DEE listing, drafting of Listing and Conservation Advices, advice to OEH about revision of NSW listing, modelling and mapping. Contracted to prepare listing for upgrade to CE.
Subtropical & Temperate Coastal Saltmarsh (EPBC Act)	Funded to prepare successful nomination
Sun Valley Cabbage Gum Forest	Successful nomination, mapping, advice to Council, SOS project panel
Swamp Sclerophyll Forest on Coastal Floodplains	Allied major research project cited in the Final Determination, TEC review (gap analysis)

Ecological community	Nature of engagement
Sydney Turpentine Ironbark Forest	Successful nomination, mapping, advice to Councils and to OEH/SC about revision
Tablelands Basalt Forest	Research, expert witness, advice to OEH about revision, modelling and mapping
Tablelands Snow Gum…Grassy Woodland	Fieldwork documenting new occurrences, modelling and mapping, advice to OEH
Upland Basalt Eucalypt Forest (EPBC Act)	Major contributor to DEE listing of this composite community that includes several NSW TECs. Draft Listing and Conservation Advices
Western Sydney Dry Rainforest and Moist Shale Woodland	SOS panel, TEC review

Consultancy projects

Short descriptions of the many larger projects that I have been involved in are available at http://ecologicalsurveys.net/?page_id=10, and a list of smaller projects is at http://ecologicalsurveys.net/?page_id=14

Voluntary and other works

- Assist **International Union for the Conservation of Nature (IUCN)** with a review of the conservation status of *Proteaceae* in eastern Australia (Melbourne, 2019).
- Assist **NSW Environmental Defenders Office** with a review of NPWS monitoring proposals to assess the effects of permitting horse riding in declared Wilderness areas (Kosciusko National Park) (2014).
- Assist **NSW Environmental Defenders Office** in the preparation of its submission to the NSW Government's review of the Noxious Weeds Act 1993 (in 2011)
- Assist **NSW Environmental Defenders Office** in the preparation of its submission to the NSW Government's review of the Threatened Species Conservation Act 1995 (in 2010)
- Assist discoverers (**Blue Mountains Bushcare**) of a previously undescribed *Epacris* species (*E. apungens* Coleby & Brown) in south Leura to prepare an article for the journal, *Telopea*, describing this species and its ecology
- Assist **NPWS** with a search for the ultra-endemic and rare rainforest plant, *Thismia clavarioides*, in Morton National Park (2010)
- Expert panel member assisting **Hawkesbury-Nepean CMA** with its Draft Climate Change Vulnerability Assessment for selected threatened ecological communities of the NSW Southern Highlands (2010)
- Assist PhD student, David Field (**University of Wollongong and CSIRO**) with information about the ecology, distribution, and conservation status of *Eucalyptus aggregata* (Black Gum) (2007)
- Fieldwork assisting with group preparation of vascular plant species lists in numerous NPWS and ACT Parks reserves in the Southern Tablelands area. **Australian Native Plants Society** (2003-2007)
- Searches for *Euphrasia scabra* (critically endangered) in Packers Swamp and Nunnock Swamp. Discovered new population (3rd in NSW) in unnamed swamp, SE Forests National Park. **Friends of Grasslands** (2004)
- Assistant part-time editor of "*Danthonia*" (now *Australasian Plant Conservation*), the journal of the **Australian Network for Plant Conservation** Inc., Canberra (2002-2003)
- Assist PhD student, David Clunas (**University of Wollongong**) with review of his research in the ecology of the nationally Rare, *Pultenaea villifera* var. *villifera* (2002)
- Provide technical assistance to four final year undergraduate Environmental Science students (**Australian Catholic University**) working in Marramarra National Park, (c. 2000)
- Discovery of and subsequent surveys for *Persoonia hirsuta* ssp. nov. 'Yengo NP'. **NPWS/RBG**
- Vascular flora and fauna (microchiropteran bats) surveys within Pilliga Nature Reserve. **NPWS** Coonabarabran
- Supervisor for undergraduate dissertation, "Environmental rehabilitation of Peats Crater and Peats Bight in Muogamarra Nature Reserve" (D. Maestri), **Southern Cross University** (1997)
- Co-supervisor for undergraduate dissertation "Riparian Vegetation of upper Cattai Creek" (D. Buckle). **Southern Cross University** (1997)
- Preliminary flora assessment for proposed subdivision and development; Red Gum Avenue, Pennant Hills. The bushland area was subsequently added to Berowra Valley Regional Park. **Friends of Berowra Valley Bushland**

- **NSW National Parks Association** (NPA) Biodiversity Audit, proposed Bargo River National Park. Team Leader, Vegetation - threatened flora
- Guided interpretive walk of Fred Caterson Reserve. **Cattai Catchment Management Committee**
- **NSW NPA** audit of Greater Sydney proposed conservation reserves and additions - assistant and author of NW Sydney reserve proposals
- **NSW NPA** Biodiversity Audit of the proposed Dyarrabin Nature Reserve (~2000 ha) - Project Co-ordinator
- **NSW NPA** Proposal for the creation of Dyarrabin Nature Reserve; revised submission and report of the second NPA Biodiversity Audit
- Preliminary flora study of Crown lands (Functional Area 1), Cattai Ridge Road, Halcrows Road, Hillside/Glenorie; submission to Director NPWS and to Baulkham Hills Council. **NSW NPA**
- Flora survey of Morans Rock Crown lands for proposed addition to Wollemi National Park. **NSW NPA**
- Proposed Welcome Reef Dam (Shoalhaven River north of Braidwood) - assist with flora and fauna surveys. **NSW NPA**. Much of the area is now within Nadgigomar Nature Reserve
- Flora survey of surplus Department of Education lands at Ellerman Park, Round Corner. The local community proposed that the area become a reserve to protect a critically endangered plant community present on the site. **Friends of Ellerman Park**
- Flora survey of Crown lands at South Maroota for proposed Crescent Reach Nature Reserve (later declared as the Maroota Ridge State Conservation Area), **NSW NPA**
- Calangara Nature Reserve Proposal in Kenthurst. Survey and report to **NSW NPA**
- Preliminary Survey of bushland in Holland Reserve, Glenhaven
- Survey of Crown Reserve (now part Scheyville NP), Pitt Town; report to **NSW NPA**

Expert report – *Persoonia nutans*

Expert report for *Persoonia nutans* (Nodding Geebung), Dr Steven Douglas, February 2019

Expert Report For

Persoonia nutans

(Nodding Geebung)

Strategic Assessment for the
Cumberland Plain Conservation Plan

Greater Macarthur, Greater Penrith to Eastern Creek,
Wilton, and Western Sydney Aerotropolis Growth Areas

Prepared for NSW Department of Planning & Environment, February 2019

Table of Contents

1. Introduction

1.1 Purpose of the Expert Report

An Expert Report may be prepared under s.6.5 of the Biodiversity Assessment Method (BAM) in place of undertaking a threatened species survey of sufficient extent, intensity and duration as would otherwise be necessary to comply with the BAM. Use of an Expert Report may be beneficial where it is highly unlikely that a species may occur within a study area; where survey cannot meet BAM specifications; and/or the reliability of detecting the species is low. In respect of *Persoonia nutans*, insufficient survey extent; constraints on the effectiveness of survey; and unreliability of detection due to aspects of the species' ecology are the primary reasons for preparing an Expert Report.

The purpose of this Report is to provide an assessment of the current status and conservation requirements of *Persoonia nutans* within the four priority growth areas of Greater Macarthur (GMGA); Wilton (WGA); Greater Penrith to Eastern Creek (GPECGA); and Western Sydney Aerotropolis (WSAGA)to determine whether:

a) The species is unlikely to be present and would thus require no further assessment; or
b) The species is known or likely to be present, and the Expert Report must provide estimates of potential habitat within growth areas and development footprints as part of the biocertification process.

1.2 Project context

The NSW Government is identifying areas for future urban land use and associated infrastructure in western Sydney. The four priority growth areas are all located in the Cumberland Subregion under the Interim Biogeographic Regionalisation for Australia (IBRA) (SEWPaC, 2012).

As part of the planning for these areas, the Department of Planning and Environment (DPE) will prepare the Cumberland Plain Conservation Plan to identify land use outcomes. A strategic assessment of this Plan is underway, and this Expert Report will assist in determining the extent and quantum of impacts of the proposed urban growth on *Persoonia nutans*.

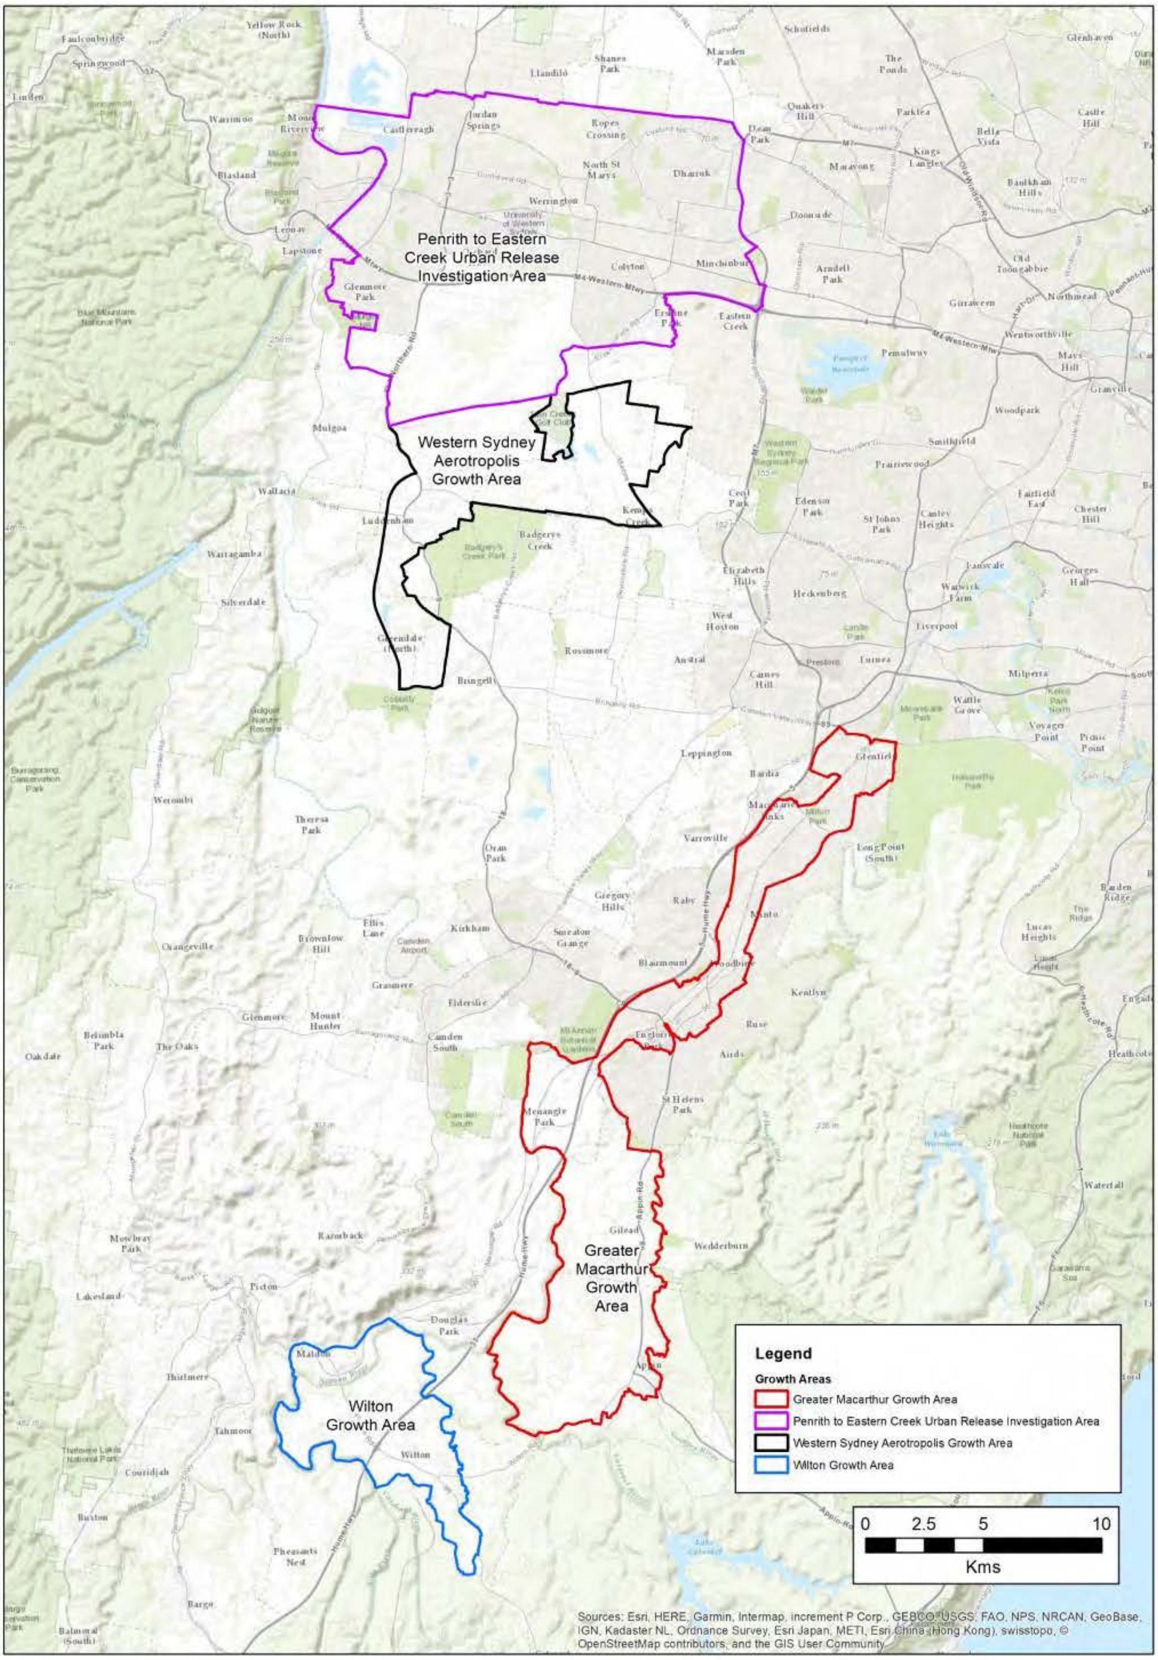
1.3 Study area



Map 1. Growth Areas subject to this Expert Report

Greater Penrith to Eastern Creek Growth Area (GPECGA)

A large portion of this Growth Area is already urbanised, with several areas of industrial land use. Significant rural and peri-urban areas remain in the central north, the centre, and the southwest. Large areas of remnant vegetation are present in the far north (former Australian Defence Industries site, now in part Wianamatta Regional Park), and the Orchard Hills Defence facility. Mining of alluvium for sand and soil continues in the far northwest of the area in the Penrith Lakes locality.

The area has been extensively cleared because of its relatively arable terrain, based mainly on shale and alluvium. Some of the remaining vegetation is associated with the much less arable to infertile Castlereagh Forests & Woodlands and its older, leached and mineralised alluvium and shale-derived soils. Strips of remnant vegetation are present along some of the larger watercourses such as Eastern and South Creeks. Significant parts of the study area are or were flood-prone, and this has influenced the retention of vegetation in some affected areas.

Western Sydney Aerotropolis Growth Area (WSAGA)

This Growth Area adjoins the Greater Penrith to Eastern Creek area, extending south to the locality of Greendale, west of Bringelly. It is currently largely rural, with villages at Luddenham and Kemps Creek. Most rural areas are pastoral, but there are significant areas of more intensive rural use, including poultry and egg production, a large dairy and associated fodder cropping, and some market gardens and enclosed fruit and vegetable production. Quarrying occurs at the localities of Badgerys Creek and Kemps Creek.

This Growth Area is extensively cleared but retains native vegetation in areas where rural uses were constrained by steeper terrain, flooding along streams, or unsuitable soils.

Greater Macarthur Growth Area (GMGA)

The GMGA occurs in southwestern Sydney on predominantly shale soils that have been heavily cleared for agriculture and urban or industrial use. The northernmost section has long-established urban and commercial / industrial land use, while the southern section is largely rural (pastoral, minor cropping), with some villages and primarily subsurface mining (e.g. coal and coal seam gas). It extends from urban Glenfield in the north, to the rural village of Appin in the south.

In the southernmost section, geological uplift and erosion have exposed infertile sandstone terrain along gullies and valleys. Much of that terrain remains naturally vegetated because it is unsuited to agriculture, however it occupies only a small percentage of the total area of this heavily-cleared region. Between the infertile sandstone valleys and the relatively arable shale plateau and hills is a geological and ecological transition zone. Whilst much of the vegetation of the shale terrain has been cleared, a greater area of vegetation remains on the transition zone, primarily in the south. Both the shale and transition zones support Critically Endangered ecological communities that are potential habitat for some threatened plant and animal species.

Wilton Growth Area (WGA)

The Wilton Growth Area is the most southerly of the four Western Sydney Growth Areas dealt with in this Report. It extends from the village of Douglas Park in the north, to the village of Wilton in the south. It is primarily rural (pastoral) area with some more intensive agriculture, significant but mostly underground mining (primarily coal), and some long-established villages. The Hume Motorway dissects this Growth Area.

The pattern of clearing and vegetation retention is broadly similar to that of Greater Macarthur, with the majority of remnant vegetation associated with infertile but biodiverse sandstone gullies and the Nepean River gorge, and with associated transition into the heavily cleared shale landscapes.

1.4 Justification for the use of an Expert Report

An Expert Report for *Persoonia nutans* is required as part of the threatened biota assessment for the Cumberland Plain Conservation Plan because:

1) Survey effort for this species did not meet the recommendations in the OEH threatened species guidelines (OEH, 2016) for field traverses due to limitations on land access, particularly in the GMGA;
2) Survey quality was constrained by drought conditions. Whilst this species is perennial, under sufficiently severe drought and associated total grazing pressure (livestock, if relevant; native species; feral species), it can be reduced to surviving as seed bank. Drought was a major limitation on survey effectiveness in this instance. A known location of another threatened species that can occur with *P. nutans* was visited by fellow botanist, Robert Miller, but could not be detected, even though the habitat was still in place. This suggests that the surveys for both species will have under-detected them because of drought and associated increased grazing/browsing pressures;
3) Survey effectiveness was further constrained by parts of the study area having been long-unburnt. This can create an unnaturally dense shrub layer that limits access and that also creates conditions likely to suppress the species such that it may retreat to the seedbank until favourable conditions return (post-fire or equivalent disturbance).

Surveys associated with biocertification of the study areas and earlier projects in those areas have been insufficient to reliably determine the presence and extent of the species. An Expert Report is required to provide an assessment of the likely presence, location, and significance of occurrences of the species in those areas.

1.5 Credentials of expert

I have worked as an ecologist since the mid-1990s, primarily in the Greater Sydney region, but also in the ACT, Central Coast, southern NSW (coast, tablelands and slopes), throughout Victoria and into eastern South Australia. I have primarily been self-employed, with a mix of government, private, and corporate clients, and have also worked as a subconsultant to larger firms, including two university-based consultancies. I have also worked directly for the NSW NPWS, and more recently for OEH (Native Vegetation Information Science). I was approved by OEH as a species expert for *Persoonia nutans* in November 2018. A summary of my credentials as required under the BAM is provided below as Table 1. I was approved by OEH as a species expert for *Persoonia nutans* under s.6.5 of the BAM in November 2018.

Table 1. Credentials of Dr Steven Douglas as Expert in relation to *Persoonia nutans*

BAM section	BAM requirement	Details
s.6.5.2.8 (g)	Name of expert	Dr Steven Douglas
s.6.5.2.3 (a)	Expert's qualifications	Bachelor of Science (Plant Ecology, Land Management, Resource & Environmental Management), Macquarie University, 1993. Master of Environmental Planning, Graduate School of Environment, Macquarie University, 1996. Doctor of Philosophy, Australian National University, 2008. Graduate Certificate of Information Literacy, ANU, 2006. BAM Accredited Ecologist, 2018.
s.6.5.2.3 (b)	History of experience in ecological research and survey method for the relevant entity	Review of BioNet and incorporated NSW Herbarium database records of *P. nutans* (DPE, 2018). Provision of expert witness evidence in relation to *P. nutans* (QUBE proposal, Moorebank; included assessment of adequacy of biobanking arrangements) L&EC 2017/81889 (2017-18). Fieldwork and advice to NPWS in relation to the species' management profile (c. 1997). Review of historic outlying collection record of the species from Hornsby Shire as part of Hornsby Shire Threatened Biota Management Plan (record deemed to be a result of taxonomic changes not reflected in BioNet/Atlas at that time, subsequently reassigned) (1999). Contributed to the update of the 1996 Draft Recovery Plan. Research and/or successful nominations of allied *Persoonia* species (*acerosa*, *hirsuta*, *glaucescens*, *bargoensis*, *oxycoccoides*, *marginata*), under TSC Act and EPBC Act (1998-onwards). Some work commissioned by NPWS / DECCW / OEH. Plot-based monitoring of allied *P. acerosa* (Blue Mountains City Council for OEH) (2015 on-going). Numerous historic surveys in northwest and western Sydney including Hawkesbury, Blacktown, Liverpool and Penrith LGAs (1994-2000) as evidenced by BioNet and NSW Herbarium records. Particular attention paid to Castlereagh, Agnes Banks and Windsor Downs Nature Reserves and associated proposed extensions (1994-6). Project Manager, Urban Bushland Biodiversity Survey (Western Sydney), including surveys and reporting (1995-7).
s.6.5.2.3 (c)	Resumé detailing projects pertaining to the survey of the relevant entity	See Appendix 1. Relevant surveys and works listed above. Minor survey of predicted habitat at locality of Kemps Creek for DPE Expert Report. Meandering transect used.

s. 6.5.2.3 (d)	Employer's name and period of employment (if relevant)	Self-employed ecological consultant, 1996 to present (continuous other than for periods of study). Employed by OEH as contracted staff from November 2015 to July 2018 (Wingecarribee Shire vegetation map, South Coast Regional vegetation map, Review of mapping issues for TECs).
s.6.5.2.3 (f)	Evidence that the person is a well-known authority on the relevant entity	Consulted by OEH Authorised Officer regarding prospective surveys and review of conservation status for *Persoonia nutans* (2017). Consulted by OEH in major review of numerous threatened flora and communities as part of an update of BioBanking Tool (2006). Approved as a BAM species expert for *Persoonia nutans* by OEH in November 2018. Recruited by IUCN to assist in the Eastern Australia conservation status review of *Proteaceae* for the Red List publication of threatened species (February 2019)

2. Species information

2.1 Description

Persoonia nutans is "An erect to spreading shrub to 2.5 m high [rarely to 3.0 m] with hairy young branches. Leaves are well separated on mature stems, linear, 1 - 3 cm long, 1 - 1.8 mm wide, usually flat, with recurved margins. They are sparsely hairy when immature, and hairless when mature. Flowers are yellow, pendant to drooping on a stalk to 12 mm long… The species is similar to *P. bargoensis*, which is found in the [far] southern part of the Cumberland Plain and nearer the Southern Highlands" (OEH, 2017).

The plant is quite variable in height depending on the time since fire. In long unburnt habitat, it is a substantial but spindly shrub to 3 m high and ~ 2 m wide. More often, it is seen at ~ 1 m high and 0.5, 0. 75 m wide. Some variation in form is also likely as a result of different habitats e.g. how sandy, rocky or clayey the substrate.

2.2 Ecology

Emery & Offord (2018, Table 1) show that *P. nutans* has not been studied for breeding system, fruit set and/or seed germination. However, some information is available through earlier research. Flowering typically occurs from November to March (peak from December to January, NPWS, 2004), with sporadic flowering all year. Flowering is likely to be suppressed during drought, then intensified when drought breaks. The species is an obligate seed regenerator (NPWS, 1996; 2002a; 2004; DEC, 2005). Although listed as a short-lived species, much of the ecology is poorly known. Maturity is expected to be about 10 years. Plants appear to set abundant fruit. Seed is likely to be dispersed, after consumption of the fruit, by large birds such as currawongs and parrots, and large mammals such as wallabies, kangaroos and possums (OEH, 2017; DEC, 2005; Douglas, pers. obs.; McDougall, pers. comm., 2018; Weston, 2003, Auld et al., 2007, Barker & Vestjans, 1990). The introduced Honey Bee (*Apis mellifera*) may be a threat to the long-term viability of at least some *Persoonia* species because it is able to collect floral resources without pollinating the flower (Paton, 2000).

"Nothing is known of the longevity of the soil-stored seed bank of *P. nutans*. It appears germination is promoted, not only by fire, but also by physical disturbance (NPWS 1996; *sensu* Burcher *et al*., 2016). It is not known whether the seed bank is completely exhausted by a single fire. The extent to which germination occurs in the absence of disturbance is unknown, although observations during the 1996 survey (NPWS 1996) indicate such germination is likely to be rare" (DEC, 2005).

"Abundance at a site appears to be related to disturbance history. Sites with higher abundance also appear to be more disturbed" (OEH, 2017; *sensu* Burcher *et al*., 2016). However, too severe or too frequent disturbance would compromise or prevent one or more of germination, maturation, and reproduction, potentially resulting in local extinction. Too frequent fire has earlier been assessed as a significant threat to the species' viability (NPWS, 1996), and was consider the likely explanation for a low number of the species throughout much of the reserve (Burcher *et al*., 2016).

Similar to the Endangered *Persoonia hirsuta* mentioned by Emery & Offord (2018: 91), *P. nutans* can be found on disturbance margins such as edges of roads and trails, in former gravel (laterite) quarries, and in infrequently slashed perimeters of habitat, but is not restricted to them. Myerscough *et al*. (2000) suggest that soil disturbance may be a surrogate for the effects of fire, particularly in areas with low fire frequency. It also occurs in long-undisturbed habitat, but population demographics will be skewed to mature or senescent plants, as recruitment is strongly linked to fire or equivalent factors. Very long-unburnt sites will entail population decline as plants senesce and die, with recruitment being absent or minimal until suitable conditions return. Drought and subsequent return to average or above-average rain may have a similar, though likely weaker effect in this regard, as drought can suppress competing understorey species, with rains promoting recruitment in areas that have a reduced understorey cover.

Mature *Persoonia nutans*. © Ben Ford

2.3 Distribution and abundance

Persoonia nutans is restricted to western Sydney between Grose Wold in the northwest (apparently only 1 plant, collected twice); adjacent to the Georges River at Macquarie Fields in the south (Simmos Beach Reserve and environs); with the most easterly populations being near the Georges River at Pleasure Point, Voyager Point and East Hills (some in Council reserves), and at an industrial site in Villawood (very small and isolated). A naturally isolated, central population occurs at the locality of Kemps Creek, along with several other threatened plant species and ecological communities.

"The species has a disjunct distribution, with the majority of populations (and 99% of individuals) occurring in the north of the species range in the Agnes Banks, Londonderry, Castlereagh, Berkshire Park and Windsor Downs areas. Core distribution occurs within the Penrith, and to a lesser extent, Hawkesbury local government areas, with isolated and relatively small populations also occurring in the Liverpool, Campbelltown, Bankstown and Blacktown local government areas" (OEH, 2017; DEC, 2005; NPWS, 2004). Most of the outlying populations occur in distinctly different habitat to the others. "This species is restricted to part of the Sydney metropolitan area and most remaining populations are threatened by development for housing and mining" (Weston & Johnson, 1991).

As part of DPE's obligations to assess the impact of proposed Growth Areas on threatened biota at State and Federal levels, I was commissioned by DPE to do a review of BioNet records for a subset of species deemed suitable for the modelling of potential habitat. This entailed addressing, where possible, a range of errors and inaccuracies. As part of this review, three records of *Persoonia nutans* were noted as being outside its accepted range. Two of these records plotted in the upper Cataract River catchment inland of the Illawarra Escarpment, west and southwest of Bulli, and were associated with upland swamps and at an elevation far higher than this species is known to occur. They were assessed as unlikely to be valid based on habitat, and they were unvouchered, meaning there was no specimen to support the identifications. They were determined to be a result of a data entry error (wrong species entered into the dataset). The third record was another unvouchered entry from incompatible habitat in Royal National Park, much further east than the species is known to occur. This record has since been invalidated, and likely relates to a common species that was misidentified or more likely, the wrong species code was entered into the dataset.

Persoonia nutans was probably never widespread across the Cumberland Plain, as it is largely confined to comparatively rare and localised Paleogene-Neogene age perched aeolian and alluvial sediments. In the north of its range, where the species can be locally abundant, these deposits are relatively extensive, though the aeolian deposits are much less so and have been extensively mined. Whereas in its central and southern habitats, the species occurs as relatively small and isolated populations because the associated deposits are far smaller in extent. Most of the outlying populations are associated with the quite different geology on the Wianamatta Shale / Hawkesbury Sandstone transition zone, usually near occurrences of Paleogene-Neogene alluvium. The Georges River (east) sites occur on a mix of Paleogene-Neogene alluvium and shale sandstone transition. The now extremely small Villawood population appears to be associated with an unmapped occurrence of Paleogene-Neogene alluvium based on descriptions of the associated vegetation. The Soil Landscape map shows that site as occurring on Wianamatta Shale, but the species is only associated with the edges of that geology where it adjoins Paleogene-Neogene alluvium or the Hawkesbury Group. Geology and Soil Landscape maps are produced at a coarse scale so are only ever indicative. Other ecological surveys in that vicinity have confirmed the presence of vegetation and geology indicative of Paleogene-Neogene alluvium (e.g. Ecological Surveys & Planning, 2013; Colin Gibson, pers. comm., 2018).

It is likely that the species' extent of occurrence prior to European settlement was broadly similar to its current extent, although there has very likely been some habitat removal in the north of the species' range due to mining (Agnes Banks area), rural and rural-residential land use (Londonderry area), and urbanisation (St Marys area). Habitat has been removed and degraded / fragmented in the central population due to clearing for schools, a sports field, rural and rural-residential uses, and some industrial uses. Habitat loss in the south is associated with industrial and housing activities, and potentially with military and infrastructural uses. The southernmost and much of the easternmost occurrences are partly within Council reserves but are threatened by the effects of adjacent urbanisation (*sensu* DEC, 2005; Douglas, pers. obs.). The isolated and tiny occurrence at Villawood is on an industrial site surrounded by long-established urban land use. It is conceivable that there were once other occurrences of the species between that location and the nearest populations near the Georges River to the south, but these were likely patchily distributed on small, unmapped occurrences of Paleogene-Neogene alluvium, and larger, mapped occurrences just to the west and southwest. There are no records of the species from those intermediate areas, but any associated populations could readily have been destroyed before any regard was given to the impacts of land uses on threatened flora.

Some habitat losses have been quantified in part by NPWS (2002b). Agnes Banks Woodland and Castlereagh Scribbly Gum Woodland are the vegetation communities that support the majority of *P. nutans*. These have been reduced to only 15.9% and 52.7% respectively of their pre-European settlement extent due mainly to mining and rural-residential land use. Assessment of more recent mapping by OEH (2013) indicates that these figures remain roughly correct. The mining of large areas that previously supported Agnes Banks Woodland would have resulted in the loss of considerable numbers of *P. nutans* (DEC, 2005).

NPWS (2002b) and DEC (2005) are now quite dated works, and more accurate vegetation maps now indicate that the PCT within the Threatened Ecological Communities with which the species is associated have been cleared as shown in Table 3 later in this Report. Data for the percentage of PCTs cleared is from the OEH BioNet Vegetation Classification Database (VCD, previously 'VIS') and relates to the extent of a PCT across its range, not just within the Cumberland Subregion. PCTs associated with *Persoonia nutans* are restricted to that area with the exception of 1081 and 1395 which extend to surrounding plateaux; and River-flat Eucalypt Forest, which extends along much of the coast and hinterland.

Known and inferred extinction of local populations are noted by DEC (2005). Further extinctions since 2005 are highly likely.

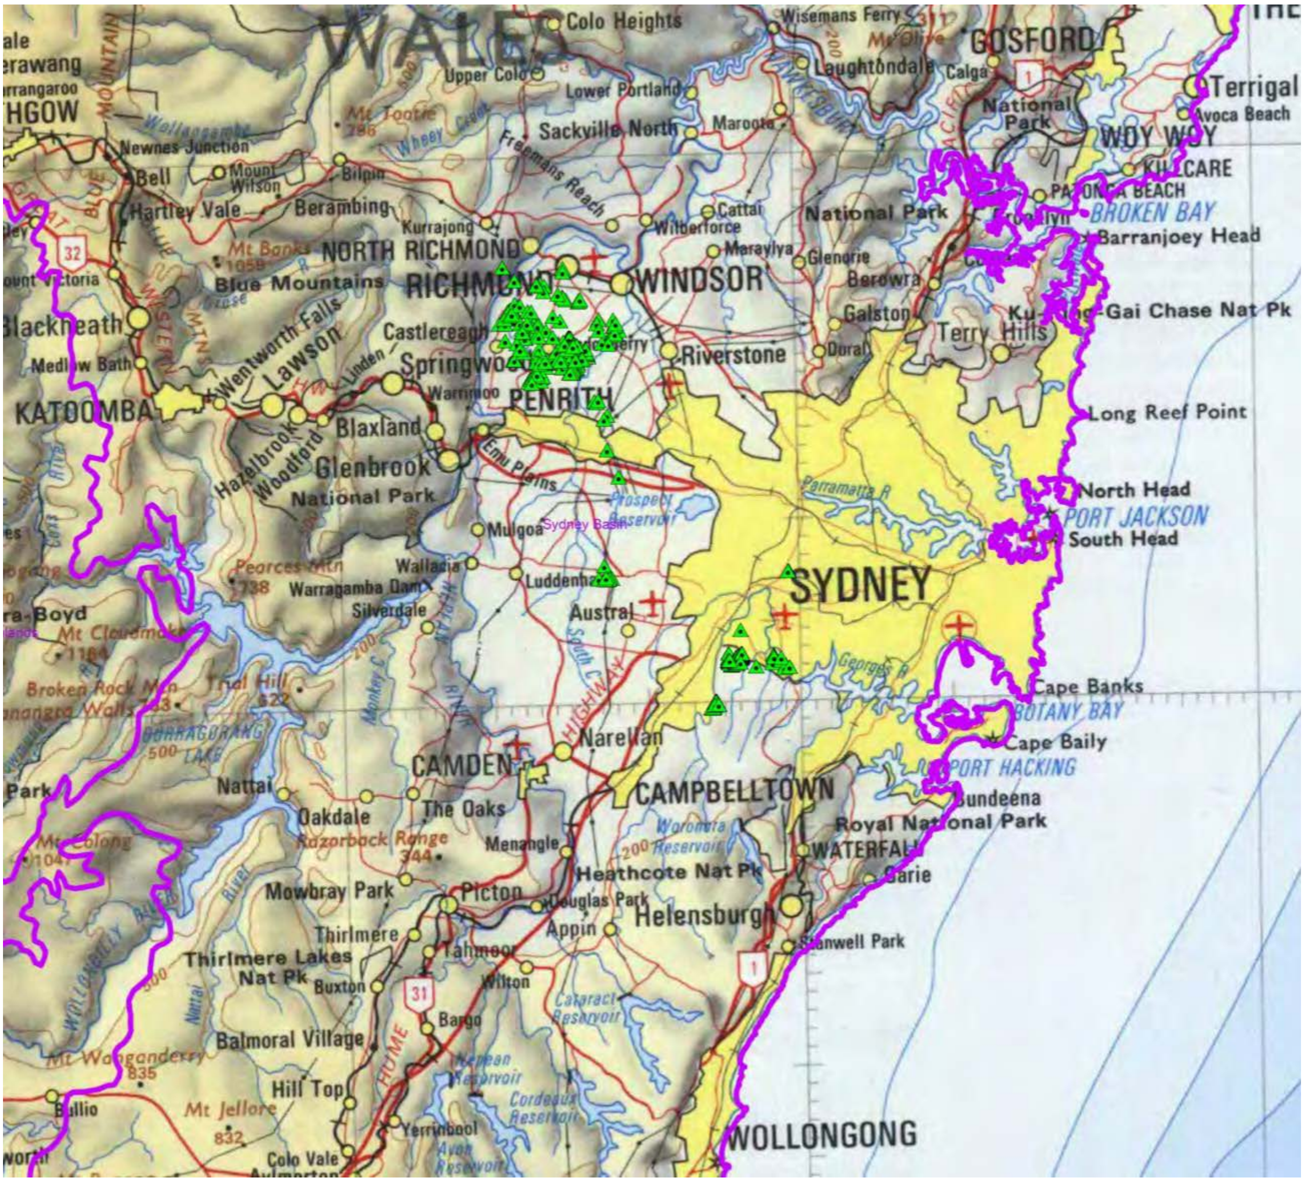
A small number of occurrences that are not documented in DEC (2005) are now known, including a substantial population just outside the far north of the GMGA at Moorebank. That area had been identified by DEC (2005) as potential habitat, but as it was then owned by the Department of Defence, it had not been surveyed. Most of that habitat is now set aside as a Biobanking reserve, but other parts of the site that included occurrences of *P. nutans* have been approved for clearing to accommodate an industrial facility. All of the Biobanking reserve was burnt severely in a suspected arson event in 2017. Whilst much of it was in need of fire to promote regeneration, the fire was extremely intense and extensive, and part of the habitat had been burnt only a few years earlier, meaning that some species would not have had time to regenerate and establish a new seed bank. The site remains at risk from too frequent fire as a result of it adjoining a main road, a railway, and suburban Wattle Grove, or conversely from too infrequent and/or too low intensity fire because of difficulties associated with fire management in such a compromised situation.

It seems likely that without significant intervention, the population at Villawood will not be viable in the long-term due to its isolation and very small population size, plus the nature of threats to what little remains of its habitat. Recent advice from botanists, Colin Gibson and Robert Miller (pers. comm., 2018), is that when the site was seen in 2014, only two plants remained – one healthy, one not, and two additional marked plants were dead – "nothing has been done to manage the site, which at that time, was in poor condition" – African Love Grass and Lantana are big problems. The associated and apparently contaminated ICI site was noted to "have been remediated [apparently in relation to chemical contamination] and bushland has been cleared."

The isolated Kemps Creek population occurs primarily on freehold tenure and is also apparently very small, though may prove to be larger were those habitats to be managed for conservation e.g. appropriately burnt then protected from weed invasion, feral animals, timber theft, and recreational damage. At present, the majority of habitat at this location is long unburnt, has an unnaturally dense regrowth tree layer, and is in slow decline. However, one young plant was recently observed north of the main habitat in an area disturbed by stocking with goats and then recent clearing for industrial land use. It occurs within a tiny linear remnant on that property's periphery and has some protection in the form of a s.88b covenant that sets aside this remnant to conserve threatened plant species and the threatened ecological community in which they occur. A Vegetation Management Plan was prescribed for that area as part of the development assessment, but the extent of threats from weeds and potential nutrient leachate from mulch stockpiled immediately adjoining the conservation area suggests that this Plan is not being implemented or is otherwise ineffective.

Across its range, the estimated area of potential habitat (i.e. suitable vegetation community and suitable soil type) for *P. nutans* is currently 5300 ha in the north of the species' range and 573 ha in the south of the species' range (DEC, 2005). "These values considerably overestimate the 'Area Of Occupancy' of *P. nutans* given that the species will not occupy all of these areas at a particular point in time, and some of this potential habitat may not be suitable habitat (e.g. may be subject to high fire frequency)" (DEC, 2005). These calculations also rely on the accuracy of regional-scale vegetation maps, which are themselves constrained by coarse scale geology and soil maps, inherently conferring a significant margin of error. There has also likely been considerable removal and degradation of habitat since 2005, both legal and illegal.

Persoonia nutans is an obligate seeder, and in the event of a fire, all affected *P. nutans* plants are killed and regeneration is dependent upon recruitment from a soil stored seed bank. *Persoonia nutans* populations are therefore relatively dynamic, particularly where fire is frequent. Fluctuations in space and time of above ground individuals is a natural occurrence. Consequently, the number of individuals and populations is difficult to estimate. Current information suggests there are 27 populations of *P. nutans* supporting greater than 5500 individuals in total. Only seven of these populations occur within conservation reserves, with the majority of populations occurring on private property and unoccupied Crown land" (DEC, 2005). Since 2005, further survey effort has documented some additional populations or at least extensions to known populations, and whilst an estimate of individuals is of relatively little merit because of the species' ecology, an updated estimate may be at least 50% greater than that given in DEC (2005).



Map 2. Cleaned BioNet occurrence data (extracted 26/11/18)

NB, each point may not designate a collection or observation at that location, as most very old records lacked any co-ordinates, or only supplied coarse co-ordinates, and may only have mentioned a town or locality. Such records will generally have a relatively poor Accuracy score (10-25 km) to indicate that the actual location of the species could be within a considerable distance of the designated point. Many such records are assigned the same indicative co-ordinates such that one point on a map may relate to several old records that were supplied with very little locational information.

2.3.1 Reservation status

OEH has not published an updated estimate of *Persoonia nutans'* reservation status since that in DEC (2005). The work of Burcher *et al*. (2016) was not required to remedy this.

The species is known to occur in Castlereagh, Agnes Banks and Windsor Downs Nature Reserves, all in the north of its range (Table 2). More recently, it is known from the relatively new Wianamatta Nature Reserve and Wianamatta Regional Park. The security and even the boundaries of the latter reserve are unclear, as some official maps show it as an eastern and larger western portion, but one OEH map only shows the eastern portion. Reportedly, only the eastern portion is gazetted as reserve, and the western portions remain freehold. The currently proposed DPE urban footprint in the GPECGA shows a large transport corridor passing through the western portion, and this includes locations of two *P. nutans* records. Of the very few records of the species from that area, most are on or just outside the eastern portion's boundary.

The Kemps Creek population remains unreserved and is only known from freehold tenure and some Council-owned or managed land. It is not managed for conservation other than to a minor and fairly ineffective degree on Council land fringing a sports oval. It is partially and incidentally conserved on a freehold property on Clifton Avenue, which is ~1 km north of where the species was previously known in that locality. This currently occurs as a single young plant that was found in what is part of a small s.88b covenanted conservation area associated with an approved industrial land use. The species was not known from that site until found during fieldwork associated with the preparation of this Expert Report. The conservation area is very thin and vulnerable to edge effects, including weed invasion from that property and nearby. It was designated to conserve the threatened plant species, *Dillwynia tenuifolia* and *Pultenaea parviflora*, and the threatened ecological community in which they occur. It is now known to also contain the threatened plant, *Hibbertia puberula* ssp. *puberula* (dealt with in an Expert Report by Robert Miller), which had also not previously been detected on the site. The area is required to be managed in accordance with a Vegetation Management Plan prepared for the property, but the Plan did not appear to be adequately enacted when the site was visited in November 2018.

Part of the Moorebank population is now afforded some protection as a Biobanking offset site. The western records that formed a minority of the population at that site have now been destroyed, with most of the eastern records retained within the reserve. However, the reserved area was burnt in a very intense fire in 2017 during severe drought, and at this stage, the status of the *P. nutans* population there has not been documented. Part of the area had been burnt only 2-3 years prior to the fire, which could result in extinction of this species in the affected area. Conversely, other parts of the site may experience a large increase in numbers of *P. nutans* because fire will have removed over-mature and dense shrub growth and facilitated germination of seed bank.

Further information about other reserved populations of the species in Biobanking sites cannot be provided here because of confidentiality constraints governing that information.

OEH advised of another potential future reserve of this species in the north of its range where ~3000 individuals have been recently documented on land owned by the NSW Government and adjacent to Castlereagh Nature Reserve. Even if this area is conserved, the vast majority of the species' habitat and occurrences in the northern population remain unprotected and unmanaged on former Crown land in the Castlereagh/Londonderry area where threats are considerable e.g. recreational vehicle use, refuse dumping, arson and otherwise inappropriate fire regimes, weed invasion, timber theft, and feral animals. It is understood that an unresolved Native Title Act claim and competing land use intentions are factors in the former Crown land having uncertain status and an absence of protective management.

Counts of individuals are based on BioNet data plus Robert Miller's new records and information from DEC (2005). *Records with no value for the attribute, 'Number of Individuals' were assigned a count of 1. Most records that have population data are for a single plant, sometimes ranging to two or three plants and rarely to <10. Records in Agnes Banks NR were counted using GIS no allowance was made for records that may be within the Reserve but plot outside it due to minor spatial errors in GPS co-ordinates or inaccuracies in the actual Reserve boundary.

Table 2. Numbers of *P. nutans* within conservation reserves

Reserve	Records	Individuals*
Agnes Banks NR	582	825
Castlereagh NR	274	274 - 1500
Wianamatta NR	26	36
Wianamatta RP east portion	2	2
Wianamatta RP west portion	4	13
Windsor Downs NR	48	48 - 500

The species is not adequately reserved across its range. It is best reserved in the largest, northern occurrences where all of the NPWS reserves that contain it occur. These are vulnerable to arson, recreational misuse, and climate change. The central population at Kemps Creek is very much at risk. The southernmost population at Simmos Beach appears to be threatened by trail proliferation and a compromised fire regime due to it adjoining an urban area. It may also be at risk of inbreeding depression, as the population is small and relatively isolated.

2.4 Habitat

2.4.1 Geology and soil

Persoonia nutans occurs in a range of open forest and woodland communities on the Cumberland Plain and some of its margins. Most occurrences are associated with Paleogene-Neogene aeolian and alluvial sediments and the Castlereagh Forests and Woodlands group of vegetation communities, and with the Agnes Banks and Berkshire Park Soil Landscapes. However, the southernmost population at Simmos Beach is associated with the Wianamatta Shale/Hawkesbury Sandstone transition (incorrectly mapped as Blacktown Soil Landscape and edges of the alluvial South Creek Soil Landscape, but better mapped as Lucas Heights Soil Landscape, which is mapped nearby).

To the east, the composite site (likely a metapopulation) at Pleasure Point, Voyager Point and East Hills is variously mapped on the Berkshire Park and Lucas Heights Soil Landscapes.

The Villawood population is mapped on the Blacktown Soil Landscape (Wianamatta Shale) but apparently occurs on an unmapped occurrence of the Berkshire Park Soil Landscape.

The northwestern outlying population is mapped as occurring on the junction of the Luddenham (shale) and Gymea (sandstone) Soil Landscapes. Only one plant has been recorded there to-date on two occasions. At a finer scale, it could be mapped as a strip of Lucas Heights Soil Landscape between the shale and the sandstone lithologies.

The spatial accuracy of Soil Landscape and geology maps is coarse (often at best 1:100,000 scale) and is only useful for broad assessments. In many instances, the transition between Wianamatta Group and Hawkesbury Group-derived soils is not mapped because the transition zone is relatively small and can be difficult to define in coarse maps. Similarly, the boundary between the Paleogene-Neogene deposits and Wianamatta Shale can be complex and too difficult to map, even at a fine scale.

2.4.2. Associated vegetation communities and NSW TECs

Vegetation types associated with *P. nutans* include Castlereagh Scribbly Gum Woodland, Cooks River/Castlereagh Ironbark Forest, Shale Gravel Transition Forest, Castlereagh Swamp Woodland and/or Agnes Banks Woodland, and Shale Sandstone Transition Forest. The latter is only associated with one of the outlying populations, but two others occur in association allied communities. All of these vegetation types are Threatened Ecological Communities (TECs) ranging from Vulnerable to Critically Endangered.

The OEH Threatened Biodiversity Data Collection (July 2018) listed the following Keith Vegetation Classes as being associated with *P. nutans*:

- Coastal Valley Grassy Woodlands;
- Cumberland Dry Sclerophyll Forests; and
- Sydney Sand Flats Dry Sclerophyll Forests

The Threatened Biodiversity Data Collection indicates that *P. nutans* is potentially associated with 8 Plant Community Yypes (PCTs) across its range. Some of these are also associated with State and Commonwealth-listed Threatened Ecological Communities (TECs). Within the Growth Areas, relevant communities and NSW TECs, excluding apparent errors, are shown in Table 3. The associated PCTs are treated by OEH as *potential* habitat, and the species may not actually occur in all of those communities.

Associations between a species and Vegetation Classes and PCTs in the Threatened Species Data Collection were determined by the species' Accountable Officer within OEH some years ago, and staff were required to take a relatively inclusive approach in accordance with the precautionary principle (Steenbeeke, pers. comm.). This may mean that for some species, Vegetation Classes and PCTs have been associated with them even though there is little or no empirical evidence to support that, but where the officer believed that these attributes credibly represent *potential* habitat. Given the limitations of vegetation mapping and that in most cases, survey effort for threatened species is incomplete across their range, such an approach is understandable.

It appears that in some cases, the associations with Vegetation Class and PCTs in the Threatened Species Data Collection may have been amended after the assignments described above, and that some more recent associations may be influenced by spatial errors in species' records and/or errors in or limitations of vegetation maps. The apparent association between *Persoonia nutans* and Coastal Valley Grassy Woodlands is one example, and any association of this kind is weak when reviewed.

An assessment of the association between *P. nutans* and PCTs was undertaken to better understand the potential habitat for this species in terms of plant communities. The assessment is constrained by limitations of BioNet data and available vegetation maps. The assessment of the species' relationship with PCTs in and near the Cumberland Subregion used OEH vegetation maps that were publicly available at the time and did not use the updated vegetation maps produced within the Growth Areas by the biocertification process.

Some records of the species were seen to not be spatially associated with a PCT. This may be because:

- the record occurs in a site now cleared of native vegetation or too degraded to be captured by mapping;
- because the record is too spatially uncertain, so has been assigned generic co-ordinates, usually in a named town or suburb, and such settled areas often lack remnant native vegetation; and/or
- the record plots just outside an area of mapped vegetation because it is on a road verge, and even most GPS records are only accurate to 5m, meaning it could plot on the road, not on the vegetated verge.

To overcome this latter problem, those records were assigned a 10 m buffer so that they would associate with the nearest mapped vegetation polygon up to 10 m from the plotted location.

A further consideration is that survey effort for the species is not evenly distributed across the area subject to analysis. Some sites of potential habitat have had very little or no effort, often due to tenure constraints, yet others have had every apparent plant recorded (mostly in reserves or as part of ecological impact assessments). This creates very substantial biases in the data, which can create misleading weightings of association between the species and particular PCTs. Furthermore, most records do not include population data, such that a record might be for one plant or many. In short, this analysis is best used only for presence/absence i.e. whether the species has been recorded at a point that is mapped as a particular PCT, or not. Analysis beyond that is very constrained by deficiencies and biases in the datasets, especially in BioNet data.

The analysis of association with PCT in Table 3 deals only with records in the Cumberland Subregion plus a 10 km buffer. Records that associate with a PCT when a 10 m buffer is used are included in the counts of sightings below and are not shown separately. Two analyses were undertaken: All records in the target area without regard to spatial Accuracy score; and only records in that area with Accuracy score of 100 m or better. The latter analysis is considered more reliable, but both sets of figures are provided. Sightings with Accuracy <=100 m are shown in square brackets **[ ]** and in bold text. Where available, the combined count of individuals associated with the records is provided in parentheses { }. Those counts relate only to records with Accuracy <=100 m. Where a record doesn't contain population data, it is assumed to relate to a single plant.

Only PCTs mapped in the Growth Areas are dealt with in Table 3. Two PCTs mapped outside the Growth Areas: 958 (Agnes Banks Woodland) and 1067 (Castlereagh Swamp Woodland) were seen to be significantly associated with the species. Both are mapped north of the GPECGA by OEH. The updated vegetation map for this project did not identify either of these PCTs within any of the Growth Areas.

Some PCTs can appear to have a greater or lesser association than is actually the case. This is evident for this species in that an uncritical review of the raw data would associate this species with PCT 835*, which is a type of grassy riverflat forest on Quaternary alluvium that is not considered habitat for this species in any of the literature. In this case, there are very few records of the species associating with this PCT, and they are reasonably spatially accurate, but the vegetation map against which they have been assessed is inaccurate at that scale. The records plot in riverflat forest but the vegetation is most likely a unit with which the species is accepted to be associated - probably Shale Gravel Transition Forest.

Similarly, the apparently stronger association with PCT 849, a form of Cumberland Plain Woodland, is likely to be an artefact of spatial errors in the species' records and/or spatial or other inaccuracies of the vegetation map. The species is not accepted to occur in Cumberland Plain Woodland. The records that appear to be associated with that vegetation were more likely in Shale Gravel Transition Forest or Shale Sandstone Transition Forest, both of which can have a broad and indistinct ecotone with Cumberland Plain Woodland such that mapping of the boundary can be very difficult, even at quite a fine map scale.

Conversely, the species has a stronger, though still low and very tightly confined association with PCT 1081 than is indicated by the raw data in Table 3. The table shows that there are no records of the species with spatial accuracy of 100 m or better known from this PCT, and that there are only five records with lesser accuracy that are associated with this PCT. This is substantially an artefact of the fact that the native vegetation at the Simmos Beach population is assigned to PCTs 1787 and 1790 which are more prevalent on the Sydney Metropolitan vegetation map than the adjoining Cumberland Plain vegetation map. The latter is by far the most relevant to all of the Growth Areas. The OEH Threatened Species Data Collection report for *P. nutans* does not list PCTs 1787 or 1790 as being habitat for this species. However, availability of the associated vegetation map post-dates the last period in which OEH sought to ensure correlations between PCTs and threatened species were correct and current (Steenbeeke, pers. comm.).

Additionally, the two PCTs mapped at Simmos Beach Reserve are strongly allied with PCT 1081 (being confusingly described in the BioNet VCD as variously derived from or a parent unit of 1081), which occurs primarily on the Cumberland Plain map and is present in the Greater Macarthur and Wilton Growth Areas. Descriptions of vegetation at this site by Miller (pers. comm.), Steenbeeke (pers. comm.) and some of the observers of the species' BioNet records, along with the presence of PCT 1395 in close proximity, suggest that much of that habitat could be sensibly mapped as 1081.

On that basis, PCT 1081 goes from having no meaningful association with this species, to having a Low relative association based on the number of records with <=100m spatial accuracy and the number of plants recorded or assumed (one record = one plant unless other data provided) at the Simmos Beach site. Alternative figures for those parameters are provided as a second row for that PCT in Table 3.

PCT 1395 also shows no credible association with *P. nutans* in the raw data, irrespective of the spatial accuracy of the records. Yet there are records that describe the species as occurring in 'shale sandstone transition forest'. One such site is at East Hills Park, but the vegetation is mapped as a form of coastal shale sandstone transition forest that is quite distinctive from the PCTs that comprise the Shale Sandstone Transition Forest TEC (principally 1395). Assuming that the OEH vegetation map is correct, this site is not informative for the purposes of determining PCT associations with this species in the Growth Areas, as it does not occur in any of them. However, there are two other records (duplicate collections of the one plant) that also mention the species occurring in Shale Sandstone Transition Forest. Once moved to the correct location based on information from the first collector (Wotherspoon, 2002), they plot in credibly mapped PCT 1395, which is informative for this Report, as this community occurs in two of the Growth Areas. Whilst the relative association with 1395 is Very Low, and relates to a single outlying site, this PCT is included as potential habitat for the species within its accepted range, plus a precautionary buffer (south to Narellan Road). Alternative 'Sightings & Populations' figures for PCT 1395 are provided as a second row in Table 3[#].

2.4.2 Associated Commonwealth TECs

The Commonwealth Department of Environment & Energy (DEE) Species Profile and Threats Database website for *Persoonia nutans* shows that as of November 2018, the Department has not released an Approved Conservation Advice for this species. It relies on the joint NSW/Commonwealth Recovery Plan for this purpose, though that Plan is now quite dated (2005), and also references the NPWS (2004) EIA Guidelines and on-line profile (OEH, 2017) for this species. Consequently, there is not an official document that clearly shows which Commonwealth TEC are associated with *P. nutans*.

However, in this case, the NSW TECs with which the species is accepted to be associated are equivalent to or components of Commonwealth TECs.

2.4.3 Habitat condition

Degraded and significantly modified areas of the PCTs that are known or likely habitat for *P. nutans* can still support it due to its ability to persist in the soil seed bank. Modified sites may have reduced or no canopy and/or midstorey, and/or reduced understorey and some weed invasion. Some may be dominated by shrubs in areas of regrowth after earlier clearing or 'under-scrubbing'.

This species is known to occur in highly modified sites such as slashed bushfire Asset Protection Zones, and road and trail verges, and in former small-scale quarries (DEC, 2005, Burcher *et al*., 2016). Some forms of disturbance, even relatively severe forms that would be considered clearing of vegetation, appear to be beneficial to this species, within limits. This situation is recognised for numerous threatened plant species in and beyond the Sydney Basin Bioregion. It may be related to the fact that modern fire regimes are likely to be significantly different to those prior to 1788, and that some native animal species that had a role in seed dispersal and understorey modification are now extinct.

The condition of potential habitat for this species is not, in itself, a reliable indicator of the species' presence, and accordingly, **all condition states except derived grassland are considered in determining potential habitat** i.e. intact, thinned, scattered, and derived shrubland. Derived grassland is not included, as in large part, PCTs that are known habitat for *P. nutans* are not subject to pastoralism, so have generally not been cleared of trees to support grazing. However, the species can survive grazing depending on the livestock type and stocking rate, and because it can survive as seedbank. Sites with long and intensive grazing history will be unlikely to retain the species in any form, especially given that fertiliser is likely to be used to promote and maintain fodder cover on the low fertility soils that this species prefers. Fertiliser use alone could suppress or eliminate this species. Only sites with relatively recent grazing history or very low stocking rates may retain the species as plants and/or seed.

Table 3. BioNet records of *P. nutans* and counts of individuals relative to mapped PCTs

PCT	PCT Name	Associated TECs (NSW BC Act)	% Cleared (VCD)	Sightings & Population	Relative association	Adjusted relative association#
724	Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain	Shale Gravel Transition Forest (E)	75	71 **[64]** {101}	Moderate	Moderate

3. Description of the study area

3.1 Landscape context and land use history

All of the Growth Areas have been significantly cleared for earlier activities, primarily timber production associated with opening areas for agriculture and pastoralism, minor areas of surface resource mining, and to varying degrees, for urban and commercial/industrial use. They are proposed to accommodate phased increases in urban land use, primarily within existing cleared or highly modified lands. Increased urban use is planned as a response to population growth.

3.1.1. Greater Macarthur Growth Area (GMGA)

The GMGA extends from Glenfield in the north to Appin in the south. It is largely within the Campbelltown LGA with the southernmost section within the Wollondilly LGA. The northern half comprises an urban renewal corridor centred on the Sydney to Southern Highlands railway line. It encompasses the existing industrial and residential suburbs of Glenfield, Macquarie Fields, Minto, Leumeah and Campbelltown. The GMGA is associated with extensively cleared, gently undulating shale terrain typical of the Cumberland Plain, and contrasts the sandstone gorges of the Woronora Plateaus across the Georges River to the east. The northern portion of the GMGA is already substantially urbanised, with remnant vegetation largely restricted to creek-lines or small patches associated with designated open space. Vegetated creek-lines include Bunbury Curran Creek, Bow Bowing Creek, Leumeah Creek, Fishers Ghost Creek and Spring Creek.

The more extensive southern half of the GMGA, south of Rosemeadow, comprises proposed urban land releases at Menangle Park, Mount Gilead and Appin. Menangle Park and Mount Gilead are subject to separate planning processes, so are not within the scope of this biocertification. In the north-west, Mount Sugarloaf (213 m AHD) forms the southern end of a hilly ridge on the Luddenham Soil Landscape above the Menangle floodplain that extends north to Denham Court, then to Cecil Hills and Prospect Hill. Some native vegetation persists, although it is often invaded by African Olive. The floodplain is dissected by Menangle Creek and its tributaries, including Nepean Creek, Woodhouse Creek and Leafs Gully.

The southern GMGA is primarily semi-rural and agricultural land, with creek corridors and some larger patches of remnant vegetation located between the Nepean and Georges Rivers. Geologically, the area comprises gently undulating hills on Wianamatta Shale intergrading via a shale sandstone transitional zone (can include the Mittagong Formation) with steeper and infertile terrain on Hawkesbury Sandstone along the rivers. Transitional and sandstone geologies are sometimes exposed along the smaller creek lines.

3.1.2. Wilton Growth Area (WGA)

The WGA is a relatively smaller area that occurs to the south of the GMGA, extending from the vicinity of Douglas Park in the north, Maldon in the north-west, and beyond Wilton in the southeast. The boundaries closely follow the Nepean River in the north and west, a tributary Allens Creek in the east, and the Cordeaux River in the south. Away from the Nepean River and gullies, a higher, gently undulating zone has been largely cleared for agriculture. The Woronora Plateau forms the southern boundary and includes the northernmost section of the large Upper Nepean State Conservation Area, with unreserved but closed areas of the Water NSW Special Area (Sydney water supply catchment) extending to the east and southeast. The Hume Motorway dissects the WGA roughly north to south, and Picton Road traverses it roughly northwest to southeast.

The WGA includes both shale, shale sandstone transition and sandstone environments. Remnant vegetation occurs predominantly along the watercourses and on associated slopes. The flatter shale terrain has soils of the Blacktown Soil Landscape, which is derived from Ashfield Shale (a member of the Wianamatta Group), and typically supported the now Critically Endangered Cumberland Plain Woodlands. Much of this area is cleared or modified for agriculture and hobby farms. It comprises native/exotic grassland with smaller areas of Derived Native Grasslands in relatively better condition. Areas above the gullies feature soils of the Lucas Heights Soil Landscape derived from the Mittagong Formation (a transitional bed between the Wianamatta and Hawkesbury Groups). These support variable shale sandstone transition woodlands and forest, some of which are also Critically Endangered. In the steeper gullies, the Hawkesbury Soil Landscape dominates, and supports Hawkesbury Sandstone Gully Forest types with Ridgetop Woodlands on some of the upper slopes.

3.1.3. Greater Penrith to Eastern Creek Growth Area (GPECGA)

The GPECGA is a relatively large area that extends from Rooty Hill, Minchinbury and Hassell Grove in the east, across the Cumberland Plain to the Hawkesbury-Nepean River in the northwest, then south through Jamisontown, Glenmore Park, to the intersection between The Northern Road and the Warragamba Water Supply Pipelines in the far south-west.

The predominant geology is Wianamatta Shale on flat to gently undulating terrain that has been extensively cleared for agriculture, and later for housing and industrial use, with some remnant vegetation on current and former Defence holdings. The shale soils support(ed) Cumberland Plain Woodlands. Overlying the extensive shale deposits are small areas of weathered Paleogene-Neogene alluvium e.g. Shalvey and Willmot, that are much more common to the north. These support(ed) the Castlereagh Forests & Woodlands complex of vegetation types, which is strongly associated with several threatened plant species. More common are broadly linear deposits of Quaternary alluvium along watercourses such as South Creek and Eastern Creek, and on the flood terraces of the Hawkesbury-Nepean River. Other lithologies occur but are very rare and of very small extent.

Very little of the GPECGA is reserved in NPWS estate. Wianamatta Regional Park (which emphasises recreational uses) encloses small areas of former Defence land in the far north. Adjacent to the southwestern boundary is the small Mulgoa Nature Reserve (emphasises biodiversity values). Two Biobanking sites adjacent to the Nature Reserve have increased the area under conservation.

3.1.4. Western Sydney Aerotropolis Growth Area (WSAGA)

The WSAGA abuts the GPECGA's southernmost border near the locality of Sovereign (east of Mulgoa), then extends south past Greendale, northeast to the locality of Badgerys Creek, east to Kemps Creek, and northward to the vicinity of Mount Vernon, excluding Twin Creeks Golf Course and associated settlement.

The lithology and soils are broadly similar to that of the GPECGA, being effectively just an extension of that area to the south to incorporate the developing Badgerys Creek Airport and environs. The area is even more severely cleared of native vegetation, except along some streams and on rare occurrences of steeper terrain. It contains no NPWS reserves, with the nearest being the small Kemps Creek Nature Reserve, outside the Area to the southeast. Gulguer Nature Reserve and Bents Basin State Conservation Area occur to the southwest of Greendale.

3.2 Geology and remnant vegetation

The dominant lithology across all of the Growth Areas is Wianamatta Shale (Ashfield and Bringelly Shales), with much smaller areas of Paleogene-Neogene alluvium occurring largely outside these boundaries, and much larger areas of Quaternary alluvium associated with floodplains of the many watercourses.

The terrain varies from almost flat through to steeply hilly areas associated with minor volcanism and more often, in association with shale ranges. In the far south, the more elevated shale landscapes have been eroded down to the underlying Hawkesbury Sandstone in a series of gullies and gorges. A transition zone between the shale and the sandstone is discernible in some areas.

On the dominant shale geology, the associated Critically Endangered Cumberland Plain Woodlands are still present in all of the four Growth Areas but have been disproportionately cleared for rural and later urban and allied uses. Much of what remains of this ecological community occurs as paddock trees and areas of remnant native ground-layer vegetation in pastoral and other contexts, with the exception of some substantial, though fragmented and isolated remnants. Remnant vegetation in these relatively fertile and arable landscapes is often in poor condition. In the most heavily cleared areas, it can be restricted to strips along watercourses. Some forms are dominated by *Casuarina* species. Weeds are common and sometimes severe in the moister situations. Weeds often extend into higher and drier terrain, especially in the form of African Olive and African Love Grass, both of which can occur on a landscape scale.

Small areas of the biodiverse Castlereagh Forests and Woodlands persist in all but the Wilton Growth Area on often-laterised Paleogene-Neogene alluvium. These variable woodlands and open forests support a particularly high number of threatened plant species, and because their soils are less suitable for agriculture and grazing, are better conserved than the Cumberland Plain Woodlands. Nonetheless, they are all listed as threatened ecological communities.

In the two southern Growth Areas, vegetation of the shale sandstone transition zone is relatively common and tends to remain in less arable areas adjoining the largely cleared former Cumberland Plain Woodlands. It is often found fringing the largely uncleared sandstone-based terrain, and ranges from highly intact to significantly modified and degraded, largely due to grazing and weed invasion. The associated Shale Sandstone Transition Forest is recognised as Critically Endangered due to extensive clearing across its substantial range, and because of the severity of other threats. Very little is present in formal conservation areas.

In the two southern Growth Areas, diverse, sandstone-based vegetation persists in association with most of the many incised watercourses. This vegetation is broadly the same as what occurs in extensive conservation estate around urban Sydney, but some communities adjoining current or former Shale Sandstone Transition Forest are not well-conserved and are threatened by further clearing and degradation.

3.2.1 Plant Community Types

The following section lists the Plant Community Types mapped in each Growth Area with brief notes about their distribution in those Areas. The list is not restricted to PCTs associated with *P. nutans*. Biobanking reserves are not dealt with fully here due to confidentiality constraints relating to their location and attributes.

3.2.1.1 Greater Macarthur Growth Area (GMGA)

The predominant ecological communities in the GMGA are or were Cumberland Plain Woodland (CPW), Shale Sandstone Transition Forest (SSTF) and River-flat Eucalypt Forest (RFEF), all of which are Threatened Ecological Communities. All have been extensively cleared and degraded, primarily by agriculture and weed invasion, but also by urban and allied uses. There are no NPWS reserves in this Growth Area. However, the very small Leacock, Edmondson and William Howe Regional Parks occur just outside the border and are managed primarily for recreation rather than conservation. Dharawal State Conservation Area and National Park border the southern portion of the Growth Area to the east.

A summary of the mapped ecological communities is found in Table 4. The maps used here are based on OEH products that have been updated by Biosis for DPE.

Table 4. Summary of all ecological communities within the Greater Macarthur Growth Area

PCT	PCT Name	Distribution & notes
830	Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain	Small patch at Menangle Sugarloaf on SE slopes.
835	Forest Red Gum – Rough- barked Apple grassy woodland on alluvial flats of the Cumberland Plain	Along creek lines in shale areas in northern and central parts of GMGA.
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	Small patches on shale soils throughout GMGA but mostly in northern and central parts.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	Very small patches on shale soils throughout GMGA, more common in southern parts on steeper terrain.
883	Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain	4 polygons, Macquarie Fields, most of which have long been historically mown (Milton Park Softball Complex). They are now subject to regeneration.
1081	Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain	One small occurrence mapped around the margins of bushland associated with Smiths Creek at Leumeah.
1105	River Oak open forest of major streams, Sydney Basin Bioregion and South East Corner Bioregion	Only mapped along the Nepean River north from Menangle Bridge.
1181	Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of west & south Sydney	Narrow zone along Nepean & Georges Rivers and tributary gullies and a small zone along Smiths Creek at Leumeah.
1292	Water Gum - Coachwood riparian scrub along sandstone streams, Sydney Basin Bioregion	Restricted to parts of the riparian zones of the more incised and larger watercourses. Very restricted extent in this Area.
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain	Relatively small remnants extend from Glenfield into the far south where it is extensive on transitional soils mostly south from Rosemeadow. Can intergrade with 849 and 1081.
1800	Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley	Only mapped to a very minor extent as highly linear remnants between Glenfield and Macquarie Fields (along the railway) and at Ingleburn (adjoining roads).

3.2.1.2 Wilton Growth Area (WGA)

The predominant ecological communities in the WGA are or were Cumberland Plain Woodland (CPW) and Shale Sandstone Transition Forest (SSTF) both of which are Threatened Ecological Communities. Sandstone-based communities occur in and surrounding the more incised watercourses. There are no NPWS reserves in this Growth Area, though Upper Nepean State Conservation Area occurs immediately to the south. There is a Biobanking site on the northern side of the river near Douglas Park (within the WGA), and three more such properties to the immediate north (including St Marys Towers) and those associated with coal mines (Steenbeeke, pers. comm.).

Table 5. Summary of all ecological communities within the Wilton Growth Area

PCT	PCT Name	Distribution & notes
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	On shale soils of higher, gently undulating terrain of northern and central areas. Small patches with scattered trees (farming properties) adjoining more extensive exotic and native grasslands.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	One patch in a derived grassland (treeless) condition in the west, and a much larger portion in the far north.
1081	Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain	Limited to a few patches in the north between 1395 on plateau edges and 1181 in sandstone gullies.
1181	Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of west & south Sydney	Common on slopes and plateau edges above and around incised sandstone-based watercourses that surround most of the Area.
1292	Water Gum – Coachwood riparian scrub along sandstone streams	Restricted to a very narrow riparian strip along the Nepean River.
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain	The most extensive community on shale sandstone transition soils between 849/850 and sandstone communities along gullies. Variable floristics.

3.2.1.3 Greater Penrith to Eastern Creek Growth Area (GPECGA)

The native vegetation of this Growth Area has been extensively cleared, with what remains classified as Threatened Ecological Communities. The majority of the Area formerly supported Cumberland Plain Woodlands, with a much smaller area supporting Shale Gravel Transition Forest and Castlereagh Forests & Woodlands. River-flat Eucalypt Forest was previously much more extensive along the Hawkesbury-Nepean River and adjoining primary floodplain, and it remains to varying degrees along many watercourses such as Eastern Creek, though frequently in poor condition, due largely to extensive weed invasion and a long interface with unsympathetic land uses. There is one NPWS reserve in this Growth Area: Wianamatta Regional Park, however it is already significantly fragmented and may be required to potentially accommodate a large transport corridor. The small Mulgoa Nature Reserve and associated Biobanking sites occur near the south-western border of this Growth Area. Yarramundi SCA occurs on the western boundary but across the Nepean River, and Wianamatta NR occurs near the NW corner.

Table 6. Summary of all ecological communities within the GPECGA

PCT	PCT Name	Distribution & notes
724	Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain	Scattered as small remnants and one larger remnant in the central portion, but with greater extent in the central north, mainly in the western ungazetted portion of Wianamatta Regional Park.
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain	A few very small remnants present south of the M4, with larger remnants within and near the gazetted and ungazetted portions of Wianamatta Regional Park.
781	Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion	Very limited extent, primarily in the far northwest, with some small remnants in the southwest, often associated with watercourses.
830	Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain	Present to a very minor extent on the southwestern edge adjoining Mulgoa Nature Reserve
835	Forest Red Gum – Rough- barked Apple grassy woodland on alluvial flats of the Cumberland Plain	Common along creek lines and associated floodplains through the south and central areas.
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	Common in and near Orchard Hills in the south, and former ADI lands in the central north, with some areas in the ungazetted portion of Wianamatta Regional Park. Other scattered remnants, particularly in the east.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	Very small patches in the south west, primarily in pastoral settings and on steeper terrain.
883	Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain	Restricted to one linear polygon in the eastern portion of Wianamatta Regional Park.
1105	River Oak open forest of major streams, Sydney Basin Bioregion and South East Corner Bioregion	Only mapped along the Hawkesbury-Nepean River, primarily near Penrith Lakes.
1800	Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley	Present as mostly-linear remnants along South Creek and Eastern Creek and tributaries, with some scattered occurrences, including along the M4.

3.2.1.4 Western Sydney Aerotropolis Growth Area (WSAGA)

The native vegetation of this Growth Area has been extensively cleared, with what remains classified as Threatened Ecological Communities. The majority of the Area formerly supported Cumberland Plain Woodlands, with a much smaller area supporting Castlereagh Forests & Woodlands near the localities of Kemps and Badgerys Creeks, and potentially in the vicinity of the water pipeline crossing of Luddenham Road. Riverflat Eucalypt Forest remains to varying degrees along most watercourses, though frequently in poor condition, due largely to extensive weed invasion and a long interface with unsympathetic land uses. Swamp Oak Forest occurs mainly along South Creek and some tributaries. There are currently no NPWS reserves in this Growth Area. The small Kemps Creek Nature Reserve occurs just outside the south-eastern corner and Gulguer Nature Reserve and Bents Basin State Conservation Area are near the south-western corner.

Table 7. Summary of all ecological communities within the WSAGA

PCT	PCT Name	Distribution & notes
724	Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain	Restricted to the Kemps and Badgerys Creek area as three patches of remnants.
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain	As above: two patches with smaller remnants nearby and on slightly higher ground than 724.
781	Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion	Very limited extent, primarily in the far northeast, with one remnant in the centre.
835	Forest Red Gum – Rough- barked Apple grassy woodland on alluvial flats of the Cumberland Plain	Common along creek lines and associated floodplains but very little remains, and most occurrences are linear.
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	The most common PCT in this Area, with remnants throughout on the dominant shale terrain.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	Only very small patches in the far south.
1800	Swamp Oak open forest on river-flats of the Cumberland Plain and Hunter valley	Present as mainly very linear remnants along most watercourses but largely absent from the southernmost portion.

4. Assessment of species' presence and suitable habitat

4.1 Existing records and surveys

The principle source of threatened flora records in NSW is the OEH BioNet database, which includes most records held by the NSW Herbarium (specimen-based), as well as sightings, including those associated with vegetation sampling for the purposes of mapping. Other databases, such as Atlas of Living Australia, largely mirror BioNet data within NSW, but are not used in this Report due to their having lower data quality control, and because they do not allow even a registered user to access data that may not have been generalised to obscure the exact location of a record. Very few flora records that are in ALA but not in BioNet are original – most are simply replicate records based on specimens held in other herbaria.

The preliminary assessment of threatened species records undertaken for the preparation of this Expert Report reiterated the merit of reviewing BioNet data and resolving a range of errors, rather than simply using data 'as held'. *Persoonia nutans* records within BioNet were reviewed, and numerous corrections were made, though the majority of these relate to the assigned spatial accuracy scores and to clarifying or correcting location placements and descriptions. Not all records were able to be checked in that stage, and a second review for records in or near the Growth Areas was conducted to further improve data quality. The reviews eliminated a range of errors and allowed many records that were otherwise too spatially vague, to be refined such that they were suitable for habitat modelling and for general reference. Not all records were reviewed, and inaccuracies remain in the dataset, but records within the Cumberland Subregion are now far more accurate in terms of their identification of the species, their location, and their spatial accuracy score.

BioNet data should only be treated as indicative, not least because there has not been comprehensive survey of all of the Growth Areas or environs, and surveys have been variously constrained. The absence of records from an area does not necessarily mean the species is absent, as it may not have been surveyed there, or survey conditions and methods may have been inadequate.

Field survey undertaken by consultancy firms engaged by DPE (Biosis and Ecoplanning) did not add any records of this species. Fellow botanist, Robert Miller and I undertook very limited survey in the Kemps Creek locality. Robert detected, and I recorded, one juvenile *Persoonia nutans* at a site on which it had not been previously recorded in two earlier consultancy assessments on behalf of the land owner and in a more recent vegetation mapping survey for DPE. The plant was likely not present during the earlier consultancy assessments, as it is clearly a young specimen that likely arose after threatening processes were removed from that habitat relatively recently. I believe that had I been given access to more freehold land in that area, I would have been able to record additional occurrences of this species. DPE made considerable and repeated efforts to obtain such access, but with very little success. However, all areas of known or potential habitat for *P. nutans* in that locality have been excluded from the proposed urban footprint / biocertified area.

4.1.1 Existing records by Growth Area

Persoonia nutans records in Greater Macarthur Growth Area

There are no records of the species from the GMGA, but there are several records associated with a population to the east at Simmos Beach on the edge of Macquarie Fields. There are a large number of records further to the northeast on an approved industrial development site on former Defence Department land at Moorebank, part of which is now within a Biobanking offset reserve.

Persoonia nutans records in Wilton Growth Area

The species has been never been recorded within the WGA. This is credible on the basis that this Area occurs at higher elevation and further south than the species is known to occur, and only one of the PCTs with which it is associated is present in this Area. That PCT, 1395, is only known to be habitat for this species at the edges of its distribution, and this Area is substantially beyond that distribution. Weston & Johnson (1991) indicate that *P. nutans*, which has a southern limit at Simmos Beach Reserve, is replaced by the allied and highly range-restricted *P. bargoensis* in the Wollondilly region in which the WGA occurs.

Persoonia nutans records in Greater Penrith to Eastern Creek Growth Area

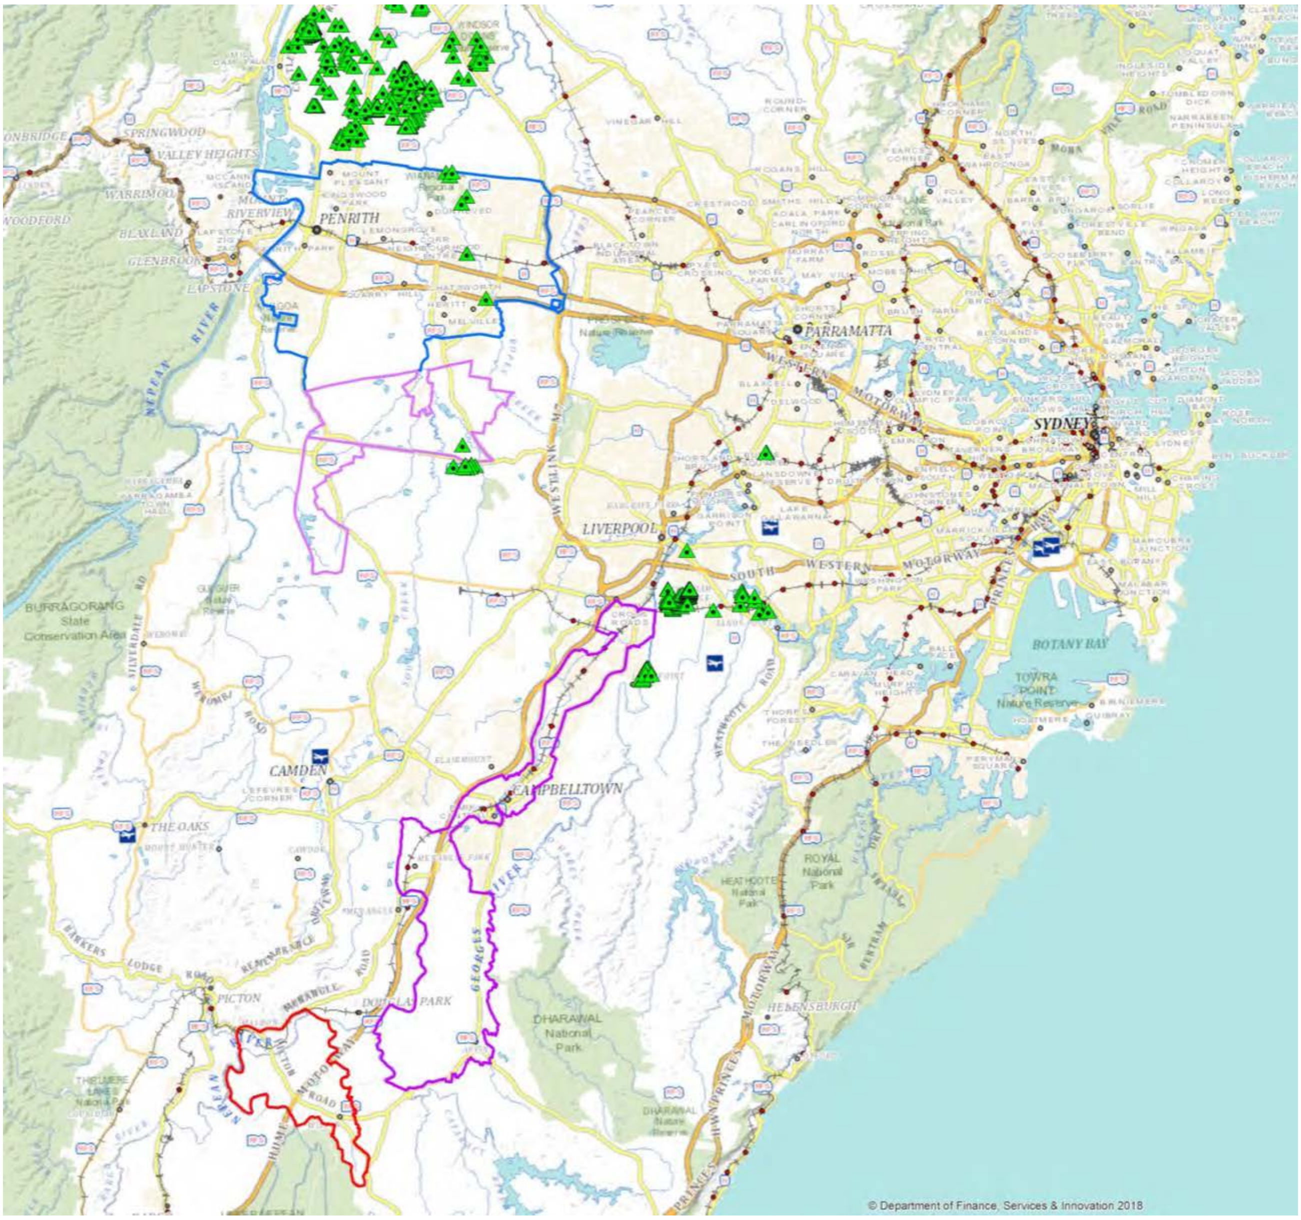
The species is known from this Growth Area in the form of both vaguely located historic records and spatially accurate recent records. Recent records occur in the central north of the Area in and near the eastern extent of the former ADI lands that are now partially urbanised and partially reserved (e.g. Wianamatta Regional Park). In the central section of this Growth Area, the very few records that exist are old or very old, and if they have any locational information, this only refers to "St Marys" or "east of St Marys", so are arbitrarily located. As part of the review of BioNet records, these were further consolidated and moved to a small strip of remnant vegetation where seedbank may remain. There are no records from the vicinity of St Marys since 1955, and the area is now extensively urbanised.

In the southeast of this Area, a single, modern record exists in a tiny patch of remnant bushland along the M4 Motorway, with records of the threatened *Acacia pubescens* nearby.

There was always relatively little habitat for this species in this Area, and even less remains today. Most of the remaining mapped potential habitat in this Area is restricted to the gazetted and proposed portions of Wianamatta Regional Park.

Persoonia nutans records in Western Sydney Aerotropolis Growth Area

There are several records of the species just outside the south east corner of this Growth Area in the locality of Kemps Creek. They are a mix of relatively old, spatially vague records; and modern, more spatially reliable records. All are associated with an isolated remnant of Paleogene-Neogene alluvium. The one record within this Growth Area was added during surveys to support this Report, and it occurs approximately 1 km north of the earlier records. Equivalent habitat remains between these records but has been progressively degraded and removed in recent years. Much of what little habitat remains is threatened by a range of legal and illegal land uses, and the fact that this species can be present in seed bank on long-unburnt sites but is too often disregarded if it is not detected during ecological assessments.



Map 3. BioNet records (cleaned as of 26/11/18) relative to Growth Areas

Each point on Map 3 may not designate a collection or observation at that location, as most very old records lacked any co-ordinates, or only supplied coarse co-ordinates, and may only have mentioned a town or locality. Such records will generally have a relatively poor Accuracy score (10-25 km) to indicate that the actual location of the species could be within a considerable distance of the designated point. Many such records are assigned the same indicative co-ordinates such that one point on a map may relate to several old records that were supplied with very little locational information.

4.1.2 Prior surveys within each Growth Area

There is no central or local registry of surveys and survey effort for threatened biota, and a large proportion of survey reports are not made public or only made public when lodged with a planning consent authority. This makes it extremely difficult, if not impossible to compile a list of surveys, methods and findings across the study area.

The OEH Authorised Officer for *P. nutans* was contacted in this regard. He advised that he does not hold a record of this information but did note some relevant results of a recent survey on public land (records now in BioNet) and referred me to the manager of threatened biota matters in the Greater Sydney OEH office for further assistance. She committed to providing the relevant information by consulting key staff. I was included in the associated emails. No additional information about this species was provided.

I separately became aware of some earlier surveys of threatened flora that OEH had commissioned for areas of NPWS estate near the GPECGA. With approval from the NPWS, the lead ecologist who undertook those surveys provided information about his work, which entailed targeted searches for *P. nutans* and the provision of a very brief report. The associated records were confirmed to have been lodged in BioNet.

Whilst seeking to obtain access to properties for fieldwork, DPE located and provided three ecological assessments relating to project proposals in the locality of Kemps Creek, north of Elizabeth Drive, within the WSAGA. These revealed that two consultants involved at one site has misidentified the PCT and TEC being assessed and had not detected all relevant threatened plant species. Those assessments did not find *P. nutans* on the site, but it was later detected during fieldwork for this Report. The third assessment relates to an adjoining development project that also reported that no threatened flora species were present. Part of that site was observed through a wire fence during fieldwork for this Report, and was seen to support a threatened *Hibbertia* species, with a very high likelihood that several other threatened plant species are present.

4.2 Summary of survey work undertaken for the biocertification assessment

4.2.1 Vegetation mapping

Vegetation mapping of the Cumberland Subregion was completed in stages by OEH in 2013 and 2016. These two vegetation layers have been used as the base to compile an updated vegetation community layer for each of the Growth Areas. This updated work has been completed by Biosis under contract to DPE. The mapping update includes checking plant community types and confirming the accuracy of boundaries to account for clearing or regrowth that may have occurred since the original mapping was completed. Field verification of the mapping was undertaken by Biosis and Ecoplanning, both of whom undertook vegetation surveys where access was permitted.

Vegetation in the Growth Areas was mapped and assessed based on five vegetation condition classes:

- Intact;
- Non-offsettable Grassland;
- Offsettable Grassland;
- Scattered Trees;
- Thinned.

4.2.2 Field survey effort

The information in section 4.2.2 has been provided by DPE but has been edited here to only deal with threatened flora where feasible. Further details are provided separately by DPE:

An initial 726 letters were sent to landholders within the Wilton and Greater Macarthur Growth Areas in late 2017 with a second letter following in March 2018. To increase the response rate, Biosis commenced targeted door-knocking in May 2018. From this, just under 20% of landholders within these Growth Areas allowed access to their property. However, this included access to large parcels of land owned by major developers, which allowed a reasonable amount of access, particularly for the Wilton Growth Area.

Floristic plot data collected:

- Wilton (86 plots across 6 PCTs)
- Greater Macarthur (82 plots across 9 PCTs)

Approximately 150 of the plots required to meet BAM requirements were obtained by supplementing Biometric plots from various recent assessments. This involved locating the previous plots and collecting additional data on stem classes, number of large trees, and litter cover to meet BAM requirements. The ecologists had no trouble locating the original survey sites and found that the additional data was quick and easy to collect (approximately 30 minutes per site).

The remaining plots in Wilton and Greater Macarthur, and all of the plots in Western Sydney Aerotropolis and Greater Penrith to Eastern Creek consisted of new plots surveyed for this project. All plots were sampled according to the methods prescribed by the BAM Manual (OEH 2017). This includes collecting information on species cover and abundance from 20 x 20 m or equivalent configuration plots within each vegetation zone.

A total of 432 letters were sent to landholders across the Western Sydney Aerotropolis Growth Area between November 2017 and August 2018 with 84 landholders responding positively to provide access. A further seven properties were accessed after doorknocking resulting in a response rate of 21%.

A small number of targeted letters were sent to landholders in the Greater Penrith to Eastern Creek Growth Area from November 2017. However, most letters (more than 1500) were sent in August 2018, which included many urban and small acreage landholders. From this, 177 landholders provided access to their properties and an additional three landholders provided permission via doorknocking (12% response rate). Not all of these properties were surveyed as some did not support vegetation patches of interest. In addition, the Open Spaces Team at Penrith Council facilitated access to 64 lots owned by Council.

Floristic plot data collected:

- Western Sydney Aerotropolis (53 plots across 6 PCTs)
- Greater Penrith to Eastern Creek (26 plots across 7 PCTs)

Targeted survey for threatened species

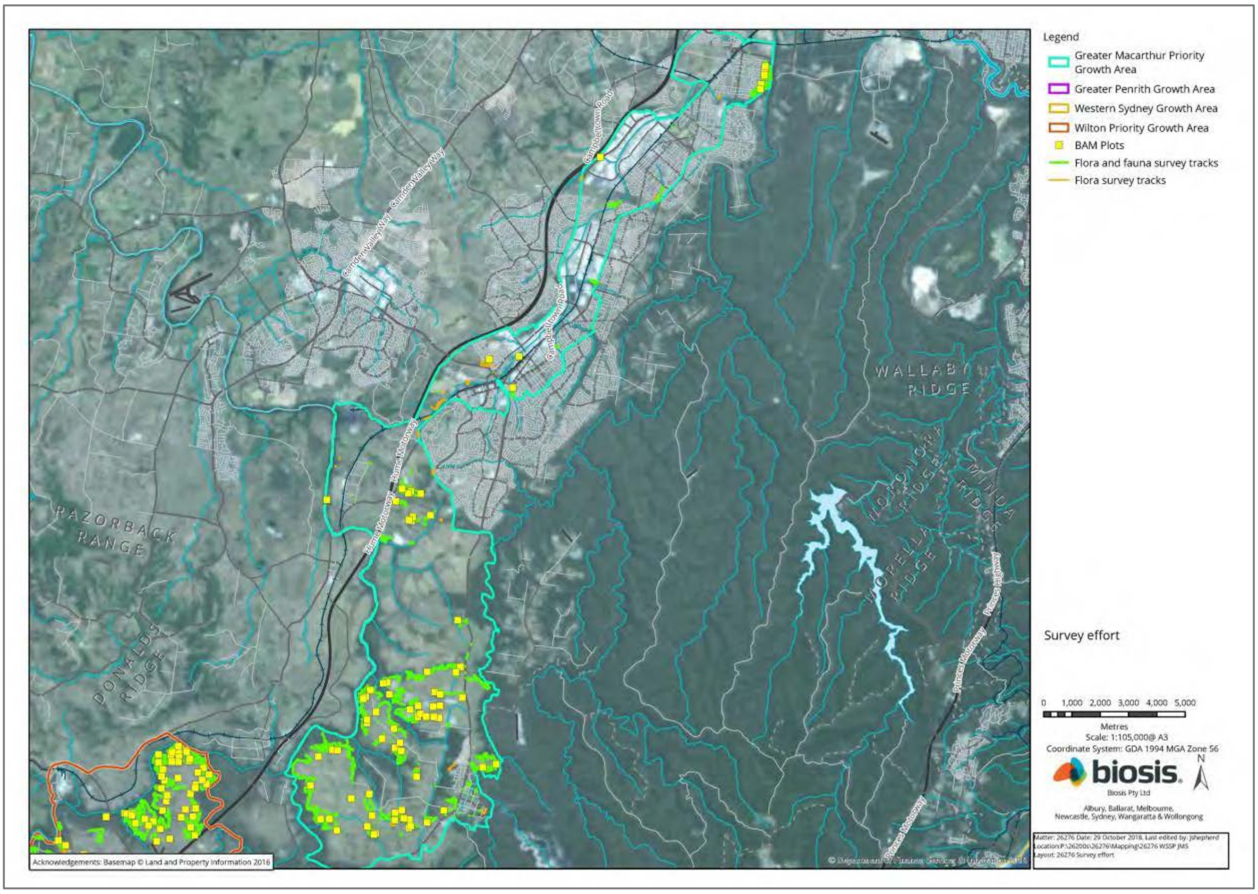
Targeted survey for threatened plant species has been conducted on lands where access has been granted. Vegetation transects and random meanders for threatened flora was conducted by Ecoplanning and Biosis in accessible areas proposed for certification, with particular attention to areas of likely habitat. The survey has included effort through each PCT and vegetation zone and has extended into suitable habitat adjacent to the edge of the future urban area where potential indirect impacts to high quality habitat may occur (up to ~50m).

Likely habitat for most threatened flora species comprised areas of lower disturbance. This includes areas with a predominantly native understorey (with or without a canopy), the base of scattered trees in paddocks, paddocks with an apparent low grazing pressure, and known topographic/habitat preferences for certain flora.

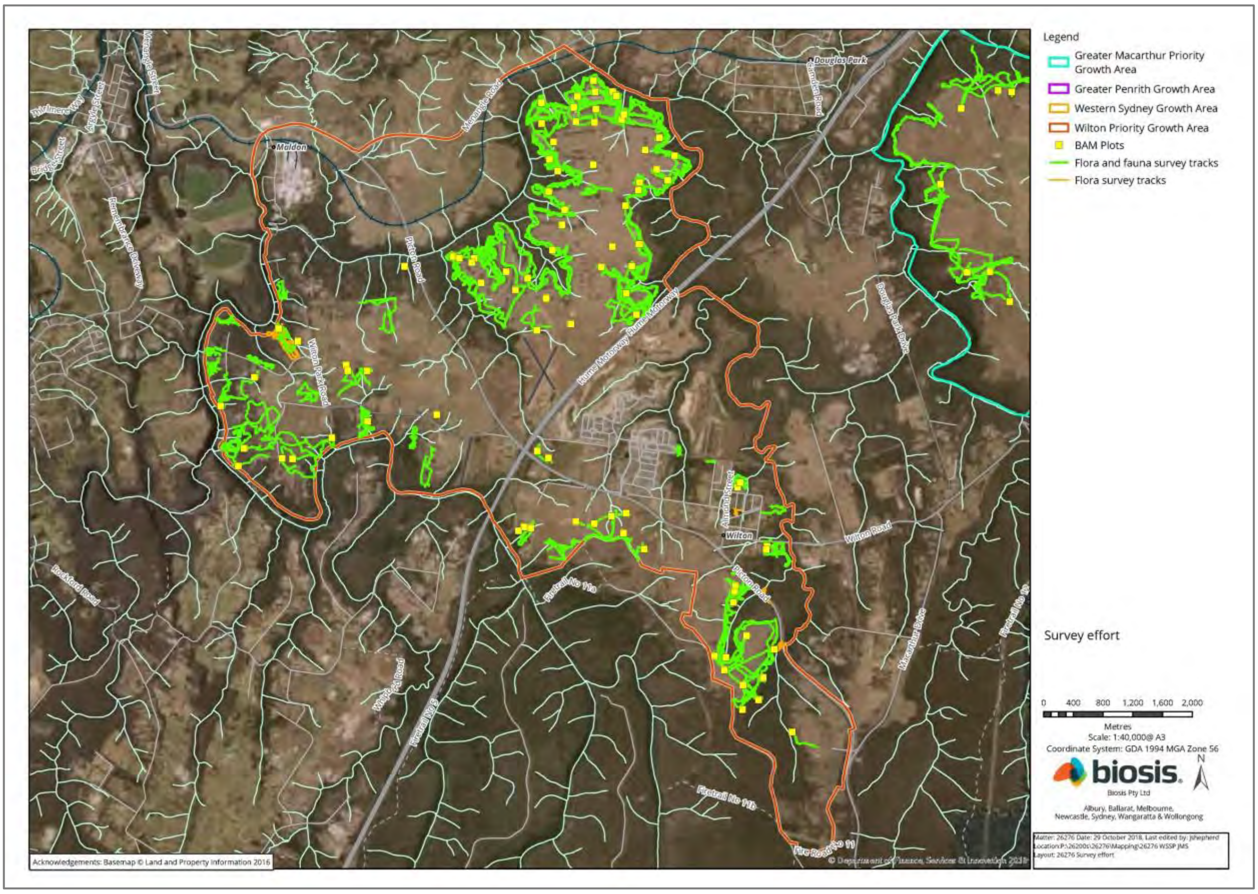
Table 8. Survey effort for threatened plant species *and* fauna habitat by PCT

PCT No.	Area of PCT in Growth Area (ha)	Area of PCT in urban zone (ha)	Field survey area (ha)	Percent of PCT surveyed within Growth Area (%)	Percent of PCT surveyed relative to urban zone (%)
724	191.3	57.0	12.1	6.3%	21.2%
725	167.4	51.4	6.9	4.1%	13.4%
781	68.9	5.6	0.9	1.4%	16.8%
830	21.6	0.8	1.7	7.8%	206.5%
835	1175.8	287.3	30.5	2.6%	10.6%
849	3078.3	637.6	125.0	4.1%	19.6%
850	522.9	294.3	36.1	6.9%	12.3%
883	7.4	0.0	0.5	6.8%	
1081	74.2	0.0	0.2	0.3%	
1105	138.6	0.0	0.0	0.0%	
1181	780.7	0.2	39.6	5.1%	19794.4%
1292	39.8	0.0	0.3	0.7%	
1395	3326.6	486.9	483.4	14.5%	99.3%
1800	232.6	20.2	7.3	3.1%	36.2%
TOTAL	**9826.1**	**1841.3**	**744.5**	**7.6%**	**40.4%**

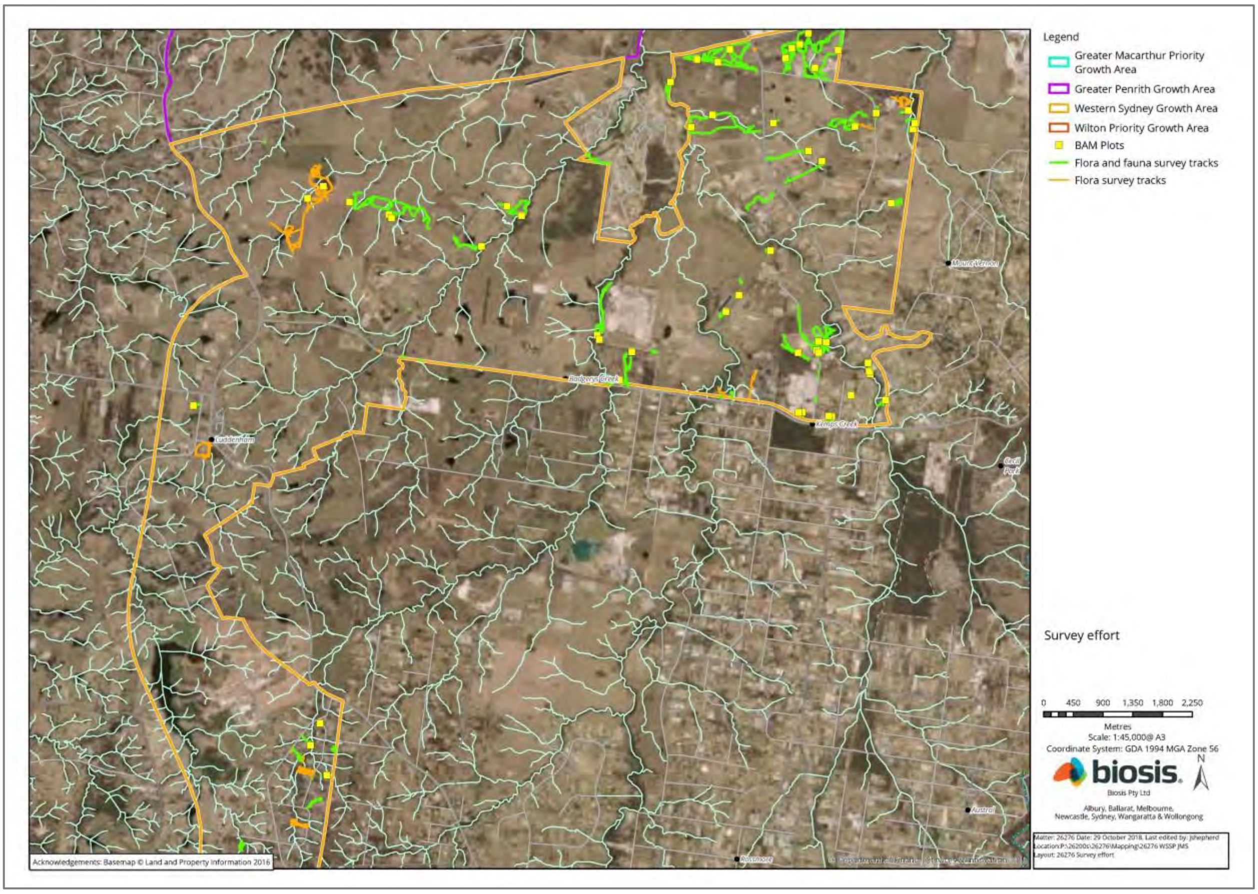
Field survey effort was not confined to the urban zone. Surveys occurred into nearby vegetation zoned for conservation. The urban zone has been revised over time and some areas where survey had already occurred were later removed. For these reasons, comparison of the survey area to the urban zone is indicative only. Survey effort has been calculated using a 20-metre buffer either side of GPS survey tracks. For the purposes of this analysis, the urban zone includes land zoned for future urban development plus transport corridors within the growth areas. It does not include any transport corridors outside the growth areas.



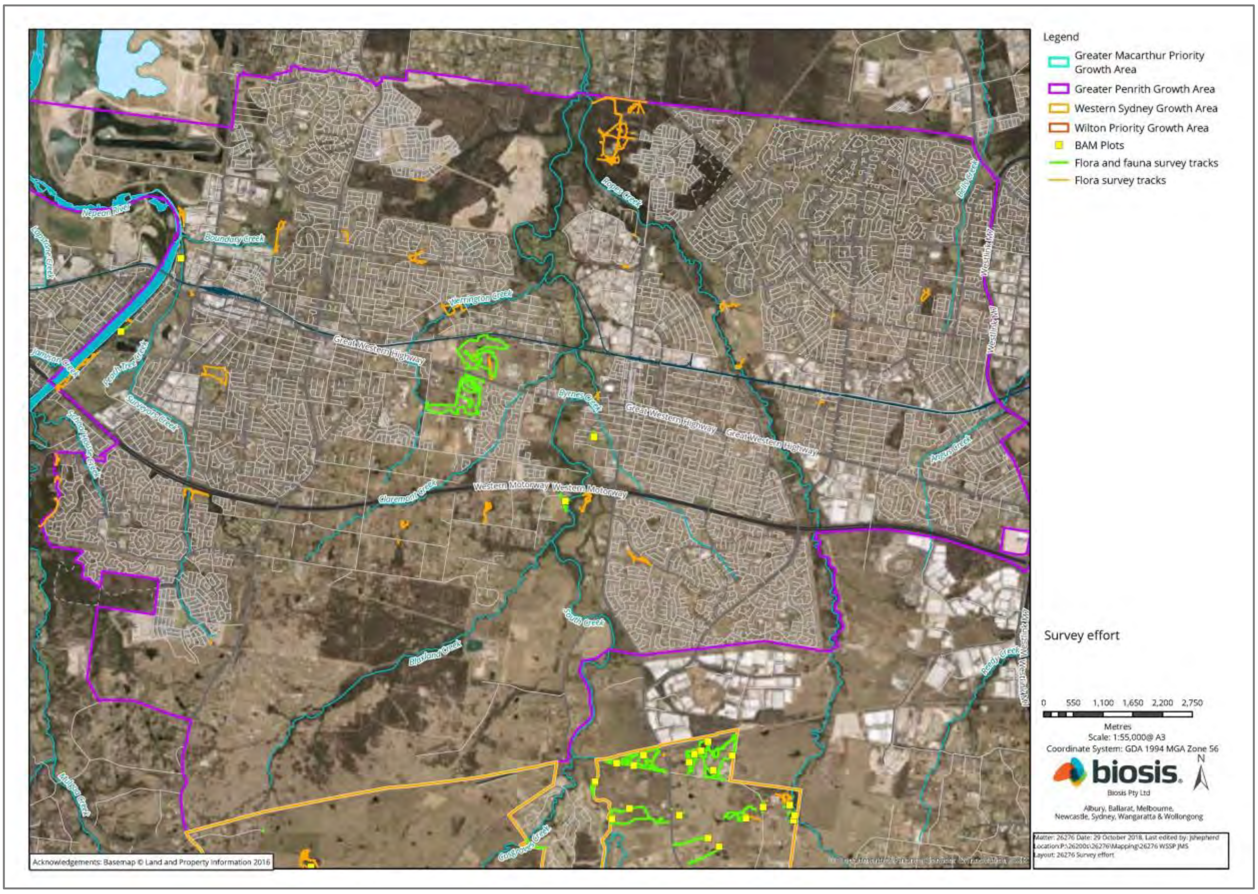
Map 4. GMGA survey effort (Biosis & Ecoplanning)



Map 5. WGA survey effort (Biosis and Ecoplanning)



Map 6. WSAGA ('Western Sydney') survey effort (Biosis and Ecoplanning)



Map 7. GPECGA survey effort (Biosis and Ecoplanning)

4.2.3 Survey constraints –timing / site conditions

As noted earlier, severe drought affected all of the study areas for some or all of the survey period. The Wilton and Greater Macarthur GAs were only surveyed during drought, whereas the Greater Penrith to Eastern Creek and the Aerotropolis GAs were surveyed both during intense drought and the subsequently slightly wetter conditions that followed in the Spring of 2018. Whilst wetter, drought remained present, and fellow Expert, Robert Miller, reported that vegetation was evidently drought-affected across all of the Growth Areas into November.

Drought, combined with increased intensity and extent of total grazing pressure, meant that affected surveys are likely to have under-recorded the target species compared to normal conditions. Whilst drought alone is unlikely to cause *P. nutans* to die back to rootstock or die and only remain as seedbank, when combined with increased herbivory due to drought, this is a far more likely outcome.

Irrespective of drought, surveys for this species are constrained by consideration of fire ecology, in that this species can be suppressed and even rendered apparently extinct at a site if the area has not been burnt for many years. Prolonged absence of fire is a constraint in some of the surveyed areas. Conversely, the species could be undetectable or not readily distinguished and identified in areas burnt recently. Areas burnt too often may also see the species suppressed or even eliminated. This is a factor in some of the survey sites closer to urban areas where a mix of hazard reduction burning and arson occur.

4.2.4 Survey constraint – surveys undertaken by generalists / non-experts

Whilst *P. nutans* is not regarded as a cryptic species, juveniles are small and infertile such that they could be missed, even by expert observers. It is more likely to be present but not recorded when surveyed by personnel not very familiar with the species and its ecology, particularly in terms of micro-habitat features. As an example, at least one young *Persoonia nutans* plant that was detected by fellow botanist, Robert Miller during survey for this Report had not been detected by consultants working for DPE, and who had recently been on that site.

Even when the prescribed OEH survey methods are used, a combination of site-based constraints, the species' ecology (e.g. dies back to seedbank without suitable disturbance), and a lack of familiarity with this species creates a situation where it is likely that it can present in plant form, but not recorded, or present only as seedbank, but not considered present because no plants were seen. *P. nutans* is one of several threatened plant species that should not be treated as absent, simply because it was not observed in plant form. If suitable habitat occurs, the species should be considered present unless there are clear reasons to rule otherwise. That approach is taken in this Report in relation to the designation of 'species polygons' (i.e. maps of where the plant is known or likely to occur).

4.3 Surveys completed specifically for this Report

I undertook a very brief survey of potential habitat for *P. nutans*, *A. bynoeana* and *A. pubescens* in the locality of Kemps Creek in mid-November 2018. Fellow botanist, Robert Miller was also present to survey for his target species. He examined some sites that I did not. He is very familiar with *P. nutans* and did not report its presence other than where he detected it and I subsequently reported it to the north of the previously documented occurrences.

The main remnant habitat in this locality is just to the south of the WSAGA but was checked by Miller for reference purposes (i.e. is the plant still present, is it still detectable during drought, what condition is the habitat in, etc.). That remnant was seen to be largely unmanaged and degrading due to several threats, and it is feasible that the species is now restricted to seed bank at that location, though it could be present on disturbance margins that were not traversed.

Relatively little potential habitat remains for this species in the WSAGA, and whilst little of this was available to be surveyed by me or by consultants engaged by DPE, all such habitat has been excluded from the proposed urban footprint.

Map 8. GPS track logs (purple lines)

I did not survey for any of my target species in the GPECGA because there is very little known and potential habitat for it there, and most of what remains is either reserved, or proposed for reservation by OEH. Surveying such areas would have added little or no information. Robert Miller did detect three new records of *P. nutans* in that area, one of which apparently duplicates an existing record. These were useful additions but do not alter my understanding of the species' ecology or distribution, and all are close to known occurrences. DPE offered access to a large area of remnant bushland in this Growth Area, but it is not mapped as suitable habitat for any of the species that I am addressing in Expert Reports, so I did not take up that offer.

I did not survey the WGA, as the species is not known from or likely to occur there.

I did not survey the GMGA, as only one small remnant of potential habitat exists there, and it was examined on my behalf by a Campbelltown Council officer familiar with the two relevant target species. A detailed survey was not undertaken and was not warranted given the nature of the habitat (highly modified and degraded, with much of it having a long history of being mown). Neither *P. nutans* or *Acacia bynoeana* was reported, but both were unlikely to be observable due to site conditions, though they may remain as seedbank. That habitat is on Council-managed parkland outside DPE's proposed urban footprint, so will not be biocertified. Having been alerted to the presence of a Threatened Ecological Community and potential habitat for these two threatened plant species, Council has recently commenced preliminary conservation work at this site.

4.4 Assessment of species' presence

4.4.1 Greater Macarthur Growth Area

The species is not known to be present in this Growth Area but may occur in or near four small patches of PCT 883 in Macquarie Fields, all of which is outside the proposed urban footprint. Other low-probability potential habitat occurs in the form of PCTs 1395 and 1081 north of Narellan Road. 1081 only occurs at one site in urban bushland associated with Smiths Creek in Leumeah. 1395 is more common but appears to be restricted primarily to generally small, often linear and likely degraded urban remnants from Glenfield, through Macquarie Fields, Ingleburn to Minto. It is unlikely to occur within the majority of this Growth Area because it was never suitable habitat or has been too heavily modified.

4.2.2 Wilton Growth Area

The species is not known nor likely to be present in this Growth Area due to it being outside the species' known geographic range by at least 20 km. The closely related *P. bargoensis* occurs in this Growth Area instead. Those species are separated by 40 km (Weston & Johnson, 1991). As of 2018, BioNet records for these species are separated by 24-28 km depending on the spatial accuracy of a record from Appin.

4.2.3 Greater Penrith to Eastern Creek Growth Area

The species is present in this Growth Area, but both known and likely habitat comprise a relatively small area in the central north, primarily with the gazetted or proposed sections of Wianamatta Regional Park. However, the proposed western addition appears to be at risk from further clearing and fragmentation to accommodate a large transport corridor. Potential and known habitat also occurs as patches along or near the M4 Motorway, roughly in the centre of this Area and to the east. The majority of this Growth Area was never suitable habitat for this species.

4.2.4 Western Sydney Aerotropolis Growth Area

The species is now known in this Growth Area from a single young plant, added during surveys associated with this Report. The extent of known and potential habitat is limited to a few patches of remnant vegetation in the localities of Kemps Creek and Badgerys Creek. Most of the WSAGA was always unsuitable habitat for this species based on geology, soil and plant community associations.

4.5 Assessment of suitable habitat for *Persoonia nutans*

4.5.1 Description and relative significance of potential habitat

As per the findings presented earlier in Table 3, combined with expert knowledge, the following PCTs are regarded as potential habitat for *P. nutans*. Not all of these PCTS are present in all Growth Areas, and not all occurrences or parts of these communities are likely to support the species in plant or seedbank forms. Wetter and sometimes more thickly vegetated areas associated with drainage lines are unlikely habitat, as this species prefers drier, more open conditions. Riparian buffer exclusions will be used as a component of the 'species polygons' discussed later. All vegetation condition classes are included except Derived Native Grassland:

Table 9. PCTs known or likely to be habitat for *P. nutans*

PCT	PCT Name	Relative significance
724	Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain	Moderate
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain	Moderate
883	Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain	Very High
1081	Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain	Low
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain	Very Low

The following sections describe the relative habitat value and local occurrences of each PCT mapped in each Growth Area.

Greater Macarthur Growth Area

The vegetation mapping provided for use in the project indicates that there is **1903.97 ha** of potential habitat for this species in this Growth Area based only on the extent of the relevant PCT.

Table 10. Potential habitat in the GMGA

PCT	Distribution	Area (ha)	Relative habitat value of local occurrences
883	Four very small polygons in low condition at Macquarie Fields.	0.91	Very low to low. The species may regenerate here if issues of mowing, absence of fire, and intense weed invasion are remedied. Any resultant population would be isolated from core habitat and surrounded by unsympathetic land uses. However, there is some scope to improve the quality and quantity of habitat on this public land.
1081	Restricted to one remnant urban bushland surrounding Smiths Creek in Leumeah.	7.52	Low, as this PCT is only associated with this species at the atypical but nearby Simmos Beach population. The proximity of housing likely makes it difficult to burn this site with sufficient intensity to support this species in the long-term.
1395	Several remnants in the north of the Area from Glenfield to Minto. Other areas to the south are outside the species' accepted range.	1895.54	Very Low, as this PCT is also only associated with the species at an outlying site in the far north of its range. There are no records of the species from this PCT in or near any of the Growth Areas.

Wilton Growth Area

The species is not known or likely to occur in this Growth Area, which is outside its known or likely distribution, even though at least one of the associated PCTs is present here. That niche is occupied by the closely related *P. bargoensis* in this Area.

Greater Penrith to Eastern Creek Growth Area

The vegetation mapping provided for use in the project indicates that there is **272.35 ha** of potential habitat for this species in this Growth Area based only on the extent of the relevant PCTs. There was always very limited scope for the species to occur in this Area, and much less so as a result of historic and on-going land clearing.

Table 11. Potential habitat in the GPECGA

PCT	Distribution	Relative habitat value of local occurrences
724	Present primarily in the far central north but extending south in association with Eastern Creek, with very small patches near the M4 Motorway.	Moderate to High, and most of the spatially accurate records in this Growth Area are associated with this PCT.
725	Mapped only in the far north as small to medium patches that are largely within the gazetted and proposed parts of Wianamatta Regional Park	Moderate, though very small patches in urban areas are likely to be less viable.
883	Mapped to a very small extent only in the far central north. Only 1 polygon in Biosis map, and entirely within Wianamatta Regional Park's eastern portion.	Very High as a PCT, and there are records of the species nearby.

Western Sydney Aerotropolis Growth Area

The vegetation mapping provided for use in the project indicates that there is **92.80 ha** of potential habitat for this species in this Growth Area based only on the extent of the relevant PCT. Only a small area of habitat ever existed in this Area, and even less remains due to historic and on-going land clearing.

Table 12. Potential habitat in the WSAGA

PCT	Distribution	Relative habitat value of local occurrences
724	Present as several patches in the localities of Kemps and Badgerys Creeks, mainly surrounded by pastoral or industrial land use.	Moderate to High. Some areas have been degraded by overstocking of grazing livestock. Others have been cleared or largely-so.
725	Present as several small patches in the localities of Kemps and Badgerys Creeks, mainly surrounded by pastoral or industrial land use.	Moderate, though very small patches adjoining unsympathetic land uses are likely to be less viable. All remnants in this area appear to be degraded by earlier clearing, grazing and weeds.
883	No longer present in the revised PCT map but habitat intermediate with 725 is present.	Very High, if this PCT or similar vegetation is present in this Growth Area. Recent record nearby.

4.5.2 Species habitat polygons

Species habitat polygons generated by this report relate to the extent of potential habitat that is proposed to be cleared for urbanisation or related purposes, such as transport corridors. These habitat polygons and associated calculations were generated to inform biodiversity offset requirements. The data presented in this section does not deal with species habitat outside proposed urban zones as those areas are treated as conservation zones or are excluded from urban and associated transport zones for a range of reasons. For this species, species polygons (proposed clearing of habitat) are only recognised in Greater Penrith to Eastern Creek and Western Sydney Aerotropolis Growth Areas because the species is not predicted to occur in the Wilton Growth Area, and potential habitat in the Greater Macarthur Growth Area is outside the scope of proposed urban impacts.

The habitat polygons include all relevant condition classes of relevant PCTs as identified in this Report. In this case, all condition classes are included except Derived Native Grassland.

Graded riparian exclusion buffers were used in recognition that *P. nutans* does not occur in riparian vegetation or close to watercourses. The buffer distances used here increase with the mapped Strahler stream order as shown in Table 13. The accuracy of the buffers is limited by available data, including the mapped location of streams. The buffer is applied either side of the mapped stream centreline. Note that these riparian buffer distances are a different concept and serve a different purpose to those applied by DPE for the purposes of protecting streamside vegetation and watercourses in its planning within the Growth Areas.

Table 13. Stream exclusion buffers

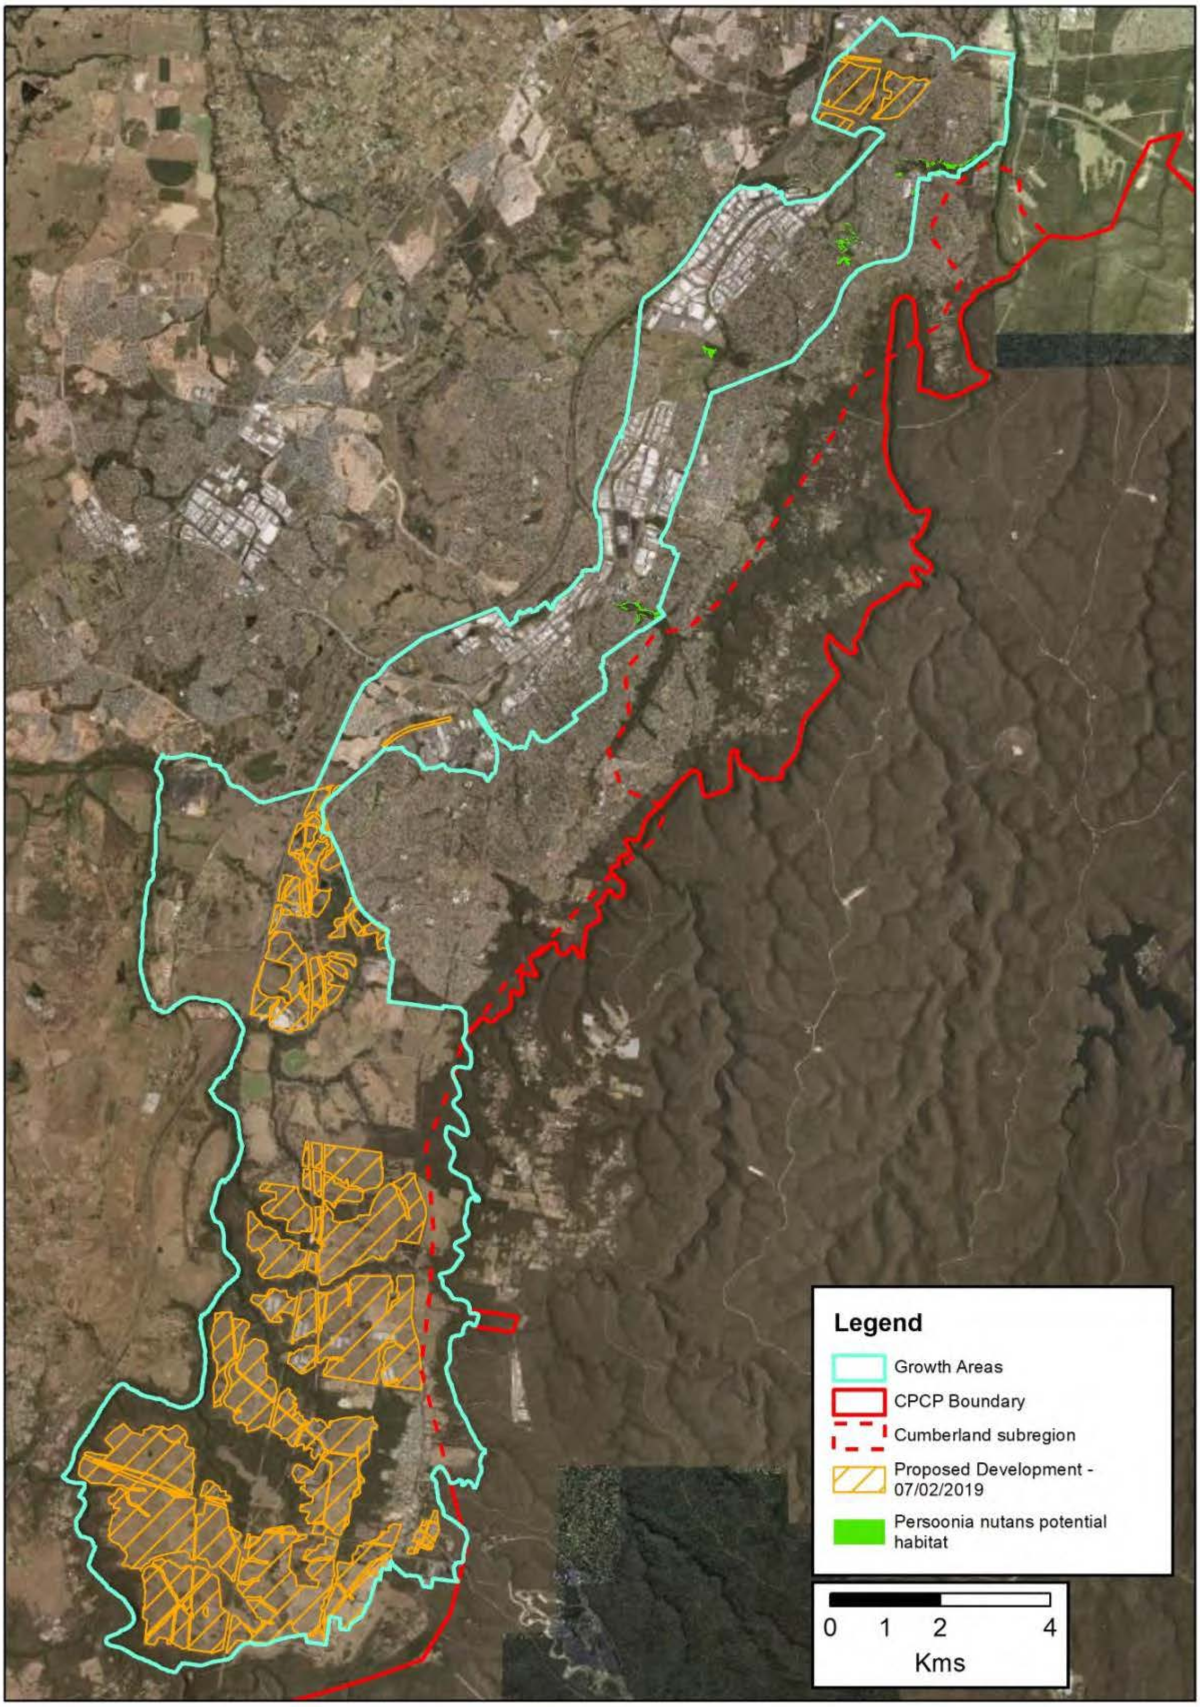
Stream order	Buffer distance (m)
1	5
2	10
3	20
4	30
5	40
6	50
7	70

Species habitat polygons in the form of GIS shape files were provided to the Biodiversity and Sustainability Branch of DPE in November 2018. The analysis of these shape files is presented in Table 14. These figures are based on precautionarily modelled *potential* habitat, and do not necessarily equate with *actual* habitat, nor do they provide any information of potential population sizes or population viability. It is unlikely that a large percentage of the potential habitat identified in this Report would actually support *P. nutans* because this species is naturally rare and patchily distributed, even though it can be locally abundant in favourable conditions.

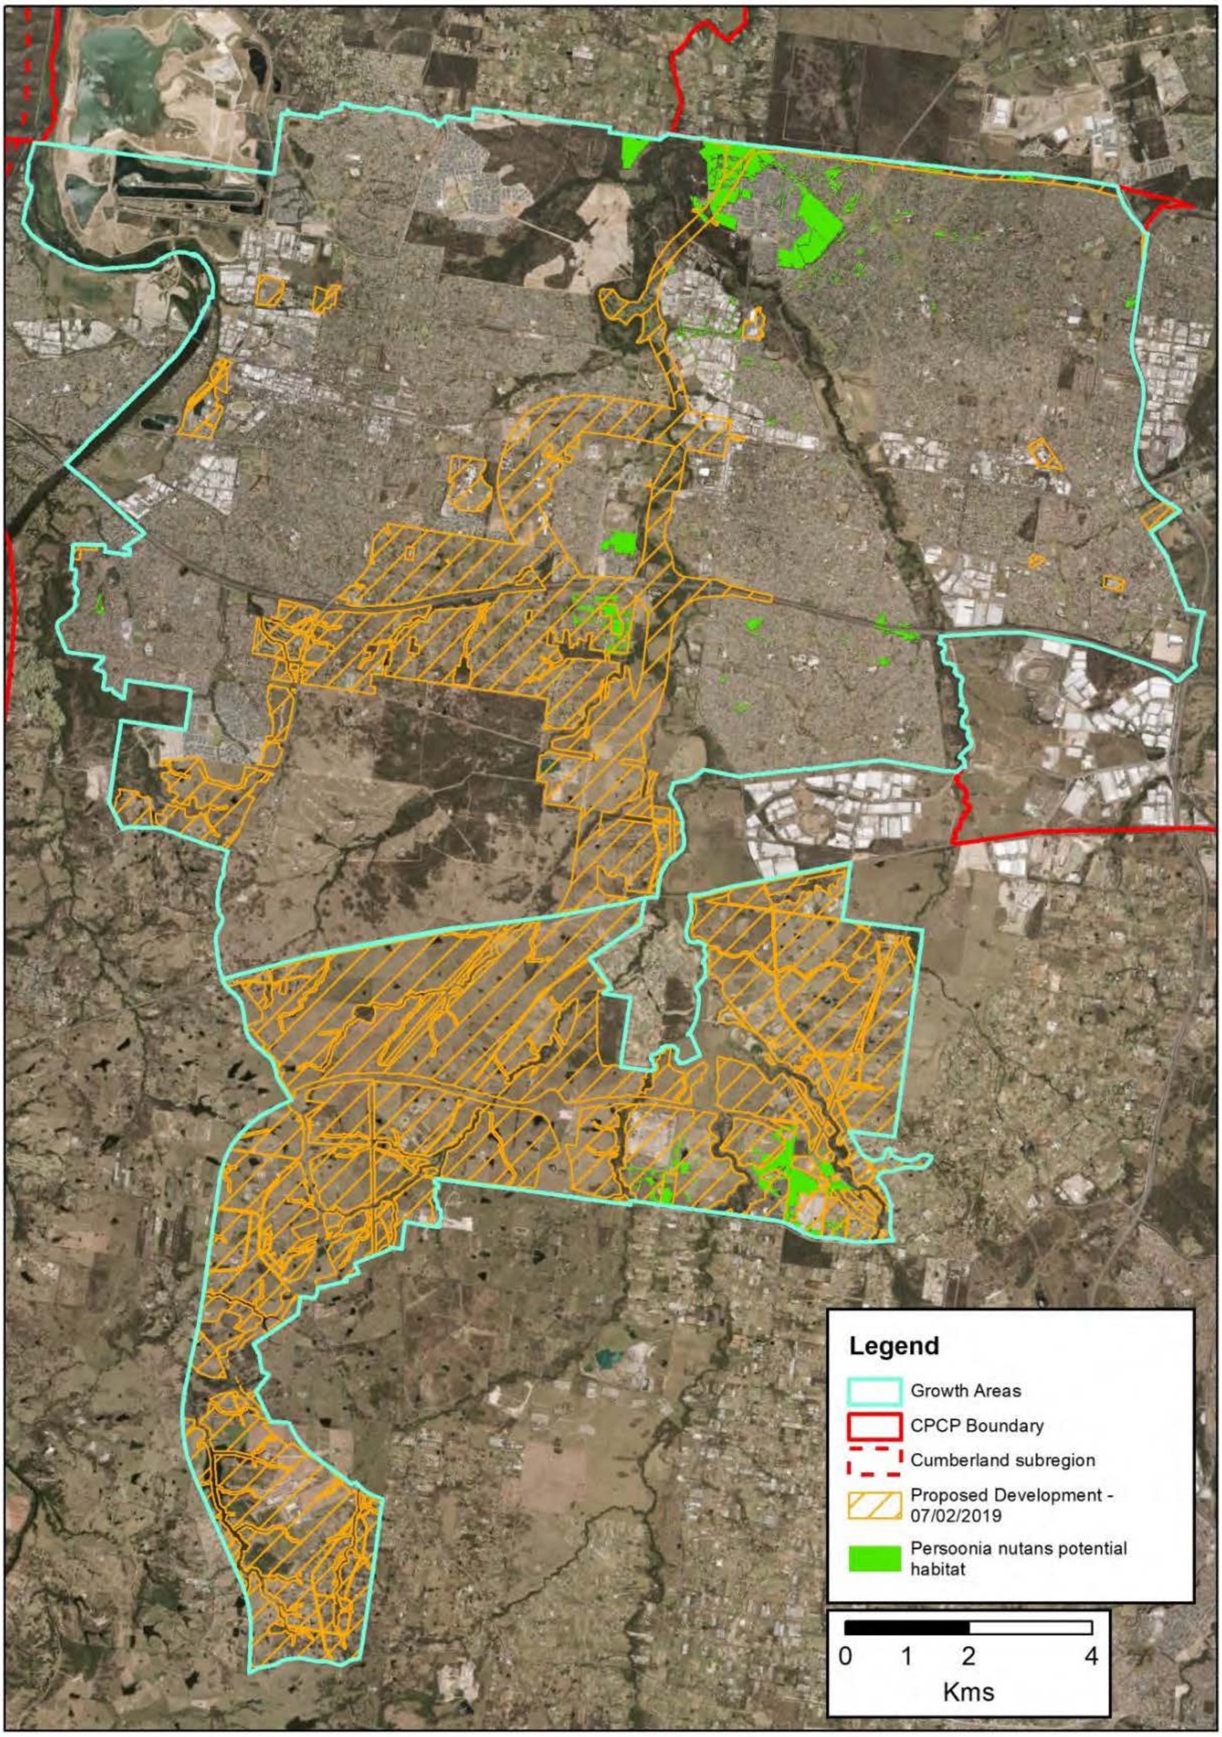
Table 14. Total of potential habitat and proposed removal of potential habitat

Growth Area	Area of potential habitat (ha)	Area of potential habitat removal (ha)	% area of potential habitat removal by GA
Greater Penrith to Eastern Creek	272.6	9.9	3.6
Western Sydney Aerotropolis	92.8	34.0	36.6
Greater Macarthur	23.6	0.0	0.00
Transport corridors **(all GAs)**	-	49.8	12.8
TOTAL	**389.0**	**93.7**	**24.1**

Map 9 Greater Macarthur - Potential habitat and proposed urban/transport habitat removal



Map 10 Greater Penrith & Eastern Creek plus Western Sydney Aerotropolis
– potential habitat and proposed urban/transport habitat removal



5. Summary and conclusion

Within the four Growth Areas, *Persoonia nutans* is currently only known from the Western Sydney Aerotropolis and Greater Penrith to Eastern Creek Growth Areas, with all currently known records outside the proposed urban areas, including transport corridors. Potential habitat for this species exists in all but the Wilton Growth Area, based on the species' known association with specified Plant Community Types, with other threatened plant species, and with Soil Landscapes, geologies, climate, etc. The most likely occurrences are within a subset of the Castlereagh Forests & Woodlands on Paleogene-Neogene alluvium. Atypical outlying populations are possible in habitat associated with the shale sandstone transition and the Mittagong Formation within the northern section of the Greater Macarthur Growth Area.

Based on current information, the proposed urban footprint and associated transport corridors of the three relevant Growth Areas would destroy 93.7 hectares of potential habitat for *P. nutans*. This equates to 24.1% of the area of potential habitat identified in those three Growth Areas. The actual extent of conflict between habitat for the species and proposed clearing for urbanisation is likely to be smaller as the species is naturally rare and patchily distributed. Not all of the area proposed for removal is of equal value as potential habitat, and different PCTs and condition classes have different probabilities of supporting *P. nutans*.

The greatest area of conflict between proposed urbanisation and the best quality / highest probability of occurrence potential habitat for this species is in the form of a proposed transport corridor through the western (apparently ungazetted) portion of Wianamatta Regional Park in the Greater Penrith to Eastern Creek Growth Area. Other significant conflicts arise in the form of the 'Urban Development Management Zone' of that Growth Area and to a greater extent, in the Western Sydney Aerotropolis Growth Area. Most such conflicts entail removal of vegetation condition classes below the Intact class. There is no conflict between potential habitat and proposed urbanisation in the Greater Macarthur Growth Area.

Because *P. nutans* is relatively tolerant, arguably dependent on some types of disturbance, and that it can persist in the soil seedbank, it may occur in areas that might generally be disregarded as potential habitat, and that may not be mapped as native vegetation. It is likely that highly modified sites that might support the species in some form are of relatively low significance for it in the context of the larger areas of more intact potential and known habitat that are excluded from urbanisation and associated clearing. It is also feasible that disturbance associated with urbanisation, particularly the creation of bushfire Asset Protection Zones (APZs) between bushland conservation areas and housing, could advantage this species, especially where the habitat has not burnt for many years. Thinning of the shrub layer by fire or mechanical means could favour the species, as may soil disturbance associated with fire trail construction. More frequent, moderate intensity burning of bushland that represents known or likely habitat for this species, may, within limits, also advantage it compared to low frequency and/or very cool burning.

The positioning of the bushland/urban interface and associated infrastructure such as APZs should have regard to this species' habitat and ecology, and appropriate buffers and other strategies are required to prevent direct and indirect harm to this species as a result of the urbanisation of adjoining lands. For example, potential habitat should not be compromised by the placement of housing nearby as might prevent that habitat being managed for conservation, especially in terms of bushfire risk management. DPE has informed me that the intention is for APZs to be accommodated within the proposed urban footprint, not in the non-biocertified bushland areas that may adjoin it.

The absence of records of this species from areas of potential habitat does not mean it could not be present because: not all areas have been surveyed historically or recently; all surveys have a range of limitations; not all discoveries of threatened species are disclosed or accurately mapped; and large areas of potential habitat are highly likely to have fire regimes that do not favour this species, meaning it may currently occur in very low numbers in dense and inaccessible habitat, or as seedbank, yet could appear in substantial numbers after an appropriate fire or equivalent disturbance. These factors have been considered in the preparation potential habitat maps and the associated generation of species habitat polygons that will inform DPE in relation to biodiversity offsetting obligations.

6. Information used in the assessment

6.1 DP&E or OEH resources

- BioNet data (internal access provided under license for use in this Expert Report and associated dataset cleaning for the purposes of species habitat modelling to meet EPBC Act requirements)
- Atlas of Living Australia on-line (partial use to check for records not in BioNet)
- EMU data (NSW Herbarium specimen database, provided by OEH)
- OEH on-line threatened species profile
- OEH Threatened Species Data Collection on-line
- OEH BioNet Vegetation Classification Database (previously known as VIS)
- EPBC Act Listing/Conservation Advice
- OEH PCT (vegetation) maps for Sydney Metropolitan and Cumberland Plain
- Field data and associated analyses from Biosis and Ecoplanning (consultancies engaged by DPE)
- GIS layers and maps provided by DPE and its contractors

7. Acknowledgements

I acknowledge the contributions of DPE staff, particularly Dayle Green, Greg Steenbeeke and Christian Marando (GIS), and DPE contractor Darren James (GIS) in the preparation and refinement of this document and associated maps. My contractor, Rhys Grogan, also assisted with GIS output in the form of drafts of the species potential habitat polygons. OEH staff assisted with some aspects of data availability and with the processing of many amendments to BioNet records.

Consultant botanist, Robert Miller assisted with fieldwork at Kemps Creek, and provided information about field observations associated with searches for his target species and with opportunistic sitings of my target species. Consultant ecologist, Paul Burcher of AES, kindly provided access to his targeted survey data and associated report to OEH / NPWS; and provided images of the species taken by Ben Ford. Botanist and bush regenerator, Colin Gibson, provided important information about the history and current status of the Villawood population, and the exact location of associated plants. The latter enabled refinement of the associated BioNet data. Consultant ecologist, Danny Wotherspoon provided information about the species' northwestern outlier, which also allowed the NSW Herbarium records and BioNet entries to be spatially corrected.

8. Statement of professional independence

Whilst I was engaged and funded by DPE to prepare this Expert Report, and a series of draft reports and maps were reviewed by DPE staff, I was not coerced by DPE to amend my work in any manner that I did not otherwise agree with. I believe that I had appropriate professional independence in the preparation of this document and associated maps.

I declare that I do not have any personal or commercial conflict of interest in the preparation of this Report. I do not own real estate or businesses with property in the Growth Areas, nor do I have other active clients with real estate or associated commercial interests in the Growth Areas.

9. Appendix 1. Author's *Curriculum Vitae*

Dr Steven Douglas (BSc., MEnv. Plan., PhD.)

I have over twenty years of experience as an ecologist and environmental planner, primarily in New South Wales, with some experience in the ACT, Victoria and South Australia. I have worked for all levels of government, for environmentalist non-government organisations (NGOs), and for a large number of private clients ranging from individuals to multinational firms, directly and as a subcontractor. I have often worked as a sole consultant but have also collaborated with other specialists and have sometimes been part of large teams involved in large-scale, even interstate projects.

I specialise in the detection, management and conservation of rare and threatened flora species and communities, and in associated ecological impact assessment and mitigation. I have qualifications and experience in a range of general and specific ecological, social, organisational and 'sustainability' fields. I have served on environment-related ministerial committees and have held other ministerial appointments in NSW, including those dealing with bushfire management. I have published in journals dealing with plant conservation, environmental law and policy, social science, and ecological ethics. Aspects of my work have been published by government, prominent NGOs, and in the popular press and other media.

This CV only contains content directly related to my botanical expertise.

Employment summary

1996 to present:

Self-employed, trading as *Ecological Surveys & Planning* (www.ecologicalsurveys.net)

Through this enterprise, I have undertaken a large number of consultancies for public and private sector clients including environmental impact assessment and mitigation; threatened biota research, profiling and management; vegetation mapping; preparing management plans for conservation estate; providing environmental planning and catchment management advice; advising on bushfire risk management; acting as an expert witness in Land & Environment Court proceedings; and developing organisational sustainability policies and practices.

July 2017 to July 2018:

Senior Ecologist, NSW Office of Environment & Heritage (NVIS, Science Division)

My work on the project below led to OEH retaining my services to research and document problems with the description, interpretation and mapping of Threatened Ecological Communities (TECs) statewide. This project provides advice to OEH, the NSW Threatened Species Scientific Committee, and through those agencies, to the Commonwealth Threatened Species Scientific Committee. It identifies technical issues with the description of TECs and their mapping, as well as wider problems of how TECs are defined. It draws on a major project undertaken by OEH for the NSW EPA and Forestry Corporation, in which TECs of the east coast and ranges were assessed and mapped for regulatory purposes on forestry estate. However, my work includes many more TECs and recent information emerging from Save Our Species project panels.

November 2015 to July 2017:

Team Leader, NSW Office of Environment & Heritage (NVIS, Science Division)

This project in Wingecarribee Shire is the first in which OEH's vegetation mapping team has worked at a very fine scale for a single local government area. The project entails auto-segmentation of digital aerial photography; supervising contract vegetation sampling; conducting strategic sampling; modelling of most vegetation communities; describing new communities; and extensive remote and on-ground map validation. I was hired partly because of my extensive familiarity with much of the vegetation of this geodiverse and biodiverse region. The role included supervision of two staff; liaison with consultants; and substantial networking with OEH and Wingecarribee Council staff. An update of vegetation classification will occur from mid 2019 onwards, and I have drafted a peer-reviewed journal article about the project that will be submitted for publication.

1995/6:

Project consultant, then Project Manager, Urban Bushland Biodiversity Survey (NPWS)

The Urban Bushland Biodiversity Survey was undertaken by the NPWS to compile comprehensive data on indigenous flora and fauna in twelve local government areas in Western Sydney. Contracted initially as a consultant to design and scope the project, I was later employed as Project Manager. Responsibilities involved an extensive literature review, preparation of a project plan and a background paper for the Survey and the overall management of the project including up to twelve staff and several consultants. The major focus was on coordinating research work, fauna and flora field surveys, and a community liaison and media campaign. Extensive flora survey work and scientific data analysis was undertaken. I provided a tour of important vegetation sites for the South Creek Catchment Management Committee. I also wrote media releases and conducted various media events including a live-to-air interview on ABC Radio National, and filming of a story in the field for the Totally Wild program.

1994:

Catchment Environment Officer (*Hawkesbury City Council*).

The project was funded by a grant from the former Hawkesbury-Nepean Catchment Management Trust and had the objective of identifying land uses on riverside properties to assess their potential to generate water pollution. The information on land use and riparian vegetation was primarily gained from aerial photo interpretation, limited land-based inspections and several water-based inspections, and was recorded in a GIS. Work site inspections, pollution control on agricultural lands, community meetings, site visits with landowners, and facilitating the formation of a Landcare group in the Sackville area.

1993/4:

Technical Officer (*Hawkesbury-Nepean Catchment Management Trust*).

Work included assisting with the preparation of a vegetation management strategy for the Trust and the outline of a revegetation strategy for South Creek. Other responsibilities involved providing scientific advice for development assessments, the preparation of hard copy and computer-based catchment maps, and advising on the implementation of revegetation projects in the catchment.

Ministerial appointments

- Appointed a member of the **National Parks & Wildlife Service Regional Advisory Committee** (South Coast) (2010-mid 2018). I opted not to reapply for this role after serving two terms. The restructure of the NPWS meant that the Committee would operate from Wollongong to the Victoria border and inland to the Tablelands. This was logistically fraught, and the role of RACs was evidently being diminished, with larger areas to manage but less meetings held.
- Appointed a member of the **NSW Sustainability Network** (2001), part of the Sustainability Advisory Council reporting to the Minister for Planning. I did not take up this position due to my relocating to Victoria.
- Nature Conservation Council representative on the former NSW **Native Vegetation Advisory Council** (1999-2001) reporting to the Minister for Land & Water Conservation under the Native Vegetation Conservation Act. I served as a member of the Regional Vegetation Planning Subcommittee, which amongst other matters, reviewed draft Regional Vegetation Management Plans and Codes of Practice for activities such as native forestry and timber plantations. I was particularly involved in reviewing and recommending amendments to the Code of Practice for plantation forestry. I resigned due to my relocating to Victoria.
- Nature Conservation Council representative on the former **Southern Catchment Management Board** (June 2000 - March 2001). I resigned due to relocating to Victoria. I expressed my dissatisfaction with the design of the catchment boards and recommended to the Minister that they be replaced with the Catchment Management Authority model used in Victoria. The Boards were later replaced with such Authorities.
- Nature Conservation Council representative on Baulkham Hills and Hornsby-Ku-ring-gai **District Bushfire Management Committees** (1995-2001).
- Australian Conservation Foundation representative on the former **Environmental Works Community Audit Committee** reporting to the Minister for Environment in relation to the Special Environment Levy imposed by the then Water Board (1993-5). I completed my term when the Committee concluded its business and dissolved upon acceptance of its final report by the Minister.

Tertiary qualifications & titles

Adjunct Research Fellow

School of Philosophical, Historical & International Studies, Monash University, 2014-16

Doctor of Philosophy

Fenner School of Environment & Society, The Australian National University, 2004-7

The research was undertaken in the transdisciplinary Human Ecology Program and covered fields such as ecological philosophy, ecotheology, environmental policy-making, policy evaluation, organisational change, and critical systemic analysis. My thesis was passed unanimously and unamended by one Australian and two USA-based professors. I was awarded a $10,000 Publication Fellowship by the Fenner School and have since published aspects of my research.

Master of Environmental Planning

Macquarie University Grad. Sch. Env., 1994-96

This course included environmental law and politics, community involvement in planning, environmental education, development approval processes, urban planning, EIA, environmental science/fieldwork and heritage management. The dissertation component involved a pioneering report on the significant flora of the Greater Cattai Region (Cattai subcatchment) in north-western Sydney and led to my being offered employment with the NSW NPWS to design and manage a biodiversity survey of western Sydney.

Bachelor of Science

Macquarie University, 1990-93

My degree majors are Resource and Environmental Management, Land Management, and Plant Biology/Ecology.

Graduate Certificate of Research Information Literacy

The Australian National University, 2004-7

This course included advanced word processing, citation management, literature gathering (including on-line literary databases and other Internet sources), on-line publishing, presentation software, and thesis production.

Professional memberships

- Founding member of the Ecological Consultants Association of New South Wales (did not renew due to my relocating to Victoria and later to the ACT).
- Member of the NSW Environmental Defenders Office (EDO) Scientific Advisory Service (continuing).

Threatened biota experience

The following threatened plant species and populations and threatened ecological communities (TECs) have been engaged with in the various forms and processes listed below. The list is not complete, and some processes are on-going. I also successfully nominated three Key Threatening Processes under the TSC Act: Bushrock Removal; Clearing of Native Vegetation; Competition from European Honey Bee.

Species / population	Work conducted
Acacia bynoeana	Fieldwork, research, successful nomination, monitoring, advice to authorities, expert witness, rediscovered lost population, documented new population near range limit, PAS2 review, SOS review panel, review and amendment of BioNet dataset. Nominated by DPE and recognised by OEH as a species expert under BC Act (Nov 2018).
A. gordonii	Fieldwork, successful nomination, advice to NPWS, PAS2 review, SOS research and monitoring program (fire ecology, BMtns NP), review and amendment of BioNet dataset.
A. prominens	Successful nomination of Endangered Population
A. pubescens	Fieldwork, contribution to Recovery Plan, confirmed disjunct southern populations, nominated population, PAS2 review, review and amendment of BioNet dataset. Nominated by DPE and recognised by OEH as a species expert under BC Act (Nov 2018).
Ancistrachne maidenii	Fieldwork, research, successful nomination, advice to NPWS, CAM review
Asterolasia elegans	Fieldwork, species profile, advice to Council and NPWS
Baloskion longipes	Research linked to *Carex klaphakei*, review of BioNet records, advice to OEH
Boronia deanei	Research, SOS review, CAM review, advice to OEH
Bossiaea oligosperma	SOS fieldwork, review of records (NW population), report to OEH, establishment of monitoring plots in Yerranderie SCA
Callistemon linearifolius	Fieldwork, research, successful nomination, advice to RMS and NPWS, PAS2 review
Callistemon megalongensis	Co-described new species, successful nominations (listing then upgrade), fieldwork, advice to Council and OEH, PAS2 review, SOS monitoring program (OEH, BMCC, on-going)
Callistemon purpurascens	Described new species, fieldwork, successful nominations, advice to Council and OEH, SOS monitoring project (2018 on-going)
Calotis glandulosa	Fieldwork (new and extended populations, Kosci NP), CAM review
Calotis pubescens	Fieldwork (new population, Kosci NP), CAM review
Carex klaphakei	SOS research project and recommendation for monitoring; resolved errors in BioNet records

Species / population	Work conducted
Commersonia prostrata	PAS2 / PKF research, fieldwork, advice to NPWS and OEH, documentation and monitoring of new and known populations for Forestry Corp, designed recovery actions for populations in Wingello and Penrose SFs
Cullen parvum	Fieldwork, located new NE population, report to NPWS
Dampiera fusca	Research, fieldwork, successful nominations, monitoring program for ACT Parks & Conservation, advice to NPWS and OEH, CAM review
Darwinia biflora	Fieldwork, research, contributor to Recovery Plan, PAS2 review, review and amendment of BioNet dataset.
Darwinia glaucophylla	Fieldwork, research, successful nomination, advice to NPWS, PAS2 review
Darwinia fascicularis ssp. *oligantha*	Fieldwork, research, successful nomination of population
Darwinia peduncularis	Research, successful nomination, CAM review
Dillwynia tenuifolia	Fieldwork, research, successful population nominations, advice to OEH
Epacris purpurascens var. *purpurascens*	Fieldwork, research, nomination, new SW range limit (Nattai NP), advice to NPWS/OEH
Eucalyptus aggregata	Research, successful nomination of species and population, fieldwork (Wingecarribee Shire) and advice to Council and OEH, CAM reviews
E. aquatica	Fieldwork, advice to Council and Forestry Corporation
E. sp. *Cattai*	Successfully argued for recognition of this entity as a new species, successful nomination, fieldwork, PAS2 review, advice to OEH, SOS project panel
E. kartzoffiana	Fieldwork, research, expert witness
E. macarthurii	Fieldwork, research, successful nominations, advice to Council and OEH
E. parvula	Fieldwork (Wadbilliga NP), CAM review
E. pulverulenta	Fieldwork (Bredbo Hills), CAM review
Galium australe	PAS2 research, recommended taxonomic review of most records in NSW based on Herbarium assessment, advice to OEH, CAM review
Grevillea juniperina ssp. *juniperina*	Fieldwork, research, advice to OEH (Colebee NR offset site)
Grevillea molyneuxii	Fieldwork, advice to OEH for CAM review
Grevillea parviflora ssp. *parviflora*	Fieldwork, research, expert witness, review and amendment of BioNet dataset.
Grevillea parviflora ssp. *supplicans*	Fieldwork, research, nomination, advice to NPWS
Grevillea raybrownii	Fieldwork, research, nomination and advice to NSWSC – listing pending
Gyrostemon thesioides	Successful nomination
Helichrysum calvertianum	Fieldwork, research, nomination, advice to NSWSC – listing pending
Hibbertia fumana	Research, minor fieldwork, expert witness
*H. incana (*syn. *superans)*	Successful nomination of population then species
H. praemorsa	ROTAP, researched, fieldwork (informal)
H. puberula ssp. *furcatula*	Fieldwork (incidental) documenting new occurrence, advice to OEH/NPWS
H. puberula ssp. *puberula*	Research, minor fieldwork with R. Miller, expert witness
Homoranthus binghiensis	CAM review (recommended changing to CE)
Keraudrenia corrolata var. *denticulata*	Successful nomination of population
Lasiopetalum joyceae	Fieldwork, research, successful nomination, species profiling for Council and NPWS, PAS2 review

Species / population	Work conducted
Leptospermum deanei	Fieldwork, research into hybridization with *L. trinervium*, advice to RBG, Council, OEH
Leucopogon fletcheri ssp. *fletcheri*	Fieldwork, research, successful nomination, advice to OEH and NPWS
Melaleuca deanei	Research, fieldwork, successful nominations, advice to NPWS/OEH and species profile for Council, review and amendment of BioNet dataset. Nominated by DPE and recognised by OEH as a species expert under BC Act (Nov 2018).
Olearia cordata	Fieldwork and report to NPWS, PAS2 review
Persoonia acerosa	Fieldwork, PAS2 review, SOS monitoring plots, advice to Council and OEH
Persoonia bargoensis	Fieldwork, research, successful nomination, PAS2 review, CAM review, review and amendment of BioNet dataset.
Persoonia hirsuta	Fieldwork, research, nominations of species and population, PAS2 review, review and amendment of BioNet dataset.
Persoonia glaucescens	Fieldwork, nomination, report to NPWS, PAS 2 review, CAM review, review and amendment of BioNet dataset.
Persoonia marginata	Fieldwork and report to OEH, CAM review
Persoonia mollis ssp. *revoluta*	Fieldwork, research, advice to OEH and Forestry Corp., nomination as Vulnerable - listing pending
Persoonia nutans	Fieldwork, nomination, advice to OEH, review and amendment of BioNet dataset. Nominated by DPE and recognised by OEH as a species expert under BC Act (Nov 2018).
Phyllota humifusa	PAS2 fieldwork and research; advice to NPWS, OEH, Council, Forestry Corp (monitoring plots, reduced APZ width), review of BioNet dataset.
Pimelea curviflora var. *curviflora*	Fieldwork, research, successful nomination, advice to OEH
Pomaderris brunnea	Incidental fieldwork and documentation of new populations and range extension; review and amendment of BioNet dataset.
P. cotoneaster	Fieldwork, research, advice to Council, NPWS, OEH, liaise with ANBG seed collectors, CAM review
P. sericea	PAS2 research (review of records and habitat), recommended consideration of Presumed Extinct or at least CE
Pultenaea elusa	PAS2 research (review of records and habitat), recommended Presumed Extinct
P. glabra	SOS fieldwork and monitoring plots. Review of Mts Wilson/Irvine records resulted in these being reallocated to an undescribed species given the interim name, *P. monticola*.
P. parviflora	SOS fieldwork and report to OEH (Colebee NR offset site); review and amendment of BioNet dataset.
P. pedunculata	Fieldwork, research, expert witness, CAM review
Solanum armourense	PAS2 fieldwork, research, report, advice to OEH, CAM review
S. celatum	Fieldwork, research, new populations (new range limit and habitat), advice to OEH, CAM review
Tetratheca glandulosa	Fieldwork, PAS2 review, advice to OEH and Cwlth DEE re conservation status
Triplarina nowraensis	SOS fieldwork, review of BioNet records, advice to OEH/NPWS, establishment of monitoring plots
Zieria involucrata	Fieldwork, input to Recovery Plan, CAM review
Zieria murphyi	Liaise with ANBG, fieldwork, advice to OEH

Threatened Ecological Communities (TECs)

My work for OEH in reviewing all NSW and EPBC Act TECs in the State has given me at least some familiarity with most of these entities and builds on already-strong knowledge of some. I have also been an expert witness in cases involving some of these communities – some entailing basic reviews and advice, and others involving in-depth considerations. All of the EPBC Act parallel listings are not included here unless I was involved in a particular nomination:

Ecological community	Nature of engagement
Blue Gum High Forest	Successful nomination, expert witness
Blue Mountains Basalt Cap Forest	SOS panel
Blue Mountains Shale Cap Forest	Successful nomination, SOS panel
Blue Mountains Swamps	Fieldwork, mapping, advice to BMtns Council, modelling
Castlereagh Scribbly Gum Woodland	Successful nomination, advice to DEE re Cwlth listing, expert witness
Cooks River / Castlereagh Ironbark Forest	Advice to DEE for EPBC Act listing
Cumberland Plain Woodland	Correction of OEH mapping, fieldwork, assessments, advice to Councils and NPWS
Eastern Suburbs Banksia Scrub	Major review for DEE Recovery Plan update, advice to OEH
Elderslie Banksia Scrub Forest	Major review for DEE Recovery Plan, SOS panel
Illawarra Lowlands Grassy Woodland	DEE review panel for EPBC Act listing
Lowland Grassy Woodland & Forest of SE Corner Bioregion	Successful nomination
Maroota Sands Swamp Forest	Successful nomination, SOS panel
Melaleuca armillaris Tall Shrubland	fieldwork, mapping, advice to OEH
Montane Peatlands & Swamps	Fieldwork, modelling and mapping, advice to OEH
Mount Gibraltar Forest	Detailed review for modelling and mapping, and advice about revised listing, advice to DEE re Upland Basalt Eucalypt Forest inclusion of NSW TECs
O'Hares Creek Shale Forest	Research and review for modelling and mapping
Pittwater & Wagstaffe Spotted Gum Forest	Successful nomination
Riverflat Eucalypts Forest on Coastal Floodplains	Successful nomination (component), research, modelling and mapping (limited extent)
Robertson Basalt Tall Open-forest	Modelling and mapping, advice to NSW SC
Robertson Rainforest	Modelling and mapping
Shale/Gravel Transition Forest	Mapping, TEC review
Shale/Sandstone Transition Forest	First to describe this concept c. 1996 based on Masters research. Formally published as a concept in NPWS (1997, UBBS). Successful nomination, research, major review and advice to DEE for EPBC Act listing, modelling and mapping
Southern Highlands Shale (Forest &) Woodland	Major contributor to DEE listing, drafting of Listing and Conservation Advices, advice to OEH about revision of NSW listing, modelling and mapping. Contracted to prepare listing for upgrade to CE.
Subtropical & Temperate Coastal Saltmarsh (EPBC Act)	Funded to prepare successful nomination
Sun Valley Cabbage Gum Forest	Successful nomination, mapping, advice to Council, SOS project panel
Swamp Sclerophyll Forest on Coastal Floodplains	Allied major research project cited in the Final Determination, TEC review (gap analysis)

Ecological community	Nature of engagement
Sydney Turpentine Ironbark Forest	Successful nomination, mapping, advice to Councils and to OEH/SC about revision
Tablelands Basalt Forest	Research, expert witness, advice to OEH about revision, modelling and mapping
Tablelands Snow Gum…Grassy Woodland	Fieldwork documenting new occurrences, modelling and mapping, advice to OEH
Upland Basalt Eucalypt Forest (EPBC Act)	Major contributor to DEE listing of this composite community that includes several NSW TECs. Draft Listing and Conservation Advices
Western Sydney Dry Rainforest and Moist Shale Woodland	SOS panel, TEC review

Consultancy projects

Short descriptions of the many larger projects that I have been involved in are available at http://ecologicalsurveys.net/?page_id=10, and a list of smaller projects is at http://ecologicalsurveys.net/?page_id=14

Voluntary and other works

- Assist **International Union for the Conservation of Nature (IUCN)** with a review of the conservation status of *Proteaceae* in eastern Australia (Melbourne, 2019).
- Assist **NSW Environmental Defenders Office** with a review of NPWS monitoring proposals to assess the effects of permitting horse riding in declared Wilderness areas (Kosciusko National Park) (2014).
- Assist **NSW Environmental Defenders Office** in the preparation of its submission to the NSW Government's review of the Noxious Weeds Act 1993 (in 2011)
- Assist **NSW Environmental Defenders Office** in the preparation of its submission to the NSW Government's review of the Threatened Species Conservation Act 1995 (in 2010)
- Assist discoverers (**Blue Mountains Bushcare**) of a previously undescribed *Epacris* species (*E. apungens* Coleby & Brown) in south Leura to prepare an article for the journal, *Telopea*, describing this species and its ecology
- Assist **NPWS** with a search for the ultra-endemic and rare rainforest plant, *Thismia clavarioides*, in Morton National Park (2010)
- Expert panel member assisting **Hawkesbury-Nepean CMA** with its Draft Climate Change Vulnerability Assessment for selected threatened ecological communities of the NSW Southern Highlands (2010)
- Assist PhD student, David Field (**University of Wollongong and CSIRO**) with information about the ecology, distribution, and conservation status of *Eucalyptus aggregata* (Black Gum) (2007)
- Fieldwork assisting with group preparation of vascular plant species lists in numerous NPWS and ACT Parks reserves in the Southern Tablelands area. **Australian Native Plants Society** (2003-2007)
- Searches for *Euphrasia scabra* (critically endangered) in Packers Swamp and Nunnock Swamp. Discovered new population (3rd in NSW) in unnamed swamp, SE Forests National Park. **Friends of Grasslands** (2004)
- Assistant part-time editor of "*Danthonia*" (now *Australasian Plant Conservation*), the journal of the **Australian Network for Plant Conservation** Inc., Canberra (2002-2003)
- Assist PhD student, David Clunas (**University of Wollongong**) with review of his research in the ecology of the nationally Rare, *Pultenaea villifera* var. *villifera* (2002)
- Provide technical assistance to four final year undergraduate Environmental Science students (**Australian Catholic University**) working in Marramarra National Park, (c. 2000)
- Discovery of and subsequent surveys for *Persoonia hirsuta* ssp. nov. 'Yengo NP'. **NPWS/RBG**
- Vascular flora and fauna (microchiropteran bats) surveys within Pilliga Nature Reserve. **NPWS** Coonabarabran
- Supervisor for undergraduate dissertation, "Environmental rehabilitation of Peats Crater and Peats Bight in Muogamarra Nature Reserve" (D. Maestri), **Southern Cross University** (1997)
- Co-supervisor for undergraduate dissertation "Riparian Vegetation of upper Cattai Creek" (D. Buckle). **Southern Cross University** (1997)
- Preliminary flora assessment for proposed subdivision and development; Red Gum Avenue, Pennant Hills. The bushland area was subsequently added to Berowra Valley Regional Park. **Friends of Berowra Valley Bushland**

- **NSW National Parks Association** (NPA) Biodiversity Audit, proposed Bargo River National Park. Team Leader, Vegetation - threatened flora
- Guided interpretive walk of Fred Caterson Reserve. **Cattai Catchment Management Committee**
- **NSW NPA** audit of Greater Sydney proposed conservation reserves and additions - assistant and author of NW Sydney reserve proposals
- **NSW NPA** Biodiversity Audit of the proposed Dyarrabin Nature Reserve (~2000 ha) - Project Co-ordinator
- **NSW NPA** Proposal for the creation of Dyarrabin Nature Reserve; revised submission and report of the second NPA Biodiversity Audit
- Preliminary flora study of Crown lands (Functional Area 1), Cattai Ridge Road, Halcrows Road, Hillside/Glenorie; submission to Director NPWS and to Baulkham Hills Council. **NSW NPA**
- Flora survey of Morans Rock Crown lands for proposed addition to Wollemi National Park. **NSW NPA**
- Proposed Welcome Reef Dam (Shoalhaven River north of Braidwood) - assist with flora and fauna surveys. **NSW NPA**. Much of the area is now within Nadgigomar Nature Reserve
- Flora survey of surplus Department of Education lands at Ellerman Park, Round Corner. The local community proposed that the area become a reserve to protect a critically endangered plant community present on the site. **Friends of Ellerman Park**
- Flora survey of Crown lands at South Maroota for proposed Crescent Reach Nature Reserve (later declared as the Maroota Ridge State Conservation Area), **NSW NPA**
- Calangara Nature Reserve Proposal in Kenthurst. Survey and report to **NSW NPA**
- Preliminary Survey of bushland in Holland Reserve, Glenhaven
- Survey of Crown Reserve (now part Scheyville NP), Pitt Town; report to **NSW NPA**

Expert report – *Pimelea spicata*

Strategic Assessment for Cumberland Plain Conservation Plan

Greater Macarthur and Wilton Growth Areas

Expert Report for *Pimelea spicata* Spiked Rice-flower

Prepared for NSW Department of Planning & Environment

Teresa James August 2018

Contents

Introduction

1.1 Purpose of the expert report

An expert report may be prepared under section 6.5 of the Biodiversity Assessment Method (OEH 2017) in place of undertaking a threatened species survey. Use of an expert report may be beneficial where it is highly unlikely that a species may occur within the study area, survey effort is inadequate and/or the reliability of detecting the species through survey is low. In respect of *Pimelea spicata*, low survey effort and unreliability of survey are the primary reasons for preparing an expert report.

The purpose of this report is to provide scientific assessment of the current status and conservation needs of *Pimelea spicata* within the Greater Macarthur and Wilton priority growth areas of western Sydney. Specifically, the report is to determine whether:

- The species is unlikely to be present and in this case no further assessment is required, or
- The species is likely to be present and in this case the expert report must provide estimates of habitat area both within the growth and biocertified or development footprint areas.

1.2 Project context

The NSW Government is identifying areas for future urban development and associated infrastructure in western Sydney. There are four priority growth areas: Wilton, Greater Macarthur (Campbelltown and Appin), Western Sydney Airport, and Greater Penrith to Eastern Creek. These new growth areas are all located within the Cumberland Interim Biogeographic Regionalisation for Australia (IBRA) sub-region.

As part of the planning for the priority growth areas, the Department of Planning and Environment (DPE) will prepare the Cumberland Plain Conservation Plan to identify development and conservation outcomes for the growth areas. A strategic assessment of this plan is underway and this expert report will assist the biodiversity assessment to assess the conservation benefits and development impacts of the Plan in respect of *Pimelea spicata*.

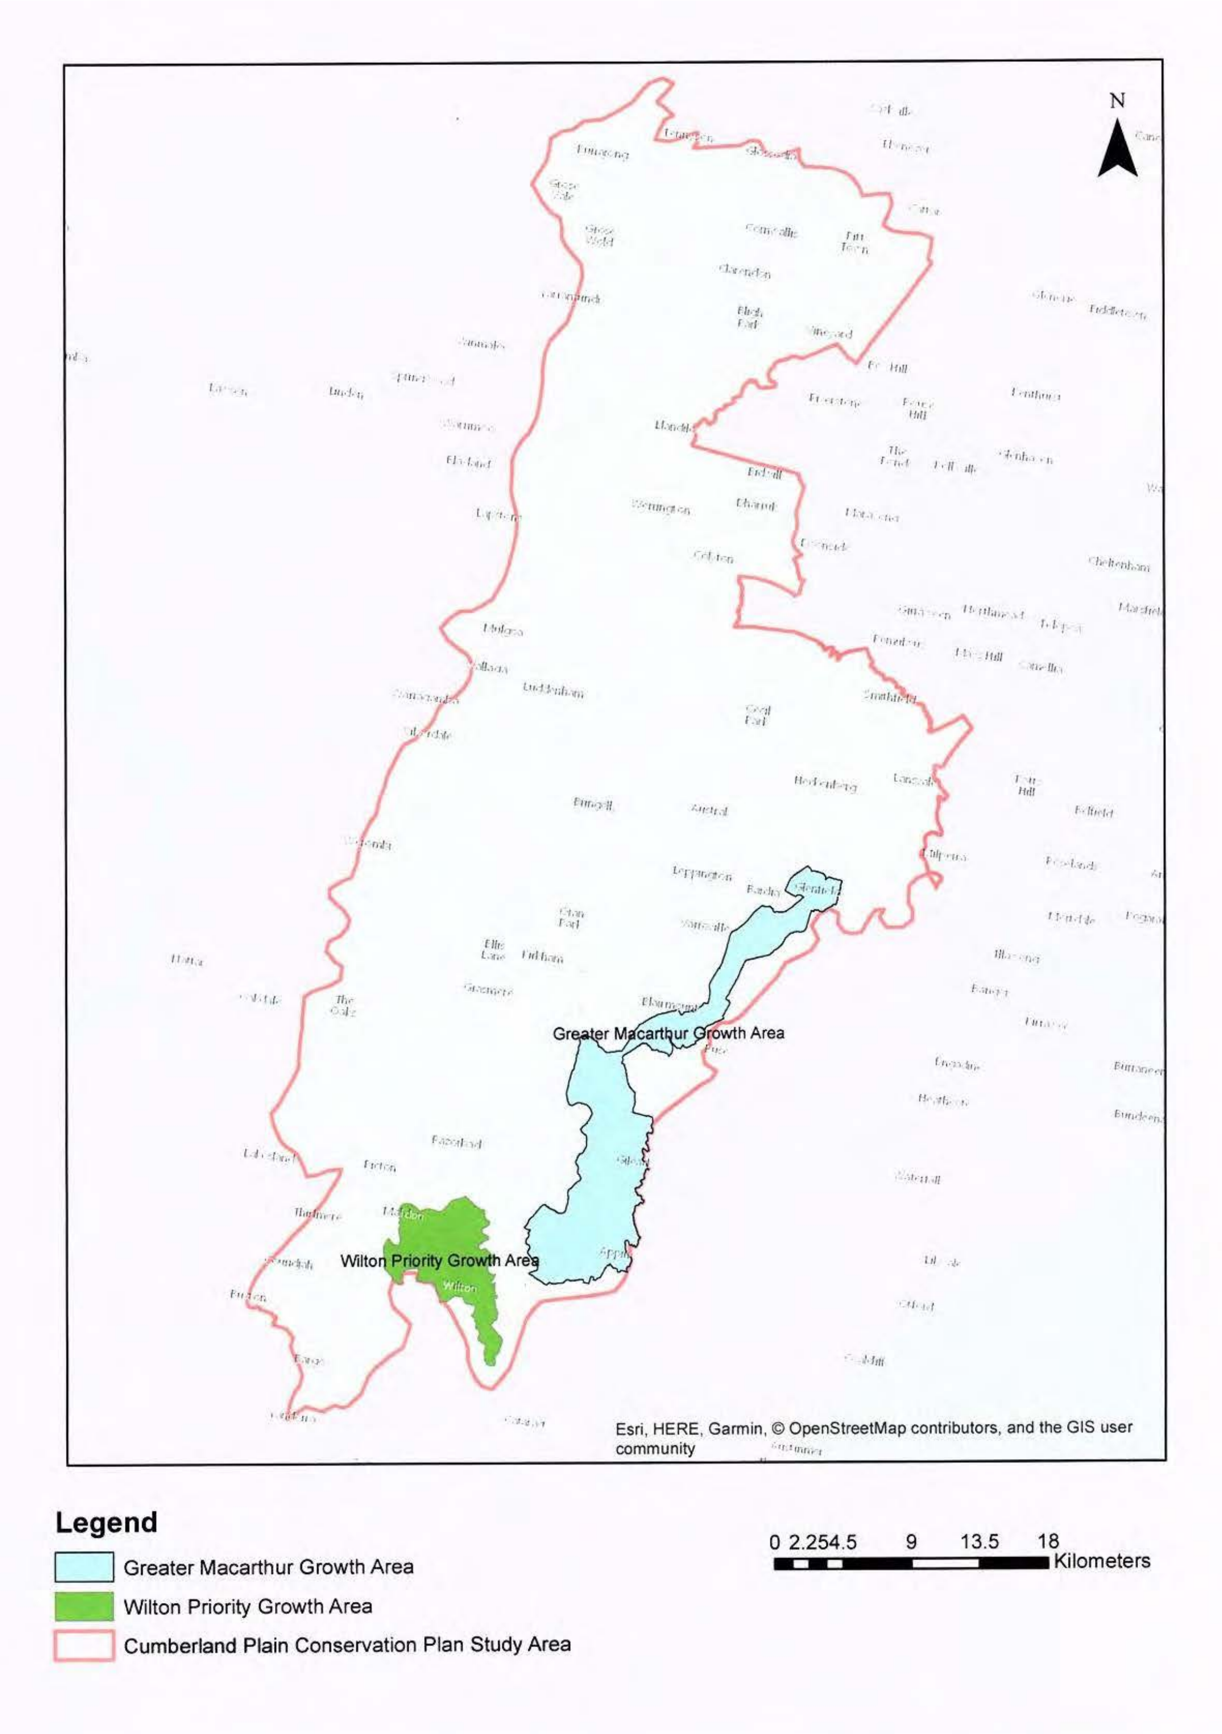
1.3 Study area

The study area for this report comprises the growth areas of Greater Macarthur (Campbelltown and Appin) and Wilton (see Figure 1). It is located within the Cumberland subregion on Triassic Wianamatta Group Shales and transitional shale/sandstone areas in south-eastern parts of the Cumberland Plain, western Sydney. The eastern and southern margins are within the Sydney Cataract subregion defined by the Triassic Hawkesbury Sandstone plateau. The study area is within the Hawkesbury-Nepean and Georges River catchments.

<u>Greater Macarthur Growth Area</u>
The Greater Macarthur PGA extends from Glenfield in the north to Appin in the south. The northern zone is already well developed with remnant vegetation largely restricted to creek-lines or small patches associated with open space reserves. Southern parts of the area, south of Rosemeadow, comprise primarily agricultural lands with larger patches of remnant vegetation associated with the Nepean and Georges Rivers, and associated tributaries.

<u>Wilton Growth Area</u>
The Wilton PGA occurs to the south of the Greater Macarthur Growth Area extending from Douglas Park in the north to south of Wilton. The boundaries closely follow the Nepean River in the north and west, and a tributary Allens Creek in the east. Away from the river and creeks the higher areas are largely cleared for agriculture and hobby farms. Remnant vegetation occurs predominantly along the watercourses and on associated slopes. The Woronora sandstone plateau (within the Upper Nepean State Conservation Area) forms the southern boundary. The Hume Highway dissects the growth area.

Figure 1. Greater Macarthur and Wilton Priority Growth Areas



1.4 Credentials of expert - Teresa James (BSc Combined Honours)

I am a botanist/ecologist with over forty years of experience in vegetation survey, plant identification, conservation assessment and threatened species, particularly in western Sydney. I have worked within the NSW government (National Herbarium of NSW, NSW National Parks & Wildlife Service) and for the last twenty years as a consultant (sole trader). A summary of my credentials as required under the Biodiversity Assessment Methodology (2014, 2016) is provided in Table 1.

Table 1. Credentials of Teresa James

BAM section	BAM requirement	Details
BAM s 6.5.2.8 (g)	Name of expert	Teresa James
BAM s 6.5.2.3 (a)	The expert's qualifications	Bachelor of Science (Honours), University of Exeter 1978 Accredited BioBanking Assessor (awarded 2008, renewed 2013)
BAM s 6.5.2.3 (b)	History of experience in ecological research and survey method, for the relevant species	Field surveys and other relevant studies: • Populations of *Pimelea spicata* across western Sydney e.g. Denham Court Road, Campbelltown (1999, 2012), Alpha Road Park, & Grey Box Reserve, Holroyd (2011), Cobham Road Reserve & Power Street Reserve, Fairfield (2016-17), Greendale (near Wallacia), private property (2016-7), Cranebrook Reserve, Penrith (2017). • Threatened community and threatened species (including *Pimelea spicata*) roadside surveys through Campbelltown LGA for Campbelltown City Council (2013) • Targeted survey for *Pimelea spicata* along Denham Court Road, near Camden Valley Way for SMEC (2012) • Expert report to DECCW: Investigation into land clearing of Shale Sandstone Transition Forest and Cumberland Plain Woodland at a property on Appin Road, Gilead (2011). • Targeted survey for *Pimelea spicata* at Menangle Park Offset Strategy for GHD (2009, 2010) • Biobanking Pilot Project at Wilton (2007). • Survey & monitoring of Cumberland Plain Woodland and *Pimelea spicata* at Faulkland Crescent Reserve, Blacktown (2004, 2007) for Blacktown City Council.
BAM s 6.5.2.3 (c)	A resume detailing projects pertaining to the survey of the relevant species	Resume attached at Appendix 1. Relevant field surveys listed above.
BAM s 6.5.2.3 (d)	Their employer's name and period of employment (where relevant)	Self-employed ecological consultant Teresa James Flora Consultant 1998 to present
BAM s 6.5.2.3 (f)	Evidence that the person is a well-known authority on the relevant species to which the survey relates	1. Author of several botanical guides to the flora of Western Sydney: • James, T.A., McDougall, L & Benson, D. (1999). Revised edition. *Rare Bushland Plants of Western Sydney.* Royal Botanic Gardens, Sydney. • James, Teresa (2013) Flora of Cumberland Plain Woodland – an identification guide. • James, Teresa (2015) Threatened Flora of the Fairfield LGA.

		• James, Teresa (2016) Native Flora of Shale Soils of the Cumberland Plain Woodland – An Identification Guide. 2. Author of flora component of Urban Bushland Biodiversity Survey of Western Sydney (1997). Included compilation of information on *Pimelea spicata* and its habitat across western Sydney local government areas. 3. Contributed information to the *Pimelea spicata* Approved Recovery Plan (2006). 4. Has acted as Expert witness in NSW Land and Environment Court in relation to threatened communities in western Sydney including: • Expert advice to OEH and Land & Environment Court in relation to alleged clearing of endangered ecological communities (Cumberland Plain Woodland and Shale Sandstone Transition Forest) at Gilead, western Sydney. Proceedings 50604 of 2011. • Expert advice to Liverpool City Council ats Muslim League of NSW – 264 Wilson Road, Green Valley. Land & Environment Court Proceedings No 10394 of 2005. Issues relating to Cumberland Plain Woodland. • Expert advice to Liverpool City Council ats AV Jennings – Stage 24 Dalmeny Drive, Prestons. Land & Environment Court Proceedings No 10395 of 2006. Issues relating to Cumberland Plain Woodland. 5. PAS2 Expert Interviews for several NSW threatened species with OEH (February-August 2012) including a range of Cumberland Plain species 6. Member of SOS Project Panel (2018) – Cumberland Plain Woodland, Western Sydney Dry Rainforest, Moist Shale Woodland, River-flat Eucalypt Forest, Agnes Banks Woodland and Castlereagh Ironbark Forest 7. Member of NPWS Cumberland Plain Recovery Team (1998)

Through this experience I have developed a good knowledge and understanding of the life history and habitat requirements of *Pimelea spicata* and associated habitats within the growth areas.

1.5 Justification for use of expert report

An expert report for *Pimelea spicata* is required as part of the threatened species assessment for the Cumberland Plain Conservation Plan for the following reasons:

1. The survey effort for this species did not meet the recommendations in the OEH threatened species guidelines (OEH 2016) for field traverse surveys due to limitations imposed by land access particularly within the Greater Macarthur Growth Area. Around 69% of total potential habitat for *Pimelea spicata* has been able to be accessed for survey with only 56% in the Greater Macarthur Growth Area.
2. Inadequate survey timing. *Pimelea spicata* is difficult to detect particularly when not in flower. Flowering is unpredictable and considered dependant on good rains (Environmental Impact Assessment Guidelines NPWS 2004, and personal knowledge). During dry periods the species is often invisible above ground but may persist in the soil as rootstock and seed. Dry, hot spring/summers have been a particular feature of the western Sydney environment in the last few years.

3. The cryptic nature of the species and extent of disturbance across the growth areas significantly reduces the likelihood of detecting the species. Many populations have only been recorded once the disturbance factor e.g. mowing, grazing or weed infestation has been removed. Many of the sites surveyed have been heavily grazed or mown.

Survey for *Pimelea spicata* has been insufficient to reliably determine the presence and extent of the species within the growth centres. An expert report is necessary to provide a more comprehensive and reliable level of scientific assessment.

1.6 Species surveys

1.6.1 *Summary of survey work undertaken*

To assess the impacts of development within the growth areas both existing and new biometric data has been used together with general and targeted survey. Extensive field sampling has been undertaken with assessment based on vegetation zones consistent with the Biodiversity Assessment Methodology (BAM 2017). Quantitative plot data has been collected to sample variability within each vegetation zone (Ecoplanning, Biosis 2017-18). More general flora and fauna survey has also been undertaken including targeted survey for threatened species including *Pimelea spicata* (Biosis). Surveys have been undertaken by Ecoplanning and Biosis.

Survey effort has varied across the study area. The northern extent of the Greater Macarthur growth area has been well surveyed by Biosis (general and targeted survey) reflecting the small areas and easy access. The only plot sampling (Ecoplanning), however, was in Georges River Reserve at Glenfield. The southern extent of the Greater Macarthur growth area has been less well surveyed with around 50% of habitat polygons surveyed (due primarily to limited access) and again mostly through general/targeted survey by Biosis. Many of the areas surveyed were reported to be heavily grazed (Bruce Mullins pers. comm.). The Wilton Growth Area has been relatively well-surveyed particularly in the north-eastern plateau area with both general and targeted survey (Biosis) and plot sampling (Ecoplanning).

The location of survey areas, tracks and plots are shown in Figures 9-11.

1.6.2 Land access

An initial 726 letters were sent to landholders within the Growth Areas in late 2017 followed by a second letter in March 2018, and targeted door knocking in May 2018 (DPE *pers.comm*.). Just under 20% of landholders responded. Surveys were undertaken on all areas of land where landowners granted access. Of the 14,984 hectares within the Wilton and Macarthur Growth Areas, of which 5,385 ha is potential native vegetation that could be impacted by development, DPE has completed surveys across 3,360 hectares (62% of the total survey area).

There is 765 hectares of total potential habitat (Cumberland Plain Woodland only) available for *Pimelea spicata* across the Wilton and Greater Macarthur Growth Areas. Of this area 530 hectares or 69% has been able to be accessed for survey. While nearly all available habitat was surveyed in the Wilton Growth Area, only 56% of potential habitat was able to be accessed in the Greater Macarthur Growth Area. Table 2 summarises the total area of habitat for *Pimelea spicata* that was surveyed.

1.6.3 Survey timing

Surveys for *Pimelea spicata* should be undertaken when flowering. Flowering is sporadic throughout the year and is likely to be in response to climatic conditions, particularly rainfall (DEC 2006). At other times plants are difficult to see or may only be present as rootstock or seed. Surveys have occurred between November 2017 to May 2018 and no sighting of this species has been recorded within the growth areas. Spring/summer was hot and dry with unfavourable conditions. Many of the Cumberland Plain Woodland sites surveyed were also heavily grazed.

Table 2. Total area of *Pimelea spicata* habitat surveyed (data provided by Dept. Planning & Environment)

Growth Area	Vegetation community	Total area (ha)	Survey area (ha)	Percent surveyed %
Greater Macarthur	849	293	204	70
	850	206	73	35
Sub-total		499	277	56
Wilton	849	236	222	94
	850	31	31	100
Sub-total		267	253	95
TOTAL		**766**	**530**	**69**

2. Species Information

2.1 Species description

A small, slender to spreading shrub or sub-shrub to c. 50 cm high; stems 1-several, glabrous. Older stems are often seen intertwining with grasses and herbs. *Pimelea spicata* has an underground carrot-like tap root recorded up to 18 cm in length that gives plants the ability to re-sprout after defoliation and periods of drought stress (NSW NPWS 1997). The leaves are mostly opposite, narrow-elliptic to elliptic in shape, to 20 mm long and 8 mm wide, spreading, soft and often bluish-green. Inflorescence is a raceme, dense when young, elongated and interrupted at maturity, bracts absent. Flowers tubular, white to pink tinged, 7-10 mm long with four spreading lobes. Fruit is a narrow-ovoid nut, c. 3 mm long, 1-seeded, mostly green.

Pimelea spicata leaves & flowers (left)
fruit (above)

2.2 Biology/ecology

Pimelea spicata is incapable of effective vegetative spread (Benson and McDougall 2001) although more recent observations suggest that mature individuals can spread over short distances through underground rhizomes (OEH 2017). Seed production, however, is the primary means of recruitment. Flowering is sporadic throughout the year and is likely in response to climatic conditions, particularly rainfall (DEC 2006). Flowering and fruiting has been observed in plants 1.5-2 years old (NPWS 1997); flowers continue to be produced as fruits mature. Native bees are known pollinators and moths may also contribute to pollination (DEC 2006). The species may also be capable of spontaneous self-pollination (DEC 2006). Fruiting is highly variable depending on environmental conditions. Seed viability has been recorded as relatively high ranging from 83% - 86% (Nash & Matthes 1995, Willis et al. 2003 cited in DEC 2006). Seed dispersal is highly localised with the majority of seedlings observed within 30 cm of adult plants following fire (Hogbin pers. obs. cited in DEC 2006). *Pimelea spicata* maintains a long-lived soil-stored seed bank resulting in potential for considerable recruitment following disturbance. The soil seed bank can survive under infestations of invasive weeds (Willis et al cited in DEC 2006).

Seed germination can be triggered by disturbance including fire, slashing/mowing, grazing and soil disturbance (NPWS 1997, Willis et al 2003 cited in DEC 2006). Monitoring of seedlings following fire revealed 80% survival in the first year (NPWS 1997 cited in DEC 2006). Ex-situ trials found that smoke application increased seed germination (Tozer & Robertson 1998), however, Willis et al. (2003) cited in DEC (2006) found only a 20-30% germination rate for seed in any trial.

Re-sprouting from the taproot occurs following defoliation caused by fire, drought or physical damage (NPWS 1997). The species can survive periods of drought stress or weed infestation by dying back to the tap root and re-sprouting when favourable conditions return. It is unknown at what age the tap root has to be of a sufficient size to facilitate re-sprouting.

2.3 Distribution and abundance

Pimelea spicata occurs in two disjunct regions of the Sydney Basin IBRA bioregion, the Cumberland Plain in western Sydney and the coastal region of the Illawarra, south of Sydney.

<u>Cumberland Plain</u>
On the Cumberland Plain *Pimelea spicata* is found on clay soils derived from Wianamatta Group Shales. The current known distribution extends from Freeman's Reach in the north to Douglas Park in the south and west from Penrith to Georges Hall in the east. *Pimelea spicata* has been recorded in the following vegetation communities:

PCT 849 – Grey Box – Forest Red Gum grassy woodlands on flats of the Cumberland Plain
PCT 850 - Grey Box – Forest Red Gum grassy woodlands on shale of the southern Cumberland Plain
PCT 806 & 807 – Derived grasslands on shale hills and shale plains of the Cumberland Plain
PCT 830 – Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain

These communities are equivalent to the Cumberland Plain Woodland and Moist Shale Woodland threatened ecological communities.

The recovery plan for *Pimelea spicata* (DEC 2006) identified 25 populations on the Cumberland Plain. Currently there are approx. 70 sites (Bionet Atlas records, June 2018). The main concentration of sites is found in the Blacktown, Prospect, Bankstown and Narrellan districts. More recent records (post 2014) are from near Wallacia and Horsley Park - Cecil Park. Populations in Campbelltown and Wollondilly LGAs are close to the south-eastern limit of the specie's geographical range.

<u>Coastal Illawarra</u>
In the Illawarra *Pimelea spicata* is associated with coastal headlands and hill tops from Mount Warrigal south to just north of Kiama. The recovery plan for *Pimelea spicata* (DEC 2006) identified 5 populations in the Illawarra.

In 2006, the total population of *Pimelea spicata* across 30 known populations was estimated to be around 4300. Populations varied from a few individuals to >500 plants although larger populations were rare with over half with <50 individuals and small habitat areas of less than 0.5 ha (DEC 2006, Dept. Environment & Heritage 2016*)*. Since 2006 several populations are likely to have been lost to development or habitat modification. At several sites survey has failed to re-locate plants including at Menangle and along Denham Court Road near Camden Valley Way (*James* 2009, 2010, 2012). Prolonged periods of drought, increased weed invasion and heavy grazing are likely to be the main causes. Counterbalancing losses are several new records and increased abundance at some existing sites. There have been new records within Fairfield, Liverpool and Penrith LGAs (mostly <50 individuals). Increased population sizes are noted at Narellan and Prospect.

2.4 Habitat

Pimelea spicata is found in grassy woodlands on shale on the Cumberland Plain and on grassy coastal headlands in the Illawarra.

<u>Cumberland Plain</u>
On the Cumberland Plain *Pimelea spicata* occurs in Cumberland Plain Woodland, Moist Shale Woodland and derived grasslands. Associated canopy trees are Grey Box *Eucalyptus moluccana*, Forest Red Gum *E. tereticornis,* Narrow-leaved Ironbark *E. crebra* and Spotted Gum *Corymbia maculata*. The mid-storey typically contains *Acacia parramattensis, A. decurrens, Bursaria spinosa*, *Acacia implexa, A. falcata, Dillwynia sieberi* and *Indigofera australis*. Common groundcover grasses and herbs associated with occurrences include Kangaroo Grass *Themeda triandra,* Weeping Grass *Microlaena stipoides,* Kidney Weed *Dichondra repens*, Woodruff *Asperula conferta* and Blue Trumpet Flower *Brunoniella australis*.

Pimelea spicata prefers moist soil and often occurs on gentle lower slopes where groundwater seepage maintain soils damper for longer (*T. James pers. obs.*). A relatively open groundcover maintained by occasional disturbance e.g. fire or infrequent/low intensity grazing/slashing provides favourable habitat. Although the species can survive (and flower) among taller grasses and perennial weeds (e.g. at Cobham Street Road, Horsley Park) it is likely to disappear above ground under dense weed infestations. The Denham Court Road population in 2003, for example, was estimated to be hundreds yet in 2011 no plants were found where plants were previously plentiful (*T. James pers. obs.)*. The road reserve had become increasingly degraded with weed infestation in both the mid-storey layer (African Olive, Box Thorn and Lantana) and the ground-layer (Bridal Creeper, Prickly Pear, Blackberry & Mother-of Millions). The species was likely still present in the soil seed-bank.

Frequent or intensive grazing, slashing or mowing will restrict the growth of plants with re-sprouting controlled by the frequency of disturbance and environmental conditions. Frequent cutting creates open, dry and hot conditions at the soil surface resulting in die-back of plants above ground. The species can persist for many years under such a regime as a tap root and seed in the soil. There are many examples of regeneration following cessation of mowing and slashing in council reserves e.g. Faulkland Crescent Reserve and Melrose Park in Blacktown and Power Street Reserve in Fairfield.

Habitat of *Pimelea spicata* along unformed road reserve (Cobham Road, Horsley Park)

Illawarra
In coastal habitat of the Illawarra *Pimelea spicata* occurs in a wider range of geologies and soils derived from the Permian Shoalhaven (sandier than the clay soils of western Sydney). The favoured sites are on grassy headlands and hilltops with Kangaroo Grass *Themeda triandra*, Mat-grass *Lomandra longifolia* and Blady Grass *Imperata cylindrica*, often with Coast Banksia *Banksia integrifolia*. Woodland is also often dominated by Forest Red Gum *Eucalyptus tereticornis* and Thin-leaved Stringybark *E. eugenioides* above Kangaroo Grass, species also occurring in *Pimelea* habitat in western Sydney. Habitat in the Illawarra includes the endangered ecological community *Themeda Grasslands on Seacliffs and Coastal Headlands* (PCT 898).

3. Description of the study area

3.1 Landscape context and land use history

3.1.1 Greater Macarthur Growth Area (GMGA)

The Greater Macarthur PGA extends from Glenfield in the north to Appin in the south. It is largely within the Campbelltown LGA with the southernmost section within the Wollondilly LGA. The northern half of the growth area comprises an urban renewal corridor centred on the Sydney to Southern Highlands railway line. It encompasses the existing industrial and residential suburbs of Glenfield, Macquarie Fields, Minto, Leumeah and Campbelltown. The Growth Area is associated with extensively cleared, gently undulating shale terrain typical of the Cumberland Plain and contrasting with the sandstone gorges and plateaus along the Georges River to the east. The northern zone is already well developed with remnant vegetation largely restricted to creek-lines or small patches associated with open space lands. Vegetated creek-lines include Bunbury Curran Creek, Bow Bowing Creek, Leumeah Creek, Fishers Ghost Creek and Spring Creek. Bushland reserves containing Cumberland Plain Woodland and River-Flat Eucalypt Forest TECs include Bunburry Curran Reserve, Pembroke Park and John Kidd Reserve (Blair Athol).

The more extensive southern half of the PGA, south of Rosemeadow, comprises proposed land release areas at Menangle Park, Mount Gilead and Appin. In the north-west Mount Sugarloaf (213 m asl) forms the southern end of a hilly ridge on the Luddenham soil landscape above the Menangle floodplain that extends north up to Denham Court. Some native vegetation persists although invaded by African Olive. The floodplain is well dissected by Menangle Creek and its tributaries including Nepean Creek, Woodhouse Creek and Leafs Gully. These are primarily semi-rural and agricultural land, with creek corridors and some larger patches of remnant vegetation, located between the Nepean and Georges Rivers. Geologically the area comprises gently undulating hills on shale intergrading via a shale/sandstone transitional zone with steeper terrain on Hawkesbury sandstone along the rivers. Transitional and sandstone geologies are sometimes exposed along the smaller creek lines.

3.1.2 Wilton Growth Area (WGA)

The Wilton PGA occurs to the south of the Greater Macarthur PGA extending from Douglas Park in the north, Maldon in the north-west and to south of Wilton. The boundaries closely follow the Nepean River in the north and west, a tributary Allens Creek in the east and the Cordeaux River in the south. Away from the Nepean River and gullies a higher gently undulating zone has been largely cleared for agriculture. The Woronora sandstone plateau (within the Upper Nepean State Conservation Area) and part of the Sydney Water Catchment forms the south-western boundary. The Hume Highway dissects the PGA north to south and Picton Road NW to SE.

The WPGA includes both shale, shale/sandstone transitional and sandstone environments. Remnant vegetation occurs predominantly along the watercourses and on associated slopes. The flatter shale terrain has soils of the Blacktown soil landscape, which is derived from Ashfield Shale and typically support shale woodlands. Much of this area is cleared or modified for agriculture and hobby farms. It comprises native/exotic grassland with smaller areas of better condition Derived Native Grasslands. Steeper slope areas above the gullies are comprised of soils of the Lucas Heights soil landscape derived from the Mittagong Formation (located between the Ashfield Shale and Hawkesbury Sandstone). The Lucas Heights soils are a mix of clays and sands and occur within the shale/sandstone transition zone, they support variable transitional woodlands and forest. In the steeper gullies the Hawkesbury soil landscape dominates and supports Hawkesbury Sandstone Gully Forest types.

3.2 Native Vegetation

3.2.1 Greater Macarthur Growth Area

The predominant vegetation communities are Cumberland Plain Woodland (CPW), Shale Sandstone Transition Forest (SSTF) and River-flat Eucalypt Forest (RFEF), all threatened ecological communities. A summary of mapped communities based on maps provided by NSW Planning & Environment is found in Table 3.

Table 3. Summary of vegetation communities within the Greater Macarthur Growth Area

PCT No	PCT Name	TEC / Non-TEC	Distribution & notes
830	Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain	Moist Shale Woodland (MSW)	Small patch at Menangle Sugarloaf on SE slopes (map 4)
835	Forest Red Gum – Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain	River-flat Eucalypt Forest (RFEF)	Along creek lines in shale areas in northern and central parts of GMGA (maps 1-5)
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	Cumberland Plain Woodland (CPW)	Small patches on shale soils throughout GMGA but mostly in northern and central parts
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	Cumberland Plain Woodland (CPW)	Very small patches on shale soils throughout GMGA, more common in southern parts
806	Derived grasslands on shale hills of the Cumberland Plain	Cumberland Plain Woodland (CPW)	On shale soils in central and southern parts on agricultural & semi-rural lands.
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain	Shale Sandstone Transition Forest (SSTF)	Most extensive community on shale /sandstone transition soils mostly south from Rosemeadow (maps 5-7) intergrading with CPW. Along smaller creek-lines and upper slopes of Nepean River & Georges River.
1081	Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain	SSTF – higher shale influence examples otherwise not a TEC (Sydney Hinterland Transition Woodland)	One small patch mapped e.g. along Smiths Creek at Leumeah (map 3). Higher shale influenced forms are consistent with SSTF TEC.
1181	Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of west & south Sydney	Not a TEC, (Hinterland Sydney Sandstone Gully Forest)	Narrow zone along Nepean & Georges Rivers and tributary gullies (maps 5-7) and small zone along Smiths Creek at Leumeah (map 3)

3.2.2 Wilton Growth Area

The predominant vegetation communities within the growth area are Cumberland Plain Woodland (& Derived Grasslands) on the shale and Shale Sandstone Transition Forest in shale/sandstone transitional areas, both listed as critically endangered ecological communities in NSW. Cumberland Plain Woodland and Shale Sandstone Transition Forest are also listed under the EPBC Act (1999). A summary of mapped communities based on maps provided by NSW Planning & Environment and Cumberland Ecology (2016) is found in Table 4.

Table 4. Summary of vegetation communities within the Wilton Growth Area

PCT No	PCT Name	TEC / Non- TEC	Distribution & notes
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	Cumberland Plain Woodland (CPW)	On shale soils of higher gently undulating terrain of northern central parts of WGA (mostly map 2). Small patches with scattered trees (farming properties) adjoining more extensive exotic and native grasslands.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	Cumberland Plain Woodland (CPW)	Small patch in western part of WGA (map 1).
806	Derived grasslands on shale hills of the Cumberland Plain	Cumberland Plain Woodland (CPW) (NSW)	On shale soils of higher gently undulating terrain of northern central parts of WGA (mostly map 1 & 2).
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain	Shale Sandstone Transition Forest (SSTF)	The most extensive community on shale/sandstone transition soils between CPW and sandstone communities along gullies in the WGA (maps 1-3). Variable floristics.
1081	Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain	SSTF - high shale examples only otherwise not a TEC (Sydney Hinterland Transition Woodland)	Few patches restricted to flatter land (often spurs) downslope of SSTF & above gully. Higher shale influenced forms are consistent with SSTF TEC.
1181	Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of west & south Sydney	Non-TEC Hinterland Sydney Sandstone Gully Forest	Narrow zone along Nepean River and tributary gullies (maps 1-3)
1292	Water Gum – Coachwood riparian scrub along sandstone streams	Non-TEC Riparian Forest	Very narrow zone along Nepean River (maps 1 & 2).
862	Grey Gum – Hard-leaved Scribbly Gum woodland of the Cox's Valley	Non-TEC Burragorang-Nepean Hinterland Woodland	Small patches mapped by Cumberland Ecology (2016) in NE of WGA above Allens Creek. These patch are included in SHTW in the DPE mapping.

3.3 Potential habitat for *Pimelea spicata*

Pimelea spicata is known to occur in the following vegetation communities:

PCT 849 – Grey Box – Forest Red Gum grassy woodlands on flats of the Cumberland Plain
PCT 850 - Grey Box – Forest Red Gum grassy woodlands on shale of the southern Cumberland Plain
PCT 806 & 807 – Derived grasslands on shale hills and shale plains of the Cumberland Plain
PCT 830 – Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain

Potential habitat may also occur in low sandstone forms (at the shale end of the transition) of Shale Sandstone Transition Forest, *Narrow-leaved Ironbark – Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain* (PCT 1395) which is structurally and floristically very similar to Cumberland Plain Woodland at the shale end of the transition (see Section 4.3.1).

Degraded examples of these communities (i.e. reduced canopy and/or mid-layer cover or weedy areas) can still provide habitat for the species due to its long-term persistence as woody rootstock (tap root) and in the soil seed bank. The communities identified above are equivalent to the Cumberland Plain Woodland, Moist Shale Woodland and Shale Sandstone Transition Forest threatened ecological communities.

3.3.1 Greater Macarthur Growth Area

Cumberland Plain Woodland (including Derived Grasslands) comprises >50% of remnant vegetation mapped in northern parts of the GMGA (south to around Rosemeadow) and around 20% (may be higher depending on extent of derived grasslands) in the southern section. There is around 70 ha of Moist Shale Woodland mapped in the vicinity of Mount Sugarloaf. High and low sandstone influenced SSTF has not been mapped separately (can be useful) in the mapping provided, however, SSTF occurring adjacent to CPW or in shale areas away from creek-lines may provide potential habitat.

Table 5. Potential habitat in the Greater Macarthur Growth Area

Vegetation community	Distribution	Habitat value
Cumberland Plain Woodland (all conditions including mowed or slashed as long as meet final determination)	Throughout but mostly in northern parts south to Rosemeadow.	High: most records from CPW both Shale Plains and Shale Hills
Moist Shale Woodland	Highly localised at Mount Sugarloaf	High: moist conditions favour the species
Shale Sandstone Transition Forest (low sandstone influence)	Throughout but mostly in southern parts	Moderate: not typically recorded from this community, however, at the shale end of the transition examples of CPW and SSTF are difficult to distinguish
Derived Native Grasslands (including mowed, slashed or grazed)	Throughout comprising grazing lands, roadsides & council reserves	Moderate to high: several records from over-cleared CPW or derived native grasslands

3.3.2 Wilton Growth Area

Due to the smaller area and reduced influence of shale with a corresponding increase in influence from sandstone at the edge of the Cumberland Plain, the extent of potential habitat for *Pimelea spicata* is less in the WPGA than the GMPGA.

Table 6. Potential habitat in the Wilton Growth Area

Vegetation community	Distribution	Habitat value
Cumberland Plain Woodland (all condition states)	Mostly in northern parts.	High, most records from CPW both Shale Plains and Shale Hills
Shale Sandstone Transition Forest (low sandstone influence)	Throughout	Moderate, not typically recorded from this community but at shale end of the transition examples of CPW and SSTF are difficult to distinguish.

Vegetation community	Distribution	Habitat value
Derived Native Grasslands (including mown, slashed or grazed)	Mostly northern areas comprising grazing lands, roadsides & council reserves	Moderate to high. Several records from over-cleared CPW or derived grasslands with varying levels of native species

4. Assessment of species presence and suitable habitat

4.1 Species records, habitat assessments and prior surveys

4.1.1 Species records

Records used in this report have been sourced from the NSW Bionet Atlas. Only four records relating to two sites exist for the Greater Macarthur Priority Growth Area (GMPGA) and none for the Wilton Priority Growth Area (see Table 7). One record from Glenfield in the far north of the GMGPA is suspect. See Figures 2 & 3.

Table 7: *Pimelea spicata* records from within Greater Macarthur Growth Area

Location	Date of record	No. of individuals	Notes
Minto Industrial Estate	2004	?	CP2 of Recovery Plan (DEC 2006) - original population destroyed & plants translocated to buffer area
Minto Industrial Estate	12/07/2012 – 13/02/2013	1	Apparently location close to CP2, now also cleared & developed based on current imagery
Minto Industrial Estate	7/03/2013	28	Habitat 10 m x 10 m in outlying stand of *Eucalyptus crebra* (CPW)
Western end of Glenfield Waste Services site at northern edge of GMGA (based on coordinates) but location given on record is Catholic school grounds, Leacock Lane, Casula	01/03/1992	?	Coordinates likely inaccurate. The Glenfield location is not identified in the recovery plan.

The Minto population is located within a 30 m wide strip of Cumberland Plain Woodland along Pembroke Road near the intersection with Ben Lomond Road. This habitat is part of a conservation area connected to a 60 m wide strip along Ben Lomond Road. The conservation area comprises a total area of c. 2.3 ha and is subject to a Bushland Plan of Management (Anne Clements & Associates 2010). The long-term security of this population is doubtful considering the narrow vegetation zones subject to extensive edge effects and long-term health of the remnant will depend on ongoing management.

There are several records located just outside of the Greater Macarthur Growth Area within the Liverpool -Campbelltown & Camden LGAs at Casula, Denham Court, Narellan and Mt. Annan. Records in Wollondilly are limited to one site just north-east of Douglas Park (ref Appin Mine VS#6). Information relating to the closest and highest density of records is summarised in Table 8.

Table 8. *Pimelea spicata* records just outside of the Greater Macarthur Growth Area

Location	Date of record	No. of individuals	References/notes
Appin Mine VS#6 c. 1-2km west of GMGA	2012-14	c. 100	Many records within an area of c. 5 ha on SSW facing slope. Site was subject to grazing, slashing & weeds. In Shale Hills Woodland.
Mt Annan Botanic Garden & surrounds 2 km west	1991 - 1998	Locally abundant	Conservation Area Mt Annan Botanic Gardens. Population CD1 of recovery plan.
All Saints Catholic College school grounds, Leacock Lane, Casula c. I km to the north	1992	Scattered colonies in 0.5 sq. km area	Population L2 of the recovery plan. Dry hilltops. Current status unknown, no plants see in 2003 (recovery plan), no subsequent records.

The largest and most recently recorded population is located within a secure offset site for the Appin Mine No 6 Ventilation Shaft (Niche Environment & Heritage 2011). Populations at Mount Annan (and surrounding areas) are well documented, those within the Mt Annan Botanic Gardens conservation area are likely to be secure. Other sites at Casula and Denham Court occur on private land and current status is unknown.

4.1.2 Habitat assessments and prior surveys in Greater Macarthur Growth Area

Menangle Park – targeted survey for *Pimelea spicata* (James 2009, 2010). Three remnants of Cumberland Plain Woodland totalling an area of c. 7 ha were surveyed in 2009 & 2010. They form part of Map 4 of the GMPGA and occur within the proposed urban development footprint. Based on current imagery these remnants appear to be in similar condition to that observed in 2009-10 i.e. of similar size and landscape context with ongoing grazing pressure. All sites contained potential habitat for *Pimelea spicata* although no plants were recorded. The survey was limited by prolonged dry conditions (particularly in 2009) and heavy grazing from horses. Plants are unlikely to be visible if present until grazing ceases and groundcover improves. These conditions are likely typical of similar habitat within the growth areas. Details of the sites are provided in Table 9. These sites were re-surveyed by Biosis for the strategic assessment.

It is noted that these remnants of Cumberland Plain Woodland are mapped in the strategic assessment mapping as PCT 1395 (SSTF) and not Cumberland Plain Woodland vegetation. I disagree with the mapping.

Table 9. Menangle habitat assessment sites

Site Id	Location [GDA94 MGA56]	Size	Habitat details	Survey effort & findings
1	South of Menangle Road at junction with Cummins Road 292394E, 6223452N	2 ha	CPW Grey Box – Forest Red Gum Small patch surrounded by grazing land (horses); gentle south-facing slope. Saline often bare soils. Weed invasion at shrub and ground-layer. Heavy grazing pressure. Low condition.	• 1 hour 30 mins random meander • No plants found • Conditions dry, unsuitable for survey • Low potential habitat
2	Eastern side of Cummins Road 292468E, 6223863N	2.5 ha	CPW Narrow-leaved Ironbark Small patch surrounded by grazing land (horses); moderate west-facing slope. *Bursaria spinosa* in shrub layer with *Indigofera australis*, ground cover with mix of native & exotic species. Moderate condition. Moderate grazing pressure.	• 2 hours 45 mins random meander • No plants found • Conditions dry, unsuitable for survey • Potential habit present

Site Id	Location [GDA94 MGA56]	Size	Habitat details	Survey effort & findings
3	Eastern side of Cummins Road, just north of Station Road intersection	5 ha	CPW Forest Red Gum - Narrow-leaved Ironbark; small patch surrounded by grazing land; gentle north-west facing slope. Shrub layer dominated by African Olive & Box Thorn; ground cover with mix of native & exotic species & much bare ground. Low condition with heavy grazing pressure, horses & rabbits.	• 1hour random meander • No plants found • Conditions dry, unsuitable for survey • Low potential habit present

Mt Gilead Biodiversity Assessments – NPWS (1997), Eco Logical (2017)

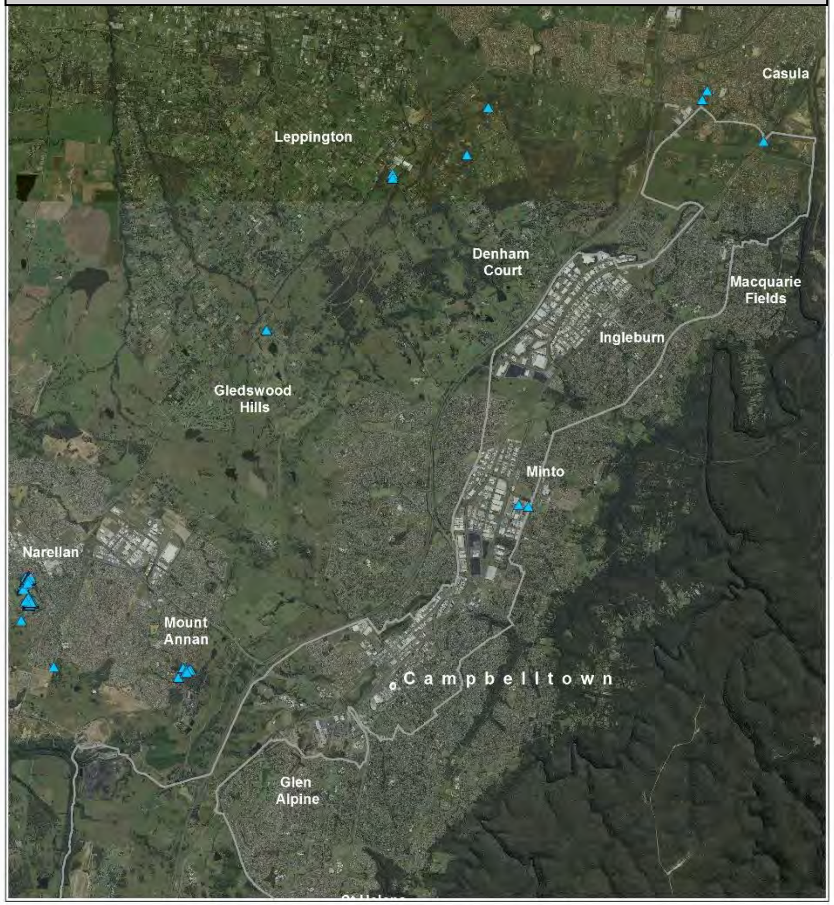
As part of the Mt Gilead *Biodiversity Certification Assessment & Biocertification Strategy* (2017) detailed survey and community verification was undertaken in 2015-2016 between Noorumba Council Reserve and Beulah Biobank Site (eastern boundary along Appin Road). Although these surveys were limited to the north-eastern section of Mt. Gilead, previous surveys had been undertaken in 2006 and 2013 across larger areas and over several months.

Table 10. Previous studies undertaken at Mt. Gilead

Previous study	Survey area	Effort (flora)	Results
ELA 2006	Mt Gilead (810 ha)	• 4-day survey Feb & March 2006 including flora, fauna & riparian health • Validation of vegetation communities, random meander • Threatened flora survey, random meander	• 4 vegetation communities (3 EECs – RFEF, CPW, SSTF) • No *Pimelea spicata* recorded
ELA 2014	Part of Mt. Gilead (210 ha)	• 4-day survey March, April, June, Sept 2013 including flora, fauna • Validation of vegetation communities, random meander & 18 Biometric plots • Threatened flora survey, random meander	• 3 EECs recorded RFEF, CPW, SSTF • No threatened flora species
ELA 2017	Part of Mt. Gilead (209 ha)	• Jan, Feb, April Sept, October 2015; Jan, Feb, Mar, August 2016 • 20 Biometric plots (9 same as in 2014) • Threatened flora survey, random meander	• 3 EECs recorded RFEF, CPW (8.75 ha), SSTF (20.62 ha) • No *Pimelea spicata* recorded

Although the land could not be accessed for the strategic assessment, survey effort has been comprehensive over several years in parts of the site. No plants of *Pimelea spicata* were recorded. Detection of plants, however, has and continues to be limited by ongoing clearing, slashing and grazing across much of the area. The extent of Cumberland Plain Woodland is also limited due to a higher sandstone influence particularly along creek-lines.

Figures 2 & 3. *Pimelea spicata* atlas records for GMGA & surrounding areas



Greater Macarthur Priority Growth Area (Northern Extent)

▲ Pimelea spicata - Bionet Records

Greater Macarthur Priority Growth Area (Southern Extent)

▲ Pimelea spicata - Bionet Records

Glenfield Waste Services (EPS 2015)
The Glenfield Waste Services site is located in the far north of the Greater Macarthur growth area along Cambridge Avenue at Glenfield. Known *Pimelea spicata* sites occur to the north and south at Casula and Minto. The location of a record just west of the site is considered dubious. Community verification and targeted survey was undertaken in 2012 and 2013. Suitable habitat occurs at the site but no plants were recorded.

Table 11. Glenfield flora survey

Previous studies	Survey area	Effort (flora)	Results
EPS (2015)	Glenfield Waste Services site (60 ha)	May & July 2012 random meander & 8 quadrats Dec 2013 – random meander targeted survey for Pimelea (12 hours, 1 hr per ha)	12 ha of Shale Plains Woodland & potential habitat No plants of Pimelea found. No details of conditions at time of survey.

Campbelltown LGA roadside habitat survey (James 2013)

Approximately 93 km of roadside habitat was surveyed over three weeks during September 2013. Sections of roadside surveyed relevant to this report are listed below:

- Glenfield – Cambridge Avenue (east of Railway Parade)
- Macquarie Fields – Victoria Road adjoining Bunbury Curran Reserve, Canterbury Road, Minto Road
- Menangle – Menangle Road (from Callaway Avenue to LGA boundary)
- Gilead – Appin Road (Noorumba Reserve to LGA boundary sign)

Pimelea spicata was targeted in remnants of CPW but no plants were found. The road reserves are typically closely mown preventing shrub regeneration except close to remnant trees and along fence-lines. Potential habitat in other areas is affected by dense woody growth of African Olive. Roads with mature habitat trees and patches of relatively intact native groundcover include Appin Road and Menangle Road. African Love Grass and Kikuyu are dominant invasive species along the roadsides in CPW resulting in loss of native species.

Based on these findings it is reasonable to expect potential habitat to exist along some of the more natural roadsides within the growth areas particularly in more rural environments of the central and southern parts. To realise this potential, however, will require appropriate protection and management. A summary of findings is provided in Table 12.

Table 12. Survey details for Campbelltown LGA roadside habitat survey

Previous studies	Survey area	Effort (flora)	Results
Campbelltown roadside survey T. James (2013)	Cambridge Avenue, Glenfield	Walking along roadsides with targeted search within patches of CPW	Confirm CPW on northern side of road adjoining Glenfield Waste Services site. Weedy. No *Pimelea spicata* recorded but potential habitat.
Campbelltown roadside survey T. James (2013	Canterbury Road Victoria Road Minto Road (Macquarie Fields)	Walking along roadsides with targeted search within patches of CPW	Small patch mapped as CPW is SSTF along Canterbury Rd. No potential PS habitat in this patch. SSTF along Victoria Rd, unlikely habitat. Minimal CPW potential habitat.

Campbelltown roadside survey T. James (2013	Menangle Road (Menangle Park)	Walking along roadsides with targeted search within patches of CPW	Small patches of CPW & derived grasslands, some mown, others with good native groundcover. Potential habitat in these patches south of Glen Alpine.
Campbelltown roadside survey T. James (2013	Appin Road (S. of Rosemeadow)	Walking along roadsides with targeted search within patches of CPW	Mostly CPW/very low sandstone influenced SSTF to just south of Mallaty Creek. Some good sections with larger remnant trees, native groundcovers/sparse shrubs & grasslands. Potential habitat.

4.1.3 Habitat assessments and prior surveys in the Wilton Growth Area

Wilton Junction New Town – Cumberland Ecology/SLR Consulting 2016

Surveys associated with the Wilton Junction/Bingara Gorge covered the eastern side of the WPGA. Comprehensive flora investigations were undertaken in 2013 and 2014 (see details below).

Table 13. Survey details for Wilton

Previous study	Survey area	Effort (flora)	Results
SLR **2013-14**	Wilton Junction /Bingara Gorge	• Walked and driven transects • Target searches for threatened species • 20 m x 20 m flora plots & 50 m transects • 68 *Over-The Fence* surveys	See below
Cumberland Ecology **2014-16**	Wilton Junction /Bingara Gorge	• Collection of biometric data within each plant community • Vegetation mapping	c. 60 ha of CPW identified c. 65 ha of SSTF (low sandstone) c. 8 ha of Derived native Grassland (CPW) No records of *Pimelea spicata*

4.2 Assessment of species presence and justification [BAM 6.5.2.8c, 6.5.2.5]

4.2.1 Greater Macarthur Growth Area

Based on atlas records and the extensive distribution of potential habitat (particularly Cumberland Plain Woodland and Moist Shale Woodland) within the GMGA it is confirmed that *Pimelea spicata* is present and could be present at other sites. The population at Minto Industrial Estate was confirmed in 2013 and is believed to be subject to some level of management. Although no known populations occur within the *biocertification* area, there are extensive areas of potential habitat and a reasonable likelihood that the species is present at other sites either as plants, rootstock or seed. The highest likelihood of occurrence is in central parts of the growth centre in the vicinity of Menangle Sugarloaf coinciding with the largest area of potential habitat in both particularly Cumberland Plain Woodland and Moist Shale Woodland.

4.2.2 Wilton Growth Area

There are no atlas records for *Pimelea spicata* within the Wilton Growth Area. The closest records are just north of Douglas Park on the western side of the Nepean River in similar undulating terrain within Cumberland Plain Woodland and on land largely cleared and used for grazing. In view of these records and presence of similar habitat within the WGA and *biocerification* area, there is a reasonable likelihood of the species being present. A significant proportion of the potential habitat comprises derived grasslands dominated by native species or a mix of native and exotic. It is noted that *Pimelea spicata* has been found in derived grassland dominated by exotics with occasional patches of native grasses and herbs e.g. at Cobham Road, Fairfield.

4.3 Assessment of suitable habitat

Suitable habitat for *Pimelea spicata* has been determined with reference to known sites, flora studies, scientific and personal knowledge. Important habitat attributes used to identify suitable habitat are discussed below.

4.3.1 Key habitat attributes & justification for use in determining suitable habitat

<u>Vegetation communities</u>
Pimelea spicata is primarily associated with *Cumberland Plain Woodland* (PCT's 849 & 850). Dominant canopy species are Narrow-leaved Ironbark *Eucalyptus crebra,* Grey Box *E. moluccana* and Forest Red Gum *E. tereticornis.* In southern parts of the Cumberland Plain, it also occurs in *Moist Shale Woodland* (PCT 830) with the same canopy species. Examples of populations occurring in Moist Shale Woodland include the following Atlas locations:

- Western Sydney Regional Park
- Denham Court (private property)
- Greendale near Wallacia (private property)
- Williamswood Biobank Site, Mount Hunter

The main occurrence of Moist Shale Woodland is at and in the vicinity of the Menangle Sugarloaf within the central zone of the GMPGA. In highly modified remnants it can be difficult to distinguish Moist Shale Woodland from Cumberland Plain Woodland with more resilient drier species replacing the moisture-loving ones until the canopy and understorey is restored.

Shale Sandstone Transition Forest (PCT 1395) may also provide suitable habitat at the shale end of the transition where it is structurally and floristically comparable to Cumberland Plain Woodland. The two communities adjoin each other extensively within the growth areas particularly in southern parts of the GMPGA and through the WPGA. Identification can be difficult particularly in modified remnants typical of these areas. Survey for alleged clearing of native vegetation at Gilead (James 2011) established that vegetation mapped as SSTF was partly Cumberland Plain Woodland. For these reasons some areas of SSTF are included within areas of identified suitable habitat.

Total habitat area of all mapped CPW (PCT's 849 & 850) and derived native grasslands within Wilton/Greater Macarthur priority growth areas is 765 ha.

<u>Physical environment</u>
Pimelea spicata is most often found on slopes in undulating low hilly terrain on Wianamatta Group shales including both Ashfield and Bringelly Shales. Within the GM and Wilton priority growth areas Ashfield Shale is the most widespread. To the south of the study area, particularly around Appin and Wilton it occurs as a capping over sandstone on ridges close to the Nepean and Georges Rivers. *Pimelea spicata* prefers moist soils (clay helps to retain the moisture) and is often found on protected south or east facing slopes close to drainage lines or seepage points. Growth and

flowering appears to be largely dependent on such moist soils with plants often not visible in dry periods and dying back to rootstock or persisting as seed in the soil seed bank.

Such conditions occur through most of the growth areas although protected slopes below ridges could be targeted as preferred habitat. The recent records from the Appin Mine location just west of the Nepean River are associated with such conditions and comparable to terrain within the southern part of the GMPGA and the WPGA.

<u>Habitat condition</u>
Optimal habitat for *Pimelea spicata* is intact woodland with an open, grassy understorey, however, it can survive in disturbed and degraded landscapes (see Section 2.4). Many of the known records are associated with regenerating native vegetation e.g. after a disturbance such as mowing or grazing has ceased. Records from many council reserves have been made in recent years as “no mow” zones have been established. Examples include:

- Faulkland Reserve, Kings Langley (Blacktown LGA)
- Melrose Park, Quakers Hill (Blacktown LGA)
- Power Street Reserve (Fairfield LGA)

Extensive areas of woody weeds such as African Olive occur within the growth areas, for example, at the Menangle Sugarloaf. These areas can still contain potential habitat (see Section 2.4) and are included. Examples of *Pimelea spicata* being recorded after removal of African Olive include a site at Greendale (Penrith LGA) and Mt. Annan.

The condition of habitat, therefore, is not a reliable indicator of species presence and accordingly **all condition states** are considered in determining suitable habitat i.e. intact, thinned, scattered, derived shrubland and grasslands.

4.3.2 Identification of habitat polygons

Areas of potential habitat are identified based on the attributes described in Section 4.3.1, landscape context and personal knowledge. Although *Pimelea spicata* is known to occur in degraded sites, very small patches within over-cleared landscapes where the soil is likely to have been modified are excluded.

Forty polygons containing a total of 542 ha of suitable habitat for *Pimelea spicata* are identified within the GMGA and six polygons with 405 ha in the WGA mostly comprising Cumberland Plain Woodland (including derived native grasslands) but also 187 ha of Moist Shale Woodlands and a total of 265 ha of CPW/low sandstone influenced SSTF (see Figures 4 & 5). The relative areas of vegetation communities are provided in Table 14.

Table 14. Areas (ha) of threatened communities identified as potential habitat for *Pimelea spicata* within the Greater Macarthur and Picton Growth Areas

Threatened Community	PCT	Area (ha) in Greater Macarthur	Area (ha) in Wilton
Cumberland Plain Woodland	850	121	0
Cumberland Plain Woodland	849	152	221
Native Grasslands (included in CPW areas)	608, 609	13	162
Moist Shale Woodland	830	187	0
River-flat Eucalypt Forest	835	0.2	0
Shale Sandstone Transition Forest (low sandstone)	1395	81.5	184

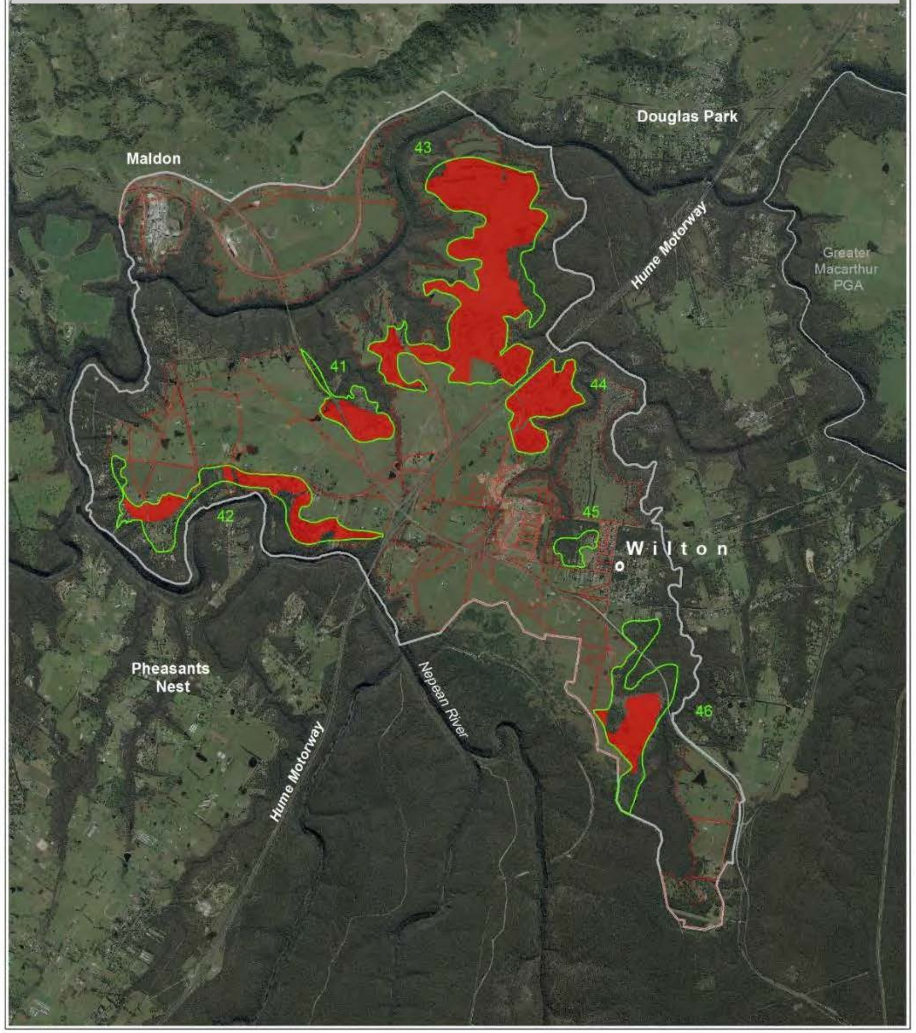
- Urban Development
- Urban development within potential habitat



Wilton Priority Growth Area

- Pimelea spicata - Bionet Fora Records
- Pimelea spicata potential habitat
- Urban Development Footprint/Biocertification Boundary
- Urban development within potential habitat

Biocertification area

Within the southern zone of the GMGA, the area of suitable habitat that is located within the development footprint is 113 ha or 21%. Within the PGA 468 ha or 82% occurs within the development zone.

4.3.3 Survey effort

Greater Macarthur GA
The nature and level of survey effort undertaken within the habitat polygons as part of the strategic assessment is a factor to consider in identifying potential habitat. Figures 9 - 11 show the overlap of surveys with areas of suitable habitat. This information is summarised in Table 15.

The northern extent of the Greater Macarthur growth area has been well surveyed reflecting the small areas and easy access. Except for polygon 2 where five Ecoplanning plots were sampled the remaining polygons were subject to general flora and fauna survey by Biosis that is reported to have included targeted survey for *Pimelea spicata* (Dayle Green *pers. comm*.). Details of the timing and conditions of surveys, however, are unknown. The spring/summer of 2017/18 was generally hot and dry, not providing suitable conditions for survey of this species (see Section 2). Many of the selected habitats are also currently subject to disturbance such as mowing in council reserves e.g. Georges River Reserve, Kanbyugal Reserve and along Bow Bowing Creek at Minto.

Table 15. Survey effort in suitable habitat polygons for *Pimelea spicata*

Growth area	No. of habitat polygons	No. of habitat polygons unsurveyed	No. of habitat polygons with plot survey	Details
Greater Macarthur (north)	16	2 12.5%	1	1 of the unsurveyed plots (No. 1) Glenfield Waste Services has been surveyed previously including plots – see Section 4.1.2. Except for plots 1 & 2 only general flora survey undertaken (Biosis)
Greater Macarthur (south)	24	12 50%	4	Low level of survey in areas with highest concentration of suitable habitat polygons.
Wilton	6	3 50%	3	Largest polygons with good level of plot survey (Ecoplanning)

The southern extent of the Greater Macarthur Growth Area has been less well surveyed with 50% of habitat polygons surveyed and again mostly through general/targeted survey by Biosis. Habitat occurring on semi-rural/grazing lands around Menangle Sugarloaf and Mount Gilead comprise some of the most potential habitat in Cumberland Plain Woodland and Moist Shale Woodland for *Pimelea spicata* within the growth areas but are among those least surveyed (both general, targeted and plot sampling). Many areas of suitable habitat in the southern extent are also still slashed and grazed or subject to African Olive infestation reducing the likelihood of the species being visible.

Wilton Growth Area
The Wilton GA has been well surveyed and although only 50% of the habitat polygons have been accessed and surveyed they are the largest ones. Reliability of these surveys in detecting *Pimelea,* however, is likely to be low in view of the hot dry conditions experienced during spring-autumn 2017-2018 and the extent of grazing. Figures 9-11 show the overlap of surveys with suitable habitat polygons with the priority growth areas.

Figure 9. Habitat polygons and survey effort for Greater Macarthur GA Northern Zone

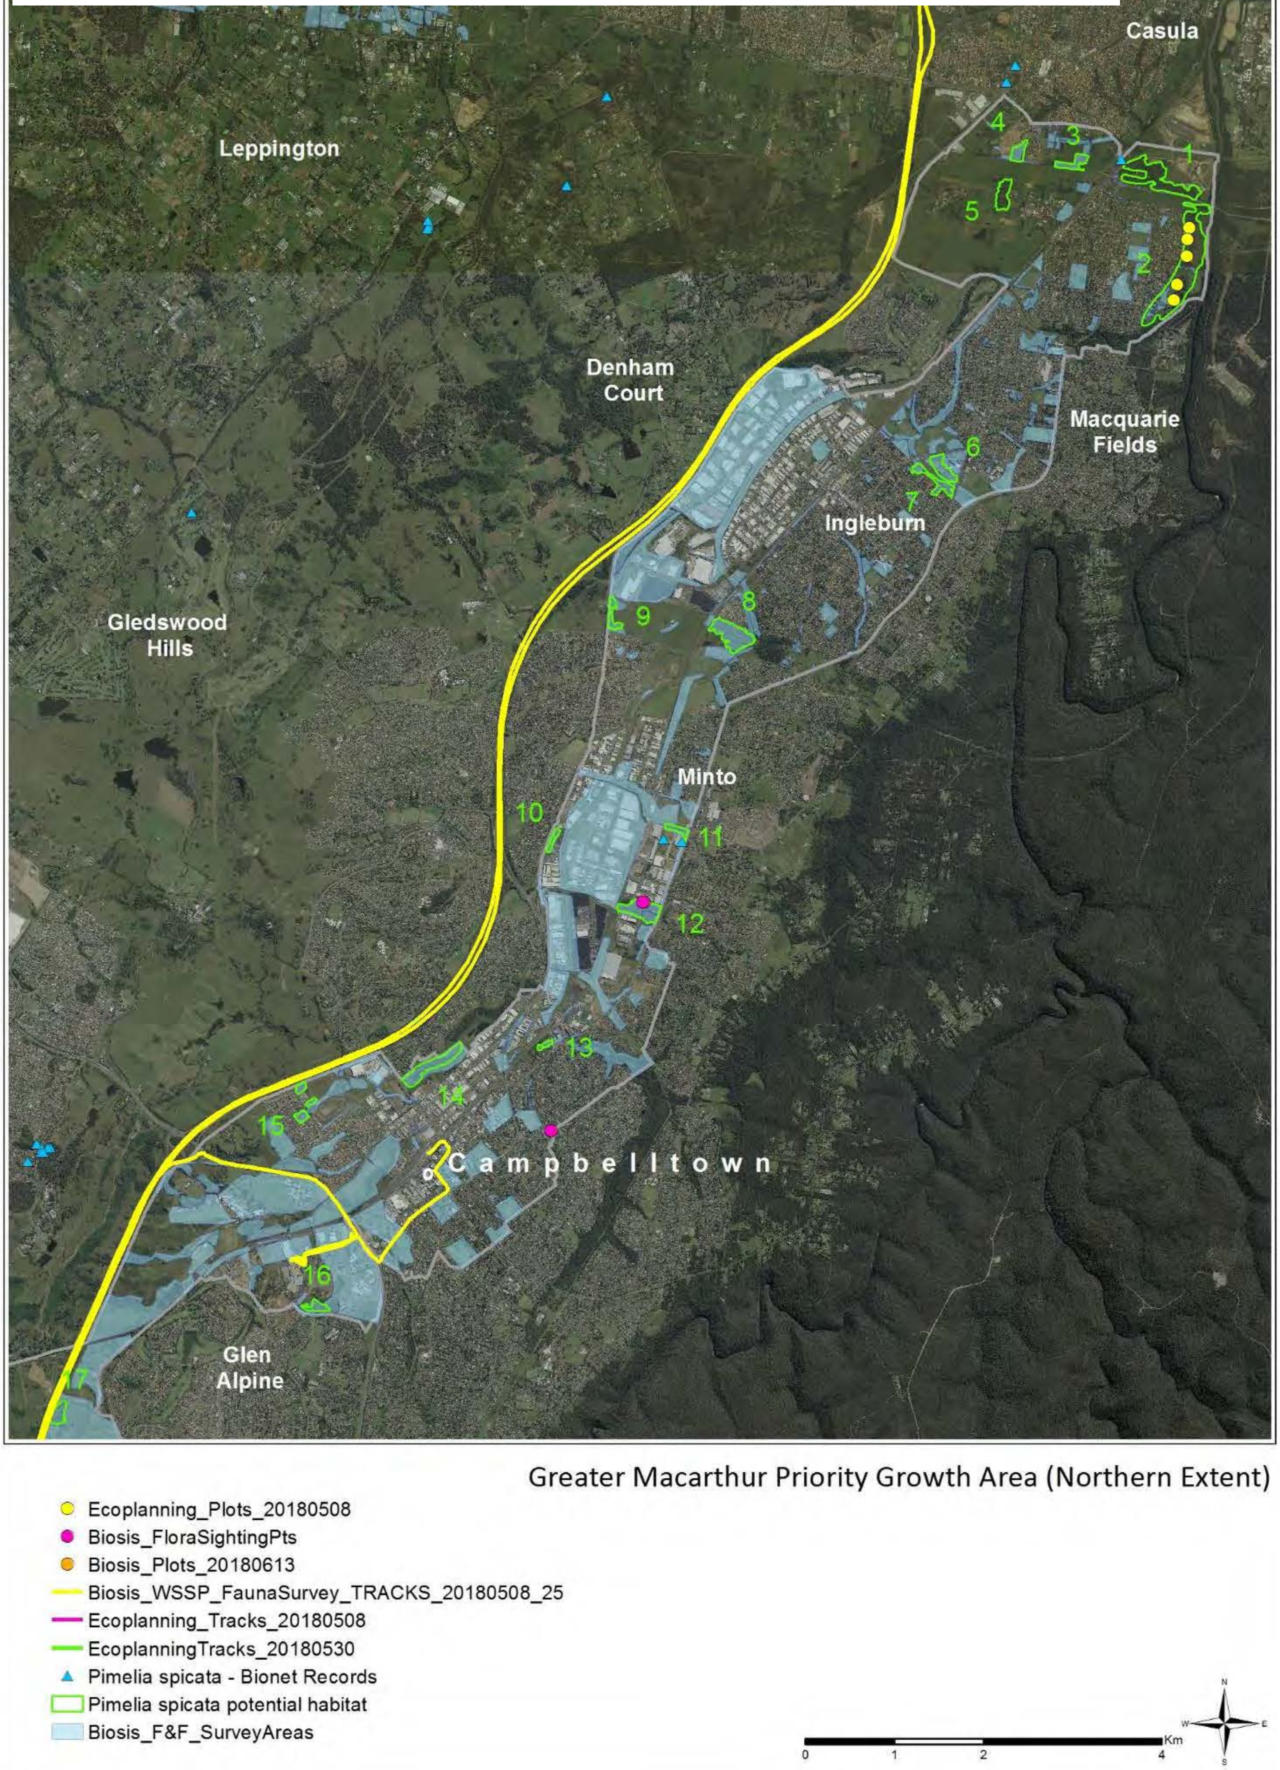


Figure 10. Habitat polygons and survey effort for Greater Macarthur GA Southern Zone

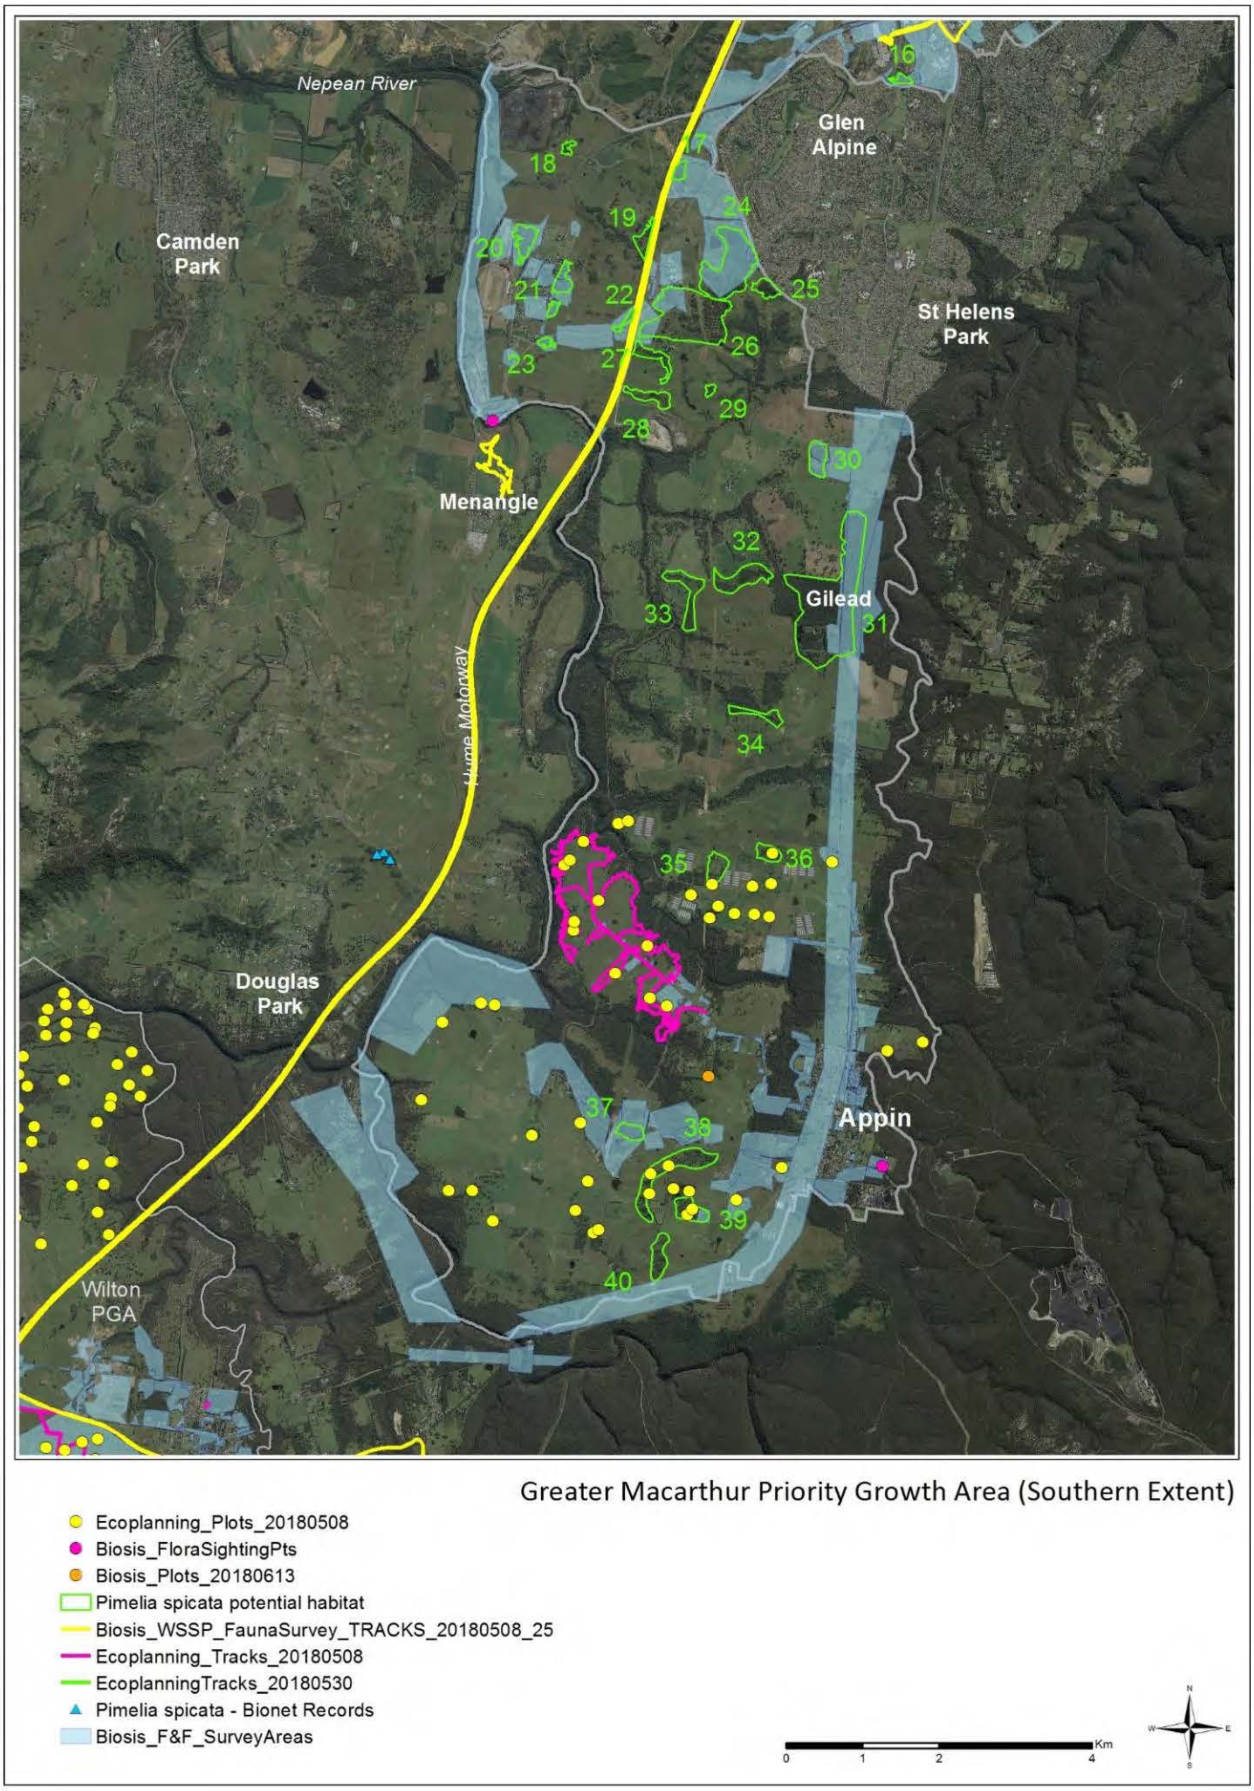

Figure 12. Habitat polygons and survey effort for Wilton GA

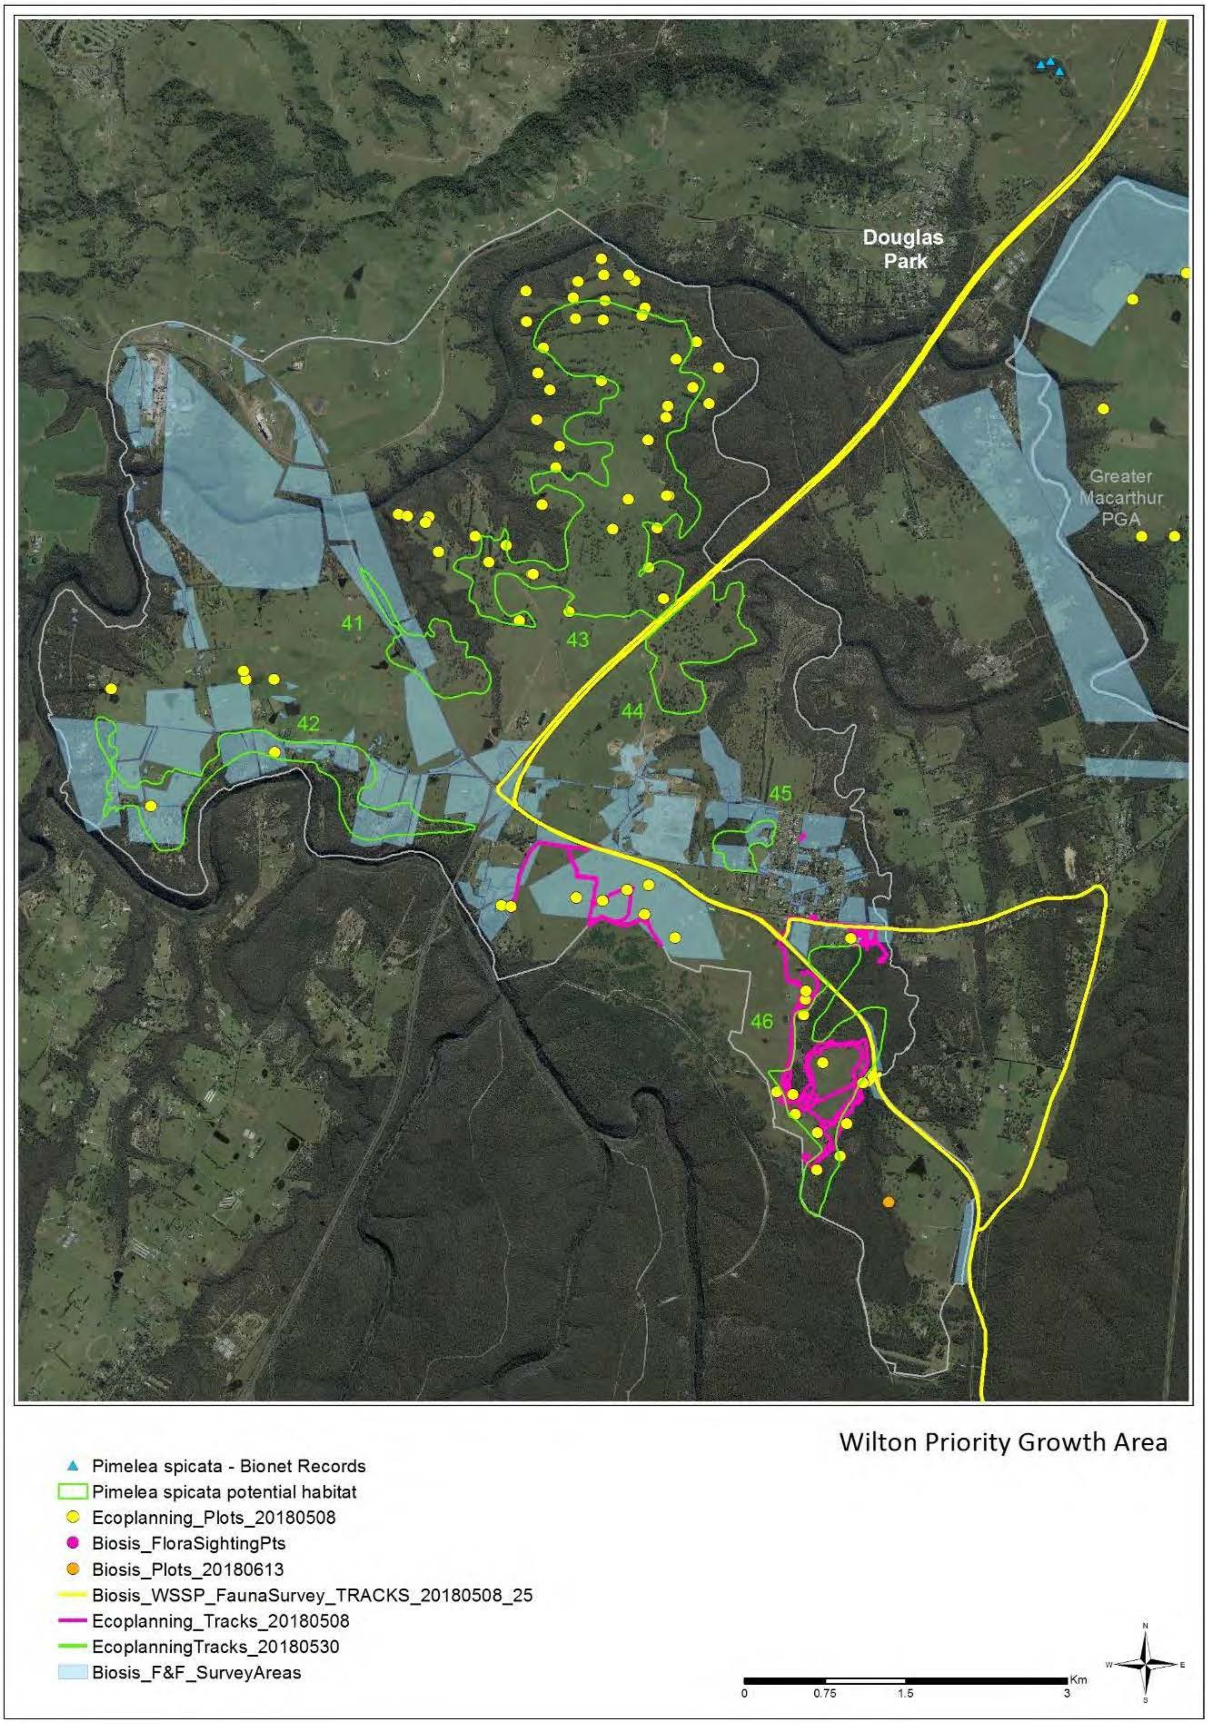

5 Summary and conclusion

Pimelea spicata is likely to be present within both the Greater Macarthur and Wilton Priority Growth Areas. Within the northern zone of the Greater Macarthur PGA one atlas record has been confirmed in recent years and has some short-term security. Several populations occur just to the north and west of the study area. The study area is considered important habitat for the species close to the south-eastern limit of its geographical range.

Likelihood of occurrence is based on the:

- Presence of local records;
- Presence of suitable habitat;
- Ability of the species to persist as rootstock and seed for long periods; and
- Ability of the species to easily regenerate when environmental conditions are suitable.

Extensive areas of suitable habitat are identified across the study area but particularly in the more rural lands of the southern extent of Greater Macarthur and the Wilton Growth Areas. A total area of 947 ha is identified within four vegetation communities (TECs) across the two growth areas (542 ha in GMGA & 405 ha in WGA). The condition of habitat is not a reliable indicator of species presence and all condition states were considered in determining suitable habitat.

Survey effort across the study area is variable. Areas with the highest potential for occurrence of *Pimelea spicata* are under-surveyed including Menangle Sugarloaf and Mt. Gilead. Throughout the study area, even where the level of survey is good, the reliability of detecting the species is low due to lack of targeted survey under suitable conditions for growth and flowering.

A high percentage of potential habitat occurs within the biocertification area or proposed development footprint and impacts on *Pimelea spicata* are expected to be high. Within the southern zone of the GMGA, the area of suitable habitat that is located within the development footprint is 113 ha or 21%. Within the WGA 468 ha or 82% occurs within the development zone.

In view of the low reliability of prior/recent surveys it is appropriate to assume the species presence and to reserve areas of suitable habitat across the study area that are protected and managed to protect the species long-term.

6. Information used in the assessment

6.1 NSW Planning & Environment resources

- Bionet sightings & other threatened species data
- Greater Macarthur & Wilton Vegetation Mapping
- Survey effort and land access details

7. Appendix 1. Curriculum Vitae for Teresa James

Home & work address: 7/58 Wharf Street, Forster NSW 2428

Mailing address: PO Box 53 Forster NSW 2428

Telephone: Mobile: 04 282 18502.

Email: t.james@optusnet.com.au

Key positions:

- Botanist/ecological consultant specialising in vegetation survey, plant identification, conservation assessment and threatened species.
- Until October 1998 held position of Identifications Botanist, Plant Sciences, National Herbarium of New South Wales, Royal Botanic Gardens, Sydney.

Qualifications:

Bachelor of Science (Combined Honours in Biology and Geography) - University of Exeter, England. 1978.

Accreditation:

Accreditation awarded (2008) as a BioBanking Assessor under the Threatened Species Conservation Act 1995 (NSW); accreditation renewed 2013. Accreditation number 0017.

Current employment (1998-present):

Self- employed flora/ecological consultant (sole trader working as Teresa James Flora Consultant).

- Flora surveys, site/conservation assessments and monitoring projects.
- Preparation of environmental impact assessment reports (e.g. 7-part test, species impact statement & review of environmental factors).
- Biobanking and Biodiversity Offset assessments.
- Preparation of threatened species management plans.
- Expert witness in the Land & Environment Court.
- Botanical training for local councils and community groups.

Previous employment

1978 (3 months)	Technical Assistant, Biological and Chemical Research Institute, Rydalmere (Department of Agriculture).
1978-1998	Employed at the Royal Botanic Gardens, Sydney.
1978-1979	Temporary Herbarium Assistant
1980-1982	Technical Officer, Botanical Information Section
1982-1986	Acting Identifications Botanist, Botanical Information Section
1987-1991	Technical Officer, Botanical Information Section
1991-1994	Acting Identifications Botanist, Botanical Information Section
1994	Secondment 4 days/week to World Heritage Assessment of the Blue Mountains (consultancy for NSW National Parks & Wildlife Service).
1994	Permanent appointment as Identifications Botanist.
1994-	Appointed Botanical Information Section Co-ordinator.
1996-1997	Secondment to NSW National Parks & Wildlife Service as Flora Officer for Urban Bushland Biodiversity Survey. Stage 1: Western Sydney.

1994-1998	Identifications Botanist & Botanical Information Section Co-ordinator.

Selected longer-term projects:

1998-1999	Vegetation sampling for NSW National Parks & Wildlife Service - Western Sydney Vegetation Mapping Project.
1999	Flora consultant to Eastern Gas Pipeline (Duke Australia Operations).
2000	Preparation of Fire Ecology Manual for Rural Fire Service and UWS.
October 2000-2003	Flora consultant to Biosis Research for Penrith City Council – proposed developments & TSC Act issues at Erskine Park.
2001	Field sampling and truthing for vegetation community mapping project - Baulkham Hills LGA. Baulkham Hills Shire Council.
2001-2003	Qualitative and quantitative vegetation surveys (including rare plant species and ecological communities, weeds and other threats, environmental assessment) of Wingecarribee Swamp with Sainty & Associates for the Sydney Catchment Authority.
February 2002-May 2002	Review of wetland boundaries and general vegetation mapping and condition assessment within Baulkham Hills local government area (for Baulkham Hills Shire Council).
2003	Vegetation survey in the Hunter, Nattai & Bargo districts as part of the National Parks & Wildlife Service Vegetation Survey Program.
2002-2007	Flora survey/monitoring at Dr Charles McKay Reserve, Mt. Druitt for Blacktown City Council.
September 2005 –2006	Field validation for Foreshore Vegetation Mapping Project on Sydney Harbour for Botanic Gardens Trust and NSW Maritime Services.
September 2000-2008	Flora consultant to Liverpool City Council – provide review & advice relating to development applications, plans of management & special projects.
February -May 2007	Field survey for Sydney Metropolitan Catchment Management Authority/DECC vegetation mapping. Plot data recorded for 100 sites within SMCMA.
May 2008-2010	Vegetation mapping and assessment of Blue Gum High Forest and Turpentine Ironbark Forest in Ku-ring-gai local government area
August 2008-present	Flora advice to Ku-ring-gai Council - review of development applications, plans of management and mapping/biodiversity projects.
February-August 2012	PAS2 Expert Interviews for NSW threatened species with Office of Environment & Heritage.

*See consultant reports for complete list of projects/surveys.

Special projects:

Assessment of the World Heritage Values of the Blue Mountains and surrounding plateaus

An assessment of the natural and cultural values of the sandstone plateaus of the Blue Mountains and surrounding areas was funded by the Federal and State Governments to determine the potential for world heritage nomination. A team of people worked on the project from the Royal Botanic Gardens, Australian Museum (cultural values) and experts from local universities. I was project co-ordinator for the assessment, wrote much of the text for the natural values sections and was editor of the final report.

This report was used as a basis for the successful Blue Mountains World Heritage nomination (June 1998).

<u>NPWS Urban Bushland Biodiversity Survey. Stage 1: Western Sydney</u>

Documentation of biodiversity and conservation values in Western Sydney was the first priority project undertaken within the State Biodiversity Survey Program. The survey gave emphasis to threatened species, communities and habitats. The region was documented on a local government area basis. I co-ordinated the flora surveys and was principal author for the flora reports.

Particular expertise:

Plant Identification:

- New South Wales plants, native and naturalised (18 years of experience in the Botanical Information Section of the Royal Botanic Gardens, Sydney). Specimens received from all over state. Also cultivated plants.
- Specialist in Sydney flora.
- Prepared taxonomic treatments for various plant families in the publication Flora of New South Wales, volumes 1-4, produced by the Royal Botanic Gardens, Sydney.
- Conduct plant identification workshops both through the RBG and the University of Western Sydney.

Documentation and conservation/ impact assessment: plant communities and species

- Extensive range of sites surveyed with species lists compiled over the last twenty-five years, particularly in Western Sydney, the Blue Mountains and Southern Highlands. Plant specimens collected and incorporated into the National Herbarium of N.S.W. Information used in numerous reports and books e.g. World Heritage Assessment of the Blue Mountains, the NPWS Urban Bushland Biodiversity Survey, Rare Bushland Plants of Western Sydney and various papers.
- Prepare Tests of Significance and Species Impact Statements as required under current legislation (TSC Act, EPBC Act).
- Prepare Statements of Evidence & Affidavits for the Land & Environment Court.
- Provide advice to the community, developers, government agencies and councils concerning the identification of communities and species, impacts of proposed developments, the ecological effects of urbanisation, flood mitigation and management practices such as mowing, burning etc.

Peer review

Assessor services provided to government (all levels), consultancies and NGO's. Including the following:

- DA applications and associated reports e.g. REF's, SIS's, Tests of Significance
- BioBanking/Offset reports
- NSW Land & Environment Court reports

Education & training

- Involvement on committees or in groups providing technical advice and training eg. Greystanes Creek Management Committee, Upper Parramatta River Catchment Trust steering committees, Hawkesbury Rainforest Network.
- Presentations/talks e.g. National Parks Association, Society of Australian Plants, University of NSW, Landcare groups, local councils.
- Conduct plant community and species identification workshops/courses/tours through the Royal Botanic Gardens, the University of Western Sydney and privately.
- Prepared Fire Ecology Manual for Rural Fire Service (2000).

- Training for local government in threatened species, endangered ecological communities and biodiversity conservation.
- Publications e.g. primary author of revised edition of Rare Bushland Plants of Western Sydney (Royal Botanic Gardens 1999*),* contributor to Flora of New South Wales *(*Royal Botanic Gardens).

Courses/workshops & tours provided to local government/catchment management trusts/consultancies:

- Sept. 2004 - Threatened Species Tour for Baulkham Hills Shire Council bush care workers & council staff
- October 2004 – Significant Plant Communities-of Baulkham Hills Shire Council – tour for council staff
- February 2005 – Community workshop in Cumberland Plain Woodland for Holroyd City Council
- July-August 2005 - Biodiversity training for Liverpool City Council – 3 workshops for council officers
- September 2005 - Threatened Species Tour for Baulkham Hills Shire Council bush care workers
- August 2007 - Threatened Species Tour for Baulkham Hills Shire Council bush care workers
- October 2007 – Identification of plants in Cumberland Plain Woodland – for Hawkesbury Nepean CMA.
- April 2008 – Basic grass identification course for Baulkham Hills Shire Council (for bushcare volunteers).
- August 2008- Threatened Species Tour for Baulkham Hills Shire Council bush care workers
- November 2008 to April 2009 – Weedy Grass Identification Workshop x 3 for Sydney Metro CMA.
- August 2009- Threatened Species Tour for Baulkham Hills Shire Council bush care workers
- October 2009 – EEC identification field day for Hawkesbury-Nepean CMA
- August 2010 - Threatened Species Tour for Baulkham Hills Shire Council bush care workers
- October 2010 – Cumberland Plain Woodland identification training for SMEC Australia
- April 2011- – Cumberland Plain Woodland identification training for SMEC Australia
- April 2011 – Field training in identification of communities & plants on the Cumberland Plain for Hawkesbury Nepean CMA.
- June 2011 – Presentation to council staff on threatened flora & fauna and biodiversity conservation within the Hills Shire.
- August 2011- Threatened Species Tour for Hills Shire Council bush care workers
- June 2012 – Eucalypt Identification workshop for Hills Shire Council.
- September 2014 - Threatened Species Tour for Hills Shire Council bush care workers
- September – November 2014 – Series of two-day workshops on threatened ecological communities in western Sydney.
- October 2014 – Plant identification training day held at Dr Charles Mckay Reserve, Mt. Druitt for Blue Tongue Ecosystems.
- March 2015 – Derived Grasslands Workshop (western Sydney) for government and community.
- May 2015 - Threatened Ecological Communities Workshop (western Sydney) for government and community.
- August 2015 – Shale Sandstone Transition Forest Workshop (western Sydney) for government and community.
- September 2015 – Northern Sydney Threatened Communities Workshop for government and community.
- April 2016 - Shale Sandstone Transition Forest Identification Workshop
- April 2016 – Introduction to Identifying Western Sydney Plants
- April 2016 – Grass Identification Workshop

- April 2016 – Cumberland Plain Woodland Workshop for Liverpool Council bushcarers
- August 2016 - Threatened Species Tour for Fairfield City Council.
- August 2016 - Threatened Species Tour for Hills Shire Council.
- April 2017 – Bushcare Training for Penrith Council
- Aug-Sept -Oct 2017 - Community bushland guided walks for Liverpool Council
- August 2017 - Threatened Species Tour for Fairfield City Council.
- August 2017 - Threatened Species Tour for Hills Shire Council.
- September 2017 – Flora workshops at Scheyville and Agnes Banks

Committee & community participation

- Member of NPWS Cumberland Plain Woodland Recovery Team (1998).
- Member of NPWS Acacia pubescens Recovery Team (1998 to 2002).
- Member, Green Corridors Strategy Steering Committee.Upper Parramatta River Catchment Trust. (1997-2000).
- Member, Water Quality Strategy Steering Committee. Upper Parramatta River Catchment Trust (1995-7).
- Member, State of the Environment Report Steering Committee for Holroyd City Council (1995-2002).
- Botanical Advisor for Management Committee, Greystanes Creek Restoration Project (1993-2000).
- Blue Gum High Forest Workshop / Advisory Committee – Ku-ring-gai Council. (2007).

- James, T.A. (May 2006). Preliminary flora report – proposed Penrith Great River Walk. Report to Australian Museum Business Services for Penrith City Council).
- James, T.A. (May 2006). Autumn surveys in Dr Charles McKay Reserve, Mt. Druitt. Ongoing survey & monitoring for Blacktown City Council.
- James, T.A. (May 2006). Update of Species Impact Statement for proposed development at 8 Narabang Way, Belrose. Report to Access Industrial Holdings Pty Ltd.
- James, T.A. (May 2006). Review of Environmental Management Plan and site inspection for proposed stabilisation works along Birrong rail cutting. Advice to RailCorp.
- James, T.A. (July 2006). Flora investigation of alleged poisoning of vegetation on Lot 42 Warlands Creek via Blandford, Upper Hunter Valley. Report to Department of Environment & Conservation (Legal Branch).
- James, T.A. & Barker, C. H. (June-August 2006). Preliminary flora & fauna survey for Hyland Road Reserve (North), Greystanes. Report to Holroyd City Council.
- James, T.A. (September 2006) Threatened Flora Surveys – western Sydney. Targeted survey for Department of Environment & Conservation.

- James, T.A. (November 2006). Flora survey and assessment for proposed footbridge construction over Cabramatta Creek. Report to Liverpool City Council.
- November 2006. Targeted field survey for *Gentiana wingecarribiensis* at Wingecarribee Swamp, Southern Highlands. Assistance to Parsons Brincherhoff Australia.
- February-May 2007. Field survey of Sydney Metropolitan Catchment Management Authority area. Royal Botanic Gardens Trust and Sydney Metropolitan Catchment Management Authority.
- T.A. James (February 2007). Faulkland Crescent Reserve - flora survey and review. Report to Blacktown City Council.
- James, T.A. (April 2007). Upgrade of Great Western Highway at Wentworth Falls - proposed stockpile, compound and spill basin areas - Flora survey and assessment. Report to Australian Museum Business Services for RTA.
- James, T.A. (May 2007). Upgrade of Great Western Highway at Bullaburra – flora survey and assessment. Report to Australian Museum Business Services for RTA.
- BioBanking Pilot Program (May 2007). Field survey & assessment at three Sydney sites (Wilton, Camden & Cranebrook) to test draft assessment methodology. Undertaken with Australian Museum Business Services for Department of Environment & Conservation.
- James, T.A. (August 2007). Flora review – proposed re-zoning of land along Pacific Highway, Pymble with particular reference to Blue Gum High Forest. Report to Ku-ring-gai Council.
- James, T.A. & C. H. Barker (October 2007). Flora & Fauna Survey and Assessment – Castle Hill Cemetery. Report to Baulkham Hills Shire Council.
- James, T. A. (Nov 2007). Investigation of clearing of native vegetation at Lot 2 DP 559922, 280-282 Captain Cook Drive, Kurnell. Report to NSW Department of Environment & Climate Change (DECC).
- James, T.A. (Nov 2007). Review of flora assessment for proposed residential development at 216-220 New Line Road, Dural. Report to Hornsby Council.
- November 2007. Assistance to SMEC Australia with base-line ecological monitoring in Upper Nepean Special Area for SCA.
- James, T.A (Dec 2007-Feb 2008). Targeted survey for *Hibbertia superans.* Report to Indigenous Business Services.
- November 2007- January 2008. Targeted survey for *Gentiana wingecarribiensis* and *Prasophyllum uroglossum* at Wingecarribee and Hanging Rock Swamps. Report to NSW Department of Environment & Climate Change (DECC).
- March 2008. Flora survey for upgrade of Great Western Highway at Bullaburra. Report to nghenvironmental for RTA.
- James, T.A. (March 2008). Flora survey of Plumpton Park Reserve. Report to Blacktown City Council.
- James, T.A. (April 2008). Review of Water Street DA, Wahroonga. Report to Ku-ring-gai Council.
- James, T.A. (April 2008). Flora survey of Gum Tree Reserve, Guildford and Bolaro Avenue, Greystanes. Report to Holroyd City Council.
- May 2008-June 2009. Assistance to Ku-ring-gai Council to map and assess Blue Gum High Forest and Turpentine Ironbark Forest.
- James, T.A. (August 2008). Flora review of Species Impact Statement prepared for proposed industrial development at 37 Beaumont Road, Mt. Ku-ring-gai. Report to Hornsby Shire Council.
- James, T. A. (May 2009). Preliminary flora report for proposed residential development at 38-40 Grove Avenue, Narwee.
- James, T.A. & Barker, C. (2006-2009). Monitoring of flora and fauna at Hyland Road Reserve. Report to Holroyd City Council.

- James, T. A. (Sept 2009). Ecological issues relating to the Turramurra Deferred Area within Ku-ring-gai LGA. Report to Friends of Turramurra.
- James, T.A. (Sept 2009). Targeted survey for *Pimelea spicata* at Menangle Park. Assistance to GHD Pty Ltd.
- James, T.A. (Sept 2009). Investigation into land clearing of Shale Sandstone Transition Forest and Cumberland Plain Woodland - 561 Appin Road, Gilead. Report to Campbelltown City Council.
- James, T.A. (Nov 2009). Peer review of subdivision proposal at Kellyville. Shale Sandstone Transition Forest & threatened species present. Report to Hills Shire Council.
- James, T.A (2010). Field survey and ecological assessment for proposed park at Water Street, Wahroonga. Report to A. Parr.
- James, T.A. (March 2010). Survey of *Pimelea spicata* at Menangle Park for GHD.
- March-April 2010. Advice on threatened species for Growth Centres Strategic Assessment under EPBC Act to EcoLogical Australia.
- Lewis Ecological Surveys & James, T.A. (May –June 2010). Flora and fauna assessment for extension of Kirkwood Road, Tweed Heads. Report to Tweed Heads Shire Council.
- Lewis Ecological Surveys & James, T.A. (May –June 2010). Compensatory habitat assessment for the Kempsey to Eungai pacific highway upgrade.
- Joint project with Australian Museum (October 2010 - March 2011) – Flora & fauna survey for Stage 2 of the Narrabeen Lagoon Multi-use Trail.
- Joint project with Australian Museum (October 2010 - December 2011) – City of Sydney Biodiversity Survey & Strategy.
- James, T.A. (2011). Investigation into land clearing of Shale Sandstone Transition Forest and Cumberland Plain Woodland - 561 Appin Road, Gilead. Expert report to DECCW.
- James, T.A. (2011) Flora survey for three reserves in Holroyd LGA to document regeneration following the cessation of mowing. Report to Holroyd City Council.
- James, T.A. (2011) Flora survey of Grey Box Reserve, Greystanes. Report to Holroyd City Council.
- Douglas, S & James, T (2011) Review of listing advice and conservation advice for Shale Sandstone Transition Forest EEC under the EPBC Act – in progress.
- James, T.A. (2011) External Review of White Box – Yellow Box – Blakeley's Red Gum grassy woodlands and derived native grassland ecological community for the Mt. Pleasant Project (EPBC 2011/5795). Report to Dept. of Sustainability, Environment, Water, Population and Communities.
- Ecological advice to SMEC Australia (July-August, 2011). Impact assessment for *Pimelea spicata* – upgrade of Camden Valley Way, western Sydney.
- Ecological advice to SMEC Australia (August-September, 2011). Survey and assessment for Eastern Flame Pea – Trans Grid Dapto substation upgrade.
- Field assistance to SMEC Australia (February 2012) - Targeted survey for *Pimelea spicata* and general survey for RTA Camden Valley Way upgrade.
- PAS2 Expert Interviews for NSW threatened species with Office of Environment & Heritage (February-August 2012).
- Plot survey and ground verification of vegetation mapping within Hills Shire Council (June 2012).
- Threatened species management plans for several species prepared for Hills Shire Council (June 2012) – multi-species plan for Paulls Road (South Maroota), individual plans for *Persoonia hirsuta* and *Epacris purpurascens* at Fred Caterson reserve.
- Joint project with Australian Museum - Narrabeen Lagoon multi-trail (stage 2) Species Impact Statement (June 2012)

- Field assistance to SMEC Australia - Western Sydney Parklands vegetation monitoring project for WSP Trust (July – August 2012).
- Biodiversity/conservation assessment for 12-14 Cabernet Circuit Orchard Hills. Unpublished report to Wayne Olling of CCA (October 2012)
- PAS Reviews for selected NSW threatened species with Office of Environment & Heritage (November 2012).
- Vegetation Peer Review for the Northern Beaches Health Service Project. Report to Health Infrastructure (January 2013).
- Flora survey and assessment on private properties within the Balmoral Release Area, Kellyville (15, 16-20, 24, 26 & 28) for the Hills Shire Council (May-June 2013).
- Preparation of a Threatened Species Plan of Management for *Dillwynia tenuifolia* endangered population along Maquires Road, Maraylya for the Hills Shire Council (May-June 2013).
- Biobanking Assessment Report for the Northern Beaches Hospital Precinct development (a State Significant Development). July 2013. Report to SMEC Australia and Health Infrastructure.
- Threatened species roadside survey and verification of threatened ecological communities for Campbelltown City Council (September-October 2013).
- Peer Review of Species Impact Statement for 34-36 Britton Street, Smithfield for Holroyd City Council (November 2013).
- Flora survey and condition assessment for Pacific Highway Upgrade Woolgoolga to Ballina (Feb - April 2014). Assistance to Ecosure for Roads and Maritime Services.
- Matching of threatened entities occurring in the Greater Sydney Region area to newly mapped vegetation/community types in the Sydney Metro CMA and other parts of the Greater Sydney Region (May-June 2014) for Office of Environment and Heritage (Sydney).
- Parramatta Park baseline flora survey and report for Parramatta Park & Western Sydney Parklands Trust (September 2014).
- Assistance to SMEC with survey and biodiversity report for commonwealth-owned land at Badgerys Creek (Sept-Oct 2014). Report to Department of Infrastructure and Regional Development.
- Identification of Shale Sandstone Transition Forest in the Hills Shire – report to Hills Shire Council (July 2015).
- Assistance with field survey to SMEC Australia at the Holsworthy Training Area for Department of Defence (September 2015).
- Assistance with field survey (base line monitoring) to SMEC Australia at the Kapooka Biodiversity Offset Site near Wagga Wagga for Roads and Maritime Services (Sept-Oct 2015).
- Assistance to SMEC Australia in preparation of a Species Impact Statement for the Mona Vale Road upgrade for RMS (Nov 15-Jan16).
- Assistance to Ecosure in field survey/assessment for Mosman Flora and Fauna Bushland Audit (Jan-Feb 2016).
- Ecological Survey of Sackville Cemetery – report to The Hills Shire Council (May 2016)
- Field survey with 20 m x 20 m plot sampling for OEH Western Cumberland Plain and Bargo Gap Project (targeting transitional areas) – June 2016

Strategic Assessment for Cumberland Plain Conservation Plan

Greater Penrith to Eastern Creek and Western Sydney Aerotropolis Growth Areas

Expert Report for *Pimelea spicata* Spiked Rice-flower

Prepared for NSW Department of Planning & Environment

Teresa James April 2019

Contents

*GIS mapping prepared for report by Anthea Whitlam

Executive summary

Pimelea spicata is known to be present within the Greater Penrith to Eastern Creek Growth Area (9 records) and is likely to be present within the Western Sydney Aerotropolis Growth Area with one unsubstantiated record, >500 ha of potential habitat and a large population recently discovered just to the east. The study area is considered important habitat for the species at the western limit of its known extent on the Cumberland Plain.

Potential habitat is based on the:

- Presence of local records;
- Presence of suitable habitat;
- Ability of the species to persist as rootstock and seed for long periods; and
- Ability of the species to easily regenerate when environmental conditions are suitable.

Extensive areas of suitable habitat are identified across the study area. A total area of 2714 ha is identified within four vegetation communities, all threatened ecological communities (TEC's), across the two growth areas (2168 ha in the GPECGA & 564 ha in the WSAGA). The condition of habitat is not a reliable indicator of species presence and all condition states were considered in determining potential (suitable) habitat.

Survey effort within potential habitat across the study area is very low particularly for favoured Cumberland Plain Woodland habitat (only 5% and 7% for PCT 849 within the GPEC and WSA growth areas). More rural areas in western zones of the growth areas (particularly in the south) have been poorly surveyed largely reflecting private ownership and access restrictions. Where targeted survey has been undertaken, the reliability of detecting the species is considered low due to unsuitable conditions for growth and flowering with the best climatic conditions (particularly successive good rain events) occurring post-survey in late 2018 and much of the habitat being grazed and/or slashed. In view of the low reliability of surveys it is considered appropriate to assume a greater presence within the growth areas and reserve suitable habitat across its known range to protect the species long-term.

Within the Greater Penrith to Eastern Creek growth area 133 ha or 6% of potential (i.e. suitable) habitat is found within the certified zone, 178 ha (8%) is zoned for conservation and 1857 ha (86%) occurs in the non-certified zoning. The latter includes larger areas within Wianamatta Regional Park and the Orchard Hills Defence Establishment that has long been recognised for its conservation values. Small council reserves in the far north-west associated with a north to south ridge-line above the Hawkesbury-Nepean River floodplain are particularly important for known and potential *Pimelea spicata* habitat, only two of which currently have conservation zoning. With records of *Pimelea spicata* just outside of the GPECGA at Mulgoa the protection of suitable habitat adjacent and to the south of Mulgoa Nature Reserve is desirable.

In the Western Sydney Aerotropolis growth area just over 53% occurs within the certified or development zone with 43% zoned for conservation predominantly associated with the South Creek corridor (around Kemps Creek) and the upper catchment of Duncan's Creek in the vicinity of Willowdene Avenue, south of Luddenham. The latter area is close to the recently discovered population west of the Northern Road and includes similar habitat.

1. Introduction

1.1 Purpose of the expert report

An expert report may be prepared under section 6.5 of the Biodiversity Assessment Method (OEH 2017) in place of undertaking a threatened species survey. Use of an expert report may be beneficial where it is highly unlikely that a species may occur within the study area, survey effort is inadequate and/or the reliability of detecting the species through survey is low. In respect of *Pimelea spicata*, low survey effort and unreliability of survey are the primary reasons for preparing an expert report.

The purpose of this report is to provide scientific assessment of the current status and conservation needs of *Pimelea spicata* within the Western Sydney Aerotropolis and Greater Penrith to Eastern Creek growth areas of western Sydney. Specifically, the report is to determine whether:

- The species is unlikely to be present and in this case no further assessment is required, or
- The species is likely to be present and in this case the expert report must provide estimates of habitat area both within the growth and biocertified or development footprint areas.

1.2 Project context

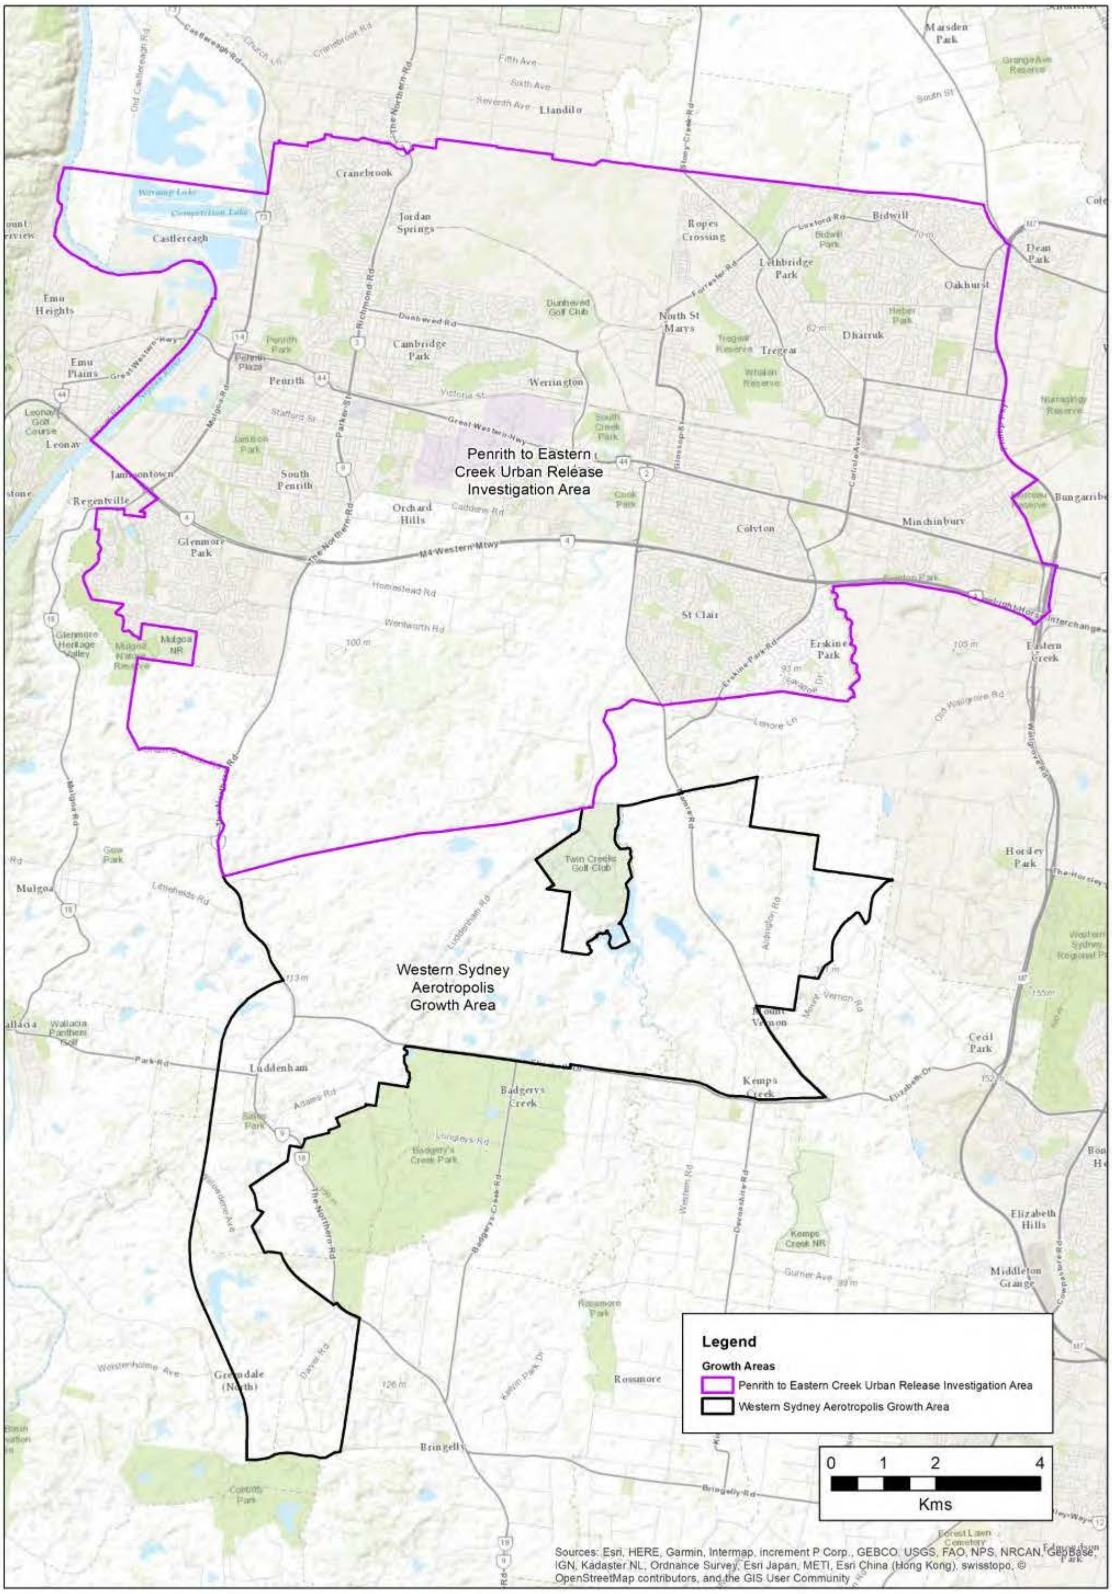
The NSW Government is identifying areas for future urban development and associated infrastructure in western Sydney. There are four priority growth areas: Wilton, Greater Macarthur (Campbelltown and Appin), Western Sydney Airport, and Greater Penrith to Eastern Creek. These new growth areas are all located within the Cumberland Interim Biogeographic Regionalisation for Australia (IBRA) sub-region.

As part of the planning for the priority growth areas, the Department of Planning and Environment (DPE) will prepare the Cumberland Plain Conservation Plan to identify development and conservation outcomes for the growth areas. A strategic assessment of this plan is underway and this expert report will assist the biodiversity assessment to assess the conservation benefits and development impacts of the Plan in respect of *Pimelea spicata*. This report is consistent with the Scope of Works for expert reports provided by DPE and dated November 2018.

1.3 The study area

The study area for this report comprises the growth areas of Western Sydney Aerotropolis and Greater Penrith to Eastern Creek (see Figure 1) and includes parts of the Penrith, Blacktown and Liverpool LGA's in far western to south-western parts of the Cumberland Plain, western Sydney. It adjoins the Western Sydney Airport in the south. The study area is located within the Cumberland subregion on Triassic Wianamatta Group sediments. The study area is within the Hawkesbury-Nepean River catchment and is dissected north to south by South Creek (and its tributaries). It is associated with low-lying to gently undulating land (<100 m a.s.l.) with clay soils (Blacktown and Luddenham soil landscapes) and recent alluvium on floodplains with soils of the Richmond, Freeman's Reach and South Creek soil landscapes.

Figure 1. Western Sydney Aerotropolis and Greater Penrith to Eastern Creek Priority Growth Areas



1.4 Reasons for use of an expert report

An expert report for *Pimelea spicata* is required as part of the threatened species assessment for the Cumberland Plain Conservation Plan for the following reasons:

1. The survey effort for this species did not meet the recommendations in the OEH threatened species guidelines (OEH 2016) for targeted surveys largely due to limitations imposed by land access. Around 3.7 % of total potential habitat for *Pimelea spicata* has been accessed for survey within the Greater Penrith to Eastern Creek Growth Area and 6% in the Western Sydney Aerotropolis Growth Area.
2. Poor survey timing. *Pimelea spicata* is difficult to detect particularly when not in flower. Flowering is unpredictable and considered dependant on good rains (Environmental Impact Assessment Guidelines NPWS 2004, and personal knowledge). During dry periods the species is often invisible above ground but may persist in the soil as rootstock and seed. Dry, hot spring/summers have been a particular feature of the western Sydney environment in the last few years and survey has not been timed to coincide with suitable conditions following good rain events.
3. The cryptic nature of the species and extent of disturbance across the growth areas significantly reduces the likelihood of detecting the species. Many populations have only been recorded once the disturbance factor e.g. mowing, grazing or weed infestation has been removed. Many of the sites surveyed are heavily grazed or mown/slashed.

Survey for *Pimelea spicata* has been insufficient to reliably determine the presence and extent of the species within the growth centres. An expert report is necessary to provide a more comprehensive and reliable level of scientific assessment appropriate for an endangered species.

1.5 Credentials of expert

I am a botanist/ecologist with over forty years of experience in vegetation survey, plant identification, conservation assessment and threatened species, particularly in western Sydney. I have worked within the NSW government (National Herbarium of NSW, NSW National Parks & Wildlife Service) and for the last twenty years as a consultant (sole trader). A summary of my credentials as required under the Biodiversity Assessment Methodology (2014, 2016) is provided in Table 1. Under 6.5.2.4 of the BAM I am recognized as a biodiversity expert for *Pimelea spicata*.

Table 1. Credentials of Teresa James

BAM section	BAM requirement	Details
BAM s 6.5.2.8 (g)	Name of expert	Teresa James
BAM s 6.5.2.4	Biodiversity expert	*Pimelea spicata*
BAM s 6.5.2.3 (a)	The expert's qualifications	Bachelor of Science (Honours), University of Exeter 1978 Accredited BioBanking Assessor (awarded 2008, renewed 2013)
BAM s 6.5.2.3 (b)	History of experience in ecological research and survey method, for the relevant species	Field surveys and other relevant studies: • Populations of *Pimelea spicata* across western Sydney e.g. Denham Court Road, Campbelltown (1999, 2012), Alpha Road Park, & Grey Box Reserve, Holroyd (2011), Cobham Road Reserve & Power Street Reserve, Fairfield (2016-17), Greendale (near Wallacia), private property (2016-7), Cranebrook Reserve, Penrith (2017). • Threatened community and threatened species (including *Pimelea spicata*) roadside surveys through Campbelltown

		LGA for Campbelltown City Council (2013) • Targeted survey for *Pimelea spicata* along Denham Court Road, near Camden Valley Way for SMEC (2012) • Expert report to DECCW: Investigation into land clearing of Shale Sandstone Transition Forest and Cumberland Plain Woodland at a property on Appin Road, Gilead (2011). • Targeted survey for *Pimelea spicata* at Menangle Park Offset Strategy for GHD (2009, 2010) • Biobanking Pilot Project at Wilton (2007). • Survey & monitoring of Cumberland Plain Woodland and *Pimelea spicata* at Faulkland Crescent Reserve, Blacktown (2004, 2007) for Blacktown City Council.
BAM s 6.5.2.3 (c)	A resume detailing projects pertaining to the survey of the relevant species	Resume attached at Appendix 1. Relevant field surveys listed above.
BAM s 6.5.2.3 (d)	Their employer's name and period of employment (where relevant)	Self-employed ecological consultant Teresa James Flora Consultant 1998 to present
BAM s 6.5.2.3 (f)	Evidence that the person is a well-known authority on the relevant species to which the survey relates	1. Author of several botanical guides to the flora of Western Sydney: • James, T.A., McDougall, L & Benson, D. (1999). Revised edition. *Rare Bushland Plants of Western Sydney.* Royal Botanic Gardens, Sydney. • James, Teresa (2013) Flora of Cumberland Plain Woodland – an identification guide. • James, Teresa (2015) Threatened Flora of the Fairfield LGA. • James, Teresa (2016) Native Flora of Shale Soils of the Cumberland Plain Woodland – An Identification Guide. 2. Author of flora component of Urban Bushland Biodiversity Survey of Western Sydney (1997). Included compilation of information on *Pimelea spicata* and its habitat across western Sydney local government areas. 3. Contributed information to the *Pimelea spicata* Approved Recovery Plan (2006). 4. Has acted as Expert witness in NSW Land and Environment Court in relation to threatened communities in western Sydney including: • Expert advice to OEH and Land & Environment Court in relation to alleged clearing of endangered ecological communities (Cumberland Plain Woodland and Shale Sandstone Transition Forest) at Gilead, western Sydney. Proceedings 50604 of 2011. • Expert advice to Liverpool City Council ats Muslim League of NSW – 264 Wilson Road, Green Valley. Land & Environment Court Proceedings No 10394 of 2005. Issues relating to Cumberland Plain Woodland. • Expert advice to Liverpool City Council ats AV Jennings – Stage 24 Dalmeny Drive, Prestons. Land & Environment Court Proceedings No 10395 of 2006. Issues relating to Cumberland Plain Woodland.

		5. PAS2 Expert Interviews for several NSW threatened species with OEH (February-August 2012) including a range of Cumberland Plain species 6. Member of SOS Project Panel (2018) – Cumberland Plain Woodland, Western Sydney Dry Rainforest, Moist Shale Woodland, River-flat Eucalypt Forest, Agnes Banks Woodland and Castlereagh Ironbark Forest 7. Member of NPWS Cumberland Plain Recovery Team (1998) 8. Author of expert report for *Pimelea spicata* in Greater Macarthur and Wilton growth areas (2018)

Through this experience I have developed a good knowledge and understanding of the life history and habitat requirements of *Pimelea spicata* and associated habitats within the growth areas.

2. Species Information

2.1 Species description

A small, slender to spreading shrub or sub-shrub to c. 50 cm high; stems 1-several, glabrous. Older stems are often seen intertwining with grasses and herbs. *Pimelea spicata* has an underground carrot-like tap root recorded up to 18 cm in length that gives plants the ability to re-sprout after defoliation and periods of drought stress (NSW NPWS 1997). The leaves are mostly opposite, narrow-elliptic to elliptic in shape, to 20 mm long and 8 mm wide, spreading, soft and often bluish-green. Inflorescence is a raceme, dense when young, elongated and interrupted at maturity, bracts absent. Flowers tubular, white to pink tinged, 7-10 mm long with four spreading lobes. Fruit is a narrow-ovoid nut, c. 3 mm long, 1-seeded, mostly green.

Pimelea spicata leaves (left); flowers & fruit (above)

2.2 Life cycle

Pimelea spicata is incapable of effective vegetative spread (Benson and McDougall 2001) although more recent observations suggest that mature individuals can spread over short distances through underground rhizomes (OEH 2017) giving rise to "clumps" of plants. Seed production, however, is the primary means of recruitment. Flowering is sporadic throughout the year and is likely in response to climatic conditions, particularly rainfall (DEC 2006). Flowering and fruiting has been observed in plants 1.5-2 years old (NPWS 1997); flowers continue to be produced as fruits mature. Native bees are known pollinators and moths may also contribute to pollination (DEC 2006). The species may also be capable of spontaneous self-pollination (DEC 2006). Fruiting is highly variable depending on environmental conditions. Seed viability has been recorded as relatively high ranging from 83% - 86% (Nash & Matthes 1995, Willis et al. 2003 cited in DEC 2006). Seed dispersal is highly localised with the majority of seedlings observed within 30 cm of adult plants following fire (Hogbin pers. obs. cited in DEC 2006). *Pimelea spicata* maintains a long-lived soil-stored seed bank resulting in potential for considerable recruitment following disturbance. The soil seed bank can survive under infestations of invasive weeds (Willis et al. cited in DEC 2006).

Seed germination can be triggered by disturbance including fire, slashing/mowing, grazing and soil disturbance (NPWS 1997, Willis et al. 2003 cited in DEC 2006). Monitoring of seedlings following fire revealed 80% survival in the first year (NPWS 1997 cited in DEC 2006). Ex-situ trials found that smoke application increased seed germination (Tozer & Robertson 1998), however, Willis et al. (2003) cited in DEC (2006) found only a 20-30% germination rate for seed in any trial.

Re-sprouting from the taproot occurs following defoliation caused by fire, drought or physical damage (NPWS 1997). The species can survive periods of drought stress or weed infestation by dying back to the tap root and re-sprouting when favourable conditions return. It is unknown at what age the tap root has to be of a sufficient size to facilitate re-sprouting.

2.3 Distribution and abundance

Pimelea spicata occurs in two disjunct regions of the Sydney Basin IBRA bioregion, the Cumberland subregion in western Sydney and the coastal region of the Illawarra, south of Sydney.

<u>Cumberland subregion</u>
In the Cumberland subregion *Pimelea spicata* is found on clay soils derived from Wianamatta Group Shales. The current known distribution extends from Freeman's Reach in the north to Douglas Park in the south and west from Penrith to Georges Hall in the east. *Pimelea spicata* has been recorded in the following vegetation communities:

PCT 849 – Grey Box – Forest Red Gum grassy woodlands on flats of the Cumberland Plain
PCT 850 - Grey Box – Forest Red Gum grassy woodlands on shale of the southern Cumberland Plain
PCT 830 – Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain
PCT 835 – Forest Red Gum – Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain (most commonly when intergrading with CPW)

These communities are equivalent to the Cumberland Plain Woodland, Moist Shale Woodland and River-flat Eucalypt Forest threatened ecological communities and include derived grasslands.

The recovery plan for *Pimelea spicata* (DEC 2006) identified 25 populations on the Cumberland Plain. Currently there are approx. 70 sites (Bionet Atlas records, June 2018). The main concentration of sites is found in the Blacktown, Prospect, Bankstown and Narrellan districts. More recent records (post 2014) are from near Wallacia, Horsley Park - Cecil Park and Greendale. Populations in the Penrith LGA are at the western limit of the specie's geographical range.

<u>Coastal Illawarra</u>
In the Illawarra *Pimelea spicata* is associated with coastal headlands and hill tops from Mount Warrigal south to just north of Kiama. The recovery plan for *Pimelea spicata* (DEC 2006) identified 5 populations in the Illawarra.

In 2006, the total population of *Pimelea spicata* across 30 known populations was estimated to be around 4300. Populations varied from a few individuals to >500 plants although larger populations were rare with over half with <50 individuals and small habitat areas of less than 0.5 ha (DEC 2006, Dept. Environment & Heritage 2016*)*. Since 2006 several populations are likely to have been lost to development or habitat modification. At several sites survey has failed to re-locate plants including at Menangle and along Denham Court Road, Camden Valley Way and Jamisontown (James 2009, 2010, 2012, 2019). Prolonged periods of drought, increased weed invasion, heavy grazing/slashing or soil disturbance are likely to be the main causes. Counterbalancing losses are several new records within Fairfield, Liverpool, Penrith and Liverpool LGAs (mostly <50 individuals). A new site south-west of Luddenham within the Western Sydney Airport impact zone is by far the largest known population with >4000 plants recorded in 2017, however, is likely to be cleared. Increased population sizes are noted at Narellan and Prospect although numbers at any site at any one time will depend on the timing of rainfall and other environmental factors. Ongoing monitoring of the new population near Luddenham noted a decline from more than 4000 above-ground plants (after good summer and autumn rains in early 2017 together with exclusion of grazing and slashing) to around 400 by December 2017 (GHD 2018). Area of known habitat is likely to be a more accurate measure of population size than number of above-ground plants.

2.4 Habitat requirements

Pimelea spicata is found in grassy woodlands or at grassland sites on the Cumberland Plain and in the Illawarra.

<u>Cumberland subegion</u>
In the Cumberland subregion *Pimelea spicata* occurs in Cumberland Plain Woodland (CPW), intergrading zones between CPW and River-flat Eucalypt Forest, Moist Shale Woodland and associated derived grasslands. Associated canopy trees are Grey Box *Eucalyptus moluccana*, Forest Red Gum *E. tereticornis,* Narrow-leaved Ironbark *E. crebra* and Spotted Gum *Corymbia maculata*. The mid-storey typically contains *Acacia parramattensis, A. decurrens, Bursaria spinosa*, *Acacia implexa, A. falcata, Dillwynia sieberi* and *Indigofera australis*. Common groundcover grasses and herbs associated with most occurrences include Kangaroo Grass *Themeda triandra,* Weeping Grass *Microlaena stipoides,* Kidney Weed *Dichondra repens*, Woodruff *Asperula conferta* and Blue Trumpet Flower *Brunoniella australis*.

Pimelea spicata prefers moist soil and typically occurs on gentle lower slopes where groundwater seepage maintains higher soil moisture levels for longer (*T. James pers. obs.*). The more resilient sites appear to be those in protected gullies close to drainage lines e.g. Mountain View Reserve, Cranebrook. A relatively open grassy groundcover maintained by occasional disturbance e.g. fire or infrequent/low intensity grazing/slashing provides favourable habitat. Although the species can survive (and flower) among taller grasses and perennial weeds (e.g. at Cobham Street Road, Horsley Park) it is likely to disappear above ground under extended weed infestations. A population along Denham Court Road (around 2003), for example, was estimated to be hundreds yet in 2011 no plants were found (*T. James pers. obs.)*. The road reserve had become increasingly degraded with weed infestation in both the mid-storey layer (African Olive, Box Thorn and Lantana) and the ground-layer (Bridal Creeper, Prickly Pear, Blackberry & Mother-of Millions). The species was likely still present, however, in the soil seed-bank.

Frequent or intensive grazing, slashing or mowing will restrict the growth of plants with re-sprouting controlled by the frequency of disturbance and environmental conditions. Frequent cutting creates open, dry and hot conditions at the soil surface resulting in die-back of plants above ground. The species can persist for many years under such a regime as a tap root and seed in the soil. There are many examples of regeneration following cessation of mowing and slashing in council reserves e.g. Faulkland Crescent Reserve and Melrose Park in Blacktown and Power Street Reserve in Fairfield.

Habitat of *Pimelea spicata* along unformed road reserve (Cobham Road, Horsley Park)

Illawarra
In coastal habitat of the Illawarra *Pimelea spicata* occurs in a wider range of geologies and soils derived from the Permian Shoalhaven Group sediments (sandier than the clay soils of western Sydney). The favoured sites are on grassy headlands and hilltops with Kangaroo Grass *Themeda triandra*, Mat-grass *Lomandra longifolia* and Blady Grass *Imperata cylindrica*, often with Coast Banksia *Banksia integrifolia*. Woodland is also often dominated by Forest Red Gum *Eucalyptus tereticornis* and Thin-leaved Stringybark *E. eugenioides* above Kangaroo Grass, species also occurring in *Pimelea* habitat in western Sydney. Habitat in the Illawarra includes the endangered ecological community *Themeda Grasslands on Seacliffs and Coastal Headlands* (PCT 898).

3. Description of the study area

3.1 Land use history

Greater Penrith to Eastern Creek Growth Area (GPECGA)
An area of approx. 18, 619 ha extending east from the Nepean River to Wallgrove Road and from the former ADI site in the north to the Warragamba to Prospect Water Pipe-line in the south. The area is highly urbanised in northern and central parts and includes the city of Penrith and suburbs of St. Mary's Mt. Druitt, St. Clair, Glenmore Park and Jordan Springs. The Great Western Highway, the western railway line and the M4 Motorway all dissect the area east to west and act as a stimulus to further residential and industrial development. In contrast, a rural landscape predominates south of the Western Motorway although close proximity to the new airport has recently increased development activity.

Western Sydney Aerotropolis Growth Area (WSAGA)
The Western Sydney Aerotropolis Growth Area comprises a smaller area of approx. 6232 ha immediately to the north and east of the Western Sydney Airport site within the Penrith and Liverpool LGA's. It extends south from the Warragamba to Prospect Water Pipe-line to Greendale and includes the Northern Gateway, North Luddenham and Luddenham to Greendale zones. The western boundary is along the Northern Road. It has a predominantly rural landscape and has been extensively cleared in the past for farming. Close proximity to the new airport has significantly stimulated new development activity for infrastructure, housing and industry.

3.2 Landscape context

Greater Penrith to Eastern Creek Growth Area (GPECGA)
Reference to the 1:100,000 Geological Series Sheet for Penrith, indicates that most of the growth area is underlain by Triassic rocks (Bringelly Shale) and unconsolidated Quaternary sediments (alluvial gravel, sand, silt and clay). Small areas of older Tertiary alluvium occur particularly in the north-east associated with Ropes Creek. The Soil Landscape Series Sheet 9030 (Bannerman & Hazelton 1990) maps six soil landscape groups in the study area:

- Luddenham and Blacktown on shale
- Richmond, Freeman's Reach and South Creek on recent alluvium

- Berkshire Park on older (Tertiary) alluvium

The topography is low-lying to gently undulating land (<100 m a.s.l.). It is dissected north to south by the South Creek floodplain and includes the tributaries of Ropes Creek and Blaxland Creek. A small ridge-line up to 50 -60 m above sea level runs north to south extending up from the Nepean floodplain in the north-west of the GA (just north of the Penrith CBD) at Mount Pleasant and Kingswood Park on the hillier Luddenham soil landscape.

Native vegetation has been extensively cleared in the north for urban development and farming in the south. Open space corridors (including bushland) are centred along the creeks, particularly South Creek and Ropes Creek. Larger bushland remnants occur within Wianamatta Regional Park (237 ha) (formerly the ADI site) in the north and the Orchards Hills Defence Establishment (c. 260 ha) in the south. Higher concentrations of smaller remnants occur in the north-west (suburbs of Cranebrook to Kingswood Park) and the east (suburbs of Mt. Druitt, Plumpton).

Western Sydney Aerotropolis Growth Area (WSAGA)
Reference to the 1:100,000 Geological Series Sheet for Penrith, indicates that most of the growth area is underlain by Triassic rocks (Bringelly Shale) and unconsolidated Quaternary sediments (alluvial gravel, sand, silt and clay). The Soil Landscape Series Sheet 9030 (Bannerman & Hazelton 1990) maps three soil landscape groups in the study area, Luddenham, Blacktown and South Creek. The northern part of the area is low-lying and dissected by four creek-lines Badgerys Creek, South Creek, Cosgrove's Creek and Kemps Creek. A hilly ridge system up to 100-120 m above sea level is found in south-western parts extending south from Orchard Hills through Luddenham associated with the Luddenham Dyke comprising olivine basalt intruded into the Bringelly shale.

Native vegetation is patchy and occurs predominantly along Cosgrove's Creek (with a larger remnant west of Twin Creeks Golf Course), in the east between Erskine Creek and Kemps Creek and in the south-west south of Luddenham.

3.3 Native Vegetation

Greater Penrith to Eastern Creek Growth Area (GPECGA)
The predominant ecological communities are Cumberland Plain Woodland (CPW) and River-flat Eucalypt Forest (RFEF), both threatened ecological communities. Cumberland Plain Woodland is listed as critically endangered at both state (*Biodiversity Conservation Act, 2016*) and national (*EPBC Act, 1999*) levels. A summary of plant community types based on mapping provided by NSW Planning & Environment is found in Table 2.

Table 2. Plant community types (PCT's) within the Greater Penrith to Eastern Creek growth area

PCT No	PCT Name	TEC / Non-TEC	Area (ha)	Distribution & notes
724	Broad-leaved Ironbark – Grey Box – Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin.	Shale Gravel Transition Forest	138.3	Main occurrence within Wianamatta Regional Park in far north. Small patches identified at Minchinbury, Claremont Meadows, St. Clair.
725	Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion	Cooks River Castlereagh Ironbark Forest	127.5	Main occurrence within Wianamatta Regional Park in far north. Small patches identified at Mount Druitt, Claremont Meadows.

PCT No	PCT Name	TEC / Non-TEC	Area (ha)	Distribution & notes
781	Coastal freshwater lagoons of the Sydney Basin Bioregion	Freshwater Wetlands on coastal floodplains	65.4	On Nepean floodplain in north-west. Small dams in southern area.
830	Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain	Moist Shale Woodland (MSW)	2.8	Small area identified at edge of Mulgoa Regional Park.
835	Forest Red Gum – Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain	River-flat Eucalypt Forest (RFEF)	826.3	Along all creeks with largest patches within Wianamatta Regional Park and along South Creek corridor.
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	Cumberland Plain Woodland (CPW)	1794	Larger remnants within Wianamatta Regional Park & Orchard Hills; medium size patches at north Luddenham, Plumpton; small patches through GA.
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	Cumberland Plain Woodland (CPW)	80.8	More common within western parts e.g. Mulgoa NR on more hilly terrain.
806	Derived grasslands on shale hills of the Cumberland Plain	Cumberland Plain Woodland (CPW)	6.99	Only small areas mapped not representative of actual extent. Other areas included within 849 & 850 or unmapped.
883	Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain	Castlereagh Scribbly Gum Woodland Castlereagh Swamp Woodland	6.5	Small linear remnants associated with watercourses in Wianamatta Regional Park, along Rope's Creek, Glenmore Park. More likely to be Castlereagh Swamp Woodland.
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain	Shale Sandstone Transition Forest (SSTF)	2	Small patch near Mulgoa, not ground-truthed.
1800	Swamp Oak open forest on river-flats of the Cumberland Plain	River-flat Eucalypt Forest	118.4	Small patches with creek corridors mostly along South Creek, Rope's Creek & Cosgrove's Creek.

Western Sydney Aerotropolis Growth Area (WSAGA)
The predominant ecological vegetation communities within the WSAGA are Cumberland Plain Woodland (CPW) and River-flat Eucalypt Forest (RFEF), both threatened ecological communities. Cumberland Plain Woodland is listed as critically endangered at both state (*Biodiversity Conservation Act, 2016*) and national (*EPBC Act, 1999*) levels. A summary of mapped plant community types based on maps provided by NSW Planning & Environment and Cumberland Ecology (2018) is found in Table 3.

Table 3. Plant community types (PCT's) within the Western Sydney Aerotropolis growth area

PCT No	PCT Name	TEC / Non-TEC	Area (ha)	Distribution & notes
724	Broad-leaved Ironbark – Grey Box – Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin.	Shale Gravel Transition Forest	52.9	Localised at Kemps Creek north of Elizabeth Drive between creek-lines.
725	Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion	Cooks River Castlereagh Ironbark Forest	39.9	Localised at Kemps Creek north of Elizabeth Drive between creek-lines.
781	Coastal freshwater lagoons of the Sydney Basin Bioregion	Freshwater Wetlands on coastal floodplains	3.5	Very small areas associated with Badgery's & South Creek but probably more common.
830	Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain	Moist Shale Woodland (MSW)		None mapped but potential to occur in far south-west associated with the Luddenham dyke.
835	Forest Red Gum – Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain	River-flat Eucalypt Forest (RFEF)	162.9	Along all creek lines in association with 1800. Largest patch within South Creek corridor north of Elizabeth Drive.
849	Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain	Cumberland Plain Woodland (CPW)	550.1	Across the GA with largest remnant south of Erskine Park and south from Luddenham on rural properties (patchy less intact remnants).
850	Grey Box – Forest Red Gum grassy woodland on shale of the Southern Cumberland Plain	Cumberland Plain Woodland (CPW)	7.7	Small area mapped but more extensive in south western parts in vicinity of The Northern Road.
806	Derived grasslands on shale hills of the Cumberland Plain	Cumberland Plain Woodland (CPW)	53.35	Other areas included within 849 & 850 or unmapped.
883	Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain	Castlereagh Scribbly Gum Woodland Castlereagh Swamp Woodland	6.5	Very small area associated with Castlereagh Woodlands at Kemps Creek.
1800	Swamp Oak open forest on river-flats of the Cumberland Plain	River-flat Eucalypt Forest	110.1	Riparian forest along creek-lines in association with 835.

4. Assessment of species presence and habitat

4.1 Existing records and surveys

Existing records used in this report have been sourced primarily from the NSW Bionet Atlas. Two records were not in the Atlas but were identified in Appendix 2 of the *Pimelea spicata* Recovery Plan (DEC 2004). Penrith City Council and Local Land Services were also contacted for any additional records. In total there are ten records relating to eight sites for the Greater Penrith to

Eastern Creek Growth Area (GPEC) and just one for the Western Sydney Aerotropolis Growth Area (WSA) that is unsubstantiated (see tables 4 & 5).

The western ADI sites are located within the Jordan Springs development area but the northern ones are within Wianamatta Regional Park. The sites are typically associated with lower slopes and drainage lines. Population size is small with <10 plants recorded at most sites. Two of the sites (PS5 & PS6) have been confirmed by the author for this study (and Penrith City Council 2018) and are in council-managed reserves although PS6 (Grey Gums Reserve) is currently zoned uncertified rather than conservation. One of the records (PS9) at Badgerys Creek may be within or very close to certified land.

Table 4: *Pimelea spicata* records from Greater Penrith to Eastern Creek Growth Area

Record Id	Location	Date of record	No. of individuals	Map unit	Notes
PS1	ADI Site, St. Mary's	30/07/2004	4	835/849	Northern bank of drainage channel. Not observed in Biosis survey 2017.
PS2	ADI Site, St. Mary's	30/07/2004	5 - 20	835/849	Weedy area. In small gully with south western facing slope. Not observed in Biosis survey 2017.
PS3 & 4	Western part of ADI Site, St. Mary's	04/09/2003	3 (2 close sites)	849	Area now or soon to be developed, Jordan Springs
PS5	South of Nepean Street, Cranebrook (Mountain View Reserve)	02/08/07	c.80	849	Bottom of south-western facing slope; habitat area of 700 sq. m adjacent to drainage line. Monitored 2017-19 (TJ).
PS6	Grey Gums Reserve, Cranebrook (2 locations)	22/10/2010	30	849	Threatened by weeds and edge effects. Development & roads nearby. Confirmed in 2018 (PCC) & 2019 (James)
PS7	Kanangra Reserve, Glebe Place, Kingswood	2003 Appendix 2 of Recovery Plan 11/10/18	7 plants 1 plant	849	Council managed CPW adjacent to water reservoir. South-facing slope. Only 1 plant in poor health located in 2018 (PCC), no plants observed in Feb 19.
PS8	St. John Jamison Catholic Cemetery, Lilac Place, Jamisontown	2003 Appendix 2 of Recovery Plan	2 plants	849	Mostly mown/slashed grassland with some remnant trees. Native species persist around trees, over abandoned burial sites. Not seen 2019.
PS9	Badgerys Creek Lot 1 DP 111726	31/05/1999	1 small group of plants	835/849	Western side of bank, just before joins South Creek. Base of steep slope with SE aspect in small patch of thinned *Eucalyptus tereticornis*, mostly cleared around.
PS10	Kingswood Park Hickeys Lane (2 locations)	13/07/2018	10+	849	Two locations close to southern edge of reserve, one within APZ
	Mulgoa Nature Reserve		Few	LLS	On lee of dam

	Outside but close to Growth Area			**Source**	
	Just west of Chain O' Ponds Road Mulgoa	01/06/2005	30-60	Atlas of Australian Plants.	In grounds of 2 private properties. Similar habitat occurs just to the north within the GA. Current status unknown
	Gow Park, Mulgoa	03/10/18	5	PCC	West of car park in council reserve
	Blacktown and Liverpool LGA's	Various	Medium to larger populations	849, 850 & derived grassland	

*PCC = Penrith City Council LLS = Local Land Services

Records close to the growth areas

To the east of the growth areas there is a comparatively high density of sites in the Prospect, Quakers Hill and Western Sydney Regional Park districts (see Figure 2). Population size in these areas is typically moderate to large e.g. 150+ plants at Faukland Road Reserve (Kings Langley), several hundred's/thousands within Prospect Nature Reserve and 400 at Cobham Road Reserve (Horsley Park). This more central Cumberland Plain location is considered to comprise core habitat for the species.

Table 5 : *Pimelea spicata* records from the WSAGA or within 5 km

Record Id	**Location**	**Date of record**	**No. of individuals**	**Notes**
PS11	Just west of Aldington Road, east of Mamre Road, Kemps Creek	?	?	Sourced from (Biosis_FloraSightingPts, 2018) but not substantiated by Biosis or EcoPlanning for this report
	Outside of Growth Area			
	Private property along Greendale Road. Steep slope above tributary of Duncan's Creek.	April 2017	25-50	Recorded by the author (TJ). In regenerating CPW/MSW on steep, southeast-facing slope (after removal of African Olive).
	West of the Northern Road, south of Luddenham.	Mar-April 2017	4000+	In remnant modified CPW on rural grazing property. Habitat area of 2.94 ha. Likely to be cleared for construction of WSA.
	Twin Creeks Resort, Luddenham Road, Orchard Hills	Extant in 2003	?	Referenced in recovery plan but needed to be confirmed. Private tenure, likely now developed.

There are three records just to the west at Greendale and Mulgoa (details in Tables 4 & 5). The closest known records in the south of the Western Sydney Aerotropolis growth area do not appear in the Bionet data but are documented in biodiversity assessments for a transmission line realignment (GHD 2017) and the Western Sydney Airport Offset Strategy (DPIRDC 2018). Some 4000+ plants were recorded in 2017 from an area of 2.94 ha just west of the Northern Road (south-west of Luddenham) and c. 1 km east of the growth area.

Several of these populations are likely to be developed in the near future e.g. Cobham Road Reserve (road upgrade within Horsley Park Urban Plan) and south-west of Luddenham for the Western Sydney Airport.

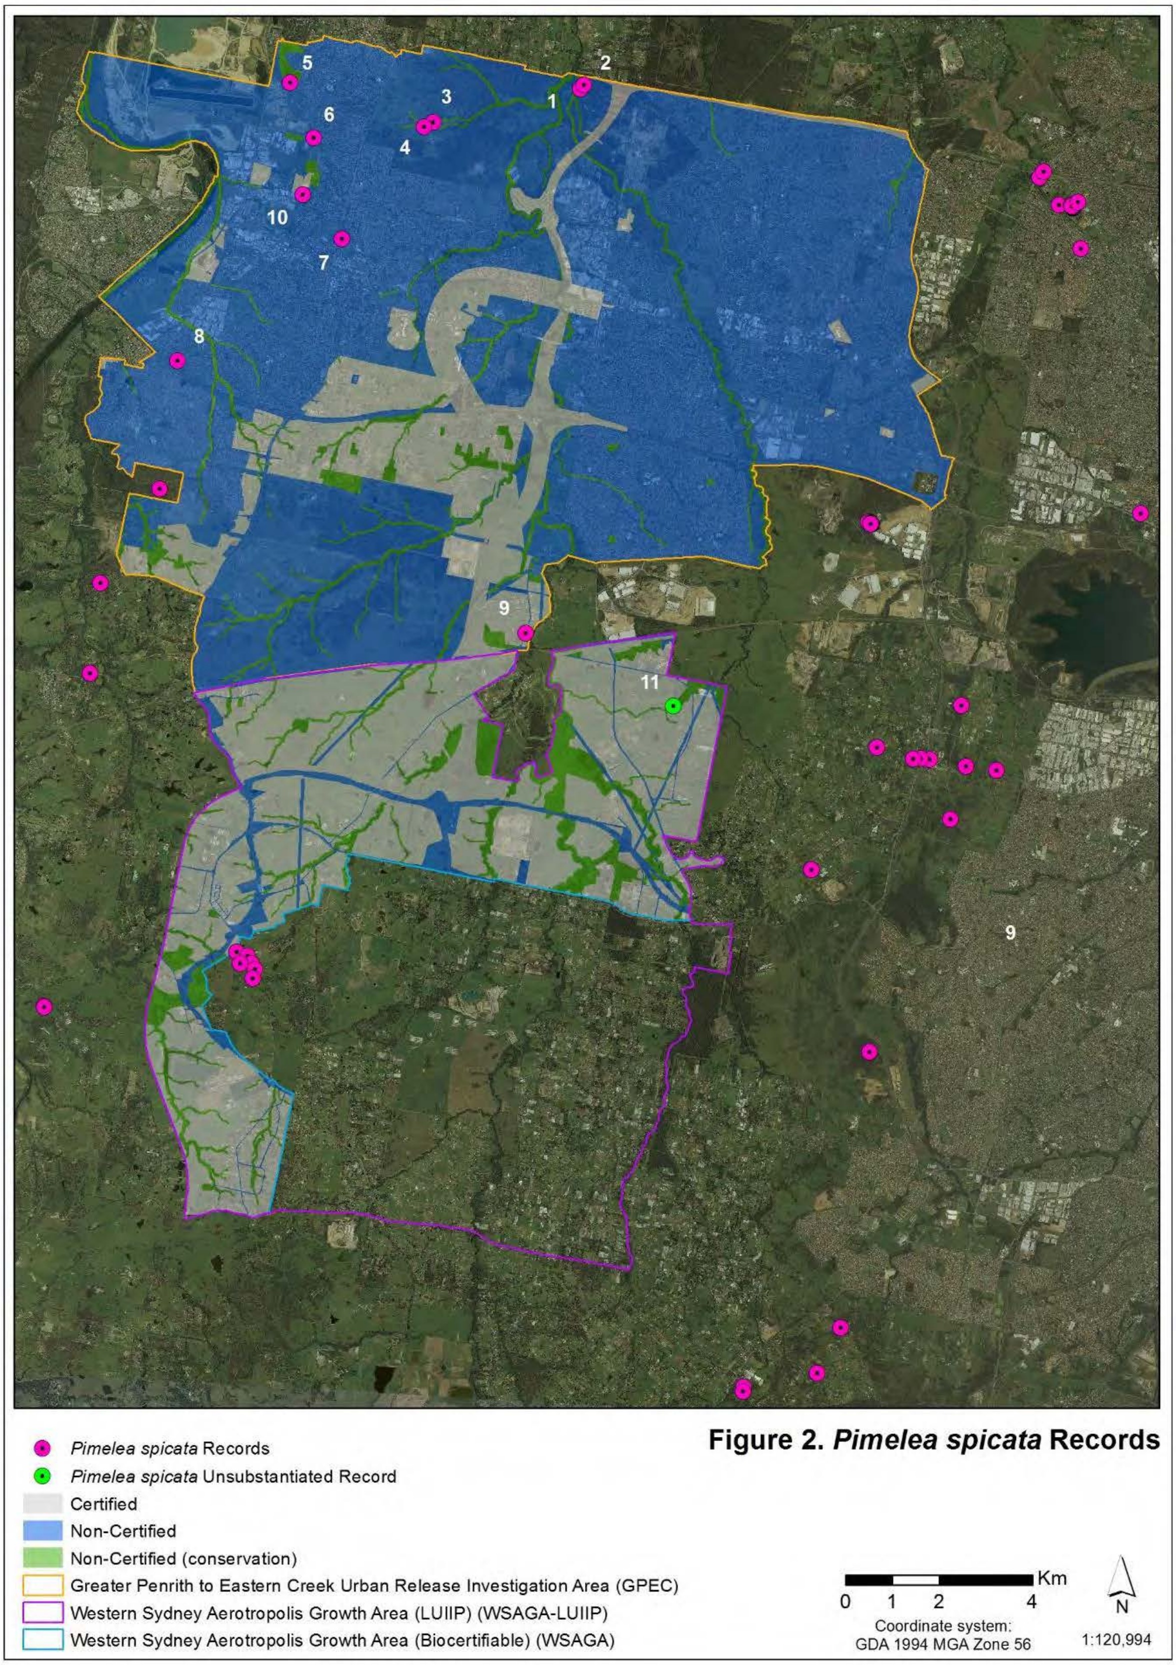


Figure 2. *Pimelea spicata* Records

4.2 Surveys completed for the biocertification

To assess the impacts of development within the growth areas new biometric data has been considered together with general and targeted survey. Field sampling and community/habitat verification has been undertaken by EcoPlanning and Biosis with assessment based on vegetation zones within Plant Community Types (PCT's) consistent with the Biodiversity Assessment Methodology (BAM 2017). No data from previous investigations within the growth areas was used. It is noted that the urban zone is being revised as the studies progress and accordingly the comparison of survey effort in relation to this zone is indicative only (DPE background information). The urban zone includes land zoned for future urban development plus transport corridors *within* the growth areas but not outside.

Survey and assessment was based on the following vegetation zones: Intact, Grasslands, Scattered Trees and Thinned. Survey effort has included the following:

- Field verification of vegetation type and condition mapping
- BAM plot sampling (all new)
- Flora and fauna habitat survey
- Targeted survey for threatened species using transects and random meanders

The location of survey areas, tracks and plots are shown in Figures 3 & 4. Quantitative plot data was collected to sample variability within each vegetation zone (EcoPlanning, Biosis 2017-18). The exact position of each plot within the vegetation patch was randomly located. Within the GPECGA a total of 10 BAM plots were sampled and within the WSAGA 56 plots.

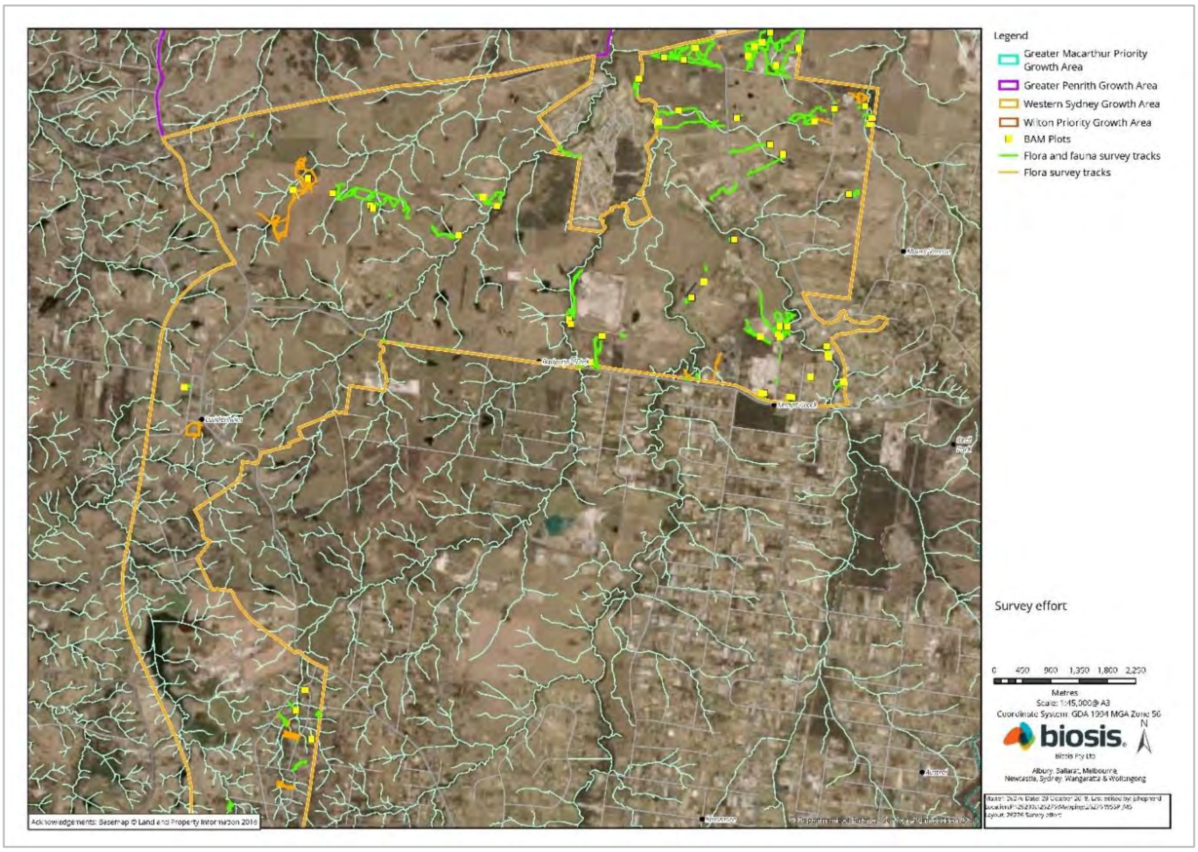
Targeted survey for threatened species, including *Pimelea spicata*, was conducted on accessible lands proposed for certification (and immediately adjacent) with particular attention to areas of lower disturbance and known topographic/habitat preferences. Survey comprised targeted random meanders (Figures 3 & 4) by Ecoplanning (orange tracks) and Biosis (green tracks). Biosis also surveyed for "fauna habitat" at the same time.

Land access
Within the GPECGA letters sent in 2017 and 2018 have led to 177 landholders providing access and an additional three landowners provided permission via door knocking with a 12% response rate. In addition access to 64 lots owned by Council was provided. Only properties with vegetation of particular interest were accessed.

A total of 432 letters were sent to landholders across the WSAGA between Nov 2017 and August 2018 with 84 granting access and a further seven properties accessed after doorknocking giving a response rate of 21%.

Survey timing
Surveys for *Pimelea spicata* should be undertaken when flowering due to its cryptic nature. Flowering is sporadic throughout the year and is likely to be in response to climatic conditions, particularly rainfall (DEC 2006). At other times plants are difficult to see or may only be present as rootstock or seed. Surveys have been undertaken mostly during 2017 and 2018 and no confirmed sighting of this species recorded within the growth areas. Periods of hot and/or dry conditions were experienced through this period although reasonable rain events occurred in February, November and December of 2018 (www.bom.gov.au/climate). Timing of surveys subsequent to such rain events is likely to be crucial in detecting the species.

Figures 3 & 4: Survey effort within GPEC (top) and WSA (bottom) growth areas



Survey effort
Threatened species survey effort within the GPEC (3.7%) and WSA (6%) growth areas is significantly lower than that completed for the Greater Macarthur and Wilton growth areas. Sites surveyed within or close to the certified zone include part of Hickeys Lane, Cranebrook (where *Pimelea spicata* was subsequently recorded by PCC), Claremont Meadows, South Creek in vicinity of Samuel Marsden Reserve, Kemps Creek (e.g. Aldington Road, South Creek), North Orchard Hills, Luddenham and Greendale North.

Most importantly survey effort for *Pimelea spicata* within preferred habitat across the growth areas is very low. For PCT 849 just 5% has been surveyed in the GPECGA and 7% in the WSAGA (see Table 6). There were no recorded sightings of *Pimelea spicata* during the surveys.

Table 6. Survey effort (20 m buffer from survey tracks) for threatened plant species (including *Pimelea spicata*) for relevant PCT's and growth area (data provided by DPE)

Growth Area	Vegetation Type (PCT)	Total area (ha) in GA	Survey area (ha)	% surveyed Within GA
Greater Penrith-Eastern Creek	849	1794	89	5
	850	81	0	0
	830	3	0	0
	835	826	13	2
Western Sydney Aerotropolis	849	550	37	7
	850	164	4	2
	835	163	12	7

A summary of plots sampled within the PCT's with potential habitat for *Pimelea spicata* is provided in the table below.

Table 7: Number of BAM plots undertaken by Growth Area, PCT & Vegetation Zone

	PCT 608	PCT 609	PCT 830	PCT 835	PCT 849	PCT 850	PCT 1395
GPEC							
Intact				2			
Grassland				2	1		
Scattered trees				1			
Thinned				4			
Total	0	0	0	9	1	0	0
WSA							
Intact				1	3	10	
Grassland				2	7	8	
Scattered trees				4	4	5	
Thinned				3	6	3	
Total	0	0	0	10	20	26	0

The level of plot sampling undertaken within potential *Pimelea spicata* habitat is very low for the GPECGA with no plots sampled within intact Cumberland Plain Woodland (PCT's 849 & 850) and just one plot sampled in modified CPW that being non-offsetable grassland (i.e. very low condition). Nine plots were sampled within River-flat Eucalypt Forest (PCT 835), however, this is not preferred habitat. No plots were sampled in Moist Shale Woodland (PCT 830) although only 2.8 ha of this community is currently mapped.

The level of survey undertaken within potential *Pimelea spicata* habitat within the WSAGA is higher with 20 plots surveyed across all vegetation zones for PCT 849 (Cumberland Plain Woodland) and 26 in PCT 850 which becomes more common on hilly terrain in the south-west. There is good coverage for River-flat Eucalypt Forest (PCT 835), however, this is not preferred habitat.

The more intensive and focused survey methodology of plot sampling is likely more reliable in detecting the species than meandering transects that often target more than one species.

4.3 Surveys completed for this assessment

Limited survey was undertaken in January and February 2019 by Teresa James and Anthea Whitlam. Survey was considered timely based on good rain events in late 2018 (www.bom.gov.au/climate) and regular storms in January and February 2019. By the mid-February, however, high temperatures and drier conditions resulted in rapid drying of soils with groundcovers, including plants of *Pimelea spicata*, showing marked signs of heat stress. Survey during December – January would have been more conducive to detection.

Confirmation of existing records
A known population at Mountain View Reserve, Cranebrook was checked in the field (January 2019) to confirm suitability of timing for survey. Other records were subsequently checked to determine presence and population status.

<u>Greater Penrith to Eastern Creek Growth Area</u>

Mountain View Reserve, Cranebrook
Moderate size population (80+), locally frequent adjacent to a small watercourse (habitat area c. 20 m x 5 m) at southern end of reserve, steep slope above to ridge-line. In Cumberland Plain Woodland dominated by Grey Box, *Eucalyptus moluccana*. Flowering and fruiting well in January 2019. By end of February flowering had ceased and leaves were shrivelling. This was used as a reference site.

Grey Gums Reserve, Cranebrook
A 2010 record was confirmed in the southern bushland area of the reserve close to the intersection of Andrews Road and Laycock Road. It is located on the lower slope below a footpath and above a drainage channel and road in Cumberland Plain Woodland dominated by Grey Box, *Eucalyptus moluccana*. Population size apparently smaller than previously with 5 clumps within an area of c. 5 m x 5 m but flowering and fruiting well. Weed invasion is reducing available habitat. A few plants were also recorded in late 2018 by PCC just above the footpath.

Kanangra Reserve, Glebe Place, Kingswood
A Council managed reserve containing Cumberland Plain Woodland adjacent to water reservoir. Seven (7) plants were recorded in 2003 (Appendix 2 of Recovery Plan), however, no details were provided relating to exact location and habitat. Search was undertaken on 28th February, 2019 for one hour and fifteen minutes focussing on intact habitat to the south and west of the reservoir. Conditions were warm and dry with native groundcovers showing signs of heat stress. The site is managed (weeding evident). Good potential habitat was observed to the south on a protected south-facing slope with a native grassy groundcover. No plants of *Pimelea spicata* were observed. Several small plants (re-sprouting from underground roots) of *Marsdenia viridiflora* subsp. *viridiflora*, however, were observed. To the west of the reservoir the groundcover is less intact in parts where scouring is evident on slopes from overwater flows and weed invasion more significant along ephemeral water courses.

Hickeys Lane Reserve, Kingswood Park (lower most disturbed part within certified area)
This reserve is south of the confirmed Cranebrook sites (see 4.3.1) on the same north-south running ridge-line. Similar habitat in Cumberland Plain Woodland exists on lower and mid parts of the slope

with high soil moisture associated with ephemeral watercourses, depressions and a wetland at the northern end. Lower slopes are dominated by Forest Red Gum *Eucalytus tereticornis* and higher slopes by Grey Box, *Eucalyptus moluccana*. Lower parts, in particular, are very weedy with dense exotic perennial grasses including Rhodes Grass, Paspalum and African Lovegrass. Condition of the vegetation improves upslope with active restoration occurring.

Survey was undertaken in January and February 2019 totalling 3 hours. Suitable habitat was observed, similar to known habitat within Grey Gums Reserve (plants at latter site were visible and flowering, although heat-stressed on the day of this survey) on slopes above the wetland in the north of the reserve. Good potential habitat also occurs on south and south-eastern slopes in the south of the reserve although unstable slopes and weeds are likely to restrict suitable sites/visibility. Subsequent to this inspection confirmation from Penrith City Council was received re a small population at two locations seen in late 2018. The lower part of this site (apparently adjacent to Hickeys Lane) was also surveyed by Biosis and EcoPlanning in mid-2018.

St. John Jamison Catholic Cemetery, Lilac Place, Jamisontown
At the time of inspection the grass had been recently mown, however, it was evident that native species persist on slopes and towards the back of the property away from the main central burial area. A range of native species were observed through the grassland, around the base of remnant trees and over old burial sites. No plants of *Pimelea spicata* were observed, however, some suitable habitat persists at the site.

<u>Western Sydney Aerotropolis Growth Area</u>

In vicinity of Aldington Road, Kemps Creek
An obscure record (included in a Biosis 2018 flora sightings file) from 99-111 Aldington Road with no date, habitat or population details. A patch of regenerating Cumberland Plain Woodland associated with a small gully off a ridge-top was searched on 06/02/19. The remainder of the property had been largely cleared except at the western end. The woodland was in moderate condition with past clearing and weed invasion (e.g. Blackberry and perennial exotic grasses). There was suitable habitat identified on protected south to south-west facing slopes of the gully but no plants were found. The far western section of the property was not accessed. Conditions were suitable for flowering with several other moisture sensitive species observed growing well and flowering.

This site and close vicinity was surveyed by Biosis/EcoPlanning in mid-2017.

Survey in potential habitat

<u>Greater Penrith to Eastern Creek Growth Area</u>

Peppermint Reserve, Kingswood
A council reserve with Cumberland Plain Woodland on gentle south-eastern and eastern facing slopes. Marginal habitat was observed (February 2019) with suitability constrained by lack of water availability in dry periods and weeds.

Werrington Creek, Kingswood
Good potential habitat was observed upslope from Werrington Creek within and south of the Western Sydney University Campus (February 2019), latter area in early stages of regeneration.

Glenmore Park (South) *Surveyor's Creek*
Drainage reserve east of Mulgoa Nature Reserve is mapped as Cumberland Plain Woodland, however, field inspection indicates it is River-flat Eucalypt Forest enhanced by plantings and landscaping and is not considered to provide potential habitat for *Pimelea spicata*. The mapping has been altered accordingly for this report.

Western Sydney Aerotropolis

Samuel Marsden Reserve, South Creek, Orchard Hills (within certified area)
Some existing records for *Pimelea spicata* are located close to creek lines in intergrading Cumberland Plain Woodland and River-flat Forest e.g. within the northern section of the former ADI site and at Badgerys Creek close to the confluence with South Creek. Similar habitat was searched on 6/02/19 along the creek at Samuel Marsden Reserve. Some flora survey was previously undertaken in spring 2018 at and in the vicinity of this site by Biosis/EcoPlanning but focussed on the eastern side of the creek and not after good rains.

The vegetation was regenerating and dominated by Forest Red Gum *Eucalytus tereticornis* (river-flat dominance) with an open, grassy groundcover. No plants of *Pimelea spicata* were observed although suitable habitat noted although limited.

West of Aldington Road, Kemps Creek
Good condition, mostly intact/regenerating Cumberland Plain Woodland on slopes above an ephemeral watercourse (mostly south-east facing) was searched on a property (53 Aldington Road) adjacent to the Aldington Road site described above in early February 2018. Despite good suitable habitat on protected lower slopes with Grey Box and Forest Red Gum no plants of *Pimelea spicata* were observed.

Greendale North/Bringelly
Small rural residential properties with modified Cumberland Plain Woodland and River-flat Forest associated with Badgerys Creek. At the time of inspection the understorey was highly modified through slashing, mowing and horse grazing. Although potential habitat for *Pimelea spicata* persists in this area, the vegetation condition and dryness at time of survey (and previous surveys) significantly limited the likelihood of plants being visible and no properties were accessed.

4.4 Assessment of species presence [BAM 6.5.2.8c]

Likelihood of species presence
Based on existing records (see Tables 4 & 5) and the extensive distribution of potential habitat (particularly Cumberland Plain Woodland including derived grasslands) it is confirmed that *Pimelea spicata* is present within the GPECGA and is likely to occur at other sites potentially within the proposed urban footprint (certified areas). There are no substantiated records for *Pimelea spicata* within the WSAGA, however, there are recent records within 1-5 km and extensive suitable or potential habitat.

Greater Penrith to Eastern Creek Growth Area (GPECGA)
Populations confirmed in this study or likely to still be present (based on habitat persistence) are summarised in Table 8. Two of the atlas records (PS 3 & 4) are no longer relevant for this report being within the Jordan Springs development footprint.

All sites, except PS7, are located in a regional park or council reserves and are assumed to have at least a moderate level of protection although it is noted that Grey Gums Reserve (PS6) is not currently zoned for conservation within the context of this report and known *Pimelea* habitat is mostly disturbed and weedy. The Badgerys Creek site appears to be in the vicinity of land zoned for conservation although the level of past and current protection and management, if any, is unknown. It is an older record (1999) with few plants recorded and the likelihood of the species persisting at the site is considered low.

There are no existing records located within the certified area although PS7 appears to be very close.

Table 8: Populations of *Pimelea spicata* confirmed or likely to persist in the GPECGA

Record Id	Location	Zoning	Protection level	Status
PS1	ADI Site, St. Mary's	Within regional park	Moderate – assumed active management	Presumed extant although not recorded in recent EcoPlanning survey
PS2	ADI Site, St. Mary's	Within regional park	Moderate – assumed active management	As above
PS5	North of Nepean Street, Cranebrook (now Mountain View Reserve)	Within council managed reserve, zoned conservation	Good – assumed active management	Confirmed 2018 (PCC), 2019 (James)
PS6	Grey Gums Reserve, Cranebrook (2 locations)	Within council reserve, zoned not certified	Low without management as in wetter more disturbed zone	Confirmed 2018 (PCC), 2019 (James)
PS9	Badgery's Creek	Probably just above riparian zone	Probably low	Unlikely but possible
PS10	Kingswood Park Hickeys Lane (2 locations)	Within council reserve	Low-moderate. In disturbed lower parts, one in APZ but council has ceased mowing at present	2018 (PCC)

Western Sydney Aerotropolis Growth Area

There are no confirmed or substantiated records for *Pimelea spicata* within the WSAGA. There is one vague record for *Pimelea spicata* west of Adlington Road, Kemps Creek (sourced from (*Biosis_FloraSightingPts*, 2018) located within the certified area, however, this record remains unsubstantiated. The site was inspected in early February 2019 but no plants were seen, however, suitable habitat was noted on this property and the adjoining one (53 Adlington Road). A very large population has been recently recorded within the adjoining airport zone less than a 1 km from the growth area boundary (see Figure 2). The plants were located on a rural grazing property in modified Cumberland Plain Woodland including derived grasslands. A summary of information on *Pimelea spicata* habitat at the airport site is provided below sourced from GHD (2017):

- Majority of plants were found in derived native grassland formerly supporting PCT 849.
- Grassland was in good condition with moderate species richness, high native grass and herb cover and low exotic plant cover.
- Clumps of plants were separated by tracks, building pads, dumped fill and dense African Olive infestations.

In view of this record, presence of similar habitat within the WSA and certified area and records to the west at Mulgoa and Greendale, there is a good likelihood of the species being present at additional sites within the growth area. A significant proportion of the potential habitat comprises derived grasslands dominated by native species or a mix of native and exotic.

Justification for determining presence

The association between known sites of *Pimelea spicata* both within and outside of the growth areas with Cumberland Plain Woodland and Moist Shale Woodland, and to a lesser extent River-flat Eucalypt Forest and Shale Sandstone Transition Forest is well documented in sections 4.3 and 4.5 of this report. Preferred habitats within these communities are described below.

<u>Physical environment</u>
Pimelea spicata is most often found on slopes in undulating low hilly terrain on Wianamatta Group shales including both Ashfield and Bringelly shales. Within the Greater Penrith and Sydney Airport growth areas Bringelly shales are the most widespread. *Pimelea spicata* prefers moist soils (clay helps to retain the moisture) and is often found on protected south or east facing slopes close to drainage lines or seepage points. Growth and flowering appears to be largely dependent on such moist soils with plants often not visible in dry periods and dying back to rootstock or persisting as seed in the soil seed bank. Such conditions occur extensively through the growth areas.

<u>Habitat condition</u>
Optimal habitat for *Pimelea spicata* is intact woodland with an open, grassy understorey, however, it can survive in disturbed and degraded landscapes e.g. recently discovered airport population south of Luddenham. Areas affected by localised woody weed infestations e.g. African Olive can also contain potential habitat. *Pimelea spicata* has been recorded after removal of African Olive at sites at Greendale (Penrith LGA) and Mt. Annan.
Many of the known records are associated with regenerating native vegetation e.g. after a disturbance such as mowing or grazing has ceased. Records from several council reserves have been made in recent years as "no mow" zones have been established. Examples include:

- Faulkland Reserve, Kings Langley (Blacktown LGA)
- Melrose Park, Quakers Hill (Blacktown LGA)
- Power Street Reserve (Fairfield LGA)

Woody weed infestations (e.g. African Olive) occur within the growth area, particularly in southern parts. These areas can still contain potential habitat (see Section 2.4) and are included.

The condition of habitat is not considered to be a reliable indicator of species presence and accordingly **all condition states** are considered in determining suitable habitat i.e. intact, thinned, scattered, derived shrubland and grasslands.

4.5 Assessment of suitable habitat [6.5.2.5]

Suitable habitat within the growth areas

Pimelea spicata is known to occur in the following vegetation communities:

PCT 849 – *Grey Box – Forest Red Gum grassy woodlands on flats of the Cumberland Plain*
PCT 850 - *Grey Box – Forest Red Gum grassy woodlands on shale of the southern Cumberland Plain*
PCT 806 & 807 – *Derived grasslands on shale hills and shale plains of the Cumberland Plain*
PCT 830 – *Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain*
PCT 835 - *Forest Red Gum – Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain* (particularly intergrading zone with PCT 849) where floodplain is not well defined
PCT 1395 - *Narrow-leaved Ironbark – Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain.* Low sandstone forms (at the shale end of the transition) of Shale Sandstone Transition Forest, which is structurally and floristically very similar to Cumberland Plain Woodland at the shale end of the transition.

The communities identified above are equivalent to the Cumberland Plain Woodland, Moist Shale Woodland, River-flat Eucalypt Forest and Shale Sandstone Transition Forest threatened ecological communities (see Tables 9 & 10). Degraded and disturbed examples of these communities (i.e.

reduced canopy and/or mid-layer cover or weedy areas) including road reserves can provide habitat for the species due to its long-term persistence as woody rootstock (tap root) and in the soil seed bank. Cumberland Plain Woodland and Moist Shale Woodland, including derived grasslands, are the most favoured habitat for *Pimelea spicata* occurring on mid to lower slopes or close to watercourses where soil moisture is retained for longer periods. Populations in such habitat appear to be more resilient to drought and other disturbances.

Within the growth areas there is extensive potential habitat for *Pimelea spicata* based on existing known sites, flora studies, scientific and personal knowledge. Important habitat attributes used to identify suitable habitat are discussed in section 4.3.

Greater Penrith to Eastern Creek Growth Area
Cumberland Plain Woodland comprises >57% of remnant vegetation in the *Greater Penrith to Eastern Creek Growth Area* with just 2.8 ha of Moist Shale Woodland. Only small patches of derived grasslands are mapped e.g. within the Orchard Hills RAAF site due to lack of targeted survey and are likely to be reasonably extensive. The 826 ha of land mapped as PCT 835 (part of River-flat Eucalypt Forest) is likely to include intergrading zones with Cumberland Plain Woodland that can provide suitable habitat for *Pimelea spicata.*

Table 9. Suitable habitat in the Greater Penrith to Eastern Creek Growth Area

Vegetation community	Distribution	Habitat value
Cumberland Plain Woodland (all conditions including mowed or slashed as long as meet final determination)	Across the GA with largest remnants within Wianamatta Regional Park & Orchard Hills RAAF base	High (primary habitat) but typically on mid to lower slopes or close to watercourses where soil moisture retained for longer periods.
Moist Shale Woodland	Restricted to small area at edge of Mulgoa Regional Park.	High: moist conditions and hilly terrain favour the species
Derived Native Grasslands (including mowed, slashed or grazed)	Throughout comprising grazing lands, roadsides & council reserves	Moderate to high: several records from over-cleared CPW or derived native grasslands
Cumberland Plain Woodland intergrading with Alluvial Woodland (RFEF) or more rarely Shale Gravel Transition Forest	Along creek corridors	Moderate to marginal depending on floodplain characteristics, again probably associated with higher moisture levels
Shale Sandstone Transition Forest	Only a small area (not confirmed in field) is mapped east of Mulgoa Nature Reserve	Moderate to high as expect very low sandstone influence & population known within the reserve (but in CPW).

The larger known populations in the north-west of the growth area are associated with a low ridge-line above the Nepean floodplain that is dissected by several ephemeral watercourses (PS 5 & 6). A relatively large patch of regenerating CPW associated with this ridge-line (south of PS 5 & 6) in Hickeys Lane Reserve provides good potential habitat and is currently not certified or zoned for conservation.

Sydney Aerotropolis Growth Area
The Sydney Aerotropolis Growth Area comprises predominantly a rural landscape with major creek corridors. Although it has been extensively cleared, patches of native vegetation, remnant trees and derived grasslands occur across the area. The dominant vegetation communities are Cumberland Plain Woodland (including derived grasslands) and River-flat Eucalypt Forest with extensive potential habitat for *Pimelea spicata*.

Table 10. Suitable habitat in the *Sydney Airport Aerotropolis* Growth Area

Vegetation community	**Distribution**	**Habitat value**
Cumberland Plain Woodland (all condition states)	Mostly in northern parts.	High, most records from CPW both Shale Plains and Shale Hills
Derived Native Grasslands (including mown, slashed or grazed)	Mostly northern areas comprising grazing lands, roadsides & council reserves	Moderate to high. Several records from over-cleared CPW or derived grasslands with varying levels of native species
Cumberland Plain Woodland intergrading with alluvial woodland part of River-flat Eucalypt Forest	Along creek corridor throughout growth area	Moderate to high, again probably driven by higher moisture levels

The large population recently discovered within the adjoining Airport zone less than a 1 km from the growth area boundary (GHD 2017) on a highly modified rural grazing property (including derived grasslands) suggests that similar habitat within the certified North Greendale district contains suitable habitat. Populations to the west of the growth area at Greendale and Mulgoa in similar habitat also supports this position.

Identification of habitat polygons

Extensive areas of potential habitat occur across the two growth areas. Potential habitat is identified based on the attributes described in Sections 4.3 of this report, existing populations, landscape context and personal knowledge. Although *Pimelea spicata* is known to occur in degraded sites, very small patches within over-cleared landscapes where the soil is likely to have been modified are excluded. Figures 5 & 6 show species polygons for the GPEC and WSA growth areas respectively.

<u>Estimate of area of habitat</u>

Ninety three (93) polygons containing a total of 2068 ha of suitable habitat within Cumberland Plain Woodland (PCT's 849 & 850) for *Pimelea spicata* are identified within the GPECGA. Small additional areas within Shale Gravel Transition Forest (PCT 724) and River-flat Eucalypt Forest (PCT 835) comprise marginal habitat. Seventy (70) polygons with 546 ha of suitable habitat are identified within the WSAGA mostly within Cumberland Plain Woodland (inclusive of derived grasslands). Small areas within Shale Gravel Transition Forest (PCT 724) and River-flat Eucalypt Forest (PCT 835) comprise marginal potential habitat in view of sandier soils and potentially denser tree canopy. The relative areas of vegetation communities are provided in Table 11..

Table 11. Areas (ha) of threatened communities identified as potential habitat for *Pimelea spicata*

Threatened Community	**PCT**	**Habitat value**	**Area (ha) in GPEC including WRP**	**Area (ha) in GPEC excluding WRP**	**Area (ha) in WSAGA**
Cumberland Plain Woodland (including derived grasslands)	850	High	59	59	3
Cumberland Plain Woodland (including derived grasslands)	849	High	2009	1511	483
River-flat Eucalypt Forest	835	Marginal	77	62	60
Shale Gravel Transition Forest	724	Marginal	18	9	0
Shale Sandstone Transition Forest (low sandstone)	1395	Marginal	2		

WRP = Wianamatta Regional Park

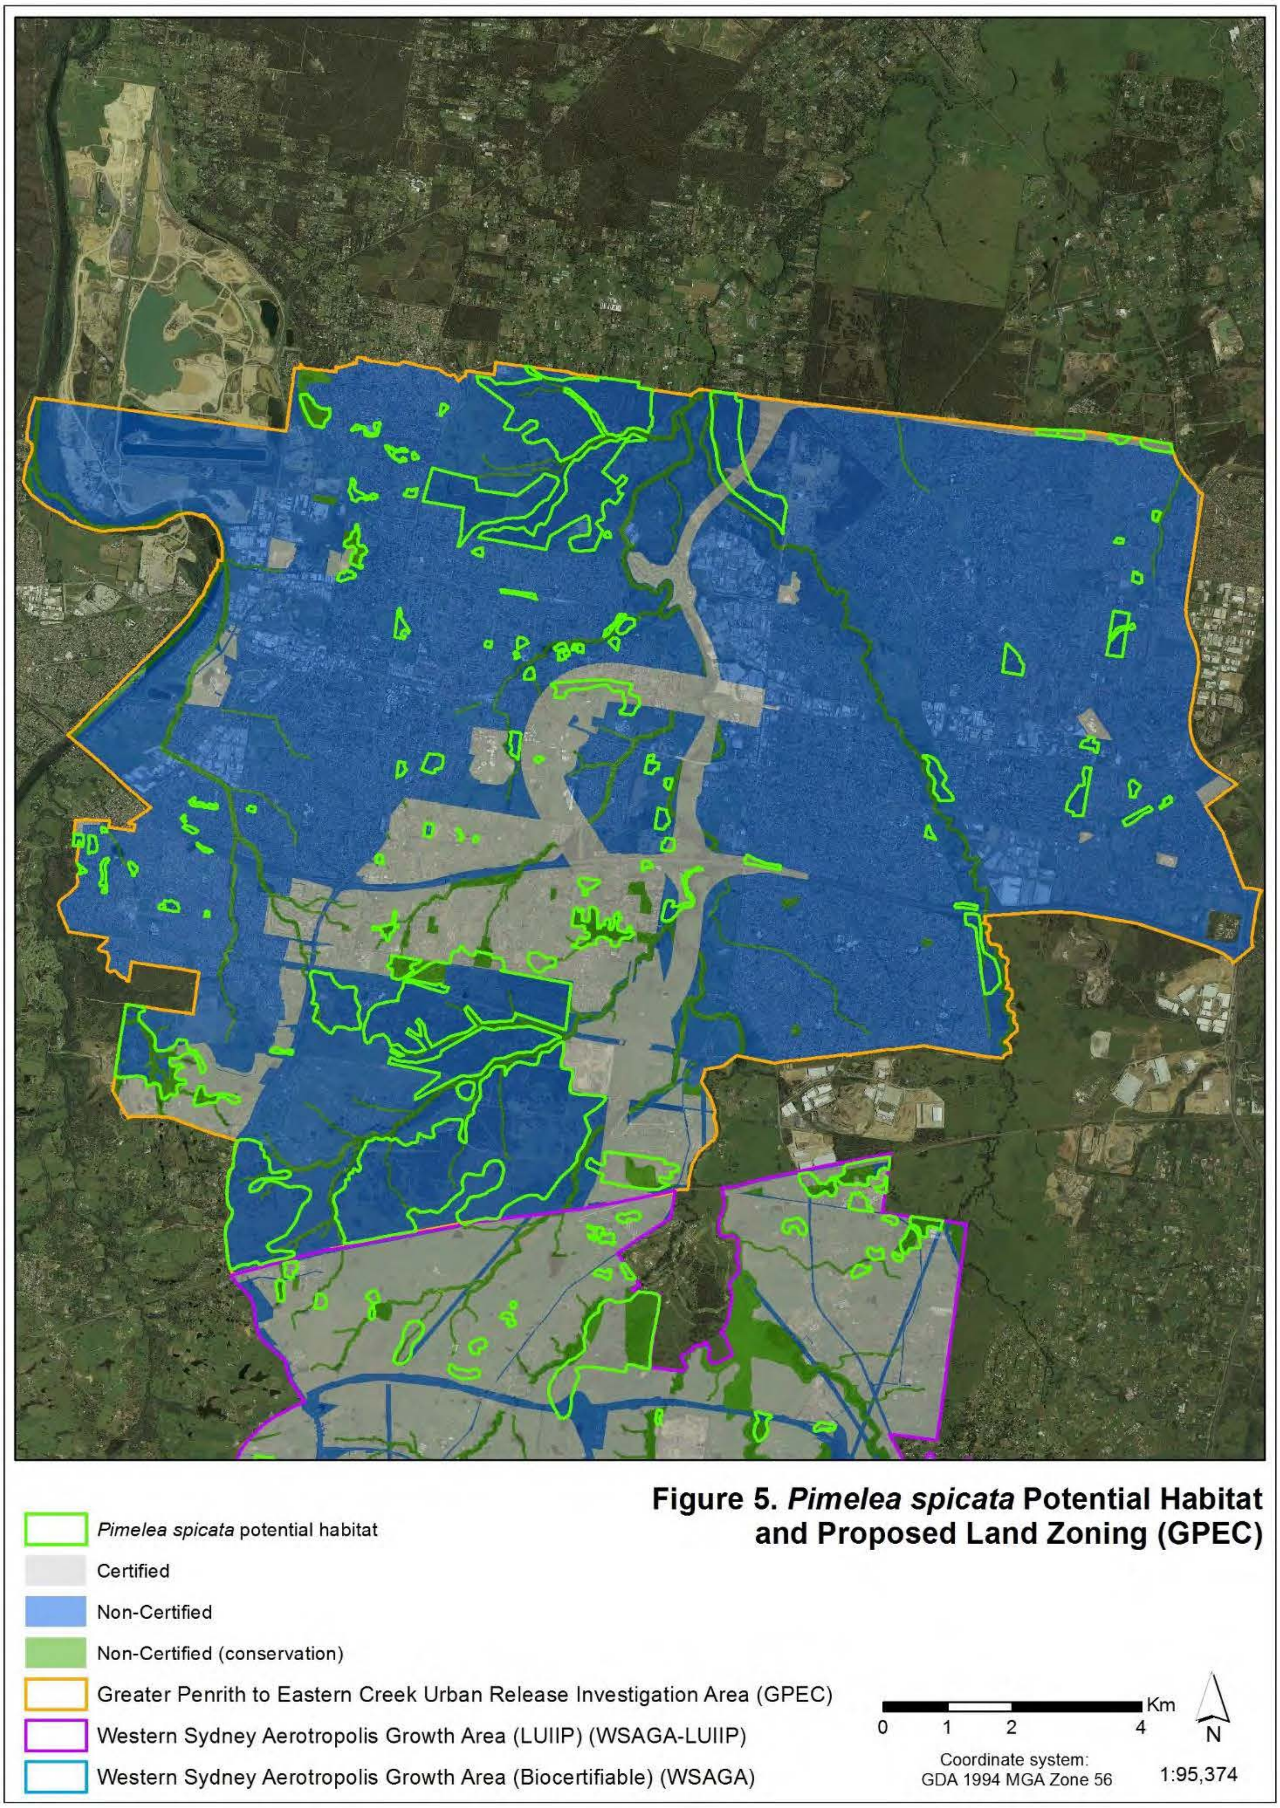


Figure 5. *Pimelea spicata* Potential Habitat and Proposed Land Zoning (GPEC)

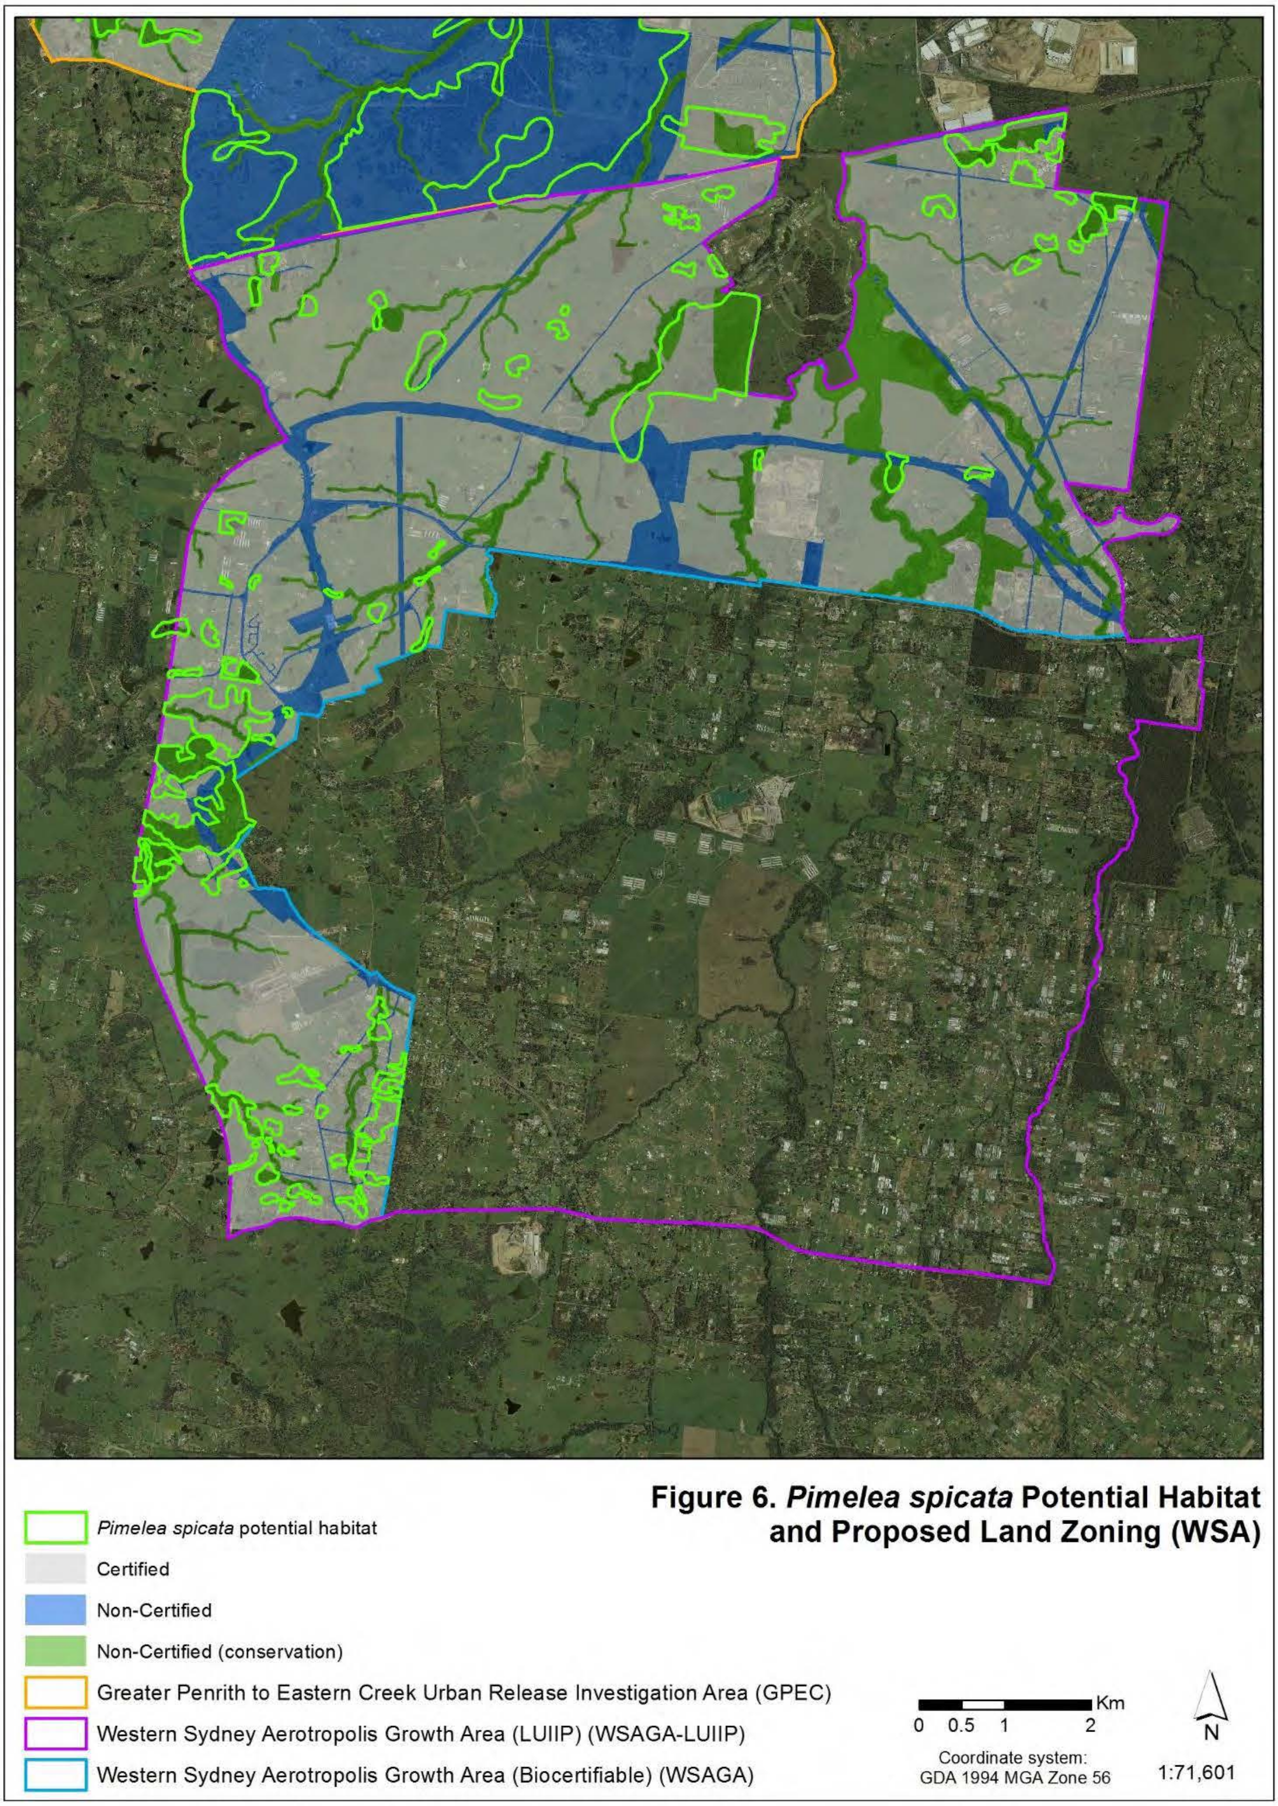

Figure 6. *Pimelea spicata* Potential Habitat and Proposed Land Zoning (WSA)

A significant proportion of the Cumberland Plain Woodland identified as potential habitat comprises native/mixed grasslands with scattered remnant trees and localised shrub regrowth. Such habitat is best represented at Orchard Hills (GPECGA) and between Luddenham and North Greendale in the WSAGA.

<u>Estimate of potential habitat relative to zoning (see Table 12)</u>

Within the Greater Penrith to Eastern Creek growth area 133 ha or 6% of potential habitat is found within the certified zone, 178 ha (8%) is zoned for conservation and 1857 ha (86%) occurs in the non-certified zoning. The latter includes larger areas within Wianamatta Regional Park [presumably with reasonable conservation prospects] and the Orchard Hills Defence Establishment that has long been recognised for its conservation values) and has been considered as an offset site for the Sydney Airport development (Dept. of Infrastructure, Regional Development & Cities, 2018).

Small council reserves in the far north-west associated with a north to south ridge-line above the Hawkesbury-Nepean River floodplain are particularly important for known and potential *Pimelea spicata* habitat, only two of which currently have conservation zoning. With records of *Pimelea spicata* (1) within and to the south of Mulgoa Nature Reserve, protection of potential habitat identified adjacent to the reserve also represents a good conservation opportunity for the species.

In the Western Sydney Aerotropolis growth area just over 53% occurs within the certified or development zone although 43% is zoned conservation predominantly associated with the South Creek corridor (around Kemps Creek) and the upper catchment of Duncan's Creek in the vicinity of Willowdene Avenue, south of Luddenham. The latter area is close to the recently discovered population west of the Northern Road and includes similar habitat. Potential habitat to the south around Greendale North is less intact and currently suppressed by a high level of grazing, however, may provide some conservation opportunities.

Table 12: Potential habitat relative to zoning

Growth Area	Greater Penrith-Eastern Creek (GPEC)	Western Sydney Aerotropolis (WSA)
Certified	133 ha	290 ha
Non-Certified	1857 ha	30 ha
Conservation	178 ha	237 ha

5. Information used in the assessment

5.1 NSW Planning & Environment and OEH resources

- Bionet sightings & other threatened species data from Atlas of Living Australia, *Pimelea spicata* Recovery Plan, Penrith City Council & LLS
- Greater Penrith to Eastern Creek and Western Sydney Airport Growth Areas Vegetation Mapping (see Table 13)
- Survey data, effort and land access details (see Table 13)

Unlike for the Wilton and Greater Macarthur growth areas all plots sampled were new i.e. surveyed for this project. Much of this information was available via the project's spatial viewer.

Table 13. Sources for existing vegetation survey data used in the biodiversity assessment

Data collector	Approx. no. plots	Survey year	Growth Area
Biosis & EcoPlanning	26	2017- 2018	Greater Penrith to Eastern Creek
Biosis & EcoPlanning	53	2017 - 2018	Western Sydney Airport

Appendix 1. Curriculum Vitae for Teresa James

Home & work address: 1 Sharland Avenue, Chatswood NSW 2067

Mailing address: As above

Telephone: Mobile: 04 282 18502.

Email: t.james@optusnet.com.au

Key positions:

- Botanist/ecological consultant specialising in vegetation survey, plant identification, conservation assessment and threatened species.
- Until October 1998 held position of Identifications Botanist, Plant Sciences, National Herbarium of New South Wales, Royal Botanic Gardens, Sydney.

Qualifications:

Bachelor of Science (Combined Honours in Biology and Geography) - University of Exeter, England. 1978.

Accreditation:

Accreditation awarded (2008) as a BioBanking Assessor under the Threatened Species Conservation Act 1995 (NSW); accreditation renewed 2013. Accreditation number 0017.

Current employment (1998-present):

Self- employed flora/ecological consultant (sole trader working as Teresa James Flora Consultant).

- Flora surveys, site/conservation assessments and monitoring projects.
- Preparation of environmental impact assessment reports (e.g. 7-part test, species impact statement & review of environmental factors).
- Biobanking and Biodiversity Offset assessments.
- Preparation of threatened species management plans.
- Expert witness in the Land & Environment Court.
- Botanical training for local councils and community groups.

Previous employment

1978 (3 months)	Technical Assistant, Biological and Chemical Research Institute, Rydalmere (Department of Agriculture).
1978-1998	Employed at the Royal Botanic Gardens, Sydney.
1978-1979	Temporary Herbarium Assistant
1980-1982	Technical Officer, Botanical Information Section
1982-1986	Acting Identifications Botanist, Botanical Information Section
1987-1991	Technical Officer, Botanical Information Section
1991-1994	Acting Identifications Botanist, Botanical Information Section
1994	Secondment 4 days/week to World Heritage Assessment of the Blue Mountains (consultancy for NSW National Parks & Wildlife Service).
1994	Permanent appointment as Identifications Botanist.
1994-	Appointed Botanical Information Section Co-ordinator.
1996-1997	Secondment to NSW National Parks & Wildlife Service as Flora Officer for Urban Bushland Biodiversity Survey. Stage 1: Western Sydney.
1994-1998	Identifications Botanist & Botanical Information Section Co-ordinator.

<u>Selected longer-term projects:</u>

1998-1999	Vegetation sampling for NSW National Parks & Wildlife Service - Western Sydney Vegetation Mapping Project.

1999	Flora consultant to Eastern Gas Pipeline (Duke Australia Operations).
2000	Preparation of Fire Ecology Manual for Rural Fire Service and UWS.
October 2000-2003	Flora consultant to Biosis Research for Penrith City Council – proposed developments & TSC Act issues at Erskine Park.
2001	Field sampling and truthing for vegetation community mapping project - Baulkham Hills LGA. Baulkham Hills Shire Council.
2001-2003	Qualitative and quantitative vegetation surveys (including rare plant species and ecological communities, weeds and other threats, environmental assessment) of Wingecarribee Swamp with Sainty & Associates for the Sydney Catchment Authority.
February 2002-May 2002	Review of wetland boundaries and general vegetation mapping and condition assessment within Baulkham Hills local government area (for Baulkham Hills Shire Council).
2003	Vegetation survey in the Hunter, Nattai & Bargo districts as part of the National Parks & Wildlife Service Vegetation Survey Program.
2002-2007	Flora survey/monitoring at Dr Charles McKay Reserve, Mt. Druitt for Blacktown City Council.
September 2005 –2006	Field validation for Foreshore Vegetation Mapping Project on Sydney Harbour for Botanic Gardens Trust and NSW Maritime Services.
September 2000-2008	Flora consultant to Liverpool City Council – provide review & advice relating to development applications, plans of management & special projects.
February -May 2007	Field survey for Sydney Metropolitan Catchment Management Authority/DECC vegetation mapping. Plot data recorded for 100 sites within SMCMA.
May 2008-2010	Vegetation mapping and assessment of Blue Gum High Forest and Turpentine Ironbark Forest in Ku-ring-gai local government area
August 2008-present	Flora advice to Ku-ring-gai Council - review of development applications, plans of management and mapping/biodiversity projects.
February-August 2012	PAS2 Expert Interviews for NSW threatened species with Office of Environment & Heritage.

*See consultant reports for complete list of projects/surveys.

Special projects:

Assessment of the World Heritage Values of the Blue Mountains and surrounding plateaus

An assessment of the natural and cultural values of the sandstone plateaus of the Blue Mountains and surrounding areas was funded by the Federal and State Governments to determine the potential for world heritage nomination. A team of people worked on the project from the Royal Botanic Gardens, Australian Museum (cultural values) and experts from local universities. I was project co-ordinator for the assessment, wrote much of the text for the natural values sections and was editor of the final report. This report was used as a basis for the successful Blue Mountains World Heritage nomination (June 1998).

NPWS Urban Bushland Biodiversity Survey. Stage 1: Western Sydney

Documentation of biodiversity and conservation values in Western Sydney was the first priority project undertaken within the State Biodiversity Survey Program. The survey gave emphasis to threatened species, communities and habitats. The region was documented on a local government area basis. I co-ordinated the flora surveys and was principal author for the flora reports.

Particular expertise:

Plant Identification:

- New South Wales plants, native and naturalised (18 years of experience in the Botanical Information Section of the Royal Botanic Gardens, Sydney). Specimens received from all over state. Also cultivated plants.
- Specialist in Sydney flora.
- Prepared taxonomic treatments for various plant families in the publication Flora of New South Wales, volumes 1-4, produced by the Royal Botanic Gardens, Sydney.
- Conduct plant identification workshops both through the RBG and the University of Western Sydney.

Documentation and conservation/ impact assessment: plant communities and species

- Extensive range of sites surveyed with species lists compiled over the last twenty-five years, particularly in Western Sydney, the Blue Mountains and Southern Highlands. Plant specimens collected and incorporated into the National Herbarium of N.S.W. Information used in numerous reports and books e.g. World Heritage Assessment of the Blue Mountains, the NPWS Urban Bushland Biodiversity Survey, Rare Bushland Plants of Western Sydney and various papers.
- Prepare Tests of Significance and Species Impact Statements as required under current legislation (TSC Act, EPBC Act).
- Prepare Statements of Evidence & Affidavits for the Land & Environment Court.
- Provide advice to the community, developers, government agencies and councils concerning the identification of communities and species, impacts of proposed developments, the ecological effects of urbanisation, flood mitigation and management practices such as mowing, burning etc.

Peer review

Assessor services provided to government (all levels), consultancies and NGO's. Including the following:

- DA applications and associated reports e.g. REF's, SIS's, Tests of Significance
- BioBanking/Offset reports
- NSW Land & Environment Court reports

Education & training

- Involvement on committees or in groups providing technical advice and training eg. Greystanes Creek Management Committee, Upper Parramatta River Catchment Trust steering committees, Hawkesbury Rainforest Network.
- Presentations/talks e.g. National Parks Association, Society of Australian Plants, University of NSW, Landcare groups, local councils.
- Conduct plant community and species identification workshops/courses/tours through the Royal Botanic Gardens, the University of Western Sydney and privately.
- Prepared Fire Ecology Manual for Rural Fire Service (2000).
- Training for local government in threatened species, endangered ecological communities and biodiversity conservation.
- Publications e.g. primary author of revised edition of Rare Bushland Plants of Western Sydney (Royal Botanic Gardens 1999*),* contributor to Flora of New South Wales *(*Royal Botanic Gardens).

Courses/workshops & tours provided to local government/catchment management trusts/consultancies:

- Sept. 2004 - Threatened Species Tour for Baulkham Hills Shire Council bush care workers & council staff
- October 2004 – Significant Plant Communities-of Baulkham Hills Shire Council – tour for council staff
- February 2005 – Community workshop in Cumberland Plain Woodland for Holroyd City Council
- July-August 2005 - Biodiversity training for Liverpool City Council – 3 workshops for council officers
- September 2005 - Threatened Species Tour for Baulkham Hills Shire Council bush care workers

- August 2007 - Threatened Species Tour for Baulkham Hills Shire Council bush care workers
- October 2007 – Identification of plants in Cumberland Plain Woodland – for Hawkesbury Nepean CMA.
- April 2008 – Basic grass identification course for Baulkham Hills Shire Council (for bushcare volunteers).
- August 2008- Threatened Species Tour for Baulkham Hills Shire Council bush care workers
- November 2008 to April 2009 – Weedy Grass Identification Workshop x 3 for Sydney Metro CMA.
- August 2009- Threatened Species Tour for Baulkham Hills Shire Council bush care workers
- October 2009 – EEC identification field day for Hawkesbury-Nepean CMA
- August 2010 - Threatened Species Tour for Baulkham Hills Shire Council bush care workers
- October 2010 – Cumberland Plain Woodland identification training for SMEC Australia
- April 2011- – Cumberland Plain Woodland identification training for SMEC Australia
- April 2011 – Field training in identification of communities & plants on the Cumberland Plain for Hawkesbury Nepean CMA.
- June 2011 – Presentation to council staff on threatened flora & fauna and biodiversity conservation within the Hills Shire.
- August 2011- Threatened Species Tour for Hills Shire Council bush care workers
- June 2012 – Eucalypt Identification workshop for Hills Shire Council.
- September 2014 - Threatened Species Tour for Hills Shire Council bush care workers
- September – November 2014 – Series of two-day workshops on threatened ecological communities in western Sydney.
- October 2014 – Plant identification training day held at Dr Charles Mckay Reserve, Mt. Druitt for Blue Tongue Ecosystems.
- March 2015 – Derived Grasslands Workshop (western Sydney) for government and community.
- May 2015 - Threatened Ecological Communities Workshop (western Sydney) for government and community.
- August 2015 – Shale Sandstone Transition Forest Workshop (western Sydney) for government and community.
- September 2015 – Northern Sydney Threatened Communities Workshop for government and community.
- April 2016 - Shale Sandstone Transition Forest Identification Workshop
- April 2016 – Introduction to Identifying Western Sydney Plants
- April 2016 – Grass Identification Workshop
- April 2016 – Cumberland Plain Woodland Workshop for Liverpool Council bushcarers
- August 2016 - Threatened Species Tour for Fairfield City Council.
- August 2016 - Threatened Species Tour for Hills Shire Council.
- April 2017 – Bushcare Training for Penrith Council
- Aug-Sept -Oct 2017 - Community bushland guided walks for Liverpool Council
- August 2017 - Threatened Species Tour for Fairfield City Council.
- August 2017 - Threatened Species Tour for Hills Shire Council.
- September 2017 – Flora workshops at Scheyville and Agnes Banks

Committee & community participation

- Member of NPWS Cumberland Plain Woodland Recovery Team (1998).
- Member of NPWS Acacia pubescens Recovery Team (1998 to 2002).
- Member, Green Corridors Strategy Steering Committee.Upper Parramatta River Catchment Trust. (1997-2000).
- Member, Water Quality Strategy Steering Committee. Upper Parramatta River Catchment Trust (1995-7).
- Member, State of the Environment Report Steering Committee for Holroyd City Council (1995-2002).
- Botanical Advisor for Management Committee, Greystanes Creek Restoration Project (1993-2000).
- Blue Gum High Forest Workshop / Advisory Committee – Ku-ring-gai Council. (2007).

- James, T.A. (May 2006). Autumn surveys in Dr Charles McKay Reserve, Mt. Druitt. Ongoing survey & monitoring for Blacktown City Council.
- James, T.A. (May 2006). Update of Species Impact Statement for proposed development at 8 Narabang Way, Belrose. Report to Access Industrial Holdings Pty Ltd.
- James, T.A. (May 2006). Review of Environmental Management Plan and site inspection for proposed stabilisation works along Birrong rail cutting. Advice to RailCorp.
- James, T.A. (July 2006). Flora investigation of alleged poisoning of vegetation on Lot 42 Warlands Creek via Blandford, Upper Hunter Valley. Report to Department of Environment & Conservation (Legal Branch).
- James, T.A. & Barker, C. H. (June-August 2006). Preliminary flora & fauna survey for Hyland Road Reserve (North), Greystanes. Report to Holroyd City Council.
- James, T.A. (September 2006) Threatened Flora Surveys – western Sydney. Targeted survey for Department of Environment & Conservation.
- James, T.A. (November 2006). Flora survey and assessment for proposed footbridge construction over Cabramatta Creek. Report to Liverpool City Council.
- November 2006. Targeted field survey for *Gentiana wingecarribiensis* at Wingecarribee Swamp, Southern Highlands. Assistance to Parsons Brincherhoff Australia.
- February-May 2007. Field survey of Sydney Metropolitan Catchment Management Authority area. Royal Botanic Gardens Trust and Sydney Metropolitan Catchment Management Authority.
- T.A. James (February 2007). Faulkland Crescent Reserve - flora survey and review. Report to Blacktown City Council.
- James, T.A. (April 2007). Upgrade of Great Western Highway at Wentworth Falls - proposed stockpile, compound and spill basin areas - Flora survey and assessment. Report to Australian Museum Business Services for RTA.
- James, T.A. (May 2007). Upgrade of Great Western Highway at Bullaburra – flora survey and assessment. Report to Australian Museum Business Services for RTA.

- BioBanking Pilot Program (May 2007). Field survey & assessment at three Sydney sites (Wilton, Camden & Cranebrook) to test draft assessment methodology. Undertaken with Australian Museum Business Services for Department of Environment & Conservation.
- James, T.A. (August 2007). Flora review – proposed re-zoning of land along Pacific Highway, Pymble with particular reference to Blue Gum High Forest. Report to Ku-ring-gai Council.
- James, T.A. & C. H. Barker (October 2007). Flora & Fauna Survey and Assessment – Castle Hill Cemetery. Report to Baulkham Hills Shire Council.
- James, T. A. (Nov 2007). Investigation of clearing of native vegetation at Lot 2 DP 559922, 280-282 Captain Cook Drive, Kurnell. Report to NSW Department of Environment & Climate Change (DECC).
- James, T.A. (Nov 2007). Review of flora assessment for proposed residential development at 216-220 New Line Road, Dural. Report to Hornsby Council.
- November 2007. Assistance to SMEC Australia with base-line ecological monitoring in Upper Nepean Special Area for SCA.
- James, T.A (Dec 2007-Feb 2008). Targeted survey for *Hibbertia superans.* Report to Indigenous Business Services.
- November 2007- January 2008. Targeted survey for *Gentiana wingecarribiensis* and *Prasophyllum uroglossum* at Wingecarribee and Hanging Rock Swamps. Report to NSW Department of Environment & Climate Change (DECC).
- March 2008. Flora survey for upgrade of Great Western Highway at Bullaburra. Report to nghenvironmental for RTA.
- James, T.A. (March 2008). Flora survey of Plumpton Park Reserve. Report to Blacktown City Council.
- James, T.A. (April 2008). Review of Water Street DA, Wahroonga. Report to Ku-ring-gai Council.
- James, T.A. (April 2008). Flora survey of Gum Tree Reserve, Guildford and Bolaro Avenue, Greystanes. Report to Holroyd City Council.
- May 2008-June 2009. Assistance to Ku-ring-gai Council to map and assess Blue Gum High Forest and Turpentine Ironbark Forest.
- James, T.A. (August 2008). Flora review of Species Impact Statement prepared for proposed industrial development at 37 Beaumont Road, Mt. Ku-ring-gai. Report to Hornsby Shire Council.
- James, T. A. (May 2009). Preliminary flora report for proposed residential development at 38-40 Grove Avenue, Narwee.
- James, T.A. & Barker, C. (2006-2009). Monitoring of flora and fauna at Hyland Road Reserve. Report to Holroyd City Council.
- James, T. A. (Sept 2009). Ecological issues relating to the Turramurra Deferred Area within Ku-ring-gai LGA. Report to Friends of Turramurra.
- James, T.A. (Sept 2009). Targeted survey for *Pimelea spicata* at Menangle Park. Assistance to GHD Pty Ltd.
- James, T.A. (Sept 2009). Investigation into land clearing of Shale Sandstone Transition Forest and Cumberland Plain Woodland - 561 Appin Road, Gilead. Report to Campbelltown City Council.
- James, T.A. (Nov 2009). Peer review of subdivision proposal at Kellyville. Shale Sandstone Transition Forest & threatened species present. Report to Hills Shire Council.
- James, T.A (2010). Field survey and ecological assessment for proposed park at Water Street, Wahroonga. Report to A. Parr.
- James, T.A. (March 2010). Survey of *Pimelea spicata* at Menangle Park for GHD.
- March-April 2010. Advice on threatened species for Growth Centres Strategic Assessment under EPBC Act to EcoLogical Australia.
- Lewis Ecological Surveys & James, T.A. (May –June 2010). Flora and fauna assessment for extension of Kirkwood Road, Tweed Heads. Report to Tweed Heads Shire Council.
- Lewis Ecological Surveys & James, T.A. (May –June 2010). Compensatory habitat assessment for the Kempsey to Eungai pacific highway upgrade.
- Joint project with Australian Museum (October 2010 - March 2011) – Flora & fauna survey for Stage 2 of the Narrabeen Lagoon Multi-use Trail.
- Joint project with Australian Museum (October 2010 - December 2011) – City of Sydney Biodiversity Survey & Strategy.
- James, T.A. (2011). Investigation into land clearing of Shale Sandstone Transition Forest and Cumberland Plain Woodland - 561 Appin Road, Gilead. Expert report to DECCW.

- James, T.A. (2011) Flora survey for three reserves in Holroyd LGA to document regeneration following the cessation of mowing. Report to Holroyd City Council.
- James, T.A. (2011) Flora survey of Grey Box Reserve, Greystanes. Report to Holroyd City Council.
- Douglas, S & James, T (2011) Review of listing advice and conservation advice for Shale Sandstone Transition Forest EEC under the EPBC Act – in progress.
- James, T.A. (2011) External Review of White Box – Yellow Box – Blakeley's Red Gum grassy woodlands and derived native grassland ecological community for the Mt. Pleasant Project (EPBC 2011/5795). Report to Dept. of Sustainability, Environment, Water, Population and Communities.
- Ecological advice to SMEC Australia (July-August, 2011). Impact assessment for *Pimelea spicata* – upgrade of Camden Valley Way, western Sydney.
- Ecological advice to SMEC Australia (August-September, 2011). Survey and assessment for Eastern Flame Pea – Trans Grid Dapto substation upgrade.
- Field assistance to SMEC Australia (February 2012) - Targeted survey for *Pimelea spicata* and general survey for RTA Camden Valley Way upgrade.
- PAS2 Expert Interviews for NSW threatened species with Office of Environment & Heritage (February-August 2012).
- Plot survey and ground verification of vegetation mapping within Hills Shire Council (June 2012).
- Threatened species management plans for several species prepared for Hills Shire Council (June 2012) – multi-species plan for Paulls Road (South Maroota), individual plans for *Persoonia hirsuta* and *Epacris purpurascens* at Fred Caterson reserve.
- Joint project with Australian Museum - Narrabeen Lagoon multi-trail (stage 2) Species Impact Statement (June 2012)
- Field assistance to SMEC Australia - Western Sydney Parklands vegetation monitoring project for WSP Trust (July – August 2012).
- Biodiversity/conservation assessment for 12-14 Cabernet Circuit Orchard Hills. Unpublished report to Wayne Olling of CCA (October 2012)
- PAS Reviews for selected NSW threatened species with Office of Environment & Heritage (November 2012).
- Vegetation Peer Review for the Northern Beaches Health Service Project. Report to Health Infrastructure (January 2013).
- Flora survey and assessment on private properties within the Balmoral Release Area, Kellyville (15, 16-20, 24, 26 & 28) for the Hills Shire Council (May-June 2013).
- Preparation of a Threatened Species Plan of Management for *Dillwynia tenuifolia* endangered population along Maquires Road, Maraylya for the Hills Shire Council (May-June 2013).
- Biobanking Assessment Report for the Northern Beaches Hospital Precinct development (a State Significant Development). July 2013. Report to SMEC Australia and Health Infrastructure.
- Threatened species roadside survey and verification of threatened ecological communities for Campbelltown City Council (September-October 2013).
- Peer Review of Species Impact Statement for 34-36 Britton Street, Smithfield for Holroyd City Council (November 2013).
- Flora survey and condition assessment for Pacific Highway Upgrade Woolgoolga to Ballina (Feb - April 2014). Assistance to Ecosure for Roads and Maritime Services.
- Matching of threatened entities occurring in the Greater Sydney Region area to newly mapped vegetation/community types in the Sydney Metro CMA and other parts of the Greater Sydney Region (May-June 2014) for Office of Environment and Heritage (Sydney).
- Parramatta Park baseline flora survey and report for Parramatta Park & Western Sydney Parklands Trust (September 2014).
- Assistance to SMEC with survey and biodiversity report for commonwealth-owned land at Badgerys Creek (Sept-Oct 2014). Report to Department of Infrastructure and Regional Development.
- Identification of Shale Sandstone Transition Forest in the Hills Shire – report to Hills Shire Council (July 2015).
- Assistance with field survey to SMEC Australia at the Holsworthy Training Area for Department of Defence (September 2015).
- Assistance with field survey (base line monitoring) to SMEC Australia at the Kapooka Biodiversity Offset Site near Wagga Wagga for Roads and Maritime Services (Sept-Oct 2015).

- Assistance to SMEC Australia in preparation of a Species Impact Statement for the Mona Vale Road upgrade for RMS (Nov 15-Jan16).
- Assistance to Ecosure in field survey/assessment for Mosman Flora and Fauna Bushland Audit (Jan-Feb 2016).
- Ecological Survey of Sackville Cemetery – report to The Hills Shire Council (May 2016)
- Field survey with 20 m x 20 m plot sampling for OEH Western Cumberland Plain and Bargo Gap Project (targeting transitional areas) – June 2016
- Field survey with 20 m x 20 m plot sampling for OEH Wingecarribee Shire Project – February 2017
- Field survey for vegetation management advice at Greendale property, western Sydney (April 2017)
- Vegetation Benchmark Values Project for the Hills Shire Council (June 2017)
- Attendance on OEH Saving Our Species expert panel (2017-2018) for several threatened ecological communities
- Provide Roadside Vegetation Management RAM workshop training for Hawkesbury River County Council (Feb 2018)
- Field survey and assessment for Persoonia nutans at TestSafe Site, Londonderry for OEH (June 2018)
- Flora and fauna assessment for expansion of Sackville Cemetery for the Hills Shire Council (June 2018)
- Strategic assessment for Cumberland Plain Conservation Plan – expert report for *Pimelea spicata* – report to Department of Planning & Environment (May-August 2018)
- Rapid Assessment/monitoring workshop for Fairfield City Council (Sept 2018)
- Review of master list for selection of plant species for landscaping and restoration appropriate to range of habitats found within the Western Sydney Parklands. Report to Western Sydney Parklands
- Independent Peer Review of SIS for Lot 11 Progress Circuit, Prestons. Report to Liverpool City Council
- Preliminary advice re impacts on GDE's at Menangle Park and additional vegetation assessment. Report to Campbelltown City Council

Pterostylis saxicola (photo Wayne Cherry)

1. Introduction

1.1 PURPOSE

I was engaged by the Department of Planning and Environment in early June 2018, to produce an expert report on the distribution and abundance of *Pterostylis saxicola* (Orchidaceae) within the proposed Greater Macarthur and Wilton Growth Areas (collectively termed "the study area"). The aim of this exercise was to assess whether *P. saxicola* (the "focal species") is native to either of the Growth Areas and, if so, to assess where suitable habitat is located and to estimate the area of habitat of *P. saxicola* in the study area.

According to Section 6.5.2 of the Biodiversity Assessment Method, an expert report must:

- identify the relevant species or population
- justify the use of an expert report
- indicate and justify the likelihood of presence of the species or population
- estimate the number of individuals or area of habitat (the latter being the unit of measurement that applies to *Pterostylis saxicola*) for the biodiversity certification assessment area, including a description of how the estimate was made
- demonstrate what information was considered, rejected and discounted in relation to the determination made in the expert report, and
- identify the expert and provide evidence of their expert credentials.

1.2 PROJECT CONTEXT

The Department of Planning and Environment is leading a strategic biocertification of several identified growth areas within Western Sydney, including the two growth areas that define the geographic scope of this report: the Greater Macarthur Growth Area and the Wilton Growth Area. The strategic biodiversity assessment is an integral part of the Cumberland Plain Conservation Plan that will determine the impact of urban development on threatened species and ecological communities within these growth areas. The Plan will also provide conservation measures to mitigate any impact, as specified by NSW and Commonwealth environmental legislation.

1.3 STUDY AREA

The Greater Macarthur and Wilton Growth Areas are located in the south western part of the Sydney Metropolitan Area, between latitudes 33°57'29"S and 34°16'44"S and longitudes 150°37'12"E and 150°54'47"E (the area outlined in blue in figures 13 to 15).

1.4 CREDENTIALS OF EXPERT

I prepared this report as an independent botanical consultant but I am also currently an Honorary Research Associate at the at the New South Wales state herbarium (the National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust). In 2016, I retired from my role as a Senior Principal Research Scientist at the state herbarium, having worked there since

1982 as a Systematic Botanist and as curator of the herbarium's collections of specimens of Orchidaceae (including *Pterostylis saxicola*) (see my *Curriculum Vitae*, attached). I now work, part-time, at the National Herbarium of New South Wales as an Honorary Research Associate. I have published, either as sole author or as a co-author, 16 papers on the systematics and ecology of the Orchidaceae in the peer-reviewed scientific literature, including the most comprehensive phylogenetic analysis of the predominantly Australian subtribe Diurideae yet published (Weston *et al.* 2014). As curator of Orchidaceae at the state herbarium, I examined all specimens of *P. saxicola* incorporated into the collection between 1986 and 2016. I was invited to contribute to floristic treatments of the Orchidaceae for *Flora of New South Wales*, (see my *Curriculum Vitae*, attached). I was also asked to be lead author of the essay on the ecology of the Orchidaceae that accompanied the "Ecology of Sydney Plants" (Weston *et al.* 2005). Throughout my career I have participated in numerous collecting trips in the field, collecting specimens in all Australian states for the state herbarium. In documenting these specimens I had to describe the habitat at each collecting site, including associated plant species, substrate, aspect, degree and kind of disturbance. I have also cultivated numerous species of *Pterostylis* as an orchid enthusiast and advised horticulturalists at the Royal Botanic Gardens on appropriate techniques for cultivating species of *Pterostylis* and other orchids.

1.5 JUSTIFICATION FOR USE OF EXPERT REPORT

Pterostylis saxicola has been collected once, questionably, within the study area, at Minto. However, two specimens of *P. saxicola* held by the state herbarium (NSW884619, NSW521907), and several observations recorded in the Bionet Wildlife Atlas, have been collected only 0.5-1.5 km east and 1.0 km south of the boundaries the Greater Macarthur Growth Area, raising the strong possibility that suitable habitat for *P. saxicola* might exist in the study area.

Moreover, the OEH Threatened Species Data Collection indicates that *Pterostylis saxicola* has the potential to occur in the following plant communities within the Wilton and Greater Macarthur Growth Areas:

- 1081 Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain
- 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest on the edges of the Cumberland Plain

If this were so, *Pterostylis saxicola* might once have lived there, or still exist in the study area as unrecorded populations.

Pterostylis saxicola is a perennial, deciduous herb that can only be identified with confidence when flowering in Spring (late September to early November). At other times of year, the plants are either not visible at all when dormant from December to March, or are visible only as leaf rosettes, which resemble the leaves of other, closely related, co-occurring species of *Pterostylis* so closely that they cannot be distinguished with confidence. Conventional surveying during October would therefore be the most appropriate way to test for its presence, if unlimited access to the study area were allowed. Although surveys were undertaken on all areas of land where landowners granted access, the timing of these was inappropriate for this species, as they were conducted between November 2017 and May 2018.

These limitations and the possibility that *Pterostylis saxicola* might be native to the Greater Macarthur and Wilton Growth Areas triggered the need for an expert report.

1.6 SPECIES SURVEYS

An initial 726 letters were sent to landholders within the Growth Areas in late 2017. A second letter was sent in March 2018, and targeted door knocking occurred in May 2018. From this, just under 20% of landholders have responded. Surveys were undertaken on all areas of land where landowners granted access. Of the 14,984 hectares within the Wilton and Macarthur Growth Areas, of which 5,385 ha is potential native vegetation that could be impacted by development, DPE has completed surveys across 3,360 hectares (62% of the total survey area). Floristic surveys were undertaken from November 2017 to May 2018, which, unsurprisingly, resulted in no sightings of *Pterostylis saxicola*, which was dormant or recently re-shooting from subterranean tubers for most of that time.

2. Species information

2.1 SPECIES DESCRIPTION

The following morphological description of *Pterostylis saxicola* is a modified version of that published by Jones and Clements (1997), updated with data gathered from more recently collected specimens held by the National Herbarium of N.S.W.

Tuberous, terrestrial herb. Tubers oblate, c. 15-20 mm wide. Leaves oblong-elliptical to ovate-elliptical or obovate, 10-45 mm long, 5-15 mm wide, 5-10 in a radical rosette, green, the margins entire, shortly petiolate, apex subacute to apiculate, often withered at anthesis. Inflorescence 10.5-35 cm tall, slender, with 3-6 ensheathing, lanceolate sterile bracts. Floral bracts lanceolate, 6-19 mm long, 3-4 mm wide, acuminate, closely sheathing. Pedicels 3-26 mm long, slender, straight or slightly curved. Ovary narrowly obovoid, 3-5 mm long, 1-2 mm wide, reddish brown. Flowers 1-10, porrect to semi-erect, 12-12 mm long, transparent with dark red-brown markings and suffusions in the galea, the lateral sepals wholly red-brown, shiny; galea gibbous at the base, curved medially, decurved suddenly to the apex; petal flanges poorly developed, not touching and not closing off the base of the galea. Dorsal sepal 11-13 mm long, cucullate, obliquely erect, Abruptly decurved in distal quarter, apical point c. 3 mm long, filamentous, acuminate. Lateral sepals deflexed, ovate in outline when flattened, fused part 7-10 mm long, 9-11 mm wide, shallowly concave, the margins strongly incurved, glabrous; sinus narrow; free points filamentous, c. 5 mm long, curved forwards, divergent, 8-10 mm apart at the tips. Petals ovate-lanceolate, 11-14 mm long, 3.5-5 mm wide, nearly straight, transparent, with brown basal markings and two or three brown lines, dorsal margin brown, ciliate, proximal flange poorly developed. Labellum highly irritable, attached by a ligulate basal claw c. 2 mm long, c. 2 mm wide; lamina broadly obovate, 4.5-6 mm long, 2.5-3.5 mm wide, dark red-brown, constricted in the proximal quarter, adaxial surface shallowly concave to broadly grooved, apex obtuse; marginal trichomes 3-5 pairs, white, the longest pair c. 3.5 mm long, arising near the proximal constriction, basal lobe large, with 1-3 pairs of trichomes c. 0-.7 mm long, abaxial surface with a narrow central channel extending from the basal lobe to the apex. Column porrect from the end of the ovary, 10-12 mm long, c. 2.5 mm wide; column wings c. 3.3 mm long, c. 2.5 mm wide, more or less rectangular, anterior margins ciliate. Stigma elliptical to broadly scutiform, c. 5 mm long, c. 2.5 mm wide, the upper margins irregular. Anther c. 1.2 mm long, obtuse. Pollinia linear-oblong to clavate, c. 2 mm long, yellow, mealy. Fruiting capsules obovoid, 7-8 mm long, c. 4-5 mm wide, brownish, erect.

2.2 LIFE CYCLE

Pterostylis saxicola is a perennial, deciduous, tuberous herb that germinates from a minute, dust-like seed. Like all other orchids, germination is reliant on invasion of the seed by the hyphae of a specific fungal associate, which, in the case of *P. saxicola*, is an unnamed species of *Ceratobasidium* (Basidiomycota: Cantharellales) (Sommerville *et al.* 2008). The first morphological change that an orchid seed undergoes during germination is swelling to form a protocorm, a rootless, shootless 'blob'. The orchid fungus forms an intracellular relationship with its host, usually in the roots and/or tubers and is thus classed as an endomycorrhiza. It forms hyphal coils, called pelotons, in the cells of its host, which are beneficial to the orchid in that they provide the host plant with nutrients such as soluble sugars (Rasmussen 1995, Warcup 1990). The duration of the association varies according to the life history of the particular orchid species, with some species of orchids being completely dependent on their mycorrhizal fungi for life while other species are capable of living without their fungi from shortly after germination. The ease of cultivation of *Pterostylis* species and the green colour of almost all plant parts strongly suggest that adult plants are not obligately dependent on their mycorrhizal associates.

Plants of *Pterostylis saxicola*, like those of most other species in Orchidaceae subfamily Orchidoideae, are deciduous, with the whole shoot system growing anew every year from a dormant tuber. The new shoot usually starts growing from an apical meristem on the tuber in late summer, with new shoots usually breaking the soil surface by March. The shoot develops into a "rosette" of crowded leaves just above ground level and in late winter a terminal raceme starts growing from the centre of the rosette, reaching anthesis in Spring. While the shoot is growing above ground, a new replacement tuber is growing below ground, from the base of the shoot. Some species of *Pterostylis* multiply and spread vegetatively by producing additional new tubers on the ends of long roots but the subgenus to which *P. saxicola* belongs, *Oligochaetochilus*, does not share this attribute (Jones 2006).

Almost all species of *Pterostylis* are deceptively pollinated by male flies that attempt to copulate with the labellum of the flower. The labellum mimics a female fly of a particular species (or species group) in size, appearance and texture and by exuding an allomone that is identical to the pheromone released by the female flies (Phillips *et al.* 2013, Kuiter & Findlater-Smith 2017). In species of *Pterostylis* for which the pollination process has been studied and described, the labellum is highly motile ("irritable"), like that of *Pterostylis saxicola*, and a male fly that lands on it is tossed inside the hood (galea) formed by the dorsal sepal and lateral petals, and trapped there. The only escape route provided by the flower is a tunnel through which the male fly must squeeze in order to escape. In the process of negotiating its exit, the fly is forced to rub past the stigma of the flower, depositing on it any pollinaria that it was already carrying. The fly is then forced to contact the anther, sticking a pollinarium on its thorax, before it can finally escape. The pollinator of *Pterostylis saxicola* is still unknown, but the pollinators of other species of *Pterostylis* subgenus

Oligochaetochilus, where known, are males of unnamed species of *Orfelia* (Mycetophilidae) (Kuiter & Findlater-Smith 2017). Sexually deceptive pollination has evolved multiple times in the Australian terrestrial orchid flora, involving hundreds of species (Weston *et al.* 2014). Most of those for which pollinators have been identified are pollinated by the males of only one species of insect and *P. saxicola* is most likely pollinated by a single species of fly too.

Fruiting capsules of *Pterostylis saxicola* mature quickly, with the most proximal capsules sometimes dehiscing before the most distal flowers have withered. They split down six sutures to release thousands of minute, wind-dispersed seeds in November to early December.

2.3 DISTRIBUTION AND ABUNDANCE

Records for *Pterostylis saxicola* are widely distributed across the Cumberland Plain and lower Blue Mountains in an area bounded by Scheyville, Freemans Reach, Glenbrook, Douglas Park, Picnic Point, Ryde (an unvouchered record) and Cattai, with an outlying record from the Gingra Range in Kanangra Boyd National Park (Bionet Atlas, National Herbarium of New South Wales specimen database, all accessed 26/7/2018). It has been recorded at altitudes ranging from 30 to 400 metres. It is very sporadically distributed, partly because much of this land has been cleared for agriculture and suburban development but the outlying record suggests that any habitat model is unlikely to be a powerful predictor of the presence of populations at particular locations.

Plants are usually gregarious, with most collectors and observers noting multiple plants co-occurring together. At two sites for which I had highly precise grid references, and which I characterised in detail, I found pre-flowering leaf rosettes in clusters: 10 plants in a 10x10 cm patch (figure 1, site PS1, Appendix 1), two plants 5 cm apart, and 57 in a patch smaller than one square metre. As *P. saxicola* does not usually multiply vegetatively (Jones 2006), these clusters must be the result of seeds germinating close to their parents.

2.4 HABITAT REQUIREMENTS

The habitat model published in the endangered species profile for *Pterostylis saxicola* (NSW Office of Environment and Heritage 2018, hereafter “NOEH 2018”) states that it is “most commonly found growing in small pockets of shallow soil in depressions on sandstone rock shelves above cliff lines. The vegetation communities above the shelves where *P. saxicola* occurs are sclerophyll forest or woodland on shale/sandstone transition soils or shale soils”. This description applies accurately to the habitat associated with some records in the southern half of the species’ distribution but not to those found elsewhere. The distributional range and habitat requirements of *P. saxicola* can be subdivided into two main sub-populations and one outlying population.

The northern sub-population is in an area bounded by Scheyville, Freemans Reach, “The Ironbarks” near Glenbrook, Toongabbie, Ryde, Glenhaven and Cattai. The substrate underlying the sites at Scheyville, Freemans Reach and Ryde is deep Ashfield Shale (Wianamatta Group), but the Cattai, Toongabbie and Glenbrook records came from Hawkesbury Sandstone – Mittagong Formation – Ashfield Shale transition zones. All of these sites are in gently rolling country, not on rugged sandstone outcrops.

I visited and characterised one of these sites at Scheyville National Park (site PS1, Appendix 1), the location of which was recorded with very high precision. I found pre-flowering *Pterostylis* rosettes

Figure 1. Pre-flowering rosettes of *Pterostylis saxicola* growing on Ashfield Shale in Scheyville National Park (site PS1, Appendix 1).

Figure 2. Site Ps1 with *Pterostylis saxicola* growing on the side of the track, next to the backpack, in Cumberland Plain Woodland on Ashfield Shale in Scheyville National Park (site PS1, Appendix 1).

there that were consistent with *Pterostylis saxicola* (figure 1, site PS1, Appendix 1). The population there was growing on the side of a track just below the crest of a ridge, the land sloping at about 5° to the south east, on Ashfield Shale, in Cumberland Plain Woodland (*sensu* Keith 2004) dominated by *Eucalyptus moluccana* and *E. crebra*, a plant community that I identified using the community identification tools in Bionet as 849 Grey Box – Forest Red Gum grassy woodland on Flats of the Cumberland Plain. This site was inconsistent with the species profile for *P. saxicola* (NOEH 2018) in both substrate (Ashfield Shale) and landform (gentle slope near ridge top). The closest sandstone outcrop to the site was at least 3.6 km to the east, the shale cap at the site being about 20-30 m thick according to the geological map covering this area (NSW Department of Minerals and Energy 1991).

The plant communities associated with recorded sites for *Pterostylis saxicola* in its northern sub-population, as determined from collectors' and observers' notes and from identification of precisely specified sites on vegetation maps (Tozer *et al.* 2010), are map unit GW p29 Cumberland Shale Plains Woodland, and map unit GW p2 Cumberland Shale Sandstone Transition Forest.

Most records from the southern sub-population, in an area bounded by Macquarie Fields, Minto, Douglas Park, Woronora River and Picnic Point differ strikingly in habitat from the northern records. In cases where they have highly precise locality data and/or detailed habitat descriptions, collections and observations from this area have been made on Hawkesbury Sandstone, on the rims and sides of the gorges of the Nepean, Georges and Woronora Rivers. Observers' notes repeatedly describe the soils as very shallow sands overlying sandstone rock shelves, as stated in the published habitat model (NOEH 2018). However, contrary to that model, only some of them were recorded above cliff lines. The only evidence of shale influence on the environment seems to be associated plant community types, with some precisely georeferenced sites being mapped by Tozer *et al.* (2010) to Cumberland Shale Sandstone Transition Forest (their map unit GW p2).

I visited and characterised four sites at which *Pterostylis saxicola* had previously been collected in the southern sub-population, at Simmos Beach Recreation Reserve Macquarie Fields (sites PS2, PS3), Boronia Road Reserve, Kentlyn (site PS4), and Amberdale Reserve, Picnic Point (site PS5, Appendix 1). At one of these I found pre-flowering rosettes identical to those of *P. saxicola* at the precise grid reference I had been provided by a previous collector, Karen Sommerville (figures 3-4, site PS3, Appendix 1). They were growing in a thin layer of dark brown humus-rich sand on a flat sandstone outcrop on a gently sloping ridge top. Other sites at which *P. saxicola* had previously been collected but where I did not find pre-flowering rosettes were similar, with sandstone rock shelves covered in a thin layer of sandy soil that was partly covered by mosses and lichens. Several plant species were associated with *P. saxicola* at all four of these southern sites: *Angophora bakeri*, *Banksia spinulosa*, *Hakea sericea*, *Leptospermum trinervium*, *Lomandra obliqua*, and *Persoonia levis*.

The plant community types that I identified at these locations, using the community identification tool in Bionet, were:

- 1081 Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain;
- 1181 Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney.

Figure 3. Pre-flowering rosettes of *Pterostylis saxicola* growing at Simmos Beach Recreation Reserve, Macquarie Fields (site PS3, Appendix 1).

Figure 4. PCT 1081 Red Bloodwood - grey gum woodland on the edges of the Cumberland Plain, at site PS3 (Appendix 1)

- 1789 Smooth-barked Apple - Blackbutt - Red Bloodwood open forest in enriched sandstone gullies of the western Woronora plateau.

In addition to these plant community types, observational records of *Pterostylis saxicola* with highly precise grid references from outside the study area were assigned to map units using the maps and classification system of Tozer *et al.* (2010). However, in order to produce a unified, internally consistent habitat model, a standard plant community classification system needs to be adopted, and I have chosen the Bionet Vegetation Classification because that is the system that has been used for detailed mapping of the study area. Consequently, the relevant map units of Tozer *et al.* (2010) were converted to their equivalents in the Bionet classification, as indicated in the references cited with each plant community type in Bionet, reproduced in table 1 below.

Map unit of Tozer *et al.* (2010)	Equivalent PCT in the Bionet vegetation classification
GW p2 Cumberland Shale Sandstone Transition Forest	1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest on the edges of the Cumberland Plain
GW p29 Cumberland Shale Plains Woodland	849 Grey Box – Forest Red Gum grassy woodland on Flats of the Cumberland Plain
DSF p37 Kowmung-Wollondilly Grassy Gorge Woodland	870 Grey Gum - Thin-leaved Stringybark grassy woodland of the southern Blue Mountains gorges
DSF p131 Coastal Sandstone Ridgetop Woodland	1083 Red Bloodwood - scribbly gum heathy woodland on sandstone plateaux
DSF p142 Hinterland Sandstone Gully Forest	1181 Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney
DSF p146 Sydney Hinterland Transition Woodland	1081 Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain

Table 1. Equivalence of some map units of Tozer *et al.* (2010) with plant community types in the Bionet Vegetation Classification.

Some of these plant community types are not represented in the study area according to the vegetation maps produced for this project. Nevertheless, they need to be incorporated into any new general habitat model for *P. saxicola*.

I am not equipped to produce a bioclimatic envelope for *Pterostylis saxicola* but univariate mean monthly rainfall and temperature statistics for the distributional range of the species can be interpreted as indicating areas of potentially suitable habitat. Climatic statistics for weather stations within its distributional range (http://www.bom.gov.au/climate/data, accessed 7/8/2018) indicate that *P. saxicola* occurs in an area where mean annual rainfall varies between 700 and 1200 mm, average minimum temperatures for the coldest month vary from 1.7° to 5.1°, winter frosts are rare to frequent and where average maximum temperatures for the warmest month vary from 27.1° to 30.3°.

Pterostylis saxicola has mostly been recorded growing in intact native vegetation but there is one notable exception: a plant described in a "Car Park growing through bitumen", adjacent to a large area of bushland from which other substantiated records had been made. Several others have come from small patches of remnant urban bushland, in some cases less than a hectare in area, surrounded by highly disturbed land, and from a long, narrow patch less than 50 m wide. However, no records mention heavily weed-infested habitats or evidence of heavy grazing introduced herbivores. Sites with significant edge effects are probably not sustainable reserves for conserving this species.

Given the significant discrepancies between the habitat model published in the threatened species profile for *Pterostylis saxicola* (NOEH 2018) and the characteristics of sites at which substantiated collections have been made, an improved habitat model is now required.

The following model incorporates habitat information associated with all of the records of *Pterostylis saxicola* from the Bionet Atlas, Atlas of Living Australia and specimen database of the National Herbarium of New South Wales (all accessed 26/7/2018).

Occurs on the Cumberland Plain along an ecological gradient from:

- Clay soils derived from Ashfield Shale (Wianamatta Group) on flat to gently hilly landscapes in PCT 849 Grey Box – Forest Red Gum grassy woodland on Flats of the Cumberland Plain;
- to: clay to sandy soils derived from Hawkesbury Sandstone – Mittagong Formation – Ashfield Shale transition substrates on gently hilly landscapes, in PCT 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest on the edges of the Cumberland Plain;
- to: thin accumulations of humus-rich sandy soil on Hawkesbury Sandstone sheets and rock shelves, on the rims and steep sides of river valleys, growing in PCT 1081 Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain, or PCT 1083 Red Bloodwood - scribbly gum heathy woodland on sandstone plateaux, or PCT 1181 Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, or PCT 1789 Smooth-barked Apple - Blackbutt - Red Bloodwood open forest in enriched sandstone gullies of the western Woronora plateau.

Also occurs outside the Cumberland Plain on Devonian slate, in PCT 870 Grey Gum - Thin-leaved Stringybark grassy woodland of the southern Blue Mountains gorges.

3. Description of the study area

3.1 LAND USE HISTORY

The following account is based largely on information gathered from Liston (1988), except where otherwise stated. The first human inhabitants of the study area were Aborigines who moved there many thousands of years ago. People of the Dharawal group were occupants of the study area when Europeans first started to settle in the Sydney Region in 1788. These hunter-gatherers would have managed the grassy woodlands that grew on Wianamatta Shales of the area using fire-stick farming methods (Benson & Howell 1990). In 1816 a large group of them were massacred by soldiers at Appin and by 1830 their community life in the Campbelltown area had disintegrated.

In 1788, six months after Sydney was founded, two bulls and four cows escaped from Sydney Cove. European exploration of the study area commenced in 1795, when 61 naturalised descendants of those bulls and cows were discovered near Menangle, in an area that became known as “the Cowpastures”. Those cattle had discovered a plentiful source of fodder on the alluvial flats of the Nepean River and adjacent grassy woodlands on Wianamatta Shales, which also proved to offer more fertile farming land than sandy soils derived from Hawkesbury Sandstone. By the end of 1809, 34 settlers had been granted land at Minto and Glenfield for farming. Further land was granted to settlers at Appin in 1811, Macquarie Fields and Airds in 1816 and at Campbelltown in 1820. From then to the 1950s, land use in both growth areas was dominated by agriculture, which necessitated extensive clearing of native vegetation from the more fertile alluvial and clayey soils. Agricultural activities conducted in the areas have included the cultivation of wheat (which was curtailed in 1864 when the whole crop was destroyed by an infestation of rust disease) and other cereal crops, grazing of sheep, cattle and horses, intensive production of pigs and poultry, and the cultivation of fruit and vegetables. Campbelltown grew slowly as an urban centre during the 19th century and first half of the 20th century, but population growth accelerated after 1950 due to the rezoning of agricultural land for housing development in the northern part of the Macarthur Growth Area, electrification of the railway line as far south as Macarthur in 1963, the release of the Three Cities Plan (Campbelltown-Camden-Appin) in 1972 and subsequent construction of a number of large-scale housing commission projects from 1973 (figure 5).

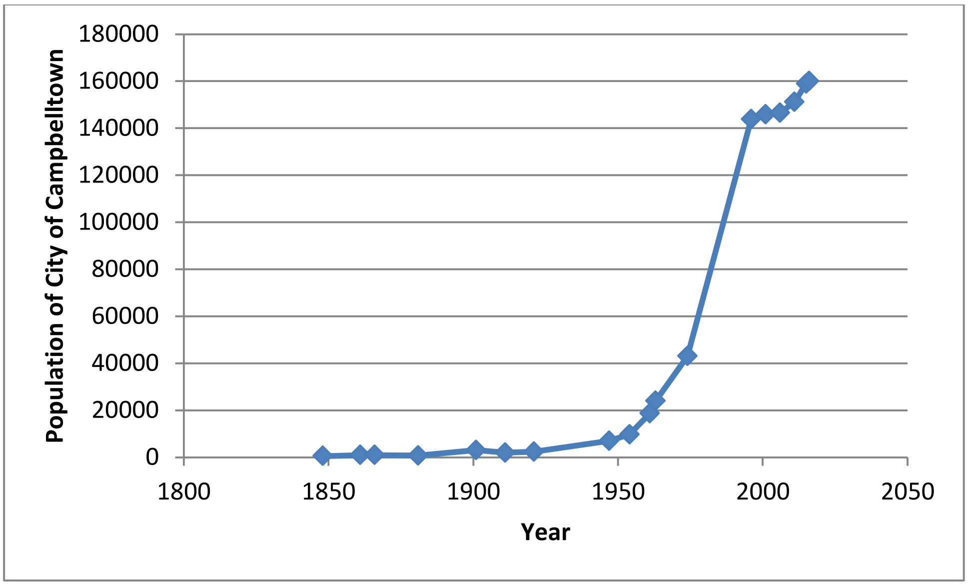

Figure 5. Population growth of Campbelltown, 1848-2016, assembled from data presented at https://www.campbelltown.nsw.gov.au/AboutCampbelltown/History/Campbelltowntimeline

Land use in the northern part of the Macarthur Growth Area is now dominated by residential housing, light industry and transport infrastructure, with only small pockets of pasture and urban bushland remaining intact, albeit weed-infested. In the southern half of the Macarthur Growth Area, south of the “waist” between Mt Annan and Glen Alpine, and in the Wilton Growth Area, land use is still largely rural, with the exception of limited residential and industrial development around Appin and Wilton. Agriculture has been largely restricted to soils derived from Wianamatta Shales and alluvium. Most areas of exposed Hawkesbury Sandstone either still support native vegetation or have been cleared for residential development.

3.2 HISTORY OF BOTANICAL EXPLORATION IN THE GROWTH AREAS

The first botanist to collect plant specimens in the same region as the growth areas was Joseph Banks’ employee, George Caley, who in 1802 made several expeditions from Prospect through the Cowpastures, reaching Mount Hunter, Menangle and Thirlmere Lakes (Webb 1995). Caley returned to the area in 1803, 1804 (during which he collected *Pterostylis saxicola* between Toongabbie and

South Creek), 1805 and 1807, once in the company of the great Scottish botanist Robert Brown. Caley mapped a section of Georges River near Ingleburn, following it to Appin, and explored the upper Nepean River system as far as Douglas Park and Appin Falls on the Cataract River (Webb 1995). On these trips, Caley and Brown made extensive botanical collections, from which Brown described numerous species that were new to science. The next botanical collector to visit the area was Franz Sieber, an Austrian who spent six months in the Sydney Region in 1823, during which time he collected specimens of 300 plant species (Ducker 1990), including many that are native to the study area. Botanical exploration of the area then became almost dormant until the late 19th century, when it intensified under the influence of J.H. Maiden, curator of the new Technological Museum, and later director of the Sydney Botanic Gardens. Botanists associated with Maiden, including R.T. Baker, J.L. Boorman, A.A. Hamilton, W.F. Blakely and E. Cheel made several thousand collections in the study area in the late 19th and early 20th centuries (National Herbarium of N.S.W. specimen database), long after much of the native vegetation on Wianamatta Shales and alluvia had been cleared for agriculture. Botanical exploration of the remnant vegetation of the study area has continued to the present day.

3.3 LANDSCAPE CONTEXT

The Greater Macarthur and Wilton Growth Areas are located on the southern to south eastern rim of the Cumberland Plain, the central part of the saucer-shaped sedimentary Sydney Basin. Here, the uppermost strata of the Sydney Basin, Cenozoic alluvia patchily overlie the Triassic Wianamatta Group rocks, mostly comprising Bringelly and Ashfield Shales, which, in turn overlie a thin layer of Mittagong Formation sandstone and shale and Triassic Hawkesbury Sandstone (Martyn 2018). Scattered small volcanic intrusions occasionally pierce the sedimentary strata, such as at Mt Annan, 0.7 km west of the “waist” in the middle of the Greater Macarthur Growth Area.

The most commonly exposed substrate in the northern part of the Greater Macarthur Growth Area is Ashfield Shale, over which patches of Bringelly Shale have been preserved on the western side, while Quaternary alluvia have accumulated in the valleys of Bow Bowing and Bunbury Curran Creeks (NSW Department of Minerals and Energy 1991, NSW Department of Mineral Resources 1985). Here, minor tributaries of the Georges River, such as Redfern, Smiths and McBarrons Creeks have exposed Hawkesbury Sandstone in narrow, shallow but steep-sided valleys.

In the southern half of the Greater Macarthur Growth Area, Bringelly Shale and Quaternary alluvium are restricted to the north west at Menangle Park. Further south, the Nepean and Georges Rivers and their tributaries have cut deep gorges through the Ashfield Shale, exposing large areas of Hawkesbury Sandstone on the steep valley sides and on the adjacent, flat to gently sloping valley borders. Large areas of transitional substrate exist here, where Ashfield Shale colluvium and soils derived from Mittagong Formation sandstones and shales thinly cover Hawkesbury Sandstone or mix with sandstone-derived soil. The landscape of the Wilton Growth Area resembles that of the southern half of the Greater Macarthur Growth Area but here the predominant substrate is Hawkesbury Sandstone over which an archipelago of thin islands of Ashfield Shale are preserved.

As the Greater Macarthur and Wilton Growth Areas are located on the southern to south eastern rim of the Cumberland Plain, they are gently tilted from south south west to north north east. However, topography also varies locally, with erosion having produced gently rolling landscapes over much of the area but steep-sided valleys contain the major water courses. The lowest point is in the far north east at Glenfield, where the banks of the Georges River are at 15 m altitude, but the land nearby rises to an altitude of 60 m at the junction of Campbelltown Road and Camden Valley Way. In the southern end of the Greater Macarthur Growth Area, just south east of Appin, the altitude reaches 260 m but drops to 230 m on the banks of the Georges River. The Wilton Growth Area varies in altitude from 105 m in the bottom of the Nepean Gorge to 310-320 m near its southern tip on the Picton Road.

Topographic variation as well as distance from the sea influences climate. The area just west of the Greater Macarthur Growth Area has the lowest average annual rainfall and the highest average January maximum temperature in the Sydney Region (Benson & Howell 1990). Both growth areas are subject to winter frosts.

3.4 NATIVE VEGETATION

In terms of the plant community types (PCTs) recognised in the Bionet Vegetation Classification and the vegetation maps that were prepared for this project, the remnant native vegetation of the growth areas consists of:

- 830 Forest Red Gum – Grey Box shrubby woodland on shale of the southern Cumberland Plain;
- 835 Forest Red Gum – Rough Barked Apple grassy woodland on alluvial flats of the Cumberland Plain;
- 849 Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain;
- 850 Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain;
- 883 Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain;
- 1081 Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain;
- 1181 Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney;
- 1292 Water Gum – Coachwood riparian scrub along sandstone streams;
- 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain.

Plant community types 830, 849 and 850 occur on Wianamatta Shales, PCT 835 on quaternary alluvium, PCTs 883, 1081 and 1395 on Hawkesbury Sandstone under a thin layer of Ashfield Shale or shale colluvium and PCTs 1181 and 1292 on Hawkesbury Sandstone.

In the course of this project, I visited 19 sites in the field, 18 of which were either in, or adjacent to, the Growth Areas, 16 of which I characterised in detail (Appendix 1).

In the northern half of the Greater Macarthur Growth Area, native vegetation is restricted to small, mostly long, narrow patches of urban bushland, most of which line water courses. A few of these are conserved as council reserves. I visited four bushland remnants either in, or close to the northern part of the Greater Macarthur Growth Area (sites N1, N7, N13, N14, Appendix 1), two of which I characterised in detail (N1, N7). I found all of these to include substantial weed infestation, especially close to water courses. Two species of privet, *Ligustrum sinense* and *L. lucidum*, were the most common woody weeds growing on sandstone, while African Olive (*Olea europea* subsp. *cuspidata*) was common on Wianamatta Shales. Common herbaceous weeds included naturalised grasses, Bridal Creeper (*Asparagus asparagoides*) and, near watercourses, Wandering Jew (*Tradescantia fluminensis*). Dumped household and garden rubbish was common near road access points in most patches of remnant bushland.

In the southern half of the Greater Macarthur Growth Area, and in the Wilton Growth Area, patches of remnant native vegetation become progressively more plentiful, on larger blocks of land, as one moves south but they are still mostly associated with water courses. According to the vegetation maps that were prepared for this project, by far the most abundant plant community type here is PCT 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain. This community type occurs on flat to gently sloping land, close to the interface between Ashfield Shale and Hawkesbury Sandstone, often adjacent to steep-sided sandstone gorges. Exposed sandstone surfaces are plentiful, with clayey to loamy soils derived from Ashfield Shale or shale colluvia occurring between rock outcrops and thin layers of humus rich sandy soil accumulating on flat sandstone surfaces, often colonised by mosses and lichens(e.g. site N9, figure 6).

Figure 6. Plant community type 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain, on Ashfield shale colluvium over Hawkesbury Sandstone at Shingle Hill, Wilton (site N9, Appendix 1).

At one such site I found pre-flowering *Pterostylis* rosettes that closely resembled those of *P. saxicola* growing in a thin layer of dark brown sand on a sandstone shelf (figures 6 and 7).

Figure 7. Pre-flowering *Pterostylis* rosettes growing in PCT 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain at Shingle Hill, Wilton (site N3, Appendix 1).

Although almost all of PCT 1395 is coded as “intact” in the vegetation maps, I found the condition of these remnants variable, depending on the extent of grazing by stock to which they had been subjected. At one of my sites (site N3, Appendix 1), a shrub stratum was completely absent and all herbaceous plants had been grazed close to the ground (figure 8).

The sides of the gorges of the Nepean and Georges Rivers and their major tributaries are typically covered by PCT 1181 Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney (e.g. site N11, figure 9). In some places this forms a mosaic with PCT 1081 Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain.

3.5 POTENTIAL HABITAT

The new, improved habitat model that I have developed for *Pterostylis saxicola* includes the following habitats that have been mapped in the study area:

- Clay soils derived from Ashfield Shale (Wianamatta Group) on flat to gently hilly landscapes in PCT 849 Grey Box – Forest Red Gum grassy woodland on Flats of the Cumberland Plain.

- Clay to sandy soils derived from Hawkesbury Sandstone – Mittagong Formation – Ashfield Shale transition substrates on gently hilly landscapes, in PCT 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest on the edges of the Cumberland Plain.
- Thin accumulations of humus-rich sandy soil on Hawkesbury Sandstone sheets and rock shelves, on the rims and steep sides of river valleys, growing in PCT 1081 Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain, PCT 1083 Red Bloodwood - scribbly gum heathy woodland on sandstone plateaux, and PCT 1181 Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney.

Figure 8. Heavily grazed understory vegetation in PCT 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain at Allen Creek, Wilton (site N3, Appendix 1).

4. Assessment of species presence and suitable habitat

4.1 SPECIES RECORDS AND HABITAT ASSESSMENTS

Pterostylis saxicola has only been recorded once in the study area, at Minto, in 1947. The precision of this record is questionable because collectors at that time usually specified their collecting locations no more precisely than as the nearest named place. “Minto” could have meant “East Minto”, which, after 1973 became known as Minto Heights, most of which is outside the study area.

Figure 9. PCT 1181 Smooth-barked Apple – Red Bloodwood – Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, east of Appin (site N12, Appendix 1).

However, *Pterostylis saxicola* has been collected or observed at several sites within 1 km of the eastern side of the Greater Macarthur Growth Area and at one site between the growth areas, within 1 km of the north eastern corner of the Wilton Growth Area and within 2 km of the south western corner of the Greater Macarthur Growth Area. No formal habitat assessment has ever been conducted in the study area.

4.2 PRIOR SPECIES SURVEYS

No formal, targeted surveys had been conducted for *Pterostylis saxicola* specifically in the study area prior to the start of this project, although Teresa James surveyed known sites of occurrence in 2007. Floristic surveys were undertaken in the study area from November 2017 to May 2018, starting at the tail end of the flowering period of *P. saxicola,* proceeding through its dormancy period, during which it persists as a subterranean tuber, to the time when plants would probably have been visible as newly emerged, pre-flowering rosettes. Only in the first two to four weeks of the survey period would plants of *P. saxicola* have been morphologically identifiable, so survey effort for this species in this project has been negligible.

4.3 ASSESSMENT OF SPECIES PRESENCE

Pterostylis saxicola is highly likely to be growing, unrecorded, in both the Greater Macarthur Growth Area and the Wilton Growth Area.

4.4 JUSTIFICATION FOR DETERMINATION

Evidence and arguments against the hypothesis that *Pterostylis saxicola* is, or once was native to the study area

Pterostylis saxicola has been recorded only once, dubiously, in the study area despite a 210 year history of botanical exploration there. This species, like most orchids, is highly reliant on associated, highly specialised symbionts for germination and pollination, so even if all other habitat variables were suitable for its growth and reproduction in the study area, it could not reproduce sustainably there if either of those symbionts were absent. Perhaps *P. saxicola* has only been recorded once in the study area because one or both of its obligate symbionts is absent there.

Evidence and arguments for the hypothesis that *Pterostylis saxicola* is native to the study area

Pterostylis saxicola has been recorded outside the study area in four plant community types (PCTs 849, 1081, 1181 and 1395) that occur in the study area, some abundantly. At each of those recorded sites the substrates mapped there by geologists (Ashfield Shale, Mittagong Formation shales and sandstones, Hawkesbury Sandstone and transitions between them) are substrates that occur in the study area. Indeed, Ashfield Shale and Hawkesbury Sandstone are the two most abundant substrates there. The whole of the study area also seems to be climatically suitable for *P. saxicola*. Its highest point, less than 320 metres in altitude, at the southern tip of the Wilton Growth Area, is comfortably within the species' altitudinal range of 30-400 metres. One has to conclude that extensive suitable habitat for *P. saxicola* occurs in the study area.

It is reasonable, however, to ask why the species has not been collected more often there. To address this question, a histogram of records over time is instructive (see figure 10, below).

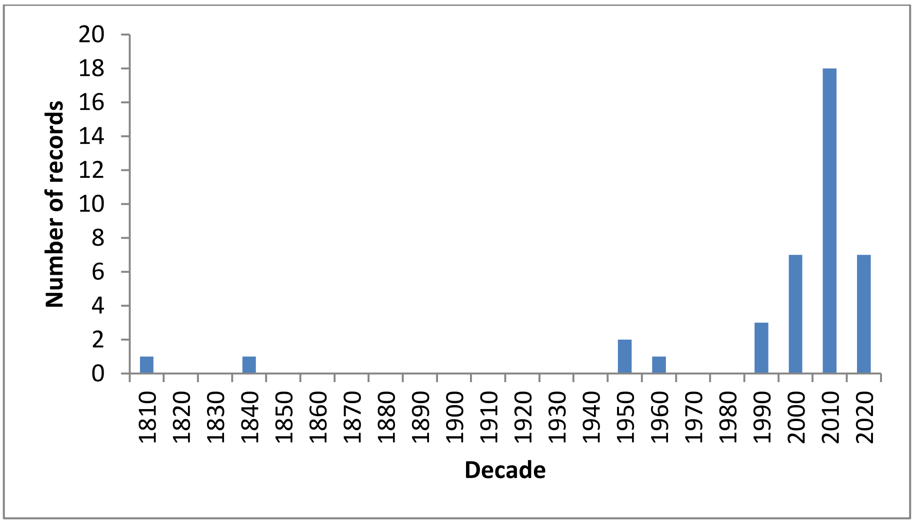

Figure 10. Histogram of the number of observational records and collections of *Pterostylis saxicola* per decade since 1800.

From 1804 to 1989, *Pterostylis saxicola* was recorded only six times. In 1997 it was recognised as specifically distinct, named and described. Botanists, conservation biologists, ecologists and orchid enthusiasts suddenly became interested in it. The collection of specimens and observations accelerated, encouraged by funding for rare plant surveys and an *ex-situ* conservation project. Most of this activity was concentrated on publicly accessible land, which accounted for 19 of the 26 records made since 1997, 18 of which were additional records from previously recorded sites. Most exploratory effort expended on *P. saxicola* was being put into detailed surveys of known populations. New populations were still being discovered as incidental benefits of other botanical work, not as the result of targeted searches in previously unexplored areas. The dearth of new records from the southern part of the study area was probably due to a lack of searches there. Absence of evidence is not necessarily evidence of absence.

Targeted exploration of new territory for previously unknown populations of *Pterostylis saxicola* would, in any case be a potentially frustrating task. This orchid is sporadically distributed, not continuously spread through its habitat. It is also difficult to find, even at locations at which it is relatively common: the plants are small, cryptically coloured, and only recognisable for a period of six weeks or less while flowering. Moreover, most of the potential habitat in the study area is on private land, much of which is inaccessible because the landowners have not given permission for biodiversity surveyors to work on their land.

4.5 LIKELIHOOD OF SPECIES PRESENCE

Figures 10 and 11 show frequency histograms of populations of *Pterostylis saxicola* from the Bionet Wildlife Atlas and state herbarium's specimen database, categorised in latitudinal and longitudinal samples 0.05 degrees wide. Populations are here defined as records, or clusters of records separated by at least 1 km. These diagrams display two perspectives of the spatial relationship between the study area and distribution and abundance of known populations of *P. saxicola*. The bimodal clustering of populations into northern and southern sub-populations is clear in the latitudinal

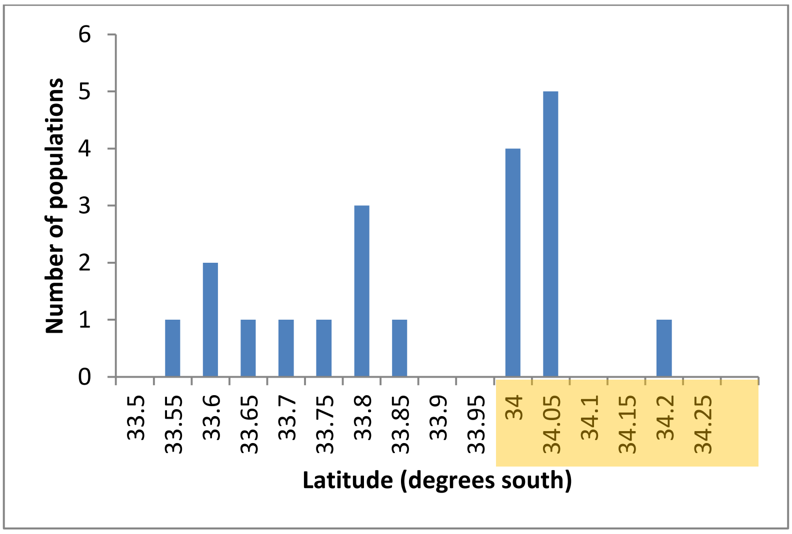

Figure 11. Frequency histogram of populations of *Pterostylis saxicola* from the Bionet Wildlife Atlas and state herbarium specimen database, classified according to latitude. The orange rectangle indicates the latitudinal extent of the study area.

distribution. The longitudinal distribution of records more closely approximates the typical Gaussian curve of many species distributions (Brown 1984). The study area is nested within the longitudinal distribution of the species and extensively overlaps the latitudinal one, despite the existence of only one dubious record from there.

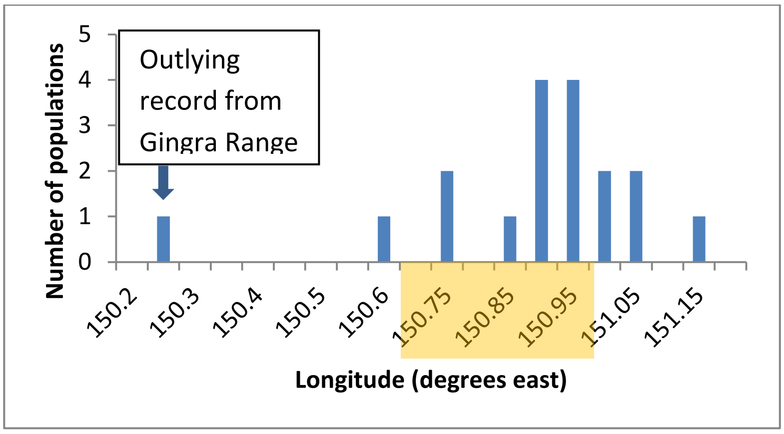

Figure 12. Frequency histogram of populations of *Pterostylis saxicola* from the Bionet Wildlife Atlas and state herbarium specimen database, classified according to longitude. The orange rectangle indicates the longitudinal extent of the study area.

If we accept the simplifying assumption that population frequencies are unbiased, then these frequency distributions can be interpreted as probability distributions, suggesting that *Pterostylis saxicola* is highly likely to be native to the study area.

4.6 ASSESSMENT OF SUITABLE HABITAT

Pterostylis saxicola has been recorded from outside the study area in four plant community types (PCTs 849, 1081, 1181 and 1395) that also occur in the study area (see sections 2.4, 3.3, 3.4, 4.4 above). These communities in the study area occur on suitable substrates (Hawkesbury Sandstone, Mittagong Formation, Ashfield Shale – see sections 3.3, 3.4), so the full extent of these plant community types should be regarded as potential ly suitable habitat for *P. saxicola* there.

Four classes of vegetation condition, were mapped for this project: “intact”, “thinned”, “scattered trees”, and “native grassland”. Having seen sites in the study area representing all of these categories I would describe them as follows:

- Intact: native vegetation structure, composition and regenerative capacity remain intact, sometimes with disturbance or thinning of the understorey and usually with weed incursion in the northern part of Greater Macarthur Growth Area;
- Thinned: the structure of native vegetation has been altered, with the canopy reduced in density and the understorey dominated by herbaceous plants;
- Scattered trees: Most canopy trees and most or all shrubs have been removed so that the structure, composition and regenerative capacity of the native vegetation have been significantly altered by land use;

- Native grassland: native vegetation has been altered so profoundly that only native grasses remain, usually intermixed with exotic species.

Although some of the patches of bushland in which *P. saxicola* has been recorded are smaller than one hectare, all but one record were reported in intact vegetation. The one exception is an extraordinary, unvouchered record of this species at the "Car Park growing through bitumen Simmos Beach Reserve, Macquarie Fields". A bitumen carpark is not a sustainable habitat for any native ground orchid but in this case a flat bitumen surface covered in a thin layer of soil might have functionally approximated a sandstone surface covered in a thin layer of humic sand for long enough for a seed to germinate, reach reproductive maturity and flower. Some species of terrestrial orchids, most notably some species of *Microtis*, can reasonably be described as weedy, readily colonising some anthropogenic habitats, but I would not include any species of *Pterostylis* in that category. I have seen some of the vegetatively multiplying species, such as *P. curta* and *P. nutans*, persisting at the margins of mown lawns but I have never seen any species of *Pterostylis* subgenus *Oligochaetochilus* growing in highly disturbed environments. *P. saxicola* has not been recorded from pastures that are largely or totally devoid of trees and shrubs, so vegetation classed as "scattered trees" and "native grassland" can be rejected as suitable habitat.

The modified eucalypt-dominated communities classed as "thinned" are the only disturbed environments that could arguably be classed as marginally suitable habitats for *Pterostylis saxicola*. An argument justifying the inclusion of thinned vegetation in an estimate of potentially suitable habitat is that such modified vegetation is capable of regenerating to the equivalent of intact condition, if the processes that caused its degradation cease to operate. Those processes include the selective culling of native plants. If thinned vegetation is managed so that regrowth of native plants is not suppressed and introduced weeds are actively removed, then suitable habitat for *P. saxicola* could be re-created from thinned vegetation. A good example of an area that has such a history and now provides suitable habitat for *P. saxicola* is Scheyville National Park, which was used for grazing and farming from the early 19th century to 1940, after which it was used as a military training base and later for a large migrants' hostel (NSW National Parks and Wildlife Service 2000). After 1972 the vegetation there was fortuitously allowed to regenerate spontaneously and much of it now has the character of residual, intact native vegetation and hosts arguably the most significant population of *P. saxicola* in the northern Cumberland Plain. If patches of thinned land that had previously supported PCTs 849, 1081, 1181 and 1395) in the study area were appropriately managed, then a similar outcome is likely to prevail there too.

However, eucalypt forests and woodlands have often been thinned in the study area to facilitate grazing by non-native herbivores: cattle, sheep and horses (see section 3.1). Grazing by stock is one of the threats listed in the threatened species profile of *P. saxicola* (NOEH 2018), because most terrestrial orchids, including *Pterostylis* are highly palatable. Duncan *et al.* (2005), in discussing threats to threatened terrestrial orchid species in Victoria, considered grazing of terrestrial orchids by introduced mammal species to be potentially “devastating”. Clearly, intact vegetation usually provides a much more suitable habitat for *P. saxicola* than similar but thinned vegetation. At issue is whether thinned, continually grazed vegetation provides any suitable habitat for the sustained existence of *P. saxicola* at all. Given that *P. saxicola* has not been reported from thinned vegetation (as distinct from highly fragmented remnants of intact vegetation), and that regeneration of thinned vegetation to intact condition would require active management if the land were embedded within a suburban context, I conclude that thinned vegetation does not presently constitute suitable habitat for the sustained existence of *P. saxicola*. It could, however, be regenerated to provide suitable habitat under sustained appropriate land management. Consequently, I have treated only intact patches of PCTs 849, 1081, 1181 and 1395 as suitable habitat for *P. saxicola*.

4.7 SPECIES POLYGONS

My species polygons for *Pterostylis saxicola* (figures 13 and 14) include all intact patches of PCTs 849, 1081, 1181 and 1395 in the Greater Macarthur and Wilton Growth Areas. They were prepared with the assistance of Darren James (DAJ Environmental), using the ArcMap software package, from vegetation maps of the study area produced by Biosis Pty Ltd. A shape file for these polygons is held by the Biodiversity and Sustainability Branch of the NSW Department of Planning and Environment.

My arguments justifying these polygons have been set out in sections 2.3, 2.4, 4.4, 4.5 and 4.6.

4.8 ESTIMATE OF AREA OF HABITAT

The areas estimated to represent suitable habitat for *Pterostylis saxicola* in figures 13 to 15 are as follows:

- Greater Macarthur Growth Area
    - Habitat mapped – 1,784.36 ha
    - Habitat impacted by development footprint – 46.51 ha
- Wilton Growth Area
    - Habitat mapped – 962.15 ha
    - Habitat impacted by development footprint – 38.92 ha

These estimates were calculated with the assistance of Darren James (DAJ Environmental), using the ArcMap software package, from vegetation maps of the study area produced by Biosis Pty Ltd. My arguments justifying the polygons from which these estimates were calculated have been set out in sections 2.3, 2.4, 4.4, 4.5 and 4.6.

5. Information used in the assessment

My assessment was based on information obtained from a diversity of sources:

- Databases of observational and vouchered specimen records of *Pterostylis saxicola*:
    - National Herbarium of New South Wales specimen database;
    - Bionet Wildlfie Atlas;

- Interviews with collectors, observers, propagators and scientists of *P. saxicola* (see section 6, acknowledgements);
- Fieldwork at 19 sites (see Appendix 1):
    - Five sites at which *P. saxicola* had previously been collected;
    - 14 sites in or near the study area that had potentially suitable habitat;
- The scientific and scholarly literature (see section 7, references);
- Vegetation maps for the study area prepared by Biosis Pty Ltd, provided by the Biodiversity and Sustainability Branch of the NSW Department of Planning and Environment;
- My personal knowledge and experience, gained from 47 years as a native orchid enthusiast and 40 years as a professional botanist.

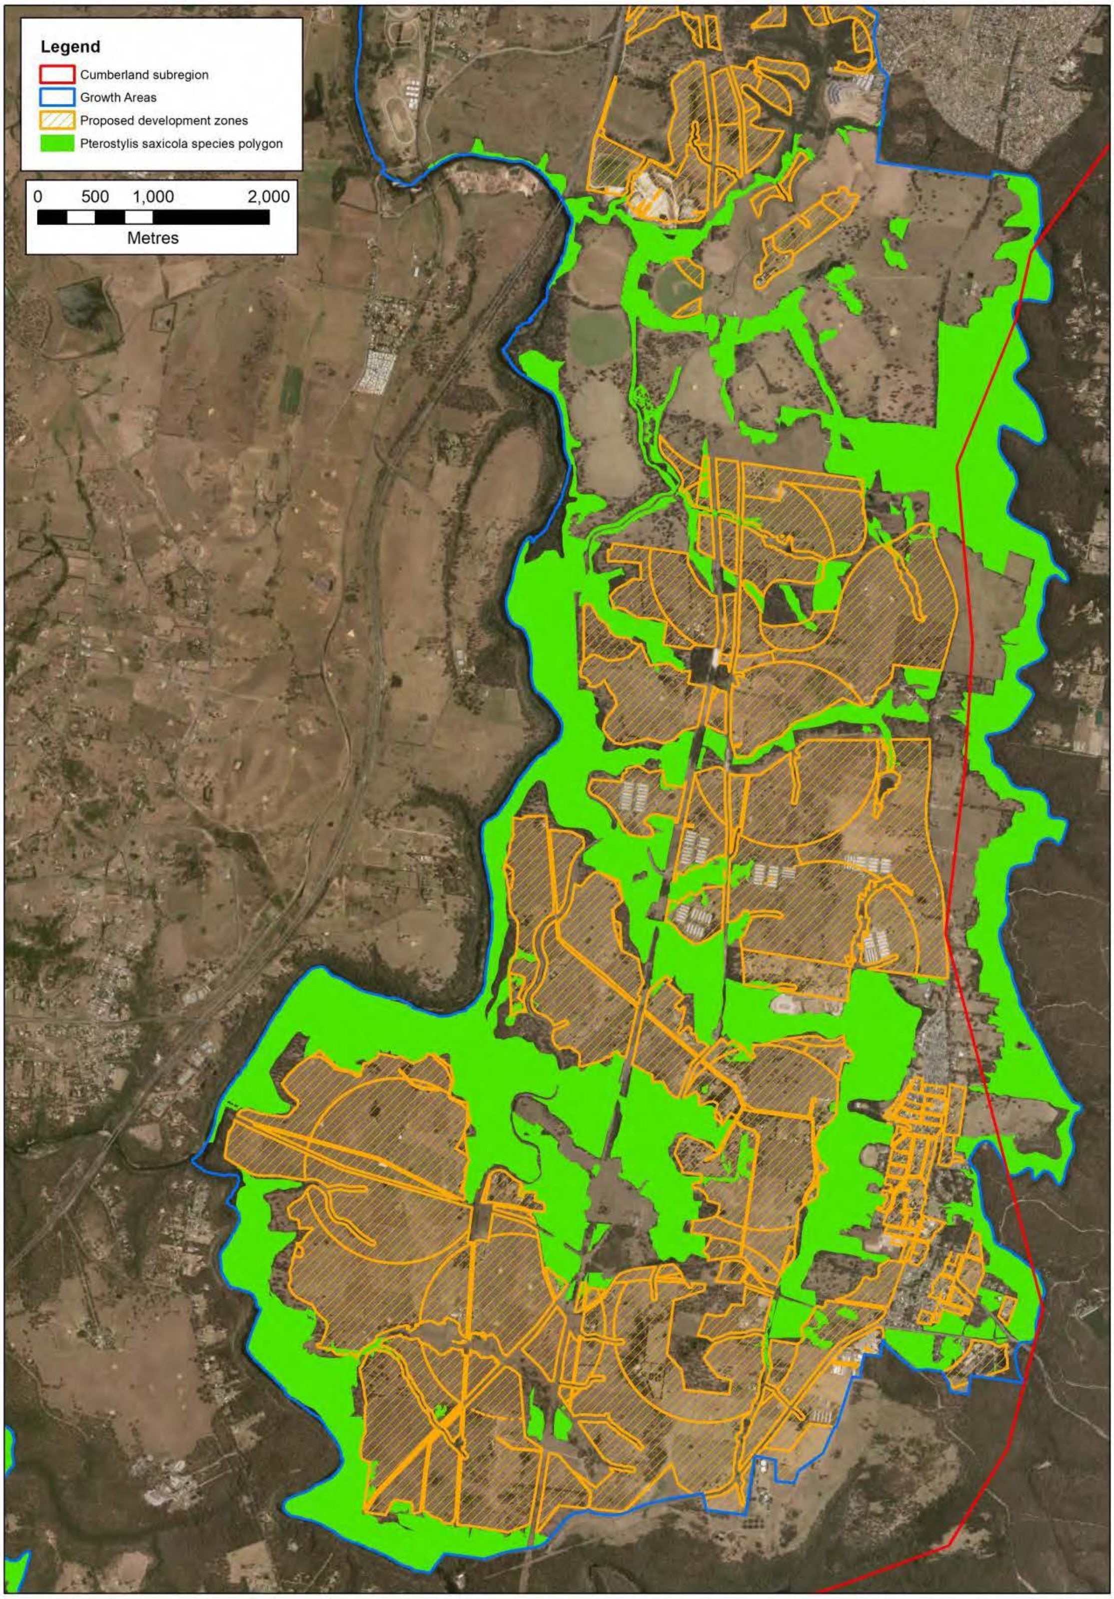

Figure 14. Species polygons for *Pterostylis saxicola* (green colouring) in the southern part of the Greater Macarthur Growth Area (outline in blue). The urban development footprint is marked with yellow cross-hatching.

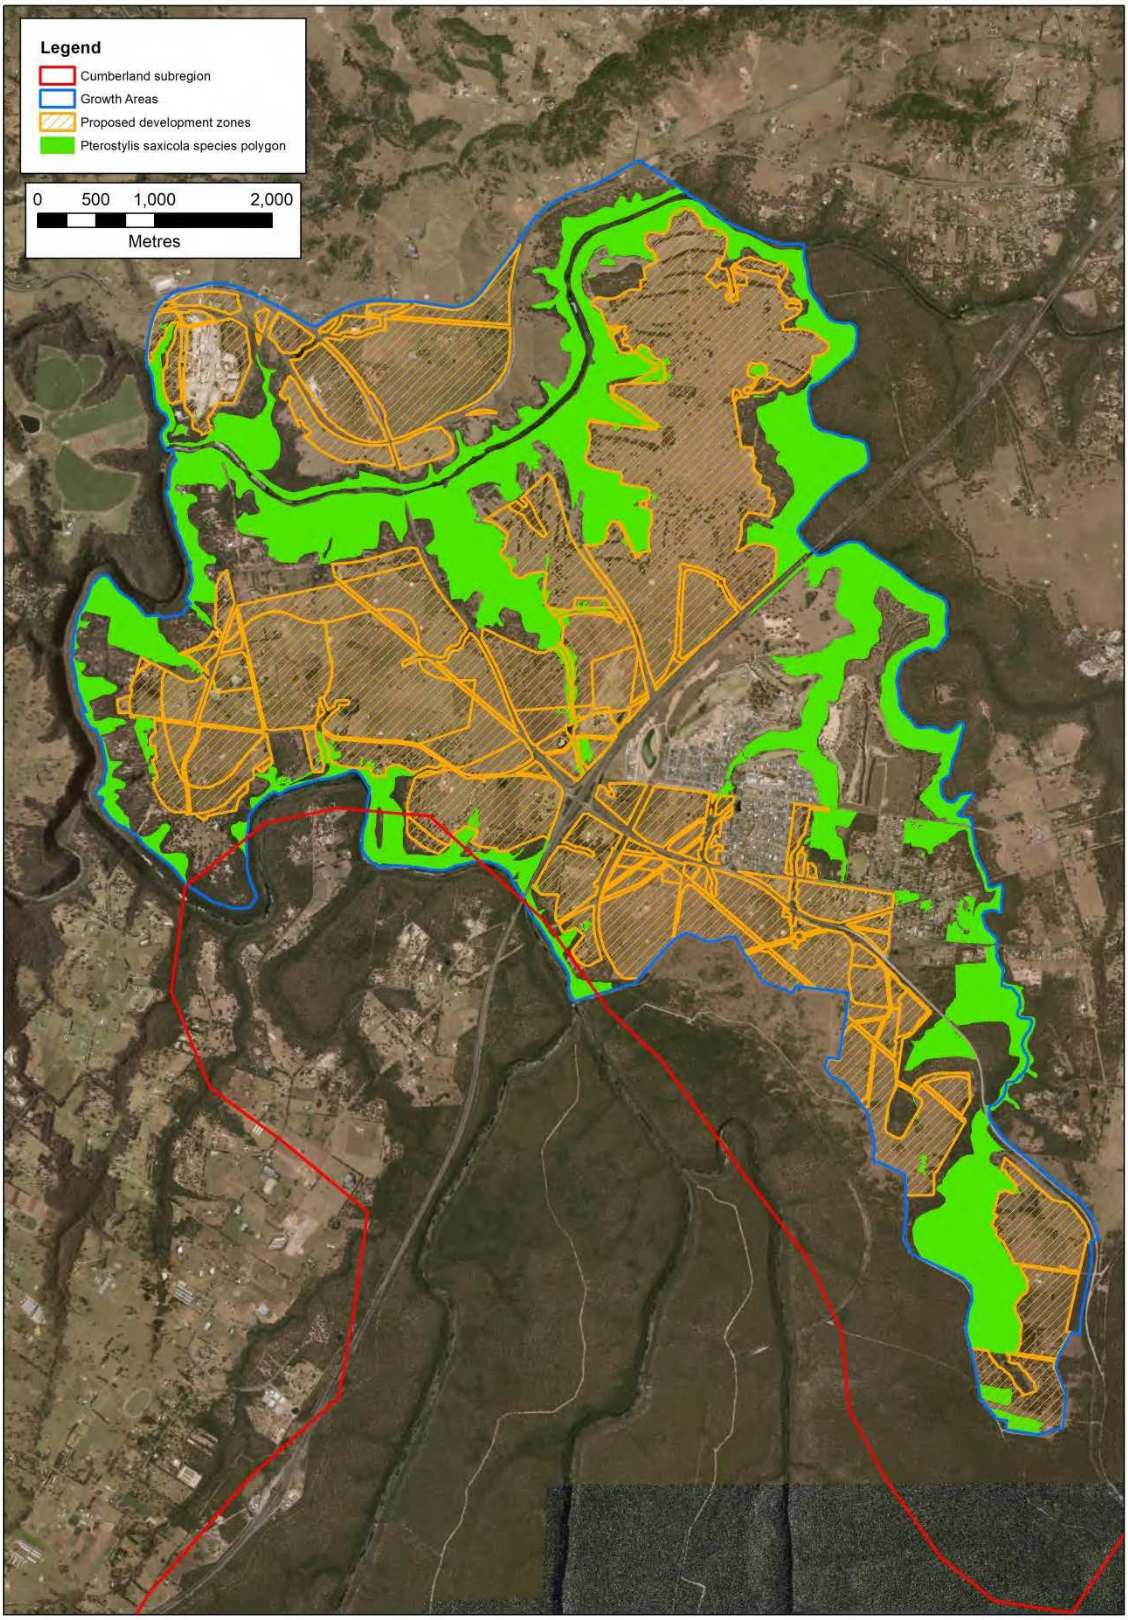

Figure 15. Species polygons for *Pterostylis saxicola* (green colouring) in the Wilton Growth Area (outline in blue). The urban development footprint is marked with yellow cross-hatching.

6. Acknowledgements

I am grateful to Andrew Orme, Teresa James, Karen Sommerville, Greg Steenbeeke, Wayne Cherry and David Keith, for happily being interviewed, and for generously sharing their knowledge about populations of *Pterostylis saxicola*. Wayne Cherry gave me permission to use his photograph of a flower of *Pterostylis saxicola* on the title page of this report. Darren James (DAJ Environmental), kindly assisted me in producing species polygons and area estimates using the ArcMap software package.

8. Appendices

APPENDIX 1: Characterisation of habitat at selected sites

The tables on following pages record data that I collected at sites both within and outside the study area. Two of these sites (N13, N14) received "over the fence" assessments and were not characterised in detail. Each site that was characterised in detail was centred either on an arbitrarily selected plant of *Pterostylis saxicola* (sites numbered PS1, PS3) or at places where the focal species had previously been reported (sites PS2, PS4, PS5) or at an arbitrarily point in the case of sites examined as potential habitat in or near the growth areas (sites N1–N14). At each site the precise latitude and longitude, altitude, substrate, soil description, slope and aspect were also recorded. Also, at each site all woody plant species and a few species of herbaceous plants that could be reliably identified from vegetative characters were recorded within a radius of 30 metres. Attributes of sites at which *P. saxicola* had been found (sites PS1–PS5) were compared with comparable attributes of sites in or near the growth areas to assess whether any sites in the growth areas closely matched *P. saxicola* sites. Locations at which *Pterostylis saxicola* has been recorded by me and/or others have had their latitudes and longitudes transformed to the nearest 10 minutes.

Site	Location	Latitude	Longitude	Altitude	substrate
PS1	Old Schofield Trail, Scheyville National Park	33°40'S	150°50'E	70 m	Ashfield Shale
PS2	Simmos Beach Recreation Reserve, Macquarie Fields	34°00'S	150°50'E	45 m	Hawkesbury Sandstone
PS3	Simmos Beach Recreation Reserve, Macquarie Fields	34°00'S	150°50'E	43 m	Hawkesbury Sandstone
PS4	Boronia Rd Reserve, Peter Meadows Creek, Kentlyn	34°00'S	150°50'E	98 m	Hawkesbury Sandstone

APPENDIX 2: PETER WESTON'S CURRICULUM VITAE

Personal details

Name: Peter Henry Weston.

Address: 18 Lyle Avenue, Lindfield, New South Wales 2070, Australia.

Date and place of birth: 22 October 1956, Lower Hutt, New Zealand.

Nationality: Australian.

Academic Qualifications

i) **B.Sc.** (first class honours; equal first in order of merit) School of Biological Sciences, University of Sydney; 1975-78, conferred 7 April 1979.
Thesis title: "The evolution and classification of *Boronia* Sm."

ii) **Ph.D.**, School of Biological Sciences, University of Sydney, 1979-83; conferred 18 May 1985.
Thesis title: "Systematics and biogeography of the Persooniinae (Proteaceae)".

Awards, Fellowships and Scholarships

2014	Nancy Burbidge Medal (awarded by the Australasian Systematic Botany Society to a person who has made a longstanding and significant contribution to Australasian systematic botany. It is the foremost award that can be conferred by ASBS).
2014	Australian Biological Resources Study-sponsored Winston Churchill Fellowship for an established career researcher in taxonomy.
2009	Grady L. Webster Structural Botany Publication Award for 2008 and 2009 from the Botanical Society of America. The BSA component of the award (it is awarded in alternate years by the BSA and the American Society of Plant Taxonomists) recognizes the most outstanding paper published in the *American Journal of Botany* in the field of structural and developmental botany (i.e., anatomy and morphology) over a two-year period. It was awarded to Gregory J. Jordan, Peter H. Weston, Raymond J. Carpenter, Rebecca A. Dillon and Timothy J. Brodribb for: "The evolutionary relations of sunken, covered, and encrypted stomata to dry habitats in Proteaceae," American Journal of Botany, Volume 95, Issue 5; May 2008.
2006	Carrick Award for Australian University Teaching from the Australian Learning and Teaching Council (one of five members of a teaching team from the University of New England cited for Outstanding Contributions to Student Learning).
1992-93	Posting to Royal Botanic Gardens, Kew, as Australian Botanical Liaison Officer.

1982	Charles Gilbert Heydon Travelling Fellowship for the biological sciences (not taken up).
1980-82	University of Sydney Postgraduate Scholarship.
1979-82	Commonwealth Postgraduate Award.
1977	G.S. Caird Scholarship for Third Year Botany, University of Sydney.
1976	Slade Prize for Practical Plant Biology, University of Sydney.

Employment

Present Position: Honorary Research Associate, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney and independent botanical consultant.

Previous positions held:
2008-2016 Senior Principal Research Scientist, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

2000-2008 Principal Research Scientist, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

1994-2000 Senior Research Scientist, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

1989-1994 Research Scientist, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

1982-1989 Scientific Officer, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

1979-82 Part-time demonstrator, School of Biological Sciences, University of Sydney.

Adjunct and visiting university appointments

2013-	Adjunct Associate Professor, La Trobe University.
2011-	Adjunct Associate Professor, University of New South Wales.
2006	Visiting Lecturer, Rhodes University, Grahamstown, South Africa.
2004-2009	Adjunct Associate Professor, University of New England.
2000-2004	Adjunct Senior Lecturer, University of New England.

Administrative/management experience

2009	Acting Manager Plant Diversity
2002-2003	Member, Plant Diversity Research Program Leaders Committee
1998-99	Systematics Liaison Officer
1997-98	Member RBGS Market testing working party

1997 Member, RBGS advisory committee for restructuring senior management

1990-91 Systematics Co-ordinator

1996-98 Member, RBGS Joint Consultative Committee

Membership of Learned Societies

1996- Society of Australian Systematic Biologists

1984- Willi Hennig Society (Elected Fellow, 1992-, Council member, 1998-2000)

1979- Society of Systematic Biologists (member, Editorial Board 1993-95)

1978- Australasian Systematic Botany Society (formerly Australian Systematic Botany Society: President, 2009-2012, Vice President, 2008-2009, Chairman, Hansjörg Eichler Research Fund Committee, 1998-2002, Council member, 1996-2002)

Membership of External Committees

2015- Financial Grants Standing Committee (formerly the Grants Policy Standing Committee) of the Australasian Systematic Botany Society

2012-2013 Conference Organising Committee of *Systematics Without Borders*, a joint conference of the Australasian Systematic Botany Society, Society of Australian Systematic Biologists and Invertebrate Biodiversity and Conservation, University of Sydney (Chairman)

2011- Editorial Board, *Phytotaxa*

2008-2009 Corresponding Member, Editorial Advisory Committee, *Australian Systematic Botany*

2006-2014 Ira Butler Memorial Trophy Committee (a joint committee of the Australasian Native Orchid Society and the Orchid Society of New South Wales) (Chairman)

2004- Editorial Advisory Board, *Kew Bulletin*

2001-2006 Panel of Judges, Eureka Prize for Biodiversity Research

2000-2012 Bushland Management Advisory Committee, Lane Cove Council (Chairman, 2008-2010)

1999-2004 Editorial Advisory Committee, *Australian Systematic Botany*

Spoken presentations at conferences (not including presentations delivered by others)

2015 Building Our Botanical Capital, annual conference of the Australasian Systematic Botany Society: “A database of variation in floral characters in the Proteaceae, and implications for key questions in floral evolution”.

2014 Next Generation Systematics, annual conference of the Australasian Systematic Botany Society: Nancy Burbidge Memorial Lecture: “Problems and progress in plant systematics since Nancy Burbidge”

2013 Genetics Society of Australasia conference, Sydney *Genetics in the Harbour City*: “Molecular phylogeny of the subtribe

Hakeinae (Green Plants: Proteaceae tribe Embothrieae) and its implications”.

2013 Joint conference of the Australasian Systematic Botany Society, Society of Australian Systematic Biologists and Invertebrate Biodiversity and Conservation, Sydney, *Systematics Without Borders*: “Molecular phylogeny of the subtribe Hakeinae (Green Plants: Proteaceae tribe Embothrieae) and its implications”.

2012 Australasian Systematic Botany Society conference, Perth, *Local knowledge, global delivery*: “Contested, Uncontested and Potentially Controversial Taxonomic Changes in the Proteaceae: How Do They Differ?”

2011 37th annual conference of the South African Association of Botanists, *Plants in a Changing World* and 9th conference of the South African Society of Systematic Biologists, *Biodiversity Matters*; plenary address: “Cenozoic environmental change and the systematics of southern hemisphere plants”

2011 XVIII International Botanical Congress, Melbourne: “Floral evolution in animal-pollinated Australian angiosperm clades: patterns and potential explanations”.

2010 VI Southern Connection Congress, Bariloche: “Cladistic biogeography, molecular dating, fossils and the Proteaceae”

2010 VI Southern Connection Congress, Bariloche: “Diversification of the Proteaceae in Mediterranean hotspots of the Southern Hemisphere and in tropical rainforests”

2010 Australian Systematic Botany Society conference *Systematic Botany Across the Ditch: Links Between Australia and New Zealand*; Keynote address: “Cenozoic environmental change and the systematics of southern hemisphere plants”

1999 XVI International Botanical Congress, Saint Louis: “Historical biogeography of Proteaceae”.

1997 II Southern Connection Congress, Valdivia: “Cladistic biogeography of a key woody group: Proteaceae”.

1997 First Biennial International Conference of the Systematic Association, Oxford: “Rolf Sattler’s Plant Morphology and Cladistic Analysis”.

1996 *An International Symposium on the Biology of Proteaceae*, Melbourne: “ITS squence variation in the Proteaceae and what it tells us about phylogeny”.

1993 Joint conference of The Systematics Associations and The Linnean Society on *Models in Phylogeny Reconstruction*, London: “Direct methods for polarising character transformation series”.

1990 IXth meeting of the Willi Hennig Society, Canberra: “Transoceanic cladistic patterns in the Proteaceae”.

2003 The Third International Conference on *the Comparative Biology of the Monocotyledons*, Ontario: “Co-evolution of *Chiloglottis* (Orchidaceae) and its Thynnine wasp pollinators”.

2005 XVII International Botanical Congress, Vienna: “Food is good but sex is better: the evolution of deceptive pollination in the tribe Diurideae (Orchidaceae)”.
2006 Australian Systematic Botany Society conference, Cairns, *Plant Diversity in the Tropics*: “A new suprageneric classification of the Proteaceae”.
2007 5th Southern Connection Congress, Adelaide: “‘I’m not dead yet’ – Gondwana (the Proteaceae are at least partially congruent with Gondwanic fragmentation)”.
1989 Australian Systematic Botany Society symposium, on *Gondwanan Elements in the Australian Flora*, Sydney: “Transpacific cladistic patterns in the Proteaceae and Elaeocarpaceae”.
1988 Symposium on *Panbiogeography of New Zealand*, Wellington: “Problems with the statistical testing of panbiogeographic hypotheses”.
1985 Australian Flora Foundation Symposium on *Waratahs*, Canberra: “Drifting waratahs or continents?”
1984 Australian Systematic Botany Society symposium on *Cladistics, Systematics and Phylogeny*, Canberra: “A reappraisal of Nelson's direct method of character analysis”.

Refereeing manuscripts, grant applications, reports and examining postgraduate theses (last five years)

2016: *Australian Systematic Botany*; *Botanical Journal of the Linnean Society*, *National Research Foundation* (South Africa).
2015: *American Journal of Botany*; Australian Research Council (4); *Australian Systematic Botany*; *Muelleria*; *Nuytsia*; *Phytotaxa*; *PLOS One*; *Telopea* (6).
2014: Australian Research Council (3); *Australian Systematic Botany* (2); *Cunninghamia*; *Journal of Biogeography* (2); *Muelleria*; National Research Foundation (South Africa); *Orchadian*; *Perspectives in Plant Ecology, Evolution and Systematics*; *Plant Systematics and Evolution*; *Telopea* (3).
2013: Australian Research Council; *Australian Systematic Botany*; *Biology Letters*; *Cladistics*; *Diversity and Distributions*; *Evolution*; *Journal of Biogeography*; *New Zealand Journal of Botany*; *Taxon*; *Telopea*.
2012: Australian Research Council (3); *Australian Systematic Botany*; “Darwin, Then and Now” (chapter of book published by University of Chicago Press); *Diversity and Distributions*; *Journal of Biogeography*; National Research Foundation (South Africa); *Phytokeys*.

Research

My research has been in the theoretical and practical aspects of systematic botany, with emphasis on the theory and practice of phylogenetic analysis, and the broader uses to which phylogenetic knowledge may be applied. I have phylogenetically analysed groups in the plant families Proteaceae, Fabaceae, Orchidaceae, Rutaceae, Winteraceae and Lauraceae, contributed to more general analyses of angiosperm phylogeny, and used the results of these analyses to improve biological classification and to test theories of historical biogeography, trait evolution, co-evolution and adaptation. I have earned an international reputation for my contributions to both theoretical and empirical developments in this field.

Herbarium curation and collections

My curatorial responsibilities at the National Herbarium of New South Wales have included the families Rutaceae (1982-1998), Proteaceae (1982-2016), Orchidaceae (1986-2016) and Fabaceae subfamily Faboideae (1986-2016). I have collected plant specimens (mostly angiosperms) in Australia, England, New Zealand, New Caledonia, Chile, South Africa, and Argentina, mostly for the herbarium and living collections of the Royal Botanic Gardens and Domain Trust, Sydney. Duplicates of my collections have been distributed to over 20 herbaria in 8 different countries.

Teaching

I have been actively involved in the preparation and teaching of four third year undergraduate courses in biosystematics:
Western Sydney University (2015-2017): “Principles of Evolution” (unit 300980), “Botany” (unit 300836).
University of New South Wales (2010-2016): “Assembling the Tree of Life” (BIOS3221)
University of New England (2000-2010): Biosystematics (Biosyst 301, Biosyst 302, Evol 301/501).
Botany Department, Rhodes University, Grahamstown, South Africa (February-March 2006): “Plant Biodiversity” course in collaboration with Associate Professor Nigel Barker.

I am currently co-supervising one postgraduate student:
Nanette Thomas (Ph.D., University of New England): Systematics of *Tasmannia* informs Biogeography of Winteraceae.

Postgraduate and honours students I have previously co-supervised include:
Margaret Stimpson (Ph.D., University of New England): Systematics, evolution and ecology of the *Banksia spinulosa* complex (graduated 2017).
Melita Milner (Ph.D., Australian National University): Phylogeography of *Lomatia and Telopea* (Proteaceae) in south eastern Australia (graduated 2015).
Samanta Oon (B.Sc. Honours, University of New South Wales): *Lomatia* likes it both ways: rampant bidirectional introgression of chloroplast genomes between two morphologically distinct species of Lomatia (Proteaceae) (graduated 2015).
Zoe Reynolds (B.Sc. Honours, Australian National University): Phylogenetic, taxonomic and functional turnover in Proteaceae assemblages (graduated 2013).
Emma McIntosh (B.Sc. Honours, University of Sydney): Hybridization and introgression between *Lomatia myricoides* and *L. silaifolia* (Proteaceae) (graduated 2011).
Margaret Stimpson (M.Sc.Stud., University of New England): Review of the *Banksia spinulosa* species complex (Proteaceae) (graduated 2011).

James Indsto (M.Sc., University of Wollongong): Pollination Ecology and Molecular Systematics of *Diuris* (Orchidaceae) of the Sydney Region (graduated 2010).
Nanette Thomas (Grad.Dip.Sci., University of New England): Phylogenetic analysis of Winteraceae (graduated 2009).
David McKenna (Ph.D., University of Wollongong: Demographic and ecological indicators for rarity in obligate-seeding *Persoonia* (Proteaceae) shrubs of the Sydney region, graduated 2007).
Paul Rymer (Ph.D., University of Wollongong: Plant rarity: species distributional patterns, population genetics, pollination biology and seed dispersal in *Persoonia* (Proteaceae), graduated, 2006).
Georgina Lloyd (B.Sc. Honours, University of Sydney: Pseudocopulation in two species of *Cryptostylis*: Implications for maintaining species integrity, graduated 2004)
Andrew Perkins (Ph.D., University of Sydney: Phylogenetic Systematics of the Genus *Calochilus* (Orchidaceae), graduated 2002).
Jim Mant (Ph.D., Australian National University: Comparative biology of *Chiloglottis* (Orchidaceae) and its thynnine wasp pollinators (Tiphiidae), graduated 2002).
Siegfried Krauss (Ph.D., University of Wollongong: Systematic pattern and evolutionary process in the complex species *Persoonia mollis* (Proteaceae), graduated 1995).

I have examined 14 honours and postgraduate theses:
Australian National University (Ph.D., 2003, 2007, 2008)
University of Melbourne (Ph.D., 1995, 2011)
University of Newcastle (M.Phil., 2003)
University of Queensland (Ph.D., 2003)
University of Sydney (Ph.D., 1991, 1994, 1997, 2009)
University of Wollongong (B.Sc. Hons., 2001, 2003)
Victoria University (Ph.D., 2007)

Competitive Research and Infrastructure Grants

Peakall, R., Pichersky, E., Linde, C., Weston, P.H. (2015-2019) The biosynthesis and evolution of novel semiochemicals in orchids. $644,800, Australian Research Council Discovery Grant DP150102762.

Hoebee, S.E., Weston, P.H., & Edwards, T.J. (2015-18) Evolution in action or the demise of iconic Australian flora? $217,700, Australian Research Council Discovery Grant DP150100508.

He, T., Lamont, B., Weston, P.H., & Cowling, R. (2012-2014) Origin and evolution of plant functional traits in relation to fire. $310,000, Australian Research Council Discovery Grant DP120103389.

Rossetto, M., Crayn, D.M. & Weston, P.H. (2008-2010) Integrating molecular and morphological data for generic delimitation and species identification in Lauraceae. $73,333, Australian Biological Resources Study.

Cantrill, D., Murphy, D. & Weston, P.H. (2008-10) Understanding the origins of the Australian flora by integrating molecular phylogenies and fossil data in the Proteaceae. $88,900, Hermon Slade Foundation.

Rossetto, M. & Weston, P.H. (2007-2009) Speciation in the Australian flora: testing explanatory hypotheses in waratahs and their allies. $78,000, Hermon Slade Foundation.

Considine, J.A., Krauss, S.L. & Weston, P.H. (2002-2004) A biological basis for the efficient breeding of native plants for export markets: a case study with the Australian Goodeniaceae. $168,126, ARC – Linkage (Krauss and Weston representing industry partners)

Whelan, R.J., Ayre, D.J., England, P., Auld, T.D., & Weston, P.H. (2000-2002) Ecology and genetics of fire-sensitive *Persoonia* species: threatened species recovery and management. $126,480, Australian Research Council (ARC– SPIRT, Auld and Weston representing industry partners).

Trent, R. *et al.* (2000) Enhancement of DNA sequencing equipment for the Sydney University and Prince Alfred Molecular Analysis Centre. $600,000, Australian Research Council (ARC-REIF).

Weston, P.H. (1999-2001) Comparative biology of *Chiloglottis* (Orchidaceae) and its thynnine wasp pollinators (Tiphiidae). $75,000, Hermon Slade Foundation.

Weston, P.H. (1997-2000) Taxonomic revision of *Dillwynia* (Fabaceae: Faboideae: Mirbelieae). $62,836, Australian Biological Resources Study.

Weston, P.H. & Thomson, J.A. (1993) A molecular approach to the evolution and biogeography of the Queensland tree waratahs. $4000, Queensland Wet Tropics Management Authority

Weston, P.H. & Thomson, J.A. (1991-92) A molecular approach to the evolution and biogeography of the waratahs. $80,100, Australian Research Council (large grants scheme).

Weston, P.H. (1984) Establishment of a data bank for eucalypt specimens held by NSW. $20,000, Australian Biological Resources Study.

Scientific Publications

Table of Contents

1. Introduction

1.1 Purpose of the expert report

I was engaged by the Department of Planning and Envionment in September 2018, to produce an expert report on the distribution and abundance of *Pterostylis saxicola* (Orchidaceae) within the proposed Western Sydney Aerotropolis, and Greater Penrith to Eastern Creek Growth Areas (collectively termed "the study area"). This immediately followed my submission of a similar report on the same species for the Greater Macarthur and Wilton Growth Areas (Weston unpublished). The aim of this exercise was to assess whether *P. saxicola* is native to either of the Growth Areas and, if so, to assess where suitable habitat is located and to estimate the area occupied by *P. saxicola* in the study area and within the development footprint.

According to Section 6.5.2 of the Biodiversity Assessment Method, an expert report must:
- identify the relevant species or population
- justify the use of an expert report
- indicate and justify the likelihood of presence of the species or population
- estimate the number of individuals or area of habitat (whichever unit of measurement applies to the species/individual) for the biodiversity certification assessment area, including a description of how the estimate was made
- demonstrate what information was considered, rejected and discounted in relation to the determination made in the expert report, and
- identify the expert and provide evidence of their expert credentials.

1.2 Project context

The Department of Planning and Environment is leading a strategic biocertification of several identified growth areas within Western Sydney, including the two growth areas that define the geographic scope of this report: the Western Sydney Aerotropolis Growth Area and the Greater Penrith to Eastern Creek Urban Release Investigation Area. The strategic biodiversity assessment is an integral part of the Cumberland Plain Conservation Plan that will determine the impact of urban development on threatened species and ecological communities within these growth areas. The Plan will also provide conservation measures to mitigate any impact, as specified by NSW and Commonwealth environmental legislation.

1.3 Study area

The stu8dy area is located in the western to south western part of the Sydney Metropolitan Area, between latitudes 33.712°S and 33.941°S and longitudes 150.654°E and 150.857°E (figure 1).

1.4 Reasons for use of expert report

Pterostylis saxicola has never been collected within the study area. However, sites at which the species has been collected or observed, according to the Bionet Wildlife Atlas, are known beyond all sides of the study area, suggesting that it is part of the distributional range of *P. saxicola*. Moreover, according to Tozer *et al.* (2010), at least one of the plant community types in which known populations of *P. saxicola* occur, PCT 849 Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, is scattered throughout the study area, raising the strong possibility that suitable habitat for *P. saxicola* might exist there. If this were so, *P. saxicola* might once have lived there, or still exist in the study area as unrecorded populations.

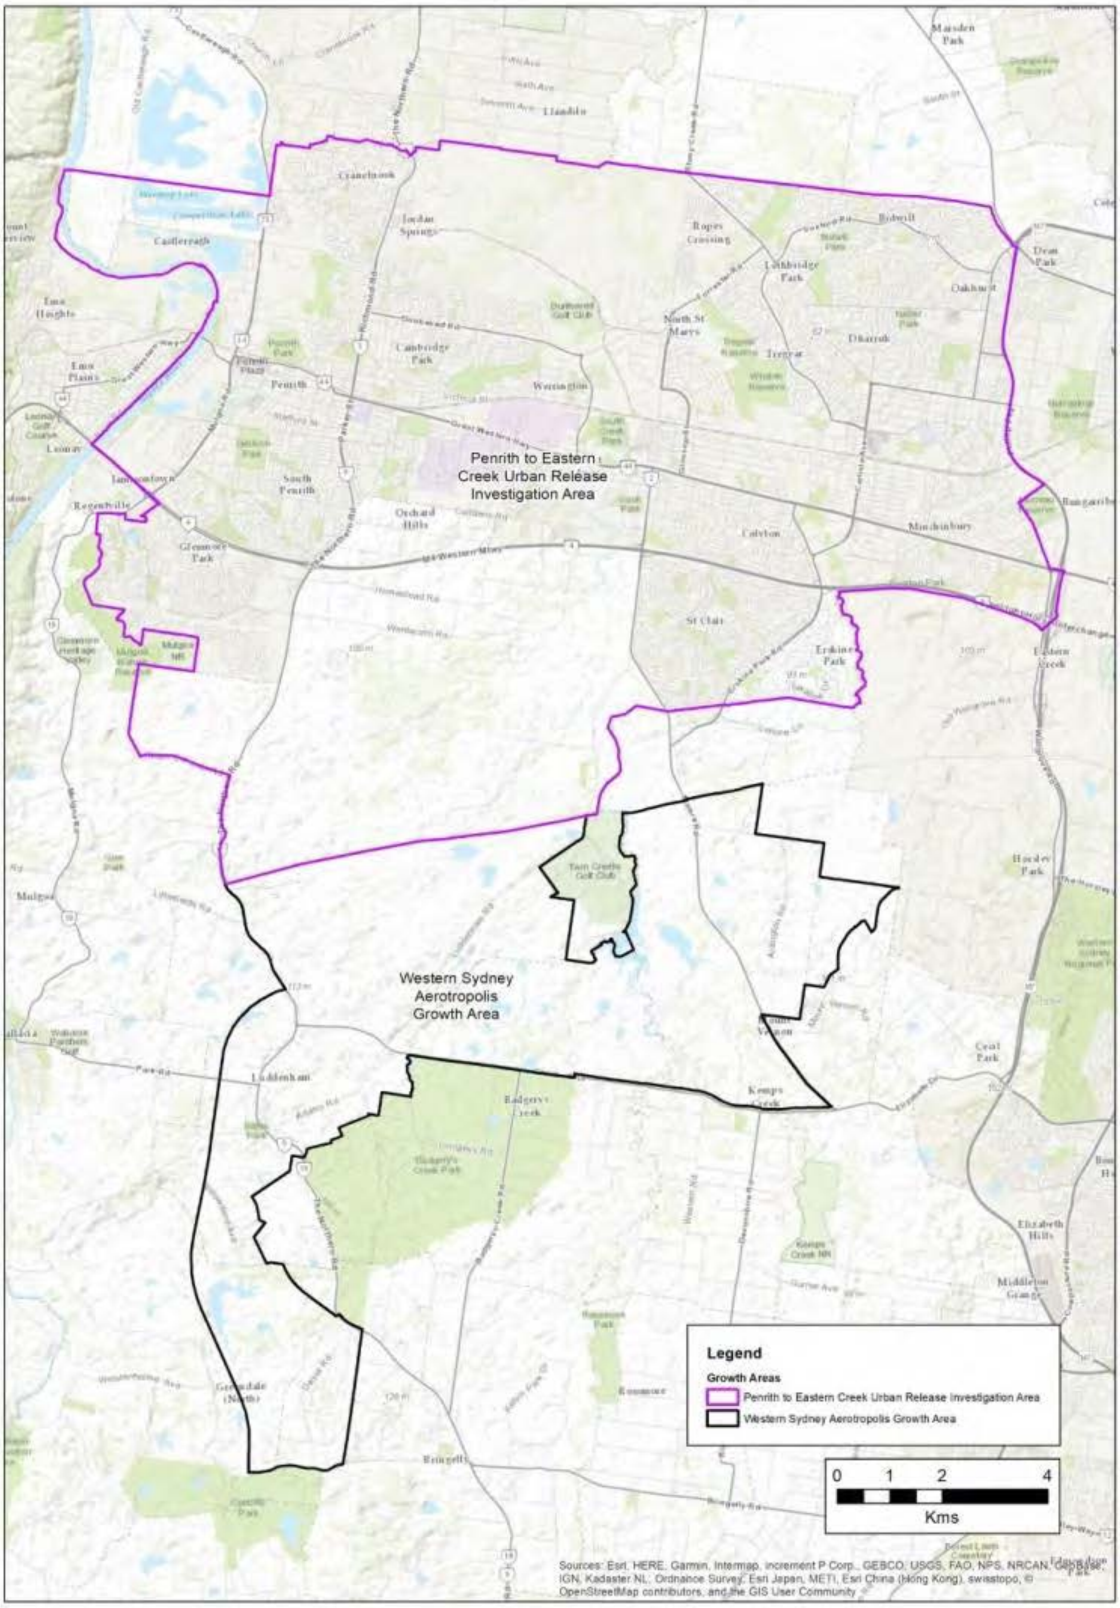

Figure 1. The Greater Penrith to Eastern Creek Urban Release Investigation Area (outlined in purple) and the Western Sydney Aerotropolis Growth Area (outlined in black). © OpenStreetMap contributors.

Pterostylis saxicola is a perennial, deciduous herb that can only be identified with confidence when flowering in Spring (late September to early November). Fortunately, the timing of the field work that I conducted for this project, 7 October to 22 November 2018, largely overlapped with this flowering period. However, the cryptic coloration and small size of this plant render it a challenging subject for conventional surveying: “drive by” surveys are not feasible and even experienced orchid spotters need to be standing within a few metres of a flowering plant to notice it. Moreover, plants may not flower if climatic conditions during the growing season from March to December (see section 2.2 below) are poor, as they have been in 2018 due to drought. Another limitation to conventional surveying was lack of access to a substantial proportion of the remnant native vegetation in the study area. Although sizeable blocks of the remnant bushland are found in public reserves, most of the native vegetation occurs on private land or land managed by the Australian Department of Defence and only 13.5% of landowners granted permission for surveys to be conducted on their land. The Australian Department of Defence land was not surveyed. These limitations and the possibility that *P. saxicola* might be native to the study area triggered the need for an expert report.

An alternative approach involves the construction of a general habitat model for *Pterostylis saxicola*, which can then be used, in conjunction with environmental maps, to identify suitable habitat on all land tenures across the study area.

1.5 Credentials of expert

I prepared this report as an independent botanical consultant but I am also currently an Honorary Research Associate at the New South Wales state herbarium (the National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust). In 2016, I retired from my role as a Senior Principal Research Scientist at the state herbarium, having worked there since 1982 as a Systematic Botanist and as curator of the herbarium’s collections of specimens of Orchidaceae (including *Pterostylis saxicola*) (see my Curriculum Vitae, attached). I now work, part-time, at the National Herbarium of New South Wales as an Honorary Research Associate. I have published, either as sole author or as a co-author, 16 papers on the systematics and ecology of the Orchidaceae in the peer-reviewed scientific literature, including the most comprehensive phylogenetic analysis of the predominantly Australian subtribe Diurideae yet published (Weston et al. 2014). As curator of Orchidaceae at the state herbarium, I examined all specimens of P. saxicola incorporated into the collection between 1986 and 2016. I was invited to contribute to floristic treatments of the Orchidaceae for Flora of New South Wales, (see my Curriculum Vitae, attached). I was also asked to be lead author of the essay on the ecology of the Orchidaceae that accompanied the “Ecology of Sydney Plants” (Weston et al. 2005). Throughout my career I have participated in numerous collecting trips in the field, collecting specimens in all Australian states for the state herbarium. In documenting these specimens I had to describe the habitat at each collecting site, including associated plant species, substrate, aspect, degree and kind of disturbance. I have also cultivated numerous species of Pterostylis as an orchid enthusiast and advised horticulturalists at the Royal Botanic Gardens on appropriate techniques for cultivating species of Pterostylis and other orchids.

In June 2018 I was appointed to prepare an expert report on *Pterostylis saxicola* in the Greater Macarthur and Wilton Growth Areas (Weston unpublished), during the preparation of which I characterised in detail the associated plant species and other ecological attributes of five plots, each of 30 metre radius, centred on highly precise grid references of sites at which *P. saxicola* had previously been collected, at two of which I found pre-flowering leaf rosettes that were indistinguishable from those of the orchid. I am personally familiar with this taxon and the habitats in which it lives.

In November 2018 I was approved by the Office of Environment and Heritage as a species expert for *Pterostylis saxicola* under section 6.5.2 of the Biodiversity Assessment Method. This approval is current for a period of six years.

1.6 Species surveys conducted on behalf of the Department of Planning and Environment

Letters were sent by the Department of Planning and Environment (DPE) to all landholders within the development footprint to request access. A total of 432 letters were sent to landholders across the Western Sydney Aerotropolis Growth Area between November 2017 and August 2018 with 84 landholders responding positively to provide access. A further seven properties were accessed after doorknocking, resulting in a response rate of 21%.

A small number of targeted letters were sent to landholders in the Greater Penrith to Eastern Creek Urban Release Investigation Area from November 2017. However, most letters (more than 1500) were sent in August 2018, which included many urban and small acreage landholders. From this, 177 landholders provided access to their properties and an additional three landholders provided permission via doorknocking (12% response rate). Not all of these properties were surveyed as some did not support vegetation patches of interest. In addition, the Open Spaces Team at Penrith Council facilitated access to 64 lots owned by Council. Surveys were undertaken by DPE's contract ecologists on all areas of land where landowners granted access. Access to the Defence Establishment Orchard Hills, which includes large patches of native vegetation, was not provided.

A targeted survey for threatened species was conducted on lands where access was granted. Vegetation transects and random meanders for threatened flora were conducted by the Ecoplanning Pty Ltd and Biosis Pty Ltd in accessible areas proposed for certification, with particular attention to areas of likely habitat. The survey included effort through each plant community type and vegetation zone, and extended into suitable habitat adjacent to the edge of the future urban area where potential indirect impacts to high quality habitat may occur (up to ~50m). Likely habitat for most flora species comprised areas of lower disturbance. This included areas with a predominantly native understorey (with or without a canopy), the base of scattered trees in paddocks, paddocks with an apparent low grazing pressure, and known topographic/habitat preferences for certain flora. *Pterostylis saxicola* was not found in the study area during this survey.

The percentages of remnant native vegetation in the growth areas that were sampled in the threatened species survey were 1.0% in Greater Penrith to Eastern Creek Urban Release Investigation Area and 7.1% in the Western Sydney Aerotropolis Growth Area. The percentages of sampled remnant native vegetation that were covered by the urban development footprint were 7.9% in Greater Penrith to Eastern Creek and 18.4% in the Western Sydney Aerotropolis. These data include a 20 m buffer from survey tracks.

2. Species information

2.1 Species description

The following morphological description of *Pterostylis saxicola* is a modified version of that published by Jones and Clements (1997), updated with data gathered from more recently collected specimens held by the National Herbarium of N.S.W.

Tuberous, terrestrial herb (see figure 2). Tubers oblate, c. 15-20 mm wide. Leaves oblong-elliptical to ovate-elliptical or obovate, 10-45 mm long, 5-15 mm wide, 5-10 in a radical rosette, green, the margins entire, shortly petiolate, apex subacute to apiculate, often withered at anthesis. Inflorescence 10.5-35 cm tall, slender, with 3-6 ensheathing, lanceolate sterile bracts. Floral bracts lanceolate, 6-19 mm long, 3-4 mm wide, acuminate, closely sheathing. Pedicels 3-26 mm long, slender, straight or slightly curved. Ovary narrowly obovoid, 3-5 mm long, 1-2 mm wide, reddish brown. Flowers 1-10, porrect to semi-erect, 12-12 mm long, transparent with dark red-brown markings and suffusions in the galea, the lateral sepals wholly red-brown, shiny; galea gibbous at the base, curved medially, decurved suddenly to the apex; petal flanges poorly developed, not touching and not closing off the base of the galea. Dorsal sepal 11-13 mm long, cucullate, obliquely erect, Abruptly decurved in distal quarter, apical point c. 3 mm long, filamentous, acuminate. Lateral sepals deflexed, ovate in outline when flattened, fused part 7-10 mm long, 9-11 mm wide, shallowly concave, the margins strongly incurved, glabrous; sinus narrow; free points filamentous, c. 5 mm long, curved forwards, divergent, 8-10 mm apart at the tips. Petals ovate-lanceolate, 11-14 mm long, 3.5-5 mm wide, nearly straight, transparent, with brown basal markings and two or three brown lines, dorsal margin brown, ciliate, proximal flange poorly developed. Labellum highly irritable, attached by a ligulate basal claw c. 2 mm long, c. 2 mm wide; lamina broadly obovate, 4.5-6 mm long, 2.5-3.5 mm wide, dark red-brown, constricted in the proximal quarter, adaxial surface shallowly concave to broadly grooved, apex obtuse; marginal trichomes 3-5 pairs, white, the longest pair c. 3.5 mm long, arising near the proximal constriction, basal lobe large, with 1-3 pairs of trichomes c. 0-.7 mm long, abaxial surface with a narrow central channel extending from the basal lobe to the apex. Column porrect from the end of the ovary, 10-12 mm long, c. 2.5 mm wide; column wings c. 3.3 mm long, c. 2.5 mm wide, more or less rectangular, anterior margins ciliate. Stigma elliptical to broadly scutiform, c. 5 mm long, c. 2.5 mm wide, the upper margins irregular. Anther c. 1.2 mm long, obtuse. Pollinia linear-oblong to clavate, c. 2 mm long, yellow, mealy. Fruiting capsules obovoid, 7-8 mm long, c. 4-5 mm wide, brownish, erect.

2.2 Life cycle

Pterostylis saxicola is a perennial, deciduous, tuberous herb that germinates from a minute, dust-like seed. Like all other orchids, germination is reliant on invasion of the seed by the hyphae of a specific fungal associate, which, in the case of *P. saxicola*, is an unnamed species of *Ceratobasidium* (Basidiomycota: Cantharellales) (Sommerville et al. 2008). The first morphological change that an orchid seed undergoes during germination is swelling to form a protocorm, a rootless, shootless ‘blob’. The orchid fungus forms an intracellular relationship with its host, usually in the roots and/or tubers and is thus classed as an endomycorrhiza. It forms hyphal coils, called pelotons, in the cells of its host, which are beneficial to the orchid in that they provide the host plant with nutrients such as soluble sugars (Rasmussen 1995, Warcup 1990). The duration of the association varies according to the life history of the particular orchid species, with some species of orchids being completely dependent on their mycorrhizal fungi for life while other species are capable of living without their fungi from shortly after germination. The ease of cultivation of *Pterostylis* species and the green colour of almost all plant parts strongly suggest that adult plants are not obligately dependent on their mycorrhizal associates as adult plants.

Plants of *Pterostylis saxicola*, like those of most other species in Orchidaceae subfamily Orchidoideae, are deciduous, with the whole shoot system growing anew every year from a dormant tuber. The new shoot usually starts growing from an apical meristem on the tuber in late summer, with new shoots usually breaking the soil surface by March. The shoot develops into a “rosette” of crowded leaves just above ground level and in late winter a terminal raceme starts growing from the centre of the rosette, reaching anthesis in Spring. While the shoot is growing above ground, a new replacement tuber is growing below ground, from the base of the shoot. Some species of *Pterostylis* multiply and spread vegetatively by producing additional new tubers on the ends of long roots but the subgenus to which *P. saxicola* belongs, *Oligochaetochilus*, does not share this attribute (Jones 2006).

Figure 2. Flowering plant of *Pterostylis saxicola*, at Scheyville National Park, showing the basal rosette of crowded leaves lying flat on the ground and a terminal, erect inflorescence, bearing one open flower from the side and an unopened flower bud.

Figure 3. Flower of *Pterostylis saxicola*, at Scheyville National Park, frontal view, showing galea, labellum and paired lateral sepals.

Almost all species of *Pterostylis* are deceptively pollinated by male flies that attempt to copulate with the labellum of the flower. The labellum mimics a female fly of a particular species (or species group) in size, appearance and texture and by exuding an allomone that is identical to the pheromone released by the female flies (Phillips et al. 2013, Kuiter & Findlater-Smith 2017). In species of *Pterostylis* for which the pollination process has been studied and described, the labellum is highly motile ("irritable"), like that of *Pterostylis* saxicola, and a male fly that lands on it is tossed inside the hood (galea) formed by the dorsal sepal and lateral petals, and trapped there. The only escape route provided by the flower is a tunnel through which the male fly must squeeze in order to escape. In the process of negotiating its exit, the fly is forced to rub past the stigma of the flower, depositing on it any pollinaria that it was already carrying. The fly is then forced to contact the anther, sticking a pollinarium on its thorax, before it can finally escape. The pollinator of *P. saxicola* is still unknown, but the pollinators of other species of *Pterostylis* subgenus *Oligochaetochilus*, where known, are males of unnamed species of *Orfelia* (Mycetophilidae) (Kuiter & Findlater-Smith 2017). Sexually deceptive pollination has evolved multiple times in the Australian terrestrial orchid flora, involving hundreds of species (Weston et al. 2014). Most of those for which pollinators have been identified are pollinated by the males of only one species of insect and *P. saxicola* is most likely pollinated by a single species of fly too.

Fruiting capsules of *Pterostylis saxicola* mature quickly, with the most proximal capsules sometimes dehiscing before the most distal flowers have withered. They split down six sutures to release thousands of minute, wind-dispersed seeds in November to early December.

2.3 Distribution and abundance

Records for *Pterostylis saxicola* are widely distributed across the Cumberland Plain and lower Blue Mountains in an area bounded by Scheyville, Freemans Reach, Glenbrook, Douglas Park, Picnic Point, Ryde (an unvouchered record) and Cattai, with an outlying record from the Gingra Range in Kanangra Boyd National Park (Bionet Atlas, National Herbarium of New South Wales specimen database, all accessed 26/7/2018). It has been recorded at altitudes ranging from 30 to 400 metres. It is very sporadically distributed, partly because much of this land has been cleared for agriculture and suburban development but the outlying record suggests that any habitat model is unlikely to be a powerful predictor of the presence of populations at particular locations.

Plants are usually gregarious, with most collectors and observers noting multiple plants co-occurring together. At two sites for which I had highly precise grid references, and which I characterised in detail, I found plants in clusters: 10 plants in a 10x10 cm patch, two plants 5 cm apart, and 57 in a patch smaller than one square metre. As *P. saxicola* does not usually multiply vegetatively (Jones 2006), these clusters must be the result of seeds germinating close to their parents.

2.4 Habitat requirements

The habitat model published in the endangered species profile for *Pterostylis saxicola* (NSW Office of Environment and Heritage 2018a) states that it is "most commonly found growing in small pockets of shallow soil in depressions on sandstone rock shelves above cliff lines. The vegetation communities above the shelves where *P. saxicola* occurs are sclerophyll forest or woodland on shale/sandstone transition soils or shale soils". This description applies accurately to the habitat associated with some records in the southern half of the species' distribution but not to those found elsewhere. The distributional range and habitat requirements of *P. saxicola* can be subdivided into two main sub-populations and one outlying population.

The northern sub-population is in an area bounded by Scheyville, Freemans Reach, "The Ironbarks" near Glenbrook, Toongabbie, Ryde, Glenhaven and Cattai. The substrate underlying the sites at

Scheyville, Freemans Reach and Ryde is deep Ashfield Shale (Wianamatta Group), but the Cattai, Toongabbie and Glenbrook records came from Hawkesbury Sandstone – Mittagong Formation – Ashfield Shale transition zones. All of these sites are in gently rolling country, not on rugged sandstone outcrops.

The plant communities associated with recorded sites for *Pterostylis saxicola* in its northern sub-population, as determined from collectors' and observers' notes and from identification of precisely specified sites on the vegetation maps of Tozer *et al.* (2010), are their map units GW p29 and GW p2. According to the references cited in the Bionet Vegetation Classification, these are equivalent to:

- 849 Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain (see figure 4);
- 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain (see figure 5).

Most records from the southern sub-population, in an area bounded by Macquarie Fields, Minto, Douglas Park, Woronora River and Picnic Point differ in habitat from the northern records. In cases where they have highly precise locality data and/or detailed habitat descriptions, collections and observations from this area have been made on Hawkesbury Sandstone, on the rims and sides of the gorges of the Nepean, Georges and Woronora Rivers. Observers' notes repeatedly describe the soils as very shallow sands overlying sandstone rock shelves, as stated in the published habitat model (NSW Office of Environment and Heritage 2018a). However, contrary to that model, only some of them were recorded above cliff lines. All of these sites occur close to outcrops of Ashfield Shale, mostly downhill from them, but for some of these sites, the only evidence of shale influence on the environment seems to be associated plant community types. Precisely georeferenced sites are mapped by Tozer *et al.* (2010) to their map units DSF p146, Sydney hinterland transition forest and their map unit GW p2, Cumberland Shale Sandstone Transition Forest. According to the references cited in the Bionet Vegetation Classification, these are equivalent to:

- 1081 Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain;
- 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain).

In addition to the two main sub-populations, there is also an outlying, precisely georeferenced, herbarium record from the Gingra Range in Kanangra Boyd National Park. This site is on Devonian metasediments, and was mapped by Tozer *et al.* (2010) to their map unit DSF p37 Kowmung-Wollondilly Grassy Gorge Woodland.

According to the references cited in the Bionet Vegetation Classification, this is equivalent to:

- 870 Grey Gum - Thin-leaved Stringybark grassy woodland of the southern Blue Mountains gorges.

Pterostylis saxicola has mostly been recorded growing in intact native vegetation but there is one notable exception: a plant described in a "Car Park growing through bitumen", adjacent to a large area of bushland from which other substantiated records had been made. Several others have come from small patches of remnant urban bushland, in some cases less than a hectare in area, surrounded by highly disturbed land, and from a long, narrow patch less than 50 m wide. However, no records mention heavily weed-infested habitats or evidence of heavy grazing by introduced herbivores. Sites with significant edge effects are probably not sustainable reserves for conserving this species.

Figure 4. PCT 849 Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain, on Ashfield Shale at Scheyville National Park (my site PS1).

Figure 5. PCT 1395 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain, on Mittagong Formation at Cattai (my site PS7).

3. Description of the study area

3.1 Land use history

This section is based primarily on information from penrithhistory.com, a website maintained by Penrith Library (Penrith Library 2018), except where other sources are explicitly cited. The first human inhabitants of the study area were Aborigines who moved there many thousands of years ago. People of the Darug language group were occupants of the study area when the British first started to settle in the Sydney Region in 1788 (Logan 2011). These hunter-gatherers would have managed the grassy woodlands that grew on Bringelly Shale and Cenozoic alluvia of the area using fire-stick farming methods (Benson & Howell 1990). They used the natural landscape seasonally, taking advantage of different food sources depending on availability, establishing temporary open camps of simple gunyahs on higher ground near water courses. The Nepean River and its tributaries were significant sources of fish, shellfish and useful plants while the wooded plains and gentle hills were sources of game, edible tubers, seeds, fruits and materials for making clothing, tools and shelters (Logan 2011).

In 1789, 18 months after the founding of Sydney, Captain Watkin Tench led a group from Rose Hill to the Nepean River, followed soon by further expeditions from there to Razorback in the south and downstream to the Hawkesbury River in the north (Fitzhardinge 1967). The alluvial flats of the Nepean River and adjacent grassy woodlands on Wianamatta Shales, offered more fertile farming land than sandy soils derived from Hawkesbury Sandstone surrounding the Cumberland Plain. However, violent clashes between the British and the Darug people led by Pemulwuy delayed settlement west of Prospect until 1802, when Governor King built a headquarters for his government stock reserve at what is now Rooty Hill (NSW Office of Environment and Heritage 2018b). King went on to issue land grants at what are now Penrith and Cranebrook in 1804, and Orchard Hills, St Marys and Badgerys Creek in 1806. Further land grants were made in what are now Mulgoa and Greendale in 1810, and Luddenham in 1813. In 1815 the Great Western Road was completed between Parramatta and Bathurst, placing the northern part of the study area on what soon became a major transport artery. Completion of the western railway line from Sydney to Penrith in 1867 and its extension to Bathurst in 1876 significantly enhanced accessibility of the northern part of the study area. From first settlement in the early 19th century to the 1950s, land use in the study area was dominated by timber production, agriculture and quarrying, all of which necessitated extensive clearing of native vegetation, especially from the more fertile alluvial and clayey soils. Agricultural activities conducted in the areas have included the cultivation of wheat (which was curtailed in 1861 when the whole crop was destroyed by an infestation of rust disease) and other cereal crops, grazing of sheep, cattle and horses, intensive production of pigs and poultry, and the cultivation of fruit, vegetables, turf and cut-flowers (Wilkinson 2011). Industrial facilities that processed saw logs and agricultural produce, such as timber mills, flour mills, milk processing plants, cattle sale yards, tanneries, canneries and wineries began to be built early in the 19th century and mostly continued operating well into the 20th century. A few manufacturing plants, producing textiles, munitions and bricks were also developed in the 19th and early 20th centuries.

Penrith grew slowly as an urban centre during the 19th century and first half of the 20th century, but population growth accelerated after 1960 due to the establishment of several social housing projects by the N.S.W. Housing Commission. This was followed from the 1970s by the gradual rezoning of much of the agricultural land in the northern part of the Greater Penrith to Eastern Creek Urban Release Investigation Area for urban development. Land use in this growth area is now dominated by residential housing, retail precincts, light industry and transport infrastructure, but Orchard Hills in the south is still largely rural. Most protected patches of remnant native vegetation are less than 20 Ha in area but the two largest reserves containing intact bushland, Wianamatta

Regional Park in the north and The Defence Establishment Orchard Hills in the south, cover approximately 900 Ha and 1370 Ha respectively.

The Western Sydney Aerotropolis Growth Area is still largely rural but includes a staggeringly small area of remnant bushland in public reserves. The largest patch consists of about 3.5 hectares of weed-infested Grey Box – Forest Red Gum grassy woodland in Sales Park, Luddenham. Soon it will be a small green oasis, surrounded by urban development.

3.2 Landscape context

The Sydney Basin is a geological entity, composed of sedimentary rocks, which is shaped a bit like a tilted, triangular, art deco saucer. In the middle of this structure is the Cumberland Plain, in the northern half of which is located the study area. Here, the uppermost strata of the Sydney Basin, Cenozoic alluvia, patchily overlie the Triassic Wianamatta Group, comprising Bringelly Shale, Minchinbury Sandstone and Ashfield Shale, which, in turn overlie Triassic Hawkesbury Sandstone, the Triassic Narrabeen Group and the Permian Shoalhaven Group (Martyn 2018). Scattered small Jurassic basalt diatremes occasionally pierce the sedimentary strata, such as at Lethbridge Park and Bidwill.

The most commonly exposed substrate in the study area is Bringelly Shale. Over this, the second most commonly exposed substrate, Quaternary alluvial clay, which has mostly been eroded from Bringelly Shale, has accumulated in a branching pattern across the study area on the floodplains of South Creek and its tributaries, including Kemps, Badgerys, Cosgrove, Blaxland, Claremont, Werrington and Ropes Creeks (NSW Department of Minerals and Energy 1991).

Other substrates are also exposed over a much smaller area on the northern and western margins of the Greater Penrith to Eastern Creek Urban Release Investigation Area. Two patches of Londonderry Clay, a Paleogene-Neogene alluvium, covering an area of about six square kilometres, have been preserved on the northern edge between St Marys and Shanes Park. On the western margin, between Mulgoa and the north-western corner, gravelly, sandy, silty and clayey Quaternary alluvia of the Cranebrook formation line the eastern bank of the Nepean River and its eastern tributaries, forming an extensive deposit up to four kilometres wide north of Regentville. On the western margin, several square kilometres of Ashfield Shale and a smaller area of Rickabys Creek Gravel, a Paleogene-Neogene alluvium, are exposed from Jamisontown to Glenmore Park.

The whole study area is gently tilted from south to north and all watercourses flow in that general direction. Topography varies subtly in the Greater Penrith to Eastern Creek Urban Release Investigation Area with low, rounded ridges alternating with flat-bottomed flood plains. The lowest point is in the north west corner at Upper Castlereagh, where the bank of the Nepean River is below 10 m altitude, and along the northern margin the altitude is less than 70 metres. The highest point in the Greater Penrith to Eastern Creek Urban Release Investigation Area is 93 metres in altitude at Sovereign, in the south west corner. Along the boundary between the two growth areas, altitude varies from 40 metres in the east to 90 metres in the west.

Topographic relief is still quite gentle, but more noticeable, with steeper slopes, in the Western Sydney Aerotropolis Growth Area. The altitude varies from 40 metres in the north eastern corner to 106 metres just south east of Luddenham village.

Topographic variation, as well as distance from the sea influence climate. The Cumberland Plain is the driest part of the Sydney Region and also experiences the most extreme temperatures in the region. Key climate statistics for the three weather stations in the study area, for which data are freely available, are shown in table 1. The whole study area is subject to winter frosts.

Weather station	Mean annual rainfall (mm)	Mean maximum temperature (°C)	Mean minimum temperature (°C)
Penrith Lakes AWS (1995-)	718.6	31.0	5.3
Orchard Hills Treatment Works (1970-)	832.7	28.5	5.3
Badgerys Creek McMasters F (1995-)	794.3	28.6	3.8

Table 1. Key climatic statistics for weather stations in the growth areas.

3.3 Native vegetation communities

In terms of the plant community types recognised in the Bionet Vegetation Classification and the vegetation maps that were prepared for this project, the remnant native vegetation of the study area consists of:

- 724 Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain (191.3 ha);
- 725 Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain (167.4 ha);
- 781 Freshwater wetland (68.9 ha);
- 830 Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion (2.8 ha);
- 835 Forest Red Gum – Rough Barked Apple grassy woodland on alluvial flats of the Cumberland Plain (989.2 ha);
- 849 Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain (2334.1 ha);
- 850 Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain (88.5 ha);
- 883 Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain (6.5 ha);
- 1105 River Oak open forest of major streams, Sydney Basin Bioregion and South East Corner Bioregion (94.2 ha);
- 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest of the edges of the Cumberland Plain (2.0 ha).
- 1800 Swamp Oak open forest on river flats of the Cumberland Plain and Hunter valley (228.5 ha).

In the study area, according to the vegetation mapping that was conducted for this project, the following substrates support the following plant community types:

- Quaternary alluvium: 781, 835, 849, 850, 1105, 1800;
- Londonderry Clay: 724, 725, 835, 849;
- Bringelly Shale: 724, 725, 835, 849, 883;
- Ashfield Shale: 835, 849, 1395;
- Rickabys Creek Gravel: 849.

PCT 849 is the most abundant plant community type throughout both growth areas, growing on most of the uncleared land above the zone of floodwater inundation, most commonly on Bringelly Shale. Over 50% of the two largest patches of remnant bushland, Wianamatta Regional Park and the Defence Establishment Orchard Hills is covered in PCT 849 and it covers most of the smaller reserves too. PCT 835 covers the second largest area and also occurs throughout the study area, vegetating the uncleared flood plains of South Creek and its tributaries on Quaternary alluvium, as well as the lowest part of the adjacent slopes. The banks of those creeks as well as some other blocks of low-lying land on Quaternary alluvium, are dominated by PCT 1800. PCTs 724 and 725 are dominant on

Londonderry Clay in the northern part of the study area but also occur patchily elsewhere on Bringelly Shale, most notably in the Kemps Creek area and on a rectangular block of regenerating vegetation 0.6-0.8 km west of Luddenham Road, 0.2-0.6 km north of the Warragamba-Prospect water pipeline. PCT 1105 dominates remnant vegetation on the banks of the Nepean River north of Penrith, on Cranebrook Formation alluvium. The remaining plant community types occur only rarely as tiny fragments in the study area. About 6.5 ha of PCT 883 occurs in two patches at the eastern end of Wianamatta Regional Park and about 15 ha remains in a block 0.6 km north of Elizabeth Drive, Kemps Creek. PCT 1395 is represented by a sliver of two hectares on Ashfield Shale at Glenmore Park. PCT 830 is restricted to a fringe of under three hectares in area on the eastern the border of Mulgoa Nature Reserve.

Weed infestation is a problem throughout the study area. This is well illustrated by two sites at Claremont Meadows. The vegetation at a site beyond the eastern end of Caddens Road, on the flood plain of South Creek, which I visited but did not include in my sampling, consisted of a closed forest of *Ligustrum sinense*, *Ligustrum lucidum* (both natives of China, the latter extending to Japan) and *Olea europaea* subsp. *cuspidata* (native of Africa), with scattered emergent trees of *Eucalyptus tereticornis* and *E. amplifoli*a. This would have been a forest of PCT 835 before weed infestation converted it into a novel, derived plant community. Only 0.6 km to the west north west of that site is a superficially pristine block of PCT 724. Even here, however, *Ligustrum sinense* and *Ligustrum lucidum* already dominate the vegetation near South Creek, *Eragrostis curvifolia* is a common component of the ground stratum and seedlings of *Olea europaea* subsp. *cuspidata* are starting to establish throughout the reserve.

4. Assessment of species presence and habitat

4.1 Existing records and surveys

A search for records of *Pterostylis saxicola* in the Bionet Atlas, conducted on 3 December 2018, returned 30 observational records. Several targeted surveys of this species seem to have been conducted since 2000. Teresa James surveyed for this species across the species' distribution in Spring 2007, for the NSW Department of Environment Climate Change and Water, submitting an unpublished report, observational records at five sites and a herbarium specimen (Teresa James personal communication). From November 2010 to January 2011, Total Earth Care Pty Ltd conducted a survey of threatened plant species in the Simmos Beach Recreation Reserve, Macquarie Fields for Campbelltown City Council, submitting an unpublished report and observational records at eight sites (Lachlan Laurie personal communication). In Spring 2011, *P. saxicola* was again targeted at Simmos Beach Recreation Reserve by a research group from The Royal Botanic Gardens and Domain Trust that investigated the mycorrhizal associates of the orchid, with the aim of identifying and culturing the relevant fungus or fungi, adding seeds of this species to the seed collection at the Australian Plantbank, and germinating seeds of the orchid in septic culture. Two scientific papers were published, and three herbarium specimens collected as part of this project. All of those surveys and searches were conducted outside the study area.

Highly precise grid references associated with a number of the Bionet records enabled me to identify the plant community types (as mapped by Tozer *et al.* (2010) and substrates (as mapped by NSW Department of Minerals and Energy 1991) at sites at which these records of *Pterostylis saxicola* occurred. They were:

- 849 Grey Box – Forest Red Gum grassy woodland on Flats of the Cumberland Plain, on Ashfield Shale;

- 870 Grey Gum - Thin-leaved Stringybark grassy woodland of the southern Blue Mountains gorges, on Devonian metasediments;
- 1081 Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain, on Hawkesbury Sandstone;
- 1083 Red Bloodwood - scribbly gum heathy woodland on sandstone plateaux, on Hawkesbury Sandstone;
- 1181 Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, on Hawkesbury Sandstone;
- 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest on the edges of the Cumberland Plain, on Ashfield Shale-Mittagong Formation-Hawkesbury Sandstone transitional landscapes.

4.2 Surveys completed for the biocertification

Apart from the surveys conducted for this expert report, no targeted surveys for *Pterostylis saxicola* were conducted for biocertification of the study area.

4.3 Surveys completed for this assessment

4.3.1 Survey Methods

In the course of preparing my expert reports on *Grevillea juniperina* subsp. *juniperina* and *Pterostylis saxicola* in the Greater Macarthur and Wilton Growth Areas (Weston unpublished a,b), I characterised 20 plots of native vegetation in detail, each plot being a circle of radius 30 m (an of area 2827 m^2), centred either on a plant of *Grevillea juniperina* subsp. *juniperina* or *P. saxicola* or on an arbitrarily chosen point (at sites where both the *Grevillea* and the *Pterostylis* were absent). I have included data from five of those plots as samples from outside the study area in my analyses for this report.

I have also used the same methods to search for *Pterostylis saxicola* and characterise 34 plots in and around the Greater Penrith to Eastern Creek Urban Release Investigation Area and Western Sydney Aerotropolis Growth Area. I chose the locations with the aim of sampling patches of accessible, remnant bushland representing as broad an ecological range and geographic extent across the two Growth Areas as time would allow, sampling more plots in areas where *Grevillea juniperina* subsp. *juniperina* had previously been recorded. Some habitats, such as freshwater wetlands, and substrates on which neither *Grevillea juniperina* subsp. *juniperina* nor *P. saxicola* had ever been recorded, such as Cranebrook Formation alluvia, were avoided. At each plot I listed all vascular plant species that could feasibly be identified, taking photographs and sometimes specimens of plants for later reference in cases where the plant's identity was in question. The latitude and longitude of the centre of each plot was determined using a GPS instrument. The altitude of each site was determined later from 1:25,000 topographic maps. The soil and topography at each site was described and the substrate identified using the Penrith 1:100,000 geological map (NSW Department of Minerals and Energy 1991) and 1:25,000 topographic maps.

I identified the plant community type in each plot using the PCT identification tool in Bionet, and my list of plant species found in each plot.

I developed an improved habitat model for *Pterostylis saxicola*, using data from the published literature, 38 observers' and collectors' records of *P. saxicola* in the Bionet Wildlife Atlas, vegetation mapping conducted for the Cumberland Plain Conservation Plan (Biosis unpublished), the geological map of the area (NSW Department of Minerals and Energy 1991) and my own botanical surveys of 7 plots where I was confident that plants of *P. saxicola* were present.

4.3.2 Results and Conclusions from my Surveys Completed for this Assessment

Site and ecological data for my plots are shown in Appendix 2. I sampled most plant community types and most substrates known in the study area in these plots, as well as one plant community type, PCT 849, in which *Pterostylis saxicola* has been recorded. However, I did not find *P. saxicola* in any plots within the study area.

According to my identifications of plant community types, *Pterostylis saxicola* was present in the following PCTs in seven of my plots outside the study area:

- 849 Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain (2 plots);
- 1081 Red Bloodwood - grey gum woodland on the edges of the Cumberland Plain (3 plots);
- 1181 Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney (1 plot);
- 1395 Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain (1 plot).

According to the vegetation mapping conducted for this study, two of these plant community types were found within the study area, PCT 849, which is common and widespread there, covering 2344 hectares, and PCT 1395, which is represented by a remnant of just two hectares at Glenmore Park.

Plant community types that I sampled in the study area, in which *Pterostylis saxicola* has never been recorded, were the following.

- 725 Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain (nine plots sampled);
- 835 Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain;
- 1800 Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley (3 plots).

Substrates on which *Pterostylis saxicola* was present in my plots outside the study area were:

- Hawkesbury Sandstone (four plots);
- Hawkesbury Sandstone – Mittagong Formation – Ashfield Shale transition zone (one plot);
- Ashfield Shale (two plots).

Hawkesbury Sandstone is not exposed anywhere in the study area. An area of 14.3 hectares of Ashfield Shale supports intact remnant vegetation of PCTs 849 and 1395 in the study area, in several small reserves at Glenmore Park and on private land north of Mulgoa. I inspected two of the reserves for plants of *Pterostylis saxicola* on 22 November 2018 (including my plot PEC29), when plants that had recently flowered outside the study area were still clearly visible but I could find no evidence of *P. saxicola* in either reserve. Nevertheless, *P. saxicola* might occur in small areas of suitable habitat within the study area but have been overlooked. Even mature plants do not flower every year, especially if climatic conditions have been poor (see section 2.4), as they have over the past 12 months of drought.

Pterostylis saxicola has never been recorded on the following substrates that are exposed in the study area:

- Bringelly Shale;

- Cenozoic Alluvium.

Previously, (Weston unpublished) I argued that the habitat model that was published as part of OEH's threatened species profile of *Pterostylis saxicola* (NSW Office of Environment and Heritage 2018a) needed updating. The new habitat model that I proposed there was as follows:

Occurs on the Cumberland Plain along an ecological gradient from:

- Clay soils derived from Ashfield Shale (Wianamatta Group) on flat to gently hilly landscapes in PCT 849 Grey Box – Forest Red Gum grassy woodland on Flats of the Cumberland Plain;
- to: clay to sandy soils derived from Hawkesbury Sandstone – Mittagong Formation – Ashfield Shale transition substrates on gently hilly landscapes, in PCT 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest on the edges of the Cumberland Plain;
- to: thin accumulations of humus-rich sandy soil on Hawkesbury Sandstone sheets and rock shelves, on the rims and steep sides of river valleys, growing in PCT 1081 Red Bloodwood – Grey Gum woodland on the edges of the Cumberland Plain, or PCT 1083 Red Bloodwood - scribbly gum heathy woodland on sandstone plateaux, or PCT 1181 Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney.

Also occurs outside the Cumberland Plain on Devonian slate, in PCT 870 Grey Gum - Thin-leaved Stringybark grassy woodland of the southern Blue Mountains gorges.

4.4 Assessment of species presence

4.4.1 Likelihood of species presence

The total area of suitable habitat in the study area (see 4.5 below) is only 14.3 ha, all of which occurs in the Greater Penrith to Eastern Creek Urban Release Investigation Area. Given the rarity and sporadic distribution of this species, the likelihood of any populations remaining undetected in those remnants is low. However, it is not zero. No suitable habitat exists in the Western Sydney Aerotropolis Growth Area and it is most unlikely to occur there.

4.4.2 Justification for determining presence

Pterostylis saxicola has never been recorded in either the Greater Penrith to Eastern Creek or Western Sydney Aerotropolis Growth Area and I failed to find any plants of it in the 30 plots that I surveyed in detail. Nevertheless, a small area of suitable habitat remains near the western margin of the Greater Penrith to Eastern Creek Urban Release Investigation Area so its presence there cannot be ruled out. A precautionary approach would treat all of the remaining suitable habitat as part of the area of occupancy of this species.

4.5 Assessment of suitable habitat

4.5.1 Suitable habitat within the study area

Assessing the suitable habitat of *Pterostylis saxicola*, given the present state of knowledge of the biology of this species, has to be a descriptive exercise. The causal processes that constrain its distribution and abundance are largely unknown but probably include physiological limits to tolerance of temperature and humidity, the availability of mineral nutrients and water, factors limiting the distribution and abundance of its obligate symbionts – its pollinators and mycorrhizal associates, and the distribution and abundance of native herbivores, pathogens and parasites. Suitable habitat has to be estimated on the basis of associations between its distribution and environmental proxies such as substrate types and plant community types, and interactions between them. Multidimensional bioclimatic modelling would extend this approach to climatic variables but such analysis is beyond the scope of this report.

Records of *Pterostylis saxicola* have been mapped to six plant community types recognised in the Bionet Vegetation Classification, two of which are known to occur in the study area:

- 849 Grey Box – Forest Red Gum grassy woodland on Flats of the Cumberland Plain, on Ashfield Shale;
- 1395 Narrow-leaved Ironbark – Broad-leaved Ironbark – Grey Gum open forest on the edges of the Cumberland Plain, on Ashfield Shale-Mittagong Formation-Hawkesbury Sandstone transitional landscapes.

Pterostylis saxicola has almost always been reported from intact native vegetation (see section 2.4), which is unsurprising, given its dependence on at least two other symbiotic associates and the vulnerability of ground orchids to grazing by introduced herbivores (Duncan *et al.* 2005). It is reasonable to conclude that only intact remnants of the two plant community types listed above comprise suitable habitat for this species.

Pterostylis saxicola is known to occur naturally on four substrate types recognised by the Geological Survey of New South Wales, only one of which is known to be exposed in the study area:

- Triassic Ashfield Shale (Wianamatta Group).

The intersection of either of the above plant community types with Ashfield Shale indicates suitable habitat for *Pterostylis saxicola*.

4.5.2 Species polygons

My species polygons for *Pterostylis saxicola* (figure 6) include all patches of PCTs 849 and 1395 growing on Ashfield Shale in the Greater Penrith to Eastern Creek Urban Release Investigation Area and Western Sydney Aerotropolis Growth Area. They were prepared with the assistance of Darren James (DAJ Environmental), using the ArcMap software package, from vegetation maps of the study area produced by Biosis Pty Ltd. A shape file for these polygons is held by the Biodiversity and Sustainability Branch of the NSW Department of Planning and Environment.

My arguments justifying these polygons have been set out in sections 2.3, 2.4, 4.1, 4.3, 4.4 and 4.5.1.

4.5.3 Estimate of area of habitat

The areas estimated to represent suitable habitat for *Pterostylis saxicola* in figure 7 are as follows:

- Greater Penrith to Eastern Creek Area Urban Release Investigation Area
    - Habitat mapped – 14.3 ha
    - Habitat impacted by development footprint – 0.8 ha
- Western Sydney Aerotropolis Growth Area
    - Habitat mapped – 0 ha
    - Habitat impacted by development footprint – 0 ha

These estimates were calculated with the assistance of Darren James (DAJ Environmental), using the ArcMap software package, from vegetation maps of the study area produced by

Biosis Pty Ltd. My arguments justifying the polygons from which these estimates were calculated have been set out in sections 2.3, 2.4, 4.1, 4.3, 4.4 and 4.5.1.

5. Information used in this assessment

My assessment was based on information obtained from a diversity of sources:

- Databases of observational and vouchered specimen records of *Pterostylis saxicola*:
    - National Herbarium of New South Wales specimen database;
    - Bionet Wildlfie Atlas;
- Interviews with collectors, observers, propagators and scientists of *P. saxicola* (see section 6, acknowledgements);
- Fieldwork at 42 sites (see Appendix 1):
    - Seven sites at which *P. saxicola* had previously been collected;
    - 14 sites in or near the study area that had potentially suitable habitat;
- The scientific and scholarly literature (see section 7, references);
- A GIS map of the study area with layers representing the boundaries, plant community types, development footprint, and the results of flora and fauna surveys, prepared by Biosis Pty Ltd, provided through the Biosis spatial viewer;
- Background information on the study area provided by the Biodiversity and Sustainability Branch of the NSW Department of Planning and Environment;
- My personal knowledge and experience, gained from 40 years as a professional botanist specialising in the systematics and ecology of the Orchidaceae.

6. Acknowledgements

I am grateful to Teresa James, Andrew Orme, Peter Ridgeway, Karen Sommerville, Greg Steenbeeke and Brian Towle, for generously sharing their knowledge about *Pterostylis saxicola* with me. Darren James (DAJ Environmental) and Phillip Rofe (Biodiversity and Sustainability Branch, NSWDPE) assisted me in producing species polygons and area estimates using the ArcMap software package. Judith Fulham kindly permitted and assisted me to survey the habitat of *P. saxicola* on her property at Cattai. Jenny Linklater and Igor Maric kindly facilitated my visit to Hawkesbury High School, Freemans Reach, after school hours to survey the population of *P. saxicola* there. I am grateful to Laura Torrible, Dayle Green and Greg Steenbeeke for the provision of support and advice throughout this project.

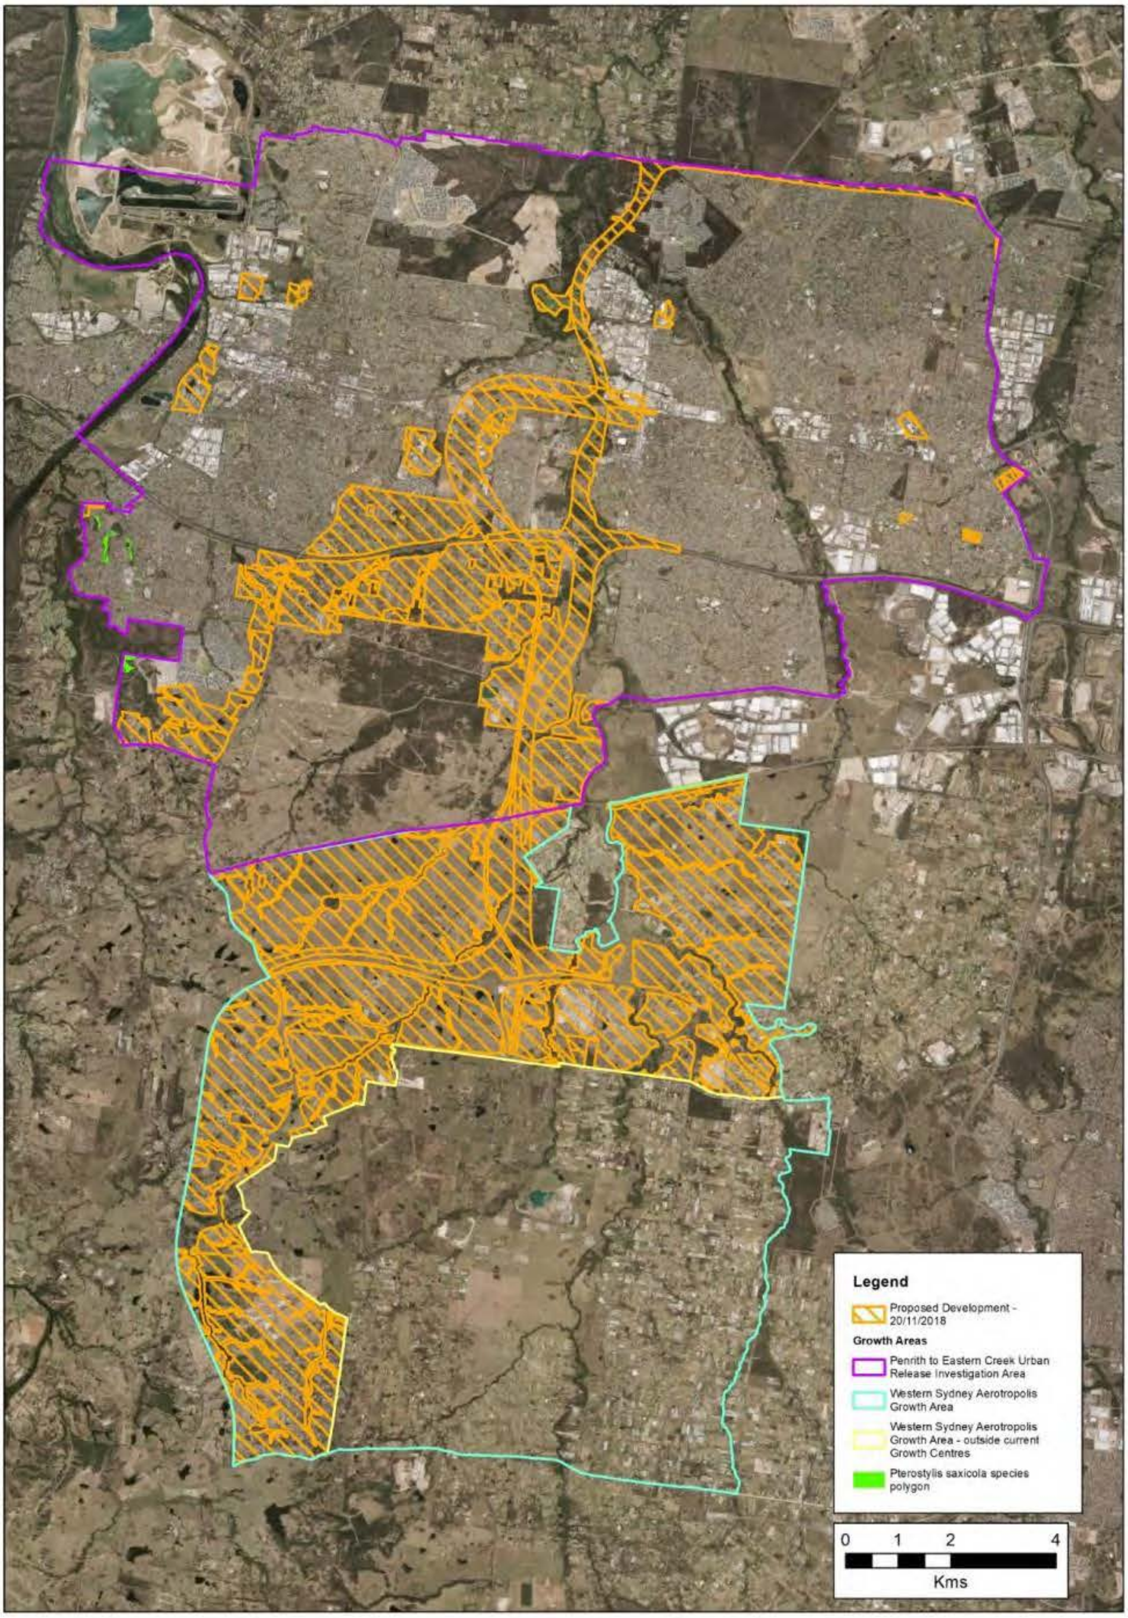

Figure 6. Polygons of suitable habitat for *Pterostylis saxicola* in the Greater Penrith to Eastern Creek Urban Release Investigation Area and Western Sydney Aerotropolis Growth Area.

8. Appendices

8.1 Appendix 1: Characterisation of habitat at selected sites

The tables on following pages record data that I collected at sites both within and outside the study area. Each site was centred on an arbitrarily selected plant of *Grevillea juniperina* subsp. *juniperina* or *Pterostylis saxicola*, or at an arbitrarily chosen point where the focal taxon was absent from the site. At each site the precise latitude and longitude, altitude, substrate, and soil description, were recorded. Also, at each site all plant species that could be reliably identified were recorded within a radius of 30 metres. Locations at which *Pterostylis saxicola* has been recorded by me and/or others have had their latitudes and longitudes transformed to the nearest 10 minutes.

Appendix 1b (continued from previous page): Data on presence (1) or absence (0) of associated species for sites characterised as part of this study.

8.2 Appendix 2: Peter Weston's curriculum vitae

Personal details

Name: Peter Henry Weston.

Address: 18 Lyle Avenue, Lindfield, New South Wales 2070, Australia.

Date and place of birth: 22 October 1956, Lower Hutt, New Zealand.

Immediate family: wife (Susan) and three children (Timothy 34, Caitlin 32, Nicholas 29).

Nationality: Australian.

Interests: soccer, reading, guitar, orchid growing, cross-country skiing, bush walking.

Academic Qualifications

i) **B.Sc.** (first class honours; equal first in order of merit) School of Biological Sciences, University of Sydney; 1975-78, conferred 7 April 1979.
Thesis title: "The evolution and classification of *Boronia* Sm."

ii) **Ph.D.**, School of Biological Sciences, University of Sydney, 1979-83; conferred 18 May 1985.
Thesis title: "Systematics and biogeography of the Persooniinae (Proteaceae)".

Awards, Fellowships and Scholarships

2014	Nancy Burbidge Medal (awarded by the Australasian Systematic Botany Society to a person who has made a longstanding and significant contribution to Australasian systematic botany. It is the foremost award that can be conferred by ASBS).
2014	Australian Biological Resources Study-sponsored Winston Churchill Fellowship for an established career researcher in taxonomy.
2009	Grady L. Webster Structural Botany Publication Award for 2008 and 2009 from the Botanical Society of America. The BSA component of the award (it is awarded in alternate years by the BSA and the American Society of Plant Taxonomists) recognizes the most outstanding paper published in the *American Journal of Botany* in the field of structural and developmental botany (i.e., anatomy and morphology) over a two-year period. It was awarded to Gregory J. Jordan, Peter H. Weston, Raymond J. Carpenter, Rebecca A. Dillon and Timothy J. Brodribb for: "The evolutionary relations of sunken, covered, and encrypted stomata to dry habitats in Proteaceae," American Journal of Botany, Volume 95, Issue 5; May 2008.
2006	Carrick Award for Australian University Teaching from the Australian Learning and Teaching Council (one of five members of a teaching team from the University of New England cited for Outstanding Contributions to Student Learning).
1992-93	Posting to Royal Botanic Gardens, Kew, as Australian Botanical Liaison Officer.
1982	Charles Gilbert Heydon Travelling Fellowship for the biological sciences (not taken up).
1980-82	University of Sydney Postgraduate Scholarship.

1979-82	Commonwealth Postgraduate Award.
1977	G.S. Caird Scholarship for Third Year Botany, University of Sydney.
1976	Slade Prize for Practical Plant Biology, University of Sydney.

Employment

Present Position: Honorary Research Associate, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney and independent botanical consultant.

Previous positions held:
2008-2016 Senior Principal Research Scientist, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

2000-2008 Principal Research Scientist, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

1994-2000 Senior Research Scientist, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

1989-1994 Research Scientist, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

1982-1989 Scientific Officer, National Herbarium of New South Wales, Royal Botanic Gardens and Domain Trust, Sydney.

1979-82 Part-time demonstrator, School of Biological Sciences, University of Sydney.

Adjunct and visiting university appointments

2013-	Adjunct Associate Professor, La Trobe University.
2011-2016	Adjunct Associate Professor, University of New South Wales.
2006	Visiting Lecturer, Rhodes University, Grahamstown, South Africa.
2004-2009	Adjunct Associate Professor, University of New England.
2000-2004	Adjunct Senior Lecturer, University of New England.

Administrative/management experience

2009	Acting Manager Plant Diversity
2002-2003	Member, Plant Diversity Research Program Leaders Committee
1998-99	Systematics Liaison Officer
1997-98	Member RBGS Market testing working party
1997	Member, RBGS advisory committee for restructuring senior management
1990-91	Systematics Co-ordinator
1996-98	Member, RBGS Joint Consultative Committee

Membership of Learned Societies

1996-	Society of Australian Systematic Biologists
1984-	Willi Hennig Society (Elected Fellow, 1992-, Council member, 1998-2000)
1979-	Society of Systematic Biologists (member, Editorial Board 1993-95)

1978- Australasian Systematic Botany Society (formerly Australian Systematic Botany Society: President, 2009-2012, Vice President, 2008-2009, Chairman, Hansjörg Eichler Research Fund Committee, 1998-2002, Council member, 1996-2002)

Membership of External Committees

2015- Financial Grants Standing Committee (formerly the Grants Policy Standing Committee) of the Australasian Systematic Botany Society

2012-2013 Conference Organising Committee of *Systematics Without Borders*, a joint conference of the Australasian Systematic Botany Society, Society of Australian Systematic Biologists and Invertebrate Biodiversity and Conservation, University of Sydney (Chairman)

2011- Editorial Board, *Phytotaxa*

2008-2009 Corresponding Member, Editorial Advisory Committee, *Australian Systematic Botany*

2006-2014 Ira Butler Memorial Trophy Committee (a joint committee of the Australasian Native Orchid Society and the Orchid Society of New South Wales) (Chairman)

2004- Editorial Advisory Board, *Kew Bulletin*

2001-2006 Panel of Judges, Eureka Prize for Biodiversity Research

2000-2012 Bushland Management Advisory Committee, Lane Cove Council (Chairman, 2008-2010)

1999-2004 Editorial Advisory Committee, *Australian Systematic Botany*

Spoken presentations at conferences (not including presentations delivered by others)

2015 Building Our Botanical Capital, annual conference of the Australasian Systematic Botany Society: “A database of variation in floral characters in the Proteaceae, and implications for key questions in floral evolution”.

2014 Next Generation Systematics, annual conference of the Australasian Systematic Botany Society: Nancy Burbidge Memorial Lecture: “Problems and progress in plant systematics since Nancy Burbidge”

2013 Genetics Society of Australasia conference, Sydney *Genetics in the Harbour City*: “Molecular phylogeny of the subtribe Hakeinae (Green Plants: Proteaceae tribe Embothrieae) and its implications”.

2013 Joint conference of the Australasian Systematic Botany Society, Society of Australian Systematic Biologists and Invertebrate Biodiversity and Conservation, Sydney, *Systematics Without Borders*: “Molecular phylogeny of the subtribe Hakeinae (Green Plants: Proteaceae tribe Embothrieae) and its implications”.

2012 Australasian Systematic Botany Society conference, Perth, *Local knowledge, global delivery*: “Contested, Uncontested and Potentially Controversial Taxonomic Changes in the Proteaceae: How Do They Differ?”

2011 37th annual conference of the South African Association of Botanists, *Plants in a Changing World* and 9th conference of the South African Society of Systematic Biologists, *Biodiversity Matters*; plenary address: “Cenozoic environmental change and the systematics of southern hemisphere plants”

2011 XVIII International Botanical Congress, Melbourne: “Floral evolution in animal-pollinated Australian angiosperm clades: patterns and potential explanations”.

2010 VI Southern Connection Congress, Bariloche: “Cladistic biogeography, molecular dating, fossils and the Proteaceae”

2010 VI Southern Connection Congress, Bariloche: “Diversification of the Proteaceae in Mediterranean hotspots of the Southern Hemisphere and in tropical rainforests”

2010 Australian Systematic Botany Society conference *Systematic Botany Across the Ditch: Links Between Australia and New Zealand*; Keynote address: "Cenozoic environmental change and the systematics of southern hemisphere plants"
1999 XVI International Botanical Congress, Saint Louis: "Historical biogeography of Proteaceae".
1997 II Southern Connection Congress, Valdivia: "Cladistic biogeography of a key woody group: Proteaceae".
1997 First Biennial International Conference of the Systematic Association, Oxford: "Rolf Sattler's Plant Morphology and Cladistic Analysis".
1996 *An International Symposium on the Biology of Proteaceae*, Melbourne: "ITS squence variation in the Proteaceae and what it tells us about phylogeny".
1993 Joint conference of The Systematics Associations and The Linnean Society on *Models in Phylogeny Reconstruction*, London: "Direct methods for polarising character transformation series".
1990 IXth meeting of the Willi Hennig Society, Canberra: "Transoceanic cladistic patterns in the Proteaceae".
2003 The Third International Conference on *the Comparative Biology of the Monocotyledons*, Ontario: "Co-evolution of *Chiloglottis* (Orchidaceae) and its Thynnine wasp pollinators".
2005 XVII International Botanical Congress, Vienna: "Food is good but sex is better: the evolution of deceptive pollination in the tribe Diurideae (Orchidaceae)".
2006 Australian Systematic Botany Society conference, Cairns, *Plant Diversity in the Tropics*: "A new suprageneric classification of the Proteaceae".
2007 5th Southern Connection Congress, Adelaide: "'I'm not dead yet' – Gondwana (the Proteaceae are at least partially congruent with Gondwanic fragmentation)".
1989 Australian Systematic Botany Society symposium, on *Gondwanan Elements in the Australian Flora*, Sydney: "Transpacific cladistic patterns in the Proteaceae and Elaeocarpaceae".
1988 Symposium on *Panbiogeography of New Zealand*, Wellington: "Problems with the statistical testing of panbiogeographic hypotheses".
1985 Australian Flora Foundation Symposium on *Waratahs*, Canberra: "Drifting waratahs or continents?"
1984 Australian Systematic Botany Society symposium on *Cladistics, Systematics and Phylogeny*, Canberra: "A reappraisal of Nelson's direct method of character analysis".

Refereeing manuscripts, grant applications, reports and examining postgraduate theses (last five years)

2018: *Candollea*; *Flora of the Hunter Region*; *Journal of Biogeography.*
2017: *Australian Systematic Botany*; *Evolution*; *New Zealand Journal of Botany*; *Nuytsia*; *South African Journal of Botany.*
2016: *Australian Systematic Botany*; *Botanical Journal of the Linnean Society*, *National Research Foundation* (South Africa).
2015: *American Journal of Botany*; Australian Research Council (4); *Australian Systematic Botany*; *Muelleria*; *Nuytsia*; *Phytotaxa*; *PLOS One*; *Telopea* (6).
2014: Australian Research Council (3); *Australian Systematic Botany* (2); *Cunninghamia*; *Journal of Biogeography* (2); *Muelleria*; National Research Foundation (South Africa); *Orchadian*; *Perspectives in Plant Ecology, Evolution and Systematics*; *Plant Systematics and Evolution*; *Telopea* (3).

Research

My research has been in the theoretical and practical aspects of systematic botany, with emphasis on the theory and practice of phylogenetic analysis, and the broader uses to which phylogenetic knowledge may be applied. I have phylogenetically analysed groups in the plant families Proteaceae, Fabaceae, Orchidaceae, Rutaceae, Winteraceae and Lauraceae, contributed to more general analyses of angiosperm phylogeny, and used the results of these analyses to improve biological classification and to test theories of historical biogeography, trait evolution, co-evolution and adaptation. I have earned an international reputation for my contributions to both theoretical and empirical developments in this field.

Herbarium curation and collections

My curatorial responsibilities at the National Herbarium of New South Wales have included the families Rutaceae (1982-1998), Proteaceae (1982-2016), Orchidaceae (1986-2016) and Fabaceae subfamily Faboideae (1986-2016). I have collected plant specimens (mostly angiosperms) in Australia, England, New Zealand, New Caledonia, Chile, South Africa, and Argentina, mostly for the herbarium and living collections of the Royal Botanic Gardens and Domain Trust, Sydney. Duplicates of my collections have been distributed to over 20 herbaria in 8 different countries.

Teaching

I have been actively involved in the preparation and teaching of four third year undergraduate courses in biosystematics:
Western Sydney University (2015-2018): “Principles of Evolution” (unit 300980), “Botany” (unit 300836).
University of New South Wales (2010-2016): “Assembling the Tree of Life” (BIOS3221)
University of New England (2000-2010): Biosystematics (Biosyst 301, Biosyst 302, Evol 301/501).
Botany Department, Rhodes University, Grahamstown, South Africa (February-March 2006): “Plant Biodiversity” course in collaboration with Associate Professor Nigel Barker.

I am currently co-supervising one postgraduate student:
Nanette Thomas (Ph.D., University of New England): Systematics of *Tasmannia* informs Biogeography of Winteraceae.

Postgraduate and honours students I have previously co-supervised include:
Margaret Stimpson (Ph.D., University of New England): Systematics, evolution and ecology of the *Banksia spinulosa* complex (graduated 2017).
Melita Milner (Ph.D., Australian National University): Phylogeography of *Lomatia and Telopea* (Proteaceae) in south eastern Australia (graduated 2015).
Samanta Oon (B.Sc. Honours, University of New South Wales): *Lomatia* likes it both ways: rampant bidirectional introgression of chloroplast genomes between two morphologically distinct species of Lomatia (Proteaceae) (graduated 2015).
Zoe Reynolds (B.Sc. Honours, Australian National University): Phylogenetic, taxonomic and functional turnover in Proteaceae assemblages (graduated 2013).
Emma McIntosh (B.Sc. Honours, University of Sydney): Hybridization and introgression between *Lomatia myricoides* and *L. silaifolia* (Proteaceae) (graduated 2011).
Margaret Stimpson (M.Sc.Stud., University of New England): Review of the *Banksia spinulosa* species complex (Proteaceae) (graduated 2011).
James Indsto (M.Sc., University of Wollongong): Pollination Ecology and Molecular Systematics of *Diuris* (Orchidaceae) of the Sydney Region (graduated 2010).
Nanette Thomas (Grad.Dip.Sci., University of New England): Phylogenetic analysis of Winteraceae (graduated 2009).

David McKenna (Ph.D., University of Wollongong: Demographic and ecological indicators for rarity in obligate-seeding *Persoonia* (Proteaceae) shrubs of the Sydney region, graduated 2007).
Paul Rymer (Ph.D., University of Wollongong: Plant rarity: species distributional patterns, population genetics, pollination biology and seed dispersal in *Persoonia* (Proteaceae), graduated, 2006).
Georgina Lloyd (B.Sc. Honours, University of Sydney: Pseudocopulation in two species of *Cryptostylis*: Implications for maintaining species integrity, graduated 2004)
Andrew Perkins (Ph.D., University of Sydney: Phylogenetic Systematics of the Genus *Calochilus* (Orchidaceae), graduated 2002).
Jim Mant (Ph.D., Australian National University: Comparative biology of *Chiloglottis* (Orchidaceae) and its thynnine wasp pollinators (Tiphiidae), graduated 2002).
Siegfried Krauss (Ph.D., University of Wollongong: Systematic pattern and evolutionary process in the complex species *Persoonia mollis* (Proteaceae), graduated 1995).

I have examined 14 honours and postgraduate theses:
Australian National University (Ph.D., 2003, 2007, 2008)
University of Melbourne (Ph.D., 1995, 2011)
University of Newcastle (M.Phil., 2003)
University of Queensland (Ph.D., 2003)
University of Sydney (Ph.D., 1991, 1994, 1997, 2009)
University of Wollongong (B.Sc. Hons., 2001, 2003)
Victoria University (Ph.D., 2007)

Competitive Research and Infrastructure Grants

Peakall, R., Pichersky, E., Linde, C., Weston, P.H. (2015-2019) The biosynthesis and evolution of novel semiochemicals in orchids. $644,800, Australian Research Council Discovery Grant DP150102762.

Hoebee, S.E., Weston, P.H., & Edwards, T.J. (2015-18) Evolution in action or the demise of iconic Australian flora? $217,700, Australian Research Council Discovery Grant DP150100508.

He, T., Lamont, B., Weston, P.H., & Cowling, R. (2012-2014) Origin and evolution of plant functional traits in relation to fire. $310,000, Australian Research Council Discovery Grant DP120103389.

Rossetto, M., Crayn, D.M. & Weston, P.H. (2008-2010) Integrating molecular and morphological data for generic delimitation and species identification in Lauraceae. $73,333, Australian Biological Resources Study.

Cantrill, D., Murphy, D. & Weston, P.H. (2008-10) Understanding the origins of the Australian flora by integrating molecular phylogenies and fossil data in the Proteaceae. $88,900, Hermon Slade Foundation.

Rossetto, M. & Weston, P.H. (2007-2009) Speciation in the Australian flora: testing explanatory hypotheses in waratahs and their allies. $78,000, Hermon Slade Foundation.

Considine, J.A., Krauss, S.L. & Weston, P.H. (2002-2004) A biological basis for the efficient breeding of native plants for export markets: a case study with the Australian Goodeniaceae. $168,126, ARC – Linkage (Krauss and Weston representing industry partners)

Whelan, R.J., Ayre, D.J., England, P., Auld, T.D., & Weston, P.H. (2000-2002) Ecology and genetics of fire-sensitive *Persoonia* species: threatened species recovery and management. $126,480, Australian Research Council (ARC– SPIRT, Auld and Weston representing industry partners).

Trent, R. *et al.* (2000) Enhancement of DNA sequencing equipment for the Sydney University and Prince Alfred Molecular Analysis Centre. $600,000, Australian Research Council (ARC-REIF).

Weston, P.H. (1999-2001) Comparative biology of *Chiloglottis* (Orchidaceae) and its thynnine wasp pollinators (Tiphiidae). $75,000, Hermon Slade Foundation.

Weston, P.H. (1997-2000) Taxonomic revision of *Dillwynia* (Fabaceae: Faboideae: Mirbelieae). $62,836, Australian Biological Resources Study.

Weston, P.H. & Thomson, J.A. (1993) A molecular approach to the evolution and biogeography of the Queensland tree waratahs. $4000, Queensland Wet Tropics Management Authority

Weston, P.H. & Thomson, J.A. (1991-92) A molecular approach to the evolution and biogeography of the waratahs. $80,100, Australian Research Council (large grants scheme).

Weston, P.H. (1984) Establishment of a data bank for eucalypt specimens held by NSW. $20,000, Australian Biological Resources Study.

Scientific Publications

About the Authors

Ascelin Gordon is an RMIT University Vice Chancellor's Senior Research Fellow within the ICON Science research group that sits within the Centre for Urban Research, in the School of Global Urban and Social Studies. He undertakes research on a range of conservation problems with a particular focus on ecological modelling, decision making for conservation, and biodiversity offsetting.

Isaac Peterson is a research fellow at RMIT University with who specializes on statistical approaches to ecological modelling and undertakes research that focusses on modelling the outcomes of biodiversity offsetting.

Acknowledgments

A range of people have been invaluable in pulling together the data required for this study and providing input into the expert elicitation. In particular we would like to thank: Tom Holden (Open Lines), Peter Hemphill (Open Lines), Rebecca Dwyer (Biosis), Darren James (DAJ Environmental), and James Shephard (Biosis), and in addition Jonathan Sanders, Greg Steenbeeke, Charles Morris, Paul Price, Peter Ridgeway, David Kirkland and David Keith, who contributed their time and knowledge to the expert elicitation process reported here.

TABLE OF CONTENTS

SUMMARY

The NSW Government has identified four urban Growth Areas, a new rail line and a series of road and rail Transport Corridors to support planned future growth in Western Sydney over the next 37 years.

As part of this process, the NSW Department of Planning, Industry and Environment (DPIE) is preparing the Cumberland Plain Conservation Plan (the Plan) to support two separate statutory approvals processes under State and Commonwealth laws to address the impacts of the proposed development on biodiversity values.

The Plan describes the proposed urban and transport development and a set of commitments and actions to achieve the Plan's objective and offset the impacts of the proposed development on biodiversity values.

This report presents the results of a trend analysis examining long-term changes in the extent and condition of a native vegetation community in the Cumberland subregion under various scenarios that approximate the development impacts of the Growth Areas and the conservation benefits of the offsets under the Plan.

The native vegetation community examined is Plant Community Type (PCT) 849 *Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion*. This is one of two PCTs that make up the threatened ecological community *Cumberland Plain Woodland in the Sydney Basin Bioregion* as defined under the Biodiversity Conservation Act (the other being PCT 850). PCT 849 is also part of the threatened ecological community *Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest* under the EPBC Act, although size and condition thresholds apply to the definition of the community under this Act.

PCT 849 is referred to in this report as 'CPW' hereafter.

The purpose of the trend analysis is to better understand, in relation to CPW extent and condition:

- Underlying trends in the subregion
- The significance of existing landscape scale threats relative to urban development
- Potential benefits of securing offsets early relative to late in program implementation
- The outcomes of different management regimes in offset areas in different existing condition states, including the potential benefits of restoring low condition sites through high intensity management

In this report, the condition of CPW is characterized using an approximation of the vegetation integrity score defined in the NSW Biodiversity Assessment Method (BAM).

The report consists of two major outputs: (i) a formal expert elicitation to gather quantitative knowledge regarding how the condition of CPW will change over time under high or low intensity management, and where subject to typical ongoing private land activities; and (ii) quantitative modelling to simulate the urban development within the Growth Areas, compensation via managing areas as offsets in a strategically defined offset region, and the ecological response of CPW.

The modelling includes 10 scenarios, with 8 of these exploring different options for implementing biodiversity offsets. These 8 scenarios vary the timing of when the offsets are implemented, the total area of offsets implemented, and the type of management implemented for the offsets (low or high intensity). The 10 scenarios examined were:

1. Do nothing — continuation of typical private land activities, with no development or offsetting.
2. Development only — development in Growth Areas, with no offsets. All subsequent scenarios use the same development model.
3. Development in Growth Areas with strategic offsets secured early, subject to low intensity management. Offsets are all implemented in the first time-step of the simulation.

4. Development in Growth Areas with strategic offsets secured incrementally, subject to low intensity management. Offsets are implemented at an approximately constant rate, such that all parcels are offset by the end of the 37 years of simulation.
5. Development in Growth Areas with strategic offsets secured early, subject to high intensity management. This is the same as Scenario 3, but with offsets subject to high intensity management.
6. Development in Growth Areas with strategic offsets secured incrementally, subject to high intensity management. This is the same as Scenario 4, but with offsets subject to high intensity management.

Four additional scenarios were also defined: scenarios 3A, 4A, 5A, and 6A. These are identical to scenarios 3-6, respectively, except that only half the parcels (randomly selected) in the strategic offset area are implemented as offsets.

The key findings of this trend analysis for CPW can be summarized as follows:

- Landscape-scale threats across the Cumberland subregion, such as weed invasion, grazing, rubbish dumping, and disturbance from recreational activities are causing significant declines.
- The negative impact of development in the Growth Areas is of a similar scale to ongoing declines from landscape scale threats across the whole Cumberland subregion over 37 years. Landscape scale threats are projected to result in a 5.8 % drop in summed vegetation integrity score over 37 years. The additional impact of development adds further losses of almost the same magnitude (another 5.78 %).
- The Plan is generally unlikely to reverse declines from landscape scale threats across the whole Cumberland subregion because the magnitude of these threats is large and the Plan only influences a proportion of the subregion. The only scenario where declines were always reversed at the landscape scale was scenario 5, where it was assumed that: (i) all parcels in the strategic offset area are implemented as offsets, (ii) all offsets were implemented immediately; and (iii) all offsets had high-intensity management. This comprises the outer bound of the best-case scenario, and may not be feasible to implement.
- In terms of whether the Plan addresses the impacts of development in the Growth Areas alone within the program area (ignoring declines from landscape scale threats), two of the four offset scenarios (scenarios 5 and 6) provided adequate compensation irrespective of whether 100% or 50% of the CPW was secured as offsets in the strategic offset area. When 100% of the CPW available in the strategic offset area is secured as an offset, three of the four offset scenarios compensate for development impacts (all except scenario 4). When 50% of the CPW available in the strategic offset area is secured as an offset, only two of the four offset scenarios provide adequate compensation.
- In terms of whether the Plan addresses the impacts of development in the Growth Areas as well as declines from landscape scale threats within the program area, three of the four offset scenarios (scenarios 3, 5, and 6) compensate for both these impact types when 100% of the CPW in the strategic offset area is secured. However, none of the offset scenarios can compensate for both these impact types in the program area if only 50% of the CPW in the strategic offset area is secured.
- The timing of offset implementation and the level of management intensity make a significant difference to the gains able to be achieved by offsets, with early implementation/high intensity management always performing best.
- The relative benefit of early implementation compared to high intensity management depends on the time period over which gains are evaluated. The results suggest that:
  - Early implementation with low or high intensity management delivers greater gains in the short term (1 to 2 decades).
  - Early implementation with high intensity management delivers the greatest gains in the long term.
- Results of expert elicitation indicate that high intensity management provides significant potential for providing restoration gains for CPW, even when starting from a low initial condition. However, low intensity management has limited capacity to improve the ecological condition of CPW, especially when starting from a low initial condition.

INTRODUCTION

BACKGROUND AND CONTEXT

The NSW Government has identified four Growth Areas, a new rail line – the Sydney Metro Stage 1 Western Sydney Airport Stage 1 (Sydney Metro Stage 1), and a series of road and rail Transport Corridors to support planned future growth in Western Sydney for the next 37 years (Figure 1). These initiatives are identified under two key planning strategies:

- *A Metropolis of Three Cities - The Greater Sydney Region Plan* (Greater Sydney Commission, 2017)
- *Future Transport 2056* (Transport NSW, 2017)

The Growth Areas program represents the strategic prioritisation and delivery of new development as part of the long-term growth of Greater Sydney provided under the Greater Sydney Region Plan. The Growth Areas are the key focus for development over the coming 37 years and will be the centres of economic activity in Western Sydney. The Growth Areas occur largely within the Cumberland subregion and are:

- Wilton
- Greater Macarthur (GMAC)
- Western Sydney Aerotropolis (WSAGA)
- Greater Penrith to Eastern Creek Urban Release Investigation Area (GPEC)

the NSW Department of Planning, Industry and Environment (DPIE) is progressing the planning and environmental approvals required for the proposed development. As part of the biodiversity approvals required, DPIE is preparing the Cumberland Plain Conservation Plan (the Plan) to provide long-term certainty for biodiversity and development in Western Sydney.

The Plan will support two separate statutory approvals processes under State and Commonwealth laws required to address the impacts of the proposed development on biodiversity values:

- Strategic biodiversity certification under Part 8 of NSW Biodiversity Conservation Act 2016 (BC Act)
- Strategic assessment under Part 10 of the Commonwealth *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act)

The objective of the Plan is to:

> *Deliver biodiversity outcomes and support the ecological function of the Cumberland Plain, improving liveability and facilitating urban development in Western Sydney*

The Plan describes the proposed urban and transport development and a set of commitments and actions to achieve the Plan's objective and offset the impacts of the proposed development on biodiversity values. This includes identifying Conservation Investigation Areas within which offsets will be strategically secured through several mechanisms, including reservation of land and Biodiversity Stewardship Agreements. These Conservation Investigation Areas are referred to hereafter as the 'strategic offset area'.

AIMS OF THIS RESEARCH

This report presents the results of a trend analysis examining long-term changes in the extent and condition of a native vegetation community in the Cumberland subregion under various scenarios that approximate the development impacts of the Growth Areas and the conservation benefits of the offsets under the Plan.

The native vegetation community examined is PCT 849 *Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion*. This is one of two PCTs that make up the threatened ecological community *Cumberland Plain Woodland in the Sydney Basin Bioregion* as defined under the BC Act (the other being PCT 850). PCT 849 is also part of the threatened ecological community *Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest* under the EPBC Act, although size and condition thresholds apply to the definition of the community under this Act.

This community is referred to in this report hereafter as CPW.

The purpose of the trend analysis is to better understand, in relation to CPW extent and condition:

- Underlying trends in the subregion
- The significance of existing landscape scale threats relative to urban development
- Potential benefits of securing offsets early relative to late in program implementation
- The outcomes of different management regimes in offset areas in different existing condition states, including the potential benefits of restoring low condition sites through high intensity management

This information can be used to support key decisions in developing the Plan, as well as inform the evaluation of the adequacy of the Plan in accordance with the requirements of the BC Act and EPBC Act.

The trend analysis builds on work already undertaken for other development projects that models the impact of development and mitigation in the form of biodiversity offsets on native vegetation (Gordon, 2015; Gordon et al., 2011a, Gordon et al., 2011b). This present work extends these existing approaches to model changes in the condition of CPW using more sophisticated metrics of ecological condition, that are an approximation of the metrics specified for vegetation integrity in the BAM (BAM; OEH, 2017).

The report consists of two major outputs: (i) a formal expert elicitation to gather quantitative knowledge regarding how the condition of CPW will change over time, under high or low intensity management, and under the case where CPW is exposed to typical ongoing private land activities; and (ii) quantitative modelling to simulate the urban development within the Growth Areas, compensation via managing areas as offsets in a strategically defined offset region, and the ecological response of CPW.

BACKGROUND THEORY

The aim of a biodiversity offset is to counterbalance a specified biodiversity loss (usually after appropriate avoidance measures have been considered (Bull et al., 2013)). When the gains attributed to the offset fully mitigate the losses attributed to the development, the offset is considered to have achieved 'No Net Loss' of biodiversity (Bull et al., 2014). However, it is important to note that there are multiple ways in which the gains and losses can be calculated and No Net Loss defined. This potentially has a large influence on whether No Net Loss can be said to have been achieved (Maron et al., 2018), or equivalently, it also has a large influence on the offset requirements needed to achieve No Net Loss.

It is important to note that the offset scheme under the NSW BC Act defines the term No Net Loss of biodiversity and establishes a process to determine whether this has been achieved, which involves the calculation of biodiversity credits under the BAM. In relation to biodiversity certification, the BC Act does not require that the value of offsets be calculated in terms of credits, or require the number of credits needed to achieve No Net Loss be secured (OEH, 2017). The objective of the Plan is to deliver biodiversity outcomes and support the ecological function of the Cumberland Plain rather than to specifically achieve 'No Net Loss' as defined under the BAM. However, here we start by introducing what is required to be able assess whether offsets have achieved No Net Loss and the relevant background theory for this.

To understand if No Net Loss is achieved, it is necessary to measure and compare the change attributable to the development actions with the change attributable to the offset actions associated with that development. Here we use terminology from impact evaluation and refer to this change as the *impact* (which can be either negative due to development or positive due to offsets).

To determine the impact, it is necessary to measure the difference between what happened on-ground subsequent to the development and offset interventions (the *outcome*) compared to what would have happened in the absence of the intervention (the *counterfactual*) (Baylis et al., 2016; Ferraro, 2009).

In traditional *ex-post* impact evaluation, the outcome is measured after the intervention, and the counterfactual is estimated (using a range of approaches depending on context) to provide the estimate of impact. In this case we undertake an *ex-ante* analysis to examine the impacts of different scenarios by estimating the outcome (via simulation) and comparing that to the estimated "do nothing" case where landscape scale threats and typical private land activities continue (the counterfactual).

The modelling presented in this report can be used to estimate the net impact of development and offsetting in the Cumberland subregion on CPW. The modelling incorporates three processes: (i) development which is assumed to remove all CPW on developed parcels; (ii) offsetting, for which offset parcels are assumed be managed in a way that improves the condition of CPW on the site; and (iii) the trajectory of the vegetation on parcels that are neither developed or offset, which is assumed to be a slow decline in condition due to landscape scale threats and typical private land activities such as grazing, and minimal weed and pest management, etc (excepting existing conservation areas—which are assumed to be managed). This is consistent with the expectations of Section 13.5 of the BAM (OEH, 2017). It is important to note that this modelling exercise involved an expert elicitation process to inform how CPW responds to management as an offset and to landscape scale threats in areas that are not developed or offset.

In this case the typical private land activities are assumed to be the counterfactual, i.e. what would have occurred without development or offsetting. This is schematically depicted in Figure 2, which shows the trajectory of the development parcel (in yellow, which goes to zero when development occurs), the offset parcel (in green, which gradually improves due to management), and the assumed counterfactual of slow ongoing decline without offsetting or development. The thick black dotted line shows the net outcome of the combined offset and development action. In this example, we use the definition of No Net Loss as relative to the counterfactual of ongoing decline (Maron et al., 2018). Under this definition, No Net Loss is achieved when the combined outcomes of the offset and development results in what would have happened without either offsetting or development (shown at t_2 in Figure 2). However, it is important to note that with this definition of No Net Loss, even when it has occurred, there has still been a loss of biodiversity relative to what was there before the development and impact occurred. We could also use a more stringent definition of No Let Loss which would require the offset to both compensated for loss due to development, and for the ongoing declines due to landscape scale threats. This would result in the net outcome being the same as what was present before the development and offset were implemented. In this case, the dashed line representing the net outcome would need to reach the level at which it started, shown at t_1.

In this report we use the former definition of No Net Loss, depicted in Figure 2, which involves the development and offset together achieving the same outcome as the ongoing background declines that would have occurred without them. Under this definition of No Net Loss, achieving the same outcome as what was present before the offset and development would be referred to as a Net Positive Impact (Maron et al., 2018).

The results of impacts and outcomes in this report are shown at two different scales: the ***program scale*** and the ***landscape scale***. Each scale is important and provides different information.

The ***program scale*** results are obtained by summing the vegetation integrity score multiplied by the area of CPW in ***all the developed and offset parcels only*** (this is equivalent to what is shown in Figure 2 with the loss and gain curves being assumed to come from multiple parcels). At this scale, the outcomes show the net ecological condition of all parcels developed and offset. This can be used to determine the extent to which the offsets have compensated for the development losses due to the program (but not ongoing declines that would have still occurred). If a net impact of zero is achieved, this means the development and offset(s) have together resulted in the same background decline that would have occurred with only typical private land activities occurring on the development and offset parcels. It can also be used to examine the extent to which it has averted the losses (or delivered additional gains) relative to what would have occurred without the development (in this case due to typical private land activities) on the program parcels. This only occurs if a net positive impact is generated so both development losses and the background declines can be compensated for. If the net result is the same or better than the biodiversity value before the interventions, then it is clear that both degrading processes (development and typical private land activities) have been compensated for.

The ***landscape scale*** results are obtained by summing the vegetation integrity score multiplied by the area of CPW in all parcels in the whole Cumberland subregion. This includes the parcels that are not part of the program and subject to ongoing declines due to typical private land activities. For the modelling results presented here, it also includes all the conservation areas outside the program that are assumed to be managed. Thus, if the net outcome at this scale achieves a value equal or greater than the starting value, the offset impacts have compensated not only for the development, but also for the ongoing declines of all the parcels that are not part of the program.

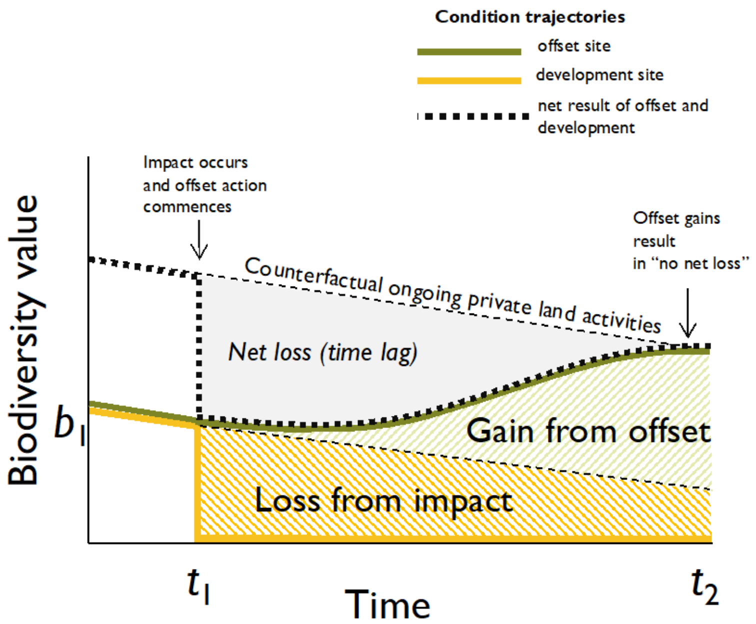

Figure 2. Schematic depiction of the biodiversity trajectory at the development site (yellow line), the offset site (green line) and net result of the offset and development (black dotted line). The counterfactual of ongoing decline is shown with the thin black dashed line. Where the net outcome is the same as the counterfactual (at t_2), no net loss can be said to occur. However, this still represents an absolute loss relative to the biodiversity value at t_1, and achieving the same outcome as what was present at t_2 would be referred to as a Net Positive Impact.

METHODS

OVERVIEW

For the modelling results presented in this report, we use the open source *R* package OffsetSim (see https://github.com/isaacpeterson/offset_simulator), developed by Isaac Peterson and Ascelin Gordon at RMIT University. This is used to simulate development, offsetting and the resulting ecological dynamics for CPW.

OffsetSim works using raster layers as one set of inputs and requires a land parcel layer, and layers showing which parcels can be developed and offset. It can also use one or more ecological features. The ecological value of a particular location is determined using a user-specified metric that can be defined over a set of one or more feature layers (e.g. using a multiple-component metric of vegetation community condition or an aggregated metric such as the BAM (OEH, 2017) or other individual features such as species-occupancy or species-abundance (Bull et al., 2016, 2013; Maron et al., 2012; Quétier and Lavorel, 2011)). Raster layers depicting the initial value of each ecological component are required, and then OffsetSim provides a model that needs to be parameterised to evolve each feature over time based on whether it is developed, managed as an offset, or not subject to any intervention. In this case, we used CPW as the ecological community of interest.

Below, we provide details of the expert elicitation used to develop the condition-change model which allows the condition (measured via an "ecological integrity score"—see below) of CPW to change over time, under each of two different management regimes, or under no management. This requires use of ecological feature layers for the richness and cover of different plant growth form groups, as specified within section 5.3.4.10 of the BAM (OEH, 2017; Oliver et al., 2019).

While OffsetSim has the capacity to select offsets for a given development such that the offsets are determined to deliver appropriate gains within some time horizon to compensate for the development losses, we do not use that feature here. Instead, the development and offset areas are pre-specified, and developments and offsets are implemented at a fixed rate throughout the simulation as described in detail below. We then use OffsetSim to evaluate the ecological impacts of these scenarios.

VEGETATION DATA

Data on the extent and condition of CPW in the Cumberland subregion was used from multiple sources. Within the Growth Areas this was based on detailed mapping of native vegetation that was informed by field surveys undertaken by Biosis in 2018 in accordance with the BAM. Within the Cumberland subregion but outside the Growth Areas, the mapping was based on existing native vegetation maps prepared by OEH, which are described in detail in Table 1.

The condition of CPW in the mapping was captured using the following categories: Intact, Thinned, Scattered Trees, Derived Native Grassland, and Urban native/Exotic. Below, these categories are explained with notes about how they were applied as part of the Biosis mapping of the Growth Areas.

- **Intact:** This condition type was assigned to areas of wooded vegetation, including regrowth, displaying a range of structural layers and likely to have fauna habitat features present (e.g. tree hollows, fallen timber, leaf litter). The canopy density is largely unmodified with a range of age classes and species present. This condition type was assigned during the desktop mapping to areas where Nearmap imagery indicated significant patches of continuous canopy and the Canopy Height Model (from LiDAR) indicated vegetation in both the upper and mid storeys.
- **Thinned:** This condition type was assigned to native vegetation in various states of modification and included: 1) wooded vegetation with a partly cleared canopy resulting in a more open structure than the

intact category of the same PCT; 2) areas of wooded vegetation that has been under-scrubbed; 3) areas of regrowth. This condition type was assigned during the desktop mapping to areas where the Nearmap imagery indicated patches of reduced density. This was typically where the Canopy Height Model indicated canopy and visible ground only, with no discernible shrub layer or structural complexity.

- **Scattered trees:** This condition type includes a single tree or small group of trees surrounded by native or exotic grassland or areas of cultivation. Typically, other structural components of the vegetation have been removed. This condition type was assigned during the desktop mapping to areas where the Nearmap imagery and LiDAR canopy polygons indicated one or a few likely native trees surrounded by cleared land.
- **Derived Native Grasslands** Areas of potential Derived Native Grassland (DNG) were identified from the Nearmap imagery and later verified in the field.
- **Urban native/exotic:** Urban native/exotic areas were areas within built up zones and residential areas that consisted of street trees, urban parks and other patches of planted vegetation that could provide habitat for native species.

There were no patches of vegetation categorized as grasslands or urban native/exotic for CPW.

Table 1. Existing native vegetation maps of the Cumberland Plain

Native vegetation dataset	Description (from VIS)
Remnant Vegetation of the Western Cumberland Subregion 2013 Update (OEH 2013)	A 2013 update to the western parts of the Remnant Vegetation of the Cumberland subregion GIS data layers (VIS_IDs 2221, 2222 and 3785) using 2011 and 2012 imagery. Update focused on removing large areas of clearing at 1:10,000-1:15,000 scale. Those areas within the Sydney Metro Catchment Management Authority boundary, which were covered by the Sydney Metro Veg V2 2013 vegetation map (VIS_ID 3817), were not updated. Provides data on native vegetation extent, type (PCTs) and condition Note: Previous update completed by the Scientific Committee and Simpson 2008 (VIS_ID 3785) was integrated into this update. Txu (<10% canopy cover of urban land) vegetation (VIS_ID 2223) is excluded from the update and this layer. Areas of significant regrowth were added.
The Native Vegetation of the Sydney Metropolitan Area Version 3.0 (OEH 2016)	Provides data on native vegetation extent, PCTs and condition for the eastern part of the Cumberland subregion. The purpose of the data is to provide a single detailed coverage of native vegetation communities in the Sydney metropolitan area using standardised vegetation classification. This classification is designed to relate to the objectives of the OEH vegetation information systems and to assist users with the assessment of threatened ecological communities listed under the NSW TSC Act and Commonwealth EPBC Act This update replaces version 2.0 (VIS_ID 3817) and creates a seamless alignment between the GIS layer and the Plant Community and Biometric Vegetation Types in the Biodiversity Assessment Method tool.

EXPERT ELICITATION

BACKGROUND

This section provides a summary of the expert elicitation process carried out to develop the ecological condition change model. This model allows the components that make up the vegetation integrity score that is defined in the BAM (OEH, 2017) to be modelled as changing through time for CPW, based on a given initial condition and a specified type of management. The expert elicitation was undertaken in two separate workshops in 2018, at the Biosis offices in Sydney.

Information was elicited from experts in a structured way such that best estimates and confidence intervals were obtained, with an opportunity for experts to refine their estimates through structured discussion. This involved using a modified Delphi procedure called "the IDEA protocol" (Investigate, Discuss, Estimate, and Aggregate) to elicit the expert judgments, in a way that has been shown to minimize contextual biases (Burgman et al., 2011; Hemming et al., 2017). This involves initially eliciting the information from the experts, and these judgments are then compiled and shown to the group anonymously, where they are discussed and visually summarised. In a second round of the elicitation, the experts then have the option to revise their estimates and update the comments on their estimates. They also have the option not to change their estimates.

The expert elicitation was led by Dr Ascelin Gordon, with Dr Isaac Peterson providing technical support. Tom Holden (Open Lines) and Rebecca Dwyer (Biosis) provided logistical support for the workshops.

SELECTION OF EXPERTS

Participants were invited to take part in the elicitation if they worked in an area that requires ecological expertise of the Cumberland subregion and had been identified as an expert by peers. Participants were sought mainly from local or state government agencies and universities.

Participants were identified by contacting an initial group of people identified by Ascelin Gordon, Tom Holden (Open Lines) and Rebecca Dwyer (Biosis). These experts were then asked to suggest additional suitably qualified experts. This process generated a list of 10 potential participants, 7 of which were available to participate in the initial workshop. The experts who participated in the first workshop were:

- David Keith (University of NSW)
- Charles Morris (University of Western Sydney)
- Peter Ridgeway (Local Land Services)
- David Kirkland (Western Sydney Parklands Trust)
- Jonathan Sanders (formerly NSW National Parks and Wildlife Service)
- Paul Price (Biosis)
- Greg Steenbeeke (on secondment to DPIE from OEH)

In a follow up workshop to finalize the elicitation, two experts were unable to attend (Peter Ridgeway and Paul Price). So, the full elicitation was only able to be completed with five experts.

In the run up to the workshop, information was compiled to brief the experts on the background of the project and provide them with details of what they would be asked to provide during the elicitation.

DETAILS OF ELICITATION

The elicitation focused on CPW, and specifically three growth form groups (*Trees*; *Grass & grass-like*; and *Forbs*) and two ecological attributes (*species richness*; and *cover* of the plant growth form type). The elicitation also used four initial conditions, and three management regimes (see below).

Information was elicited such that an approximation of the vegetation integrity score defined in the BAM (OEH, 2017; see below) could be derived, along with how it will change through time under different management regimes.

The experts were asked to provide estimates for how the ecological attributes Species Richness and a simplified value for Projected Cover changed over time for a 'vegetation zone' within CPW. The attributes are defined as follows:

- ***Plant species richness***: the mean species richness of the growth form group recorded (observed) from all the plots in the vegetation zone. This is used to calculate a 'composition condition score' in the BAM.
- ***Plant cover***: the mean cover for the growth form group recorded (observed) from all plots/transects in the vegetation zone. This is used to calculate the structure condition score of the BAM. Note that the elicitation used a simplified version of cover, being the percentage of the plot covered by the growth form group, compared to the BAM, which uses a more complex measure of cover (the sum of the individual cover values for each species in the growth form group, which can therefore be greater than 100%).

The BAM defines a *vegetation zone* as "an area of native vegetation on the subject land that is the same PCT and has a similar broad condition state" (OEH, 2017). Within a zone, the BAM specifies a plot area to be $400m^2$ (generally a standard 20m x 20m, but geometry can be varied though area remains the same), and the number of plots required for a survey varies from 1-8 depending on the overall area represented in all polygons of the vegetation zone.

The default benchmark values for each ecological component for the plant type (as drawn from the VIS-C database that informs the process) were provided as part of the elicitation. As a subset of the full canopy cover measure is being used compared to what is specified in the BAM, the experts were asked to provide estimates of what the benchmark value should be for the definition of cover we used.

The experts were asked to provide information for CPW that was in one of four initial conditions. The assumption regarding the initial conditions determined the initial value for richness or cover. After being giving an initial value for each measure, the experts were asked to provide estimates for the values of the richness and cover at 20, 40, and 60 years into the future under each of 3 different management regimes.

The initial condition states were:

- ***Low site quality:*** These are sites that were historically cleared and used for farming. They have a largely exotic ground cover and/or midstorey, and a sparse woody component. This type of site has mostly weedy grasses and a few opportunistic native forbs and grasses in the understorey. It has less than 5% cover of large old hollow-bearing trees with some canopy dieback and flowering in some years. It often includes the presence of African olives (Olea europaea subsp. cuspidata).

- ***Medium quality 1:*** This state is of similar history to *Low* but may have had less clearing of trees and less intensity of farming, and there is more resilience is clearly evident in the native groundcover clearly evident. It has a native/exotic ground layer with no dominant species, and the site has had grazing and limited fertiliser. There is some presence of perennial grass weeds (not at high density and not transformer species). There is approximately a 10% canopy cover of regrowth trees (large enough to flower but without hollows) with no presence of African Olives. It is assumed that no superphosphate or nitrogen fertilizers have been used on these sites.

- ***Medium quality 2:*** This state has been more intensively farmed and it has had the application of superphosphate. It has a greater amount of canopy regeneration and the understory has a greater presence of weeds. African olives or blackberries (*Rubus fruticosus* species complex) have a foothold and often dominate the understorey. Some native ground cover observed but limited due to the high presence of woody weeds (African olive and/or blackberry). Woody components are present and due to regrowth, often comprise a cover level greater than the benchmark for the plant community type but are not mature.

- ***High quality:*** Here the ground cover is mostly native; the site has been free of fertilizer and has had no grazing or grazing only at light to moderate intensity. The woody component is mostly native and there is little presence of African olives.

These categories were chosen as to be generally representative of current condition states that CPW would be found in within the Cumberland subregion, while being limited to no more than four condition states, due to constraints on the amount of information that could be elicited over the workshops. Figure 3 shows example photographs of CPW in each of the initial condition states.

The 3 management regimes were:

- ***Typical private land activities:*** Under this management regime, it is assumed that ongoing declines in CPW condition are expected due to a range of threatening processes. It is also assumed that there is a continuation of the typical practices as currently employed by most landholders. This includes grazing, often at high intensities; minimal weed management for agricultural weeds; and minimal pest management for agricultural pests.
- ***Low-intensity management:*** This primarily comprises threat management that focuses on control of aggressive weeds and exclusion or restriction of grazing, i.e. managing issues that change the structural and functional composition of the community. It is assumed that this management is consistent with the 'required management actions' for a biodiversity stewardship site under the BAM.
- ***High-intensity management:*** This involves the same threat management as low-intensity management, but also includes regenerative weed control, active planting of the site (via direct seeding or by using tubestock) and other techniques to increase diversity (e.g. fire, creating habitat, fauna reintroduction). It is assumed that this management is consistent with what is required for 'active restoration management' at a biodiversity stewardship site under the BAM, what are in addition to the actions required under low-intensity management.

The required management actions specified in the BAM for low-intensity management are given in Table 2 and in Table 3 for high-intensity management (OEH 2017).

Table 2. Required management actions and types of management activities for improving vegetation integrity and threatened species habitat at a biodiversity stewardship site. Source: OEH (2017).

Required management action	Types of management activities that may be undertaken as part of the required management action for ecosystem credits and species credits
Preparation of a management plan	Preparation of a management plan for the biodiversity stewardship agreement for the site
Fire management	Undertake ecological burning activities, including where identified, the prevention of fire
Grazing management	Fencing to exclude stock, or strategic grazing of stock
Native vegetation management	Restore/rehabilitate native vegetation Retain and manage regrowth Undertake nutrient control Threatened species habitat management activities related to native vegetation
Threatened species habitat management	Protection of breeding habitat features or sites Undertake any other required management action identified in the Threatened Biodiversity Data Collection to create species credits or ecosystem credits required for that threatened species
Integrated pest animal control	Undertake feral pest management including control of foxes, cats, pigs, goats, avian pests, horses and any other miscellaneous species as required
Integrated weed management and control of high threat weeds	Undertake weed management and activities to control high threat exotic and other exotic vegetation Fine-scale intensive removal of high threat exotic and other exotic vegetation
Management of human disturbance	Exclude development and clearing activities except those listed as permissible in the biodiversity stewardship agreement Identify sensitive locations and protect from disturbance Undertake rubbish removal Implement measures to restrict access to the site where necessary (vehicles, etc.)
Monitoring	Monitoring for evidence of disease Assessment of the management plan and activities against the performance measures Establishment of permanent plots to provide a baseline for assessing biodiversity outcomes Establishment of 360° photo points Review of the management plan and management activities

Table 3. Active restoration management actions that may be undertaken to improve or manage native vegetation or threatened species habitat at a biodiversity stewardship site. Source: OEH (2017).

Types of active restoration management actions	Types of management activities that may be undertaken as part of the active restoration management actions for ecosystem credits and species credits
Habitat enhancement	Inclusion of artificial nesting boxes and if the management plan specifies ongoing management, replacement and maintenance Relocation of fallen logs onto biodiversity stewardship site from appropriate sources Addition of rocks from appropriate sources Relocation and securing of dead hollow-bearing stag trees from appropriate sources
Native vegetation and habitat management and augmentation	Undertake targeted supplementary planting to: • increase native plant richness and cover above the level determined for management gain • restore or enhance the condition and species composition of recognisable PCTs • improve habitat suitability for specific threatened species • restoration of PCTs through changed hydrological flows
Integrated weed management and control of high threat exotic vegetation	Removal of high threat exotic vegetation through appropriate methods (e.g. scalping) and replacement with native vegetation Other approved methods to reduce cover of high threat exotic vegetation
Hydrology management	Create artificial frog ponds or wetlands Manage drainage Install sediment trap(s) Manage debris Undertake nutrient control
Monitoring	Assessment of performance measures of outcomes related to the active restoration components such as: • evidence of occupation of and condition of artificial hollows or relocated logs and stags • persistence and abundance of species targeted by supplementary plantings or sowings

To elicit the trends over time, each expert was asked to fill a spreadsheet (via a Google sheets link) containing information as to how each ecological attribute will change over time for each plant growth form group. Given all the combinations of the growth form groups; initial conditions; and management actions, experts were required to provide data to inform the shape of 50 curves, as detailed in Table 4.

For each curve, the experts were requested to provide their best estimate; upper; and lower bounds, for the component being elicited, at a notional time points 20, 40, and 60 years into the future.

An example of the spreadsheets used for the elicitation is available here: https://docs.google.com/spreadsheets/d/1rFkq80R3orUgCRv_rbFW6crgTZN1-1rc5Wi-J6AhU7Y/edit?usp=sharing. The spreadsheet asks the experts to provide upper and lower bounds first (in any order), and then to provide a best estimate, and additionally to provide an estimate of their confidence that the true value falls within the bounds they have provided. Curves were generated as participants enter the data to show how their bounds and best estimate change over time. The spreadsheet automatically extrapolated bounds to show the 90 percent confidence intervals based on the estimate of confidence given by the participant.

Ethics approval for undertaking this component of the research involving human participants was obtained from RMIT University (approval number CHEAN A 21472-04/18).

CONVERTING MAPPED VEGETATION CONDITION TO EXPERT ELICITATION CONDITION CLASSES

As described above in the section on Vegetation Data, the condition information in the available spatial data on native vegetation does not match the initial conditions that were required by the experts to elicit the response of richness and cover for the relevant plant growth-form groups.

The following scheme was used to convert the condition categories used in the mapping, to the condition classes used in the expert-elicited condition change model. While the correspondence between each category is not perfect, they are approximating the same kinds of condition states for native woodlands.

- ***Scattered paddock trees*** was determined to equate to ***low site quality***, as it contains a single tree or small group of trees surrounded by low-condition native or exotic grassland, or areas of cultivation. One or more structural layers may be absent (e.g. shrubs and/or grasses/forbs).

- ***Derived Native Grasslands*** (DNG) was determined to equate to ***medium quality 1*** given it contains a grassland community where the cover of native species is 50% or more, and has some presence of perennial grass weeds but not at high density.

- ***Thinned*** was determined to equate to ***medium quality 2*** given it contains:
    - Woodlands that have a partly cleared canopy resulting in a more open structure than intact vegetation.
    - Vegetation that has been under-scrubbed (shrub layer removed).
    - Some areas of regrown woodland that would otherwise approach the intact condition.

- ***Intact*** was determined to equate to ***high quality*** native woodland or open forest that is in good condition, including good DNG within short distances (distance (typically under 30 metres) of intact canopy cover. Intact CPW displays a diversity of vegetation layers and habitat features (such as tree hollows, fallen timber, groundcover, leaf litter). Tree density is close to natural, and a range of ages is present including established mature trees. Regrowth may be included if it meets the above criteria.

CALCULATING THE VEGETATION INTEGRITY SCORE

Once all the richness and cover estimates were elicited, they were converted to the vegetation integrity score via the following approach, derived from BAM (OEH, 2017).

First the *unweighted richness condition score* is calculated via

$$URC_i = 100.68\,(1 - e^{-5\left(\frac{\bar{x}_i}{B_i}\right)^{2.5}}),$$

Where $\bar{x}_i$ is the mean of species richness of the i^{th} growth form group and B_i is the benchmark richness value for the i^{th} growth form group. Weights are then calculated as follows:

$$w_i = \frac{B_i}{\sum_{j=1}^{n} B_j}$$

where w_i is the weight for the i^{th} growth form group, B_i is the benchmark richness value of the attribute for the i^{th} growth form group, and n is the number of growth form groups.

The final *richness condition score* is then given by

$$RC = \sum_{i=1}^{n} URC_i \times w_i$$

An identical procedure was undertaken to calculate the final cover condition score (*CC*), replacing the richness terms (and benchmarks) in the above equations with the cover terms (and benchmarks). Given we do not include the function condition scores which are a component in the full BAM vegetation integrity score, we calculated the final vegetation integrity score as

$$VI = \sqrt{RC \times CC}$$

This is consistent with the vegetation integrity score using only richness and cover. This vegetation integrity score is then used as the metric to evaluate how the condition of CPW changes under management regimes, and to evaluate the different development and offsetting scenarios.

The additional components that make up the BAM vegetation integrity score were excluded due to the constraints the amount of information that could be elicited from the experts.

SIMULATING DEVELOPMENT, OFFSETTING AND CONDITION CHANGE OVER TIME

The OffsetSim model has three components:

1. A ***development model***, which in this case simulates development in the Growth Areas within development footprints (see below);
2. An ***offset model***, that implements offsets with either high or low intensity management in the strategically-defined offset areas (see below); and
3. A ***vegetation condition change model*** to simulate change in the condition of CPW over time under management types of different intensity, including no management.

The simulation works by running for a specified number of time steps. In each time step the following processes occur:

1. ***Develop parcels:*** Parcels are randomly selected from the development footprint area, with the number developed at each time step set so that all parcels in the development footprint area are developed within 37 years at an approximately even rate of development.
2. ***Offset parcels:*** Depending on the scenario (see below), offsetting is done in two ways. In one case parcels are randomly selected to be offsets in the strategic offset area, at a rate such that all or half of the parcels (depending on the scenario) are offset after 37 years, with offsetting occurring at an approximately constant rate. For other scenarios all or half (depending on the scenario) of the parcels in the strategic offset area are implemented as advanced offsets in the first time step.
3. ***Update ecological condition:*** The condition of CPW in each pixel is updated based on the relevant scenario occurring on the parcel where the CPW occurs: (i) for developed parcels, the condition of CPW is set to zero; (ii) for parcels managed as offsets, the condition of CPW improves based on the expert elicited curves depending on whether high or low intensity management is being used for the offsets; (iii) for parcels that are not offset or developed, the CPW will slowly decline in condition based on the expert elicited do nothing curves, which assumes typical private land activities continue.

These three processes are repeated every time step till the simulation is finished, and the condition of every pixel of CPW is retained for every time step. This allows the generation of the trends in condition over time, where condition scores are aggregated over either the whole Cumberland subregion, or the program area.

SPATIAL DATA INPUTS

All data was rasterized to a resolution of 20 m x 20 m, as the BAM specifies 20 m x 20 m survey plots are to be used to assess the composition and structure attributes (OEH, 2017). Thus, a vegetation integrity score consistent with the BAM can be modelled for each pixel in the vegetation raster layers without any additional transformation as each pixel is the size of standard BAM survey plot.

The required spatial inputs to the OffsetSim model comprise spatial raster layers depicting the development footprints and the set of locations where strategic offsets can occur, and the package allows these to be specified in any way, including having these areas overlapping.

The development footprints and strategic offset area are shown in Figure 4. It is important to note that these areas are based on preliminary boundaries as at November 2018, and are likely to change under the final Plan. It is also important to note that the strategic offset area at November 2018 contains approximately 1,605 ha of offsets for PCT 849 (CPW). However, the current draft target for PCT 849 under the Plan is 2,802 ha. Securing this larger amount of PCT 849 would change the results of the trend analysis.

OffsetSim also requires raster layers depicting the conservation features of interest, which in this case is the extent and condition of CPW. The extent of CPW is shown in Figure 5, overlaid on the development footprints and strategic offset area for reference. This layer includes the two existing vegetation data sets described above in the section on Vegetation Data, along with the data resulting from the Biosis field surveys in the Growth Areas. Figure 6 and Figure 7 show the condition classes of the CPW, with Figure 7 showing a close up that enables more of the vegetation patches and condition classes to be visible (see the Vegetation Data section above for a description of the condition classes in Figure 6 and Figure 7).

The land parcels for the Cumberland subregion are shown in Figure 8. These were sourced from the NSW Spatial Services Digital Cadastral Database (see http://spatialservices.finance.nsw.gov.au/mapping_and_imagery/cadastral_data), and rasterized to the same 20m pixel resolution as the other data. The parcels are the objects the simulation operates upon by selecting parcels to develop that are within the development region, and parcels to offset within the offset region. For this study, land parcels less than 1 ha were excluded from the analysis, as these are predominantly urban areas with very little CPW. Including these parcels creates significant challenges in running the simulation.

The simulation included existing conservation areas in the Cumberland subregion, including Biobank areas. This data is shown in Figure 9. Biobank sites are shown in pink to differentiate them from other conservation areas (shown in green). The spatial data for this information was provided by OEH in 2018. In the simulation it was assumed that Biobank sites were managed with *high intensity management,* while other conservation areas were managed with *low intensity management* (see Expert Elicitation section, above).

Table 5 shows the total area and the proportion of CPW that occurs in each of the spatial regions defined for the analysis. Of the 14,293.9 ha of CPW in the Cumberland subregion, 5.8% of it occurs in the development footprint area, 11.2% occurs within the strategic offset area, and 10.8 % occurs in existing Biobank and other conservation areas (Table 5).

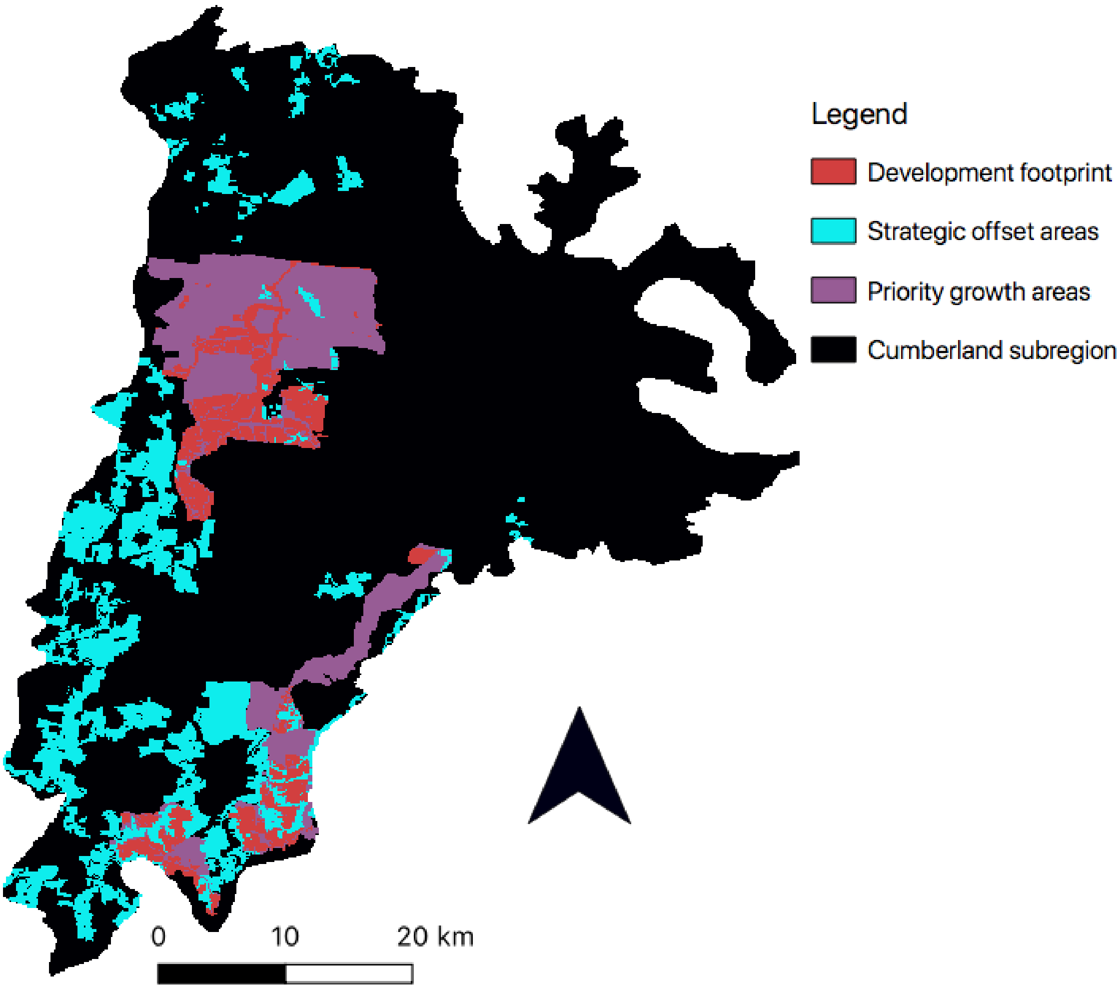

Figure 4. Map depicting the Growth Areas and the development footprint within them, and strategic offset locations within the Cumberland subregion.

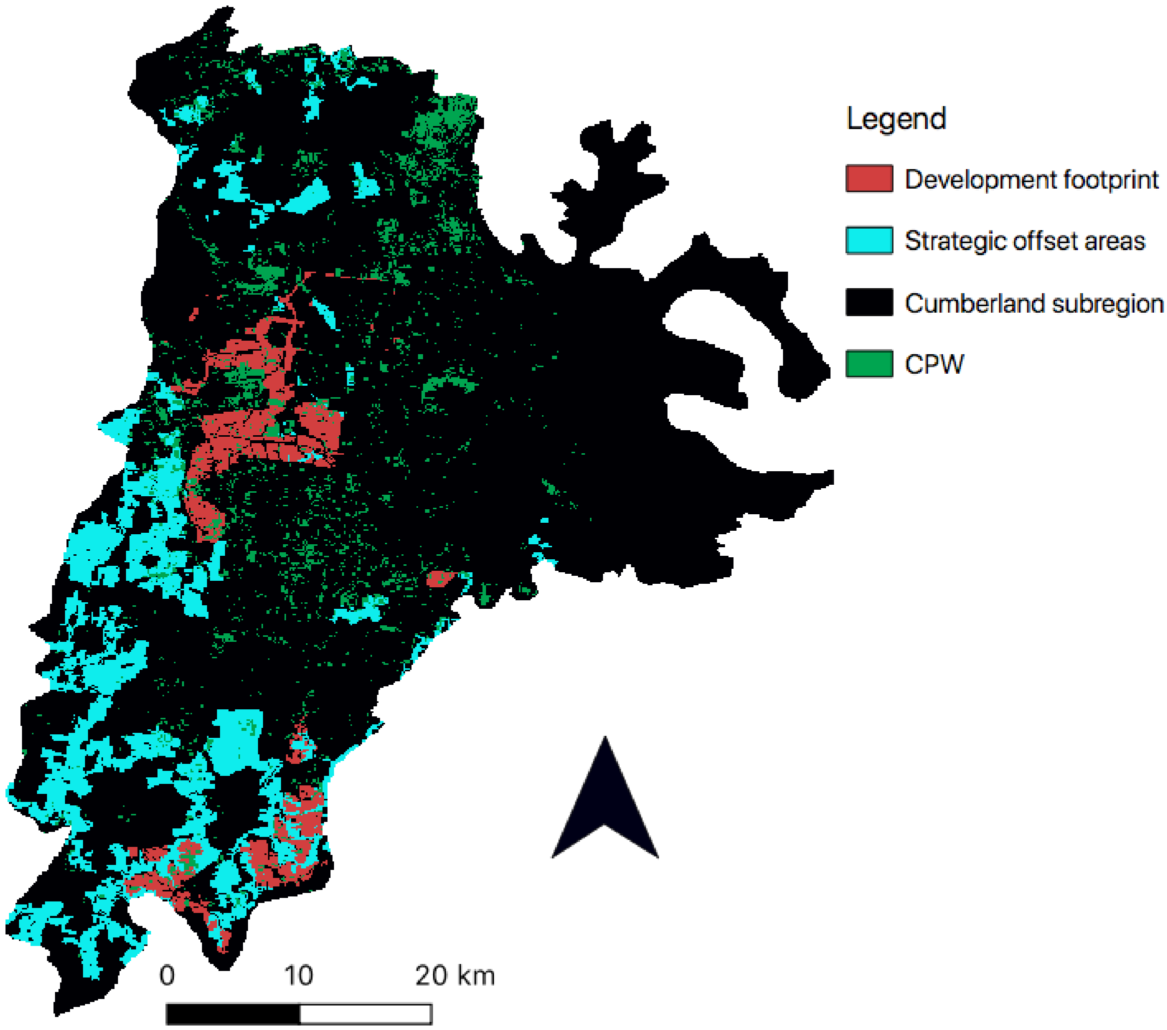

Figure 5. Map depicting the development footprint and strategic offset area, with distribution of CPW shown overlaid in green.

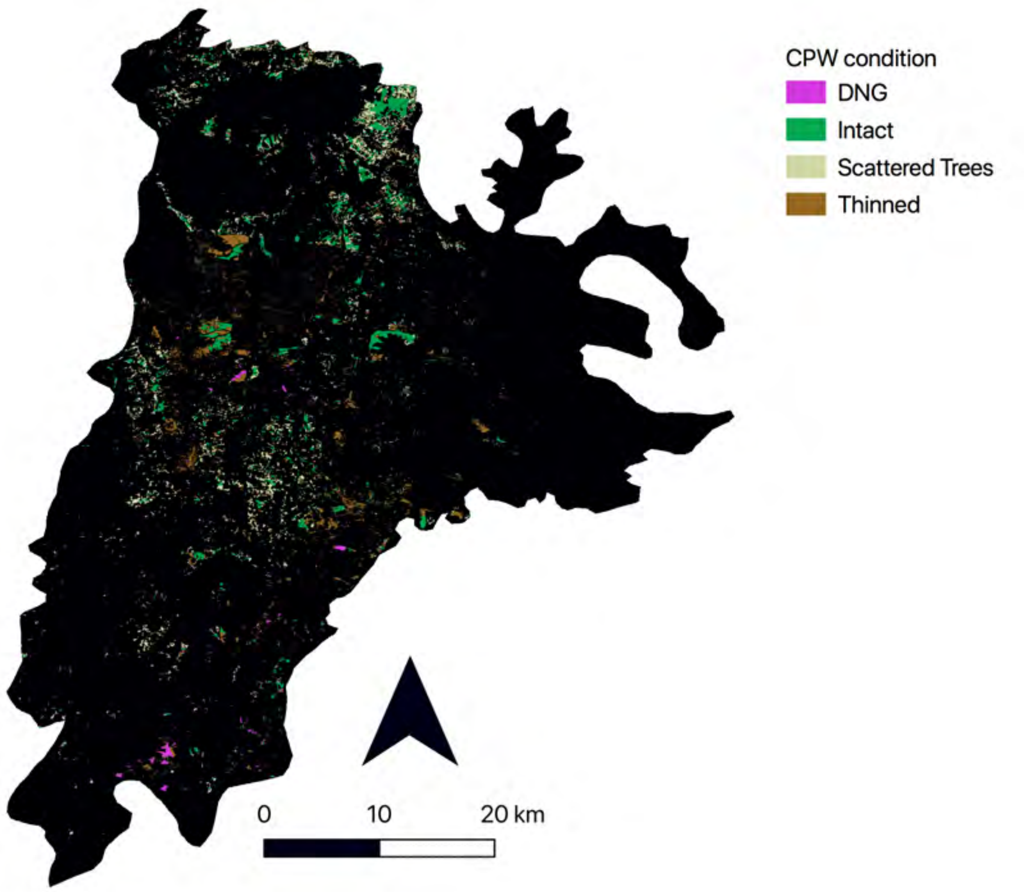

Figure 6. The distribution of CPW in the study area, showing the condition class of the vegetation.

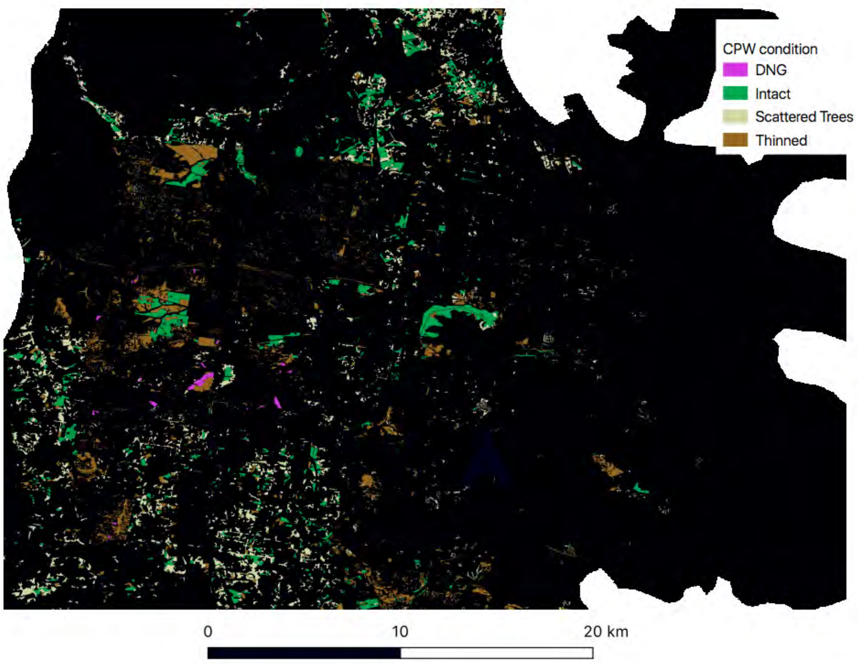

Figure 7. Close up of the layer showing the patches of CPW and their condition classes in the northern part of the Cumberland study area.

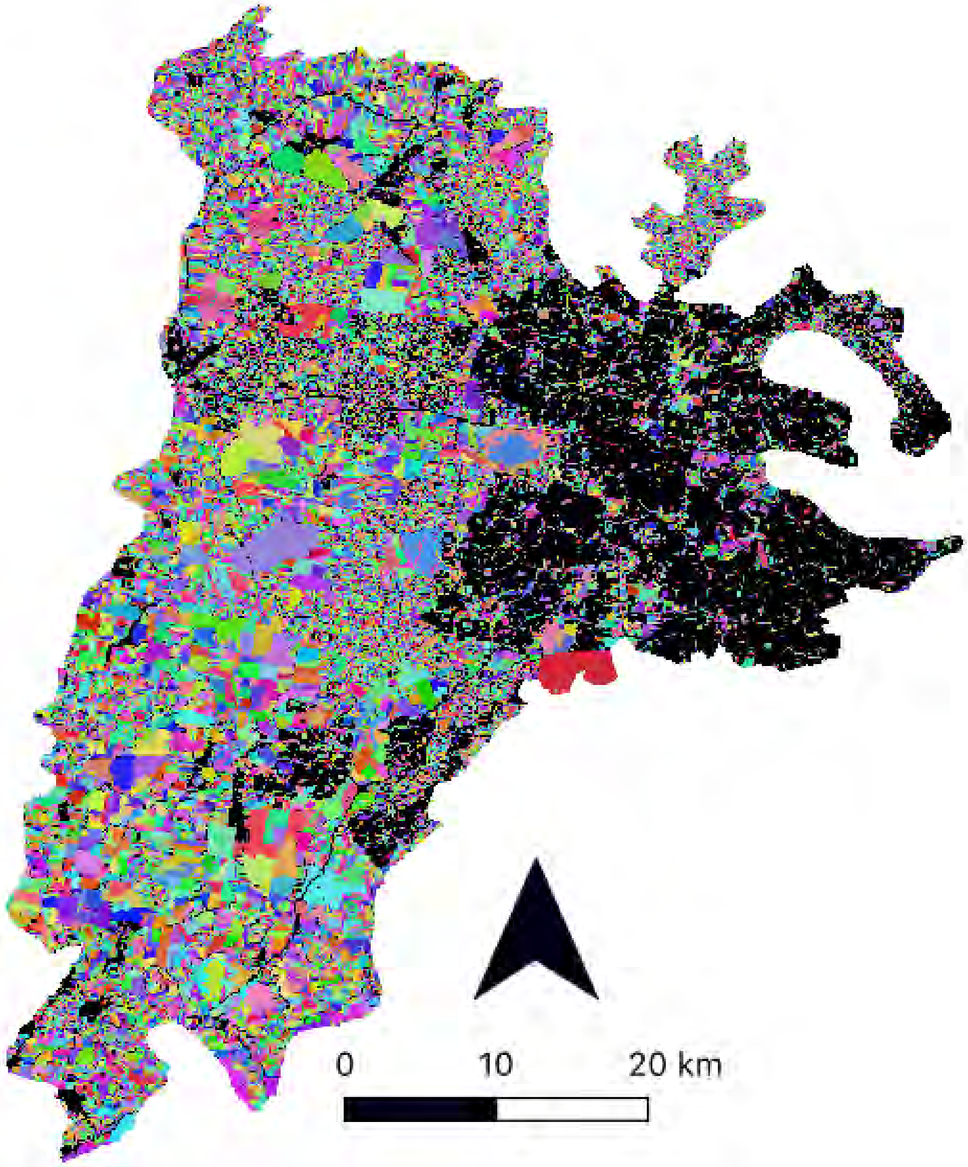

Figure 8. Map depicting the land parcels in the Cumberland subregion. Note that parcels less than 1 ha were excluded from the analysis, as these areas consisted primarily of urban areas, and contained very little CPW. Ares with excluded parcels are shown in black.

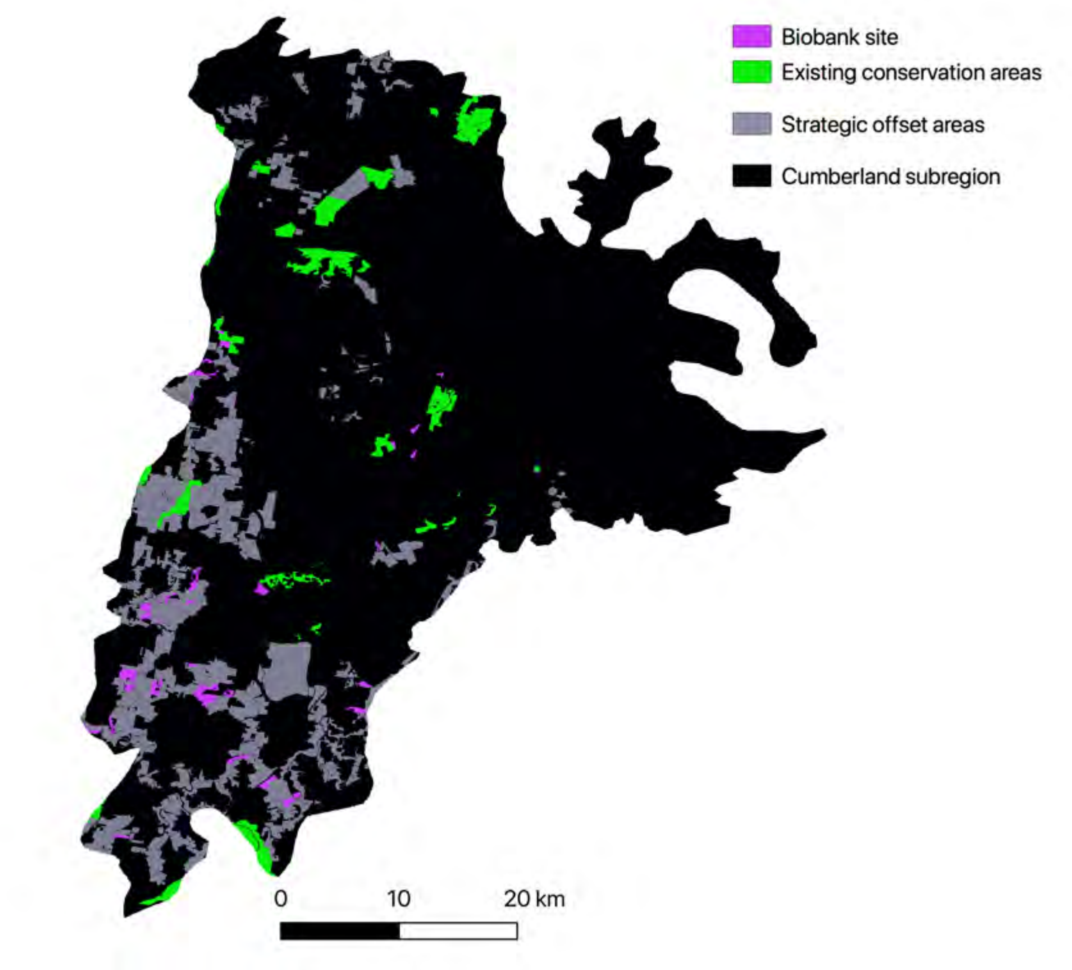

Figure 9. Existing conservation areas in the Cumberland subregion. Purple locations show existing Biobank sites, green areas show other existing conservation areas. For reference, the strategic offset areas are shown in grey.

Table 5. The total area and proportion of CPW in each of the regions used in the analysis.

Analysis feature	Area of CPW (ha)	Percentage of CPW in study area
Cumberland subregion	14,293.9	100 %
Growth Areas	3,083.7	21.6 %
Development footprint	827.0	5.8 %
Strategic offset area	1,605.3	11.2 %
Biobank sites	120.5	0.8 %
Other existing conservation areas	1,424.5	10.0 %
Phase zero areas (excluding offsets, overlaps with development region)	8,908.1	62.3 %

MODELLING CONDITION CHANGE OVER TIME

Modelling condition change involved three key steps:

- Setting the initial condition of each parcel of CPW – this was done differently depending on whether the parcel of CPW was within or outside the Growth Areas
- Applying the expert elicited curves to each parcel of CPW to predict how the initial condition changes under the scenarios (managed as an offset, developed, or subject to typical private land activities)
- Combining all the plant growth form richness and cover values into a vegetation integrity score

Firstly, the initial condition of every parcel of CPW was set to one of four condition classes used in the expert elicitation (*low*, *medium 1*, *medium 2*, or *high*, see above).

For CPW within the Growth Areas, this was done by directly converting the mapped condition classes determined during surveys undertaken by Biosis to the expert elicitation condition classes described above. Based on information from the experts during the elicitation, the mapped condition classes for CPW outside the Growth Areas is less accurate. Thus, the following approach was used to assign the initial condition classes outside the Growth Areas. First, the statistical distribution of the areas of CPW patches was determined for each of the condition classes in the Growth Areas. This characterises how likely a patch of CPW of a given size will be in a given condition class. These resulting distributions were used to undertake statistical sampling to assign an initial condition class to CPW patches outside the Growth Areas. While this means there is some randomness to the condition class assigned to these patches, it will result in the distribution of CPW patch sizes for each condition class being approximately the same for patches both within and outside the Growth Areas. The two fundamental assumptions underpinning this approach are: (i) patch area is the most important factor in determining the condition class of a patch of CPW, and (ii) that the relationship between patch area and condition is the same both inside the outside the Growth Areas. While neither of these assumptions will fully hold all the time, they are likely to provide a reasonable approximation.

Once the initial condition of each patch was determined, the initial values for richness and cover for the different plant growth form types were then determined (see the Expert Elicitation section, above). Next, the model updates the richness and cover values for each plant growth form type based on the curves provided by the experts (see Appendix A). In this analysis, the curves ***used were the means across all experts*** (see Figures A1-A5) and the particular curve applied to any given pixel of CPW depends on the scenario (i.e. managed as an offset; developed; or subject to typical private land activities).

The complexity of the condition change process comes in when a parcel moves from one state to another. For example, CPW in a given parcel might be slowly declining from some initial condition, and then at some point in the simulation the parcel is selected as an offset and management starts. From that point onwards, the trajectory of the CPW changes and starts improving based on the curve for either *high* or *low intensity management* (and it is assumed once a parcel is offset, management continues for the remaining duration of the simulation). The other change that can occur is when a parcel is developed, but in this case is it a simple transition as it goes straight to zero and then remains at zero for the duration of the simulation.

Thirdly, the plant growth form richness and cover values were combined into a vegetation integrity score, based on the equations given in the section "Calculating the Vegetation Integrity Score", above. The vegetation integrity scores of each pixel of CPW were then summed, and it is the change of summed vegetation integrity score over time that provides the *trends* for extent and condition of CPW.

SCENARIOS

To address the purpose of the trend analysis, the following scenarios were modelled:

1. Do nothing — continuation of typical private land activities, with no development or offsetting.
2. Development only — development in Growth Areas, with no offsets. Development occurs at an approximately constant rate such that all parcels in the development region are developed by the end of the 37 years of simulation. All subsequent scenarios use the same development model.
3. Development in Growth Areas with strategic offsets secured early, subject to low intensity management. In the simulation, offsets are all implemented in the first time-step of the model.
4. Development in Growth Areas with strategic offsets secured incrementally, subject to low intensity management. In the simulation, offsets are implemented at an approximately constant rate, such that all parcels are offset by the end of the 37 years of simulation.
5. Development in Growth Areas with strategic offsets secured early, subject to high intensity management. This is the same as Scenario 3, but with offsets subject to high intensity management.
6. Development in Growth Areas with strategic offsets secured incrementally, subject to high intensity management. This is the same as Scenario 4, but with offsets subject to high intensity management.

Four additional scenarios were also defined: scenarios 3A, 4A, 5A, and 6A. These are identical to scenarios 3-6, respectively, except that only half the parcels in the strategic offset area are implemented as offsets. This models the case where not all landholders in the strategic offset area are willing to secure biodiversity offsets on their land. The parcels that are selected as offsets are randomly chosen, meaning that the total area of vegetation offset differs slightly for each model realization of scenarios 3A, 4A, 5A, and 6A.

While it is recognised that the assumptions under some of the scenarios may not be realistic, the scenarios represent a set of outer bounds for what is likely to occur in practice. This is appropriate because it is more likely to allow clear differences in the scenarios to be identified, making the results of the analysis more useful. As the outputs of the modelling are subject to significant uncertainty, it is not meaningful to distinguish between a larger number of potentially more realistic, but more similar scenarios. This is due to the range of underlying uncertainties, and the variation inherent in multiple model realizations due to random processes (such as the selection of parcels to develop or offset in a given time step) may mean there is very little to distinguish difference in performance between the scenarios.

RESULTS

EXPERT ELICITATION

The expert elicitation resulted in predictions that could be used from five experts (see ‘Expert Elicitation’ section above) regarding how CPW changes under the three management regimes.

Appendix A shows how the expert estimates of the different components that make up the BAM vegetation integrity score are predicted to change over time under the three different management regimes. As described above, for each management regime, predictions are made for four different initial condition states of CPW. The components of the BAM vegetation integrity score for which estimates were made were tree; grass (and grass-like); and forb richness; as well as cover of trees; and cover of grass and grass-like. The curves resulting from each expert, along with the mean over all experts, are shown for each component in Figures A1- A5 (Appendix A).

In some cases, there can be considerable variation among the expert's predictions, such as how tree richness is predicted to change under high intensity management when CPW is initially in *low condition* (Figure A1), or how tree cover is predicted to change under high intensity management starting from the *medium 1 condition* (Figure A4). In other cases, the expert's predictions were much more similar, such as how forb richness will change under high intensity management, starting in the *medium 1* condition (Figure A3). These results in general can be used to determine the likely outcomes of restoration under low or high intensity management (as defined in the BAM), or to predict declines under no management.

As described above, the components elicited can be combined by transforming, weighting and adding together to produce a vegetation integrity score similar to that defined in the BAM (OEH, 2017). This was done for all the elicited components and combined into a single curve, representing how the vegetation integrity score varies with time for each initial condition, and management combination. As noted above, the vegetation integrity score presented here is only an approximation of the vegetation integrity score defined in the BAM, as there are additional components in the BAM version that were not included in the elicitation (OEH, 2017).

Figure 3 shows how the vegetation integrity score is predicted to change under management, based on the mean values elicited across all experts. The way the vegetation integrity score is calculated (see above), results in a vegetation community in its pristine benchmark state having a vegetation integrity score 100. This benchmark value is shown with a horizontal green line in Figure 3. For each initial condition state, undertaking no management results in approximately linear declines due to ongoing threats from typical private landholder activities. High intensity management delivered significantly greater gains in vegetation integrity over time, compared to low intensity management. In most cases, high intensity management resulted in the vegetation integrity score plateauing, as components approached their benchmark values. In some cases, the experts predicted that richness or cover values for some growth form groups could exceed their benchmark values (see Appendix A), resulting in vegetation integrity scores greater than 100. This is most prominent for high management applied to CPW initially in the *medium 1* condition (top right plot; Figure 3). This suggests that high intensity management is predicted to deliver significant restoration gains from a low or medium initial condition. This is not the case for low intensity management, which provides much smaller gains, especially if the starting condition is low.

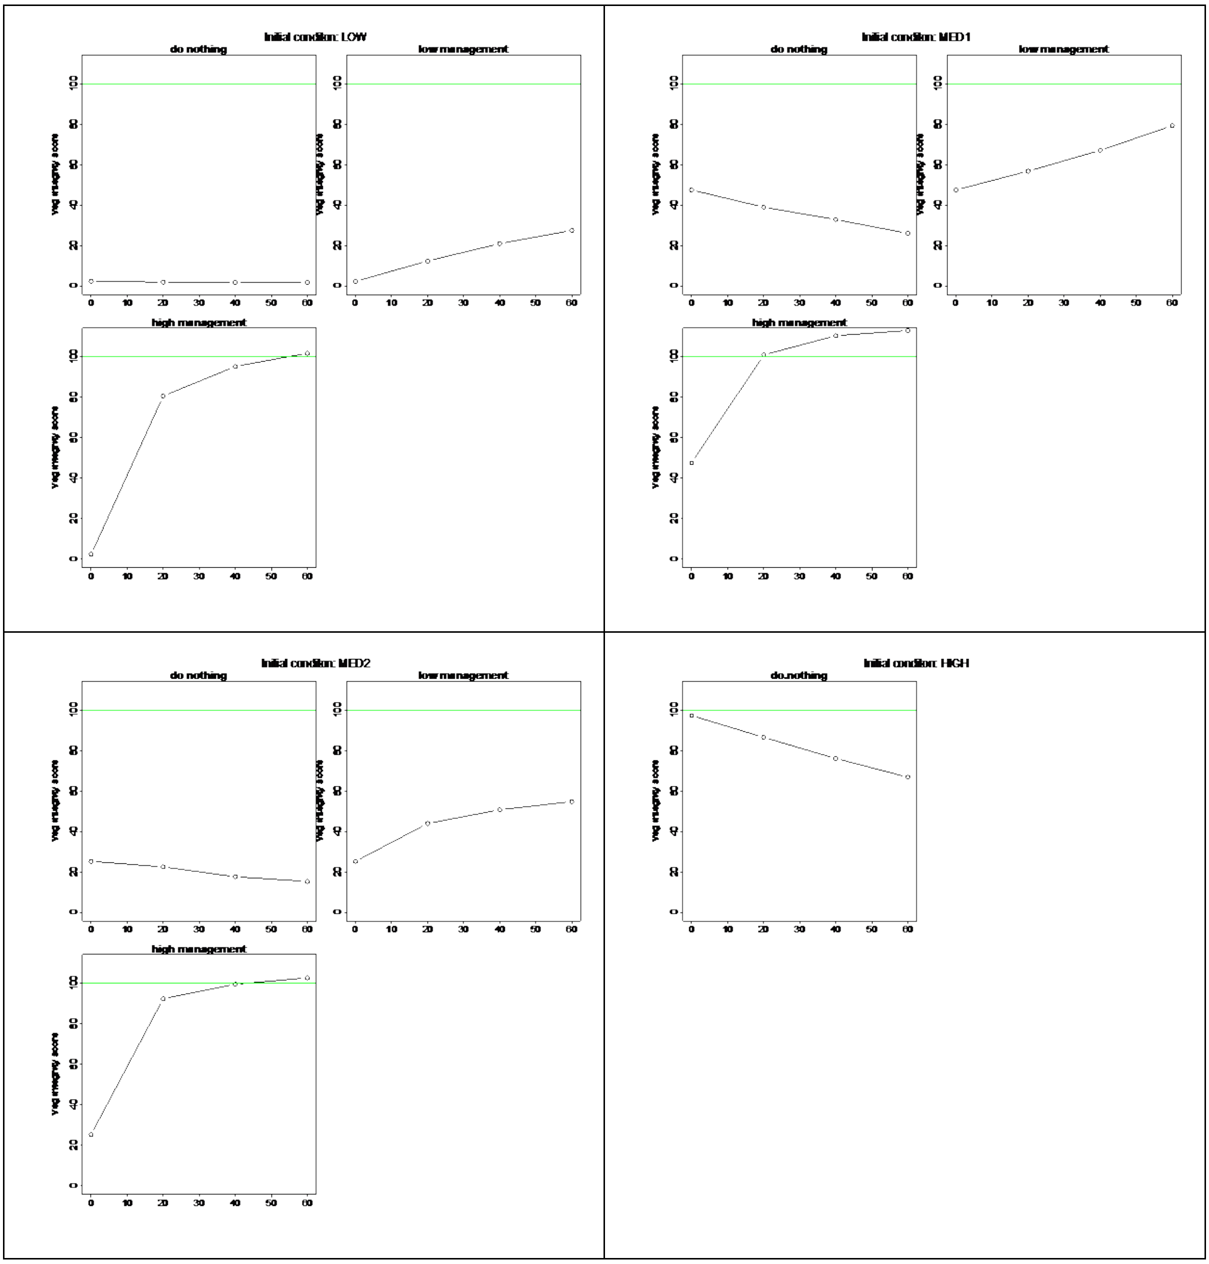

Figure 10. Results of the expert elicitation showing how the modelled version of the BAM vegetation integrity score (y-axis) changes with time (x-axis), for different management regimes and different initial conditions. Each plot shows the vegetation integrity score calculated by taking the mean value across all experts for each component that makes up the score. The top left plots show results for CPW starting in *low condition*, while the remaining plots show results for starting in *medium 1*, *medium 2* and *high conditions* (clockwise from top left). Note that for vegetation in high condition, only the do nothing scenario was elicited, as it was assumed that any management would retain the vegetation in high condition. The green horizontal line in the plots indicate the vegetation integrity score that CPW would have its pristine benchmark state (a value of 100.0).

SIMULATION OF DEVELOPMENT AND OFFSETTING

The main metric used to evaluate performance of the different scenarios is the summed BAM vegetation integrity score over the region of interest as a function of time.

The model produces a map at each time step, showing the condition of each patch of CPW, as well as the locations where development has occurred (where it is assumed that all CPW is removed) and where offsets were implemented (where it is assumed that CPW is managed under high or low intensity management).

Figure 11 shows the final maps generated by the simulation on the last time step for scenario 1 (on the left) and scenario 2 (on the right), where the condition of CPW is depicted by the shade of green (representing the modelled vegetation integrity score), and development is shown in red.

Figure 12 shows maps generated on the last time step for scenarios 3-6, after all development and offsetting has been applied. These plots show the offset regions in blue, where all parcels with CPW in the strategic offset area are implemented as offsets (left plot in Figure 12) and where only half the parcels (randomly selected) are implemented as offsets (right plot).

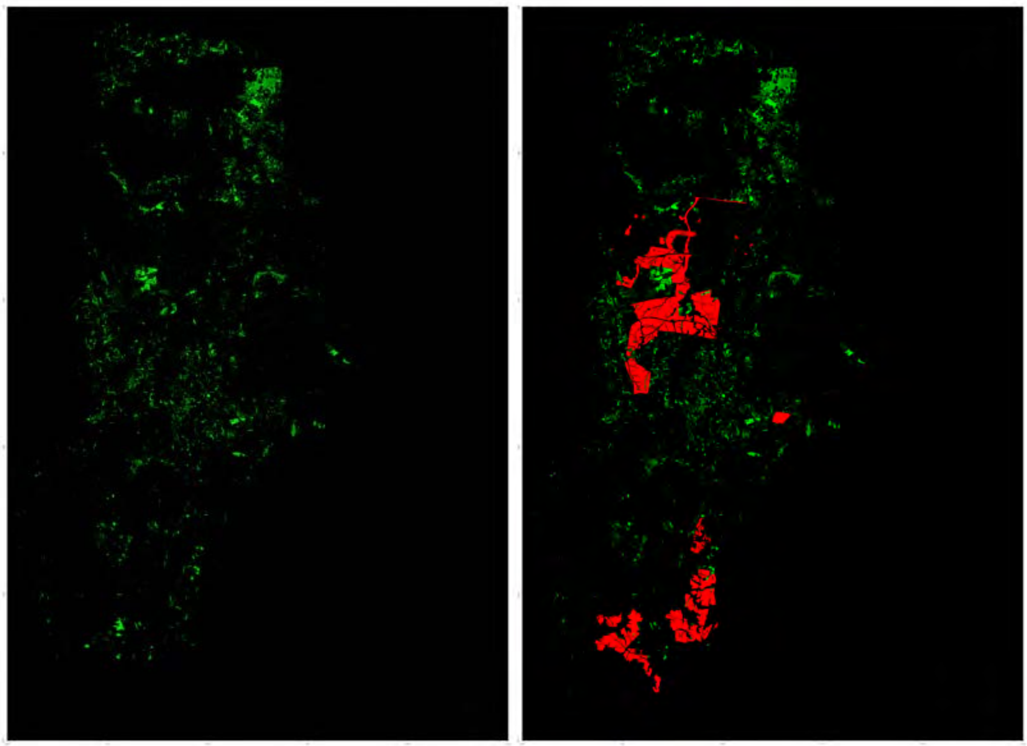

Figure 11. Maps showing modelling outputs for scenario 1 (S1: no development), and scenario 2 (S2: development only). CPW is shown in green with the lighter colour representing a higher vegetation integrity score. Developed parcels are shown in red. Maps show the results at the last time step when all development has been implemented.

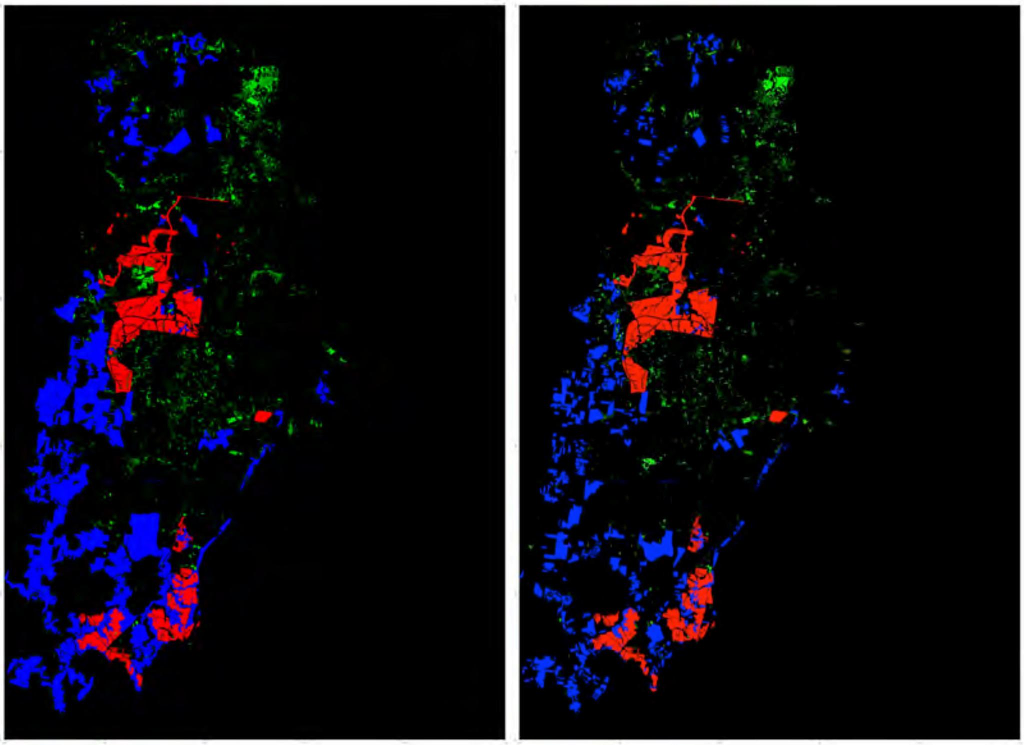

Figure 12. Maps showing outputs for scenarios with both offsetting and development. CPW is shown in green with the lighter colour representing a higher vegetation integrity score. Developed parcels are shown in red, and offset parcels are shown in blue. The map on the left shows the result when all parcels in the strategic offset area are implemented as offsets (scenarios 3-6), and the plot on the right shows one realization of the case where only half the parcels in strategic offsets area are implemented as offsets (scenarios 3A-6A). Maps show the results at the last time step when all development and offsetting has been implemented.

The predicted changes to the summed ecological integrity scores under each of the scenarios are shown in Figures 13-15 in relation to 'landscape scale and 'program scale' results.

The ***landscape scale*** results show the summed vegetation integrity score for the whole Cumberland subregion, including development and offset areas, other conservation areas and existing Biobank sites, as well as remaining areas on private and public land where the vegetation is assumed to be unmanaged.

The ***program scale*** results show the summed vegetation integrity score just for the parcels developed and offset.

The ***landscape scale*** results allow the contribution of development and offsetting to be evaluated relative to overall trends in the Cumberland subregion, while the ***program scale*** results allow an evaluation of the impacts on CPW just in the regions where development and offsetting is occurring (the program area).

Program scale results in Figures 14 and 15 are shown in terms of 'outcomes' and 'impacts'. The outcome plots show the absolute trajectory of the summed vegetation integrity score over time, starting from its initial (current) value and indicating how this value changes with time. The end point of each line shows the final summed vegetation integrity score predicted to occur under a given scenario (incorporating development losses and background declines due to ongoing typical private land activities).

The impact plots show the ***difference of each scenario relative to the counterfactual of S1*** (do nothing—ongoing private land impacts). Thus, for impact plots, values greater than zero indicate better performance relative to S1, and a value less than zero indicates worse performance than S1.

Assessing whether a scenario ***achieves No Net Loss in terms of mitigating the impacts of the development is done by determining when a scenario has an impact greater than zero on the impact plots***. Determining whether a scenario ***mitigates both development impacts and ongoing background declines is done by comparing the trajectory relative to the starting point on the outcome plots***. Where the trajectory is below the starting point, this indicates that both development and background declines have not been compensated for.

While outcome plots are provided at the landscape and program scale, the impact of the scenarios is the same at these scales. This is because the impact is the difference between a given scenario and S1 (i.e. *SX – S1*, for some scenario *X*). Everything occurring outside the program area (offset and development regions) is the same for S1 and all other scenarios, comprising management of Biobank and other conservation sites as well as ongoing decline for vegetation in other areas (i.e. SX – S1 = 0 outside the program areas). Thus, taking the difference of any given scenario, (SX) with S1 just provides the difference between what is occurring in the program area, as the summed vegetation integrity score outside the program area is the same in both scenarios. In other words, ***the impact of all scenarios at the program and landscape scale is the same***.

For all the results presented below it was assumed that existing protected areas had low intensity management and Biobank sites had high intensity management, and everywhere else outside development and offset footprints had no management. Each scenario was run 10 times (10 ***realizations***), and due to the random process in which parcels are selected for offsetting and development in a given time step, each realization has some variation in the summed vegetation integrity score over time due to different parcels being selected in different time steps. The plots show each realization as a fine line and the mean over all realizations for a given scenario as a thick line. Each scenario is shown in a different colour.

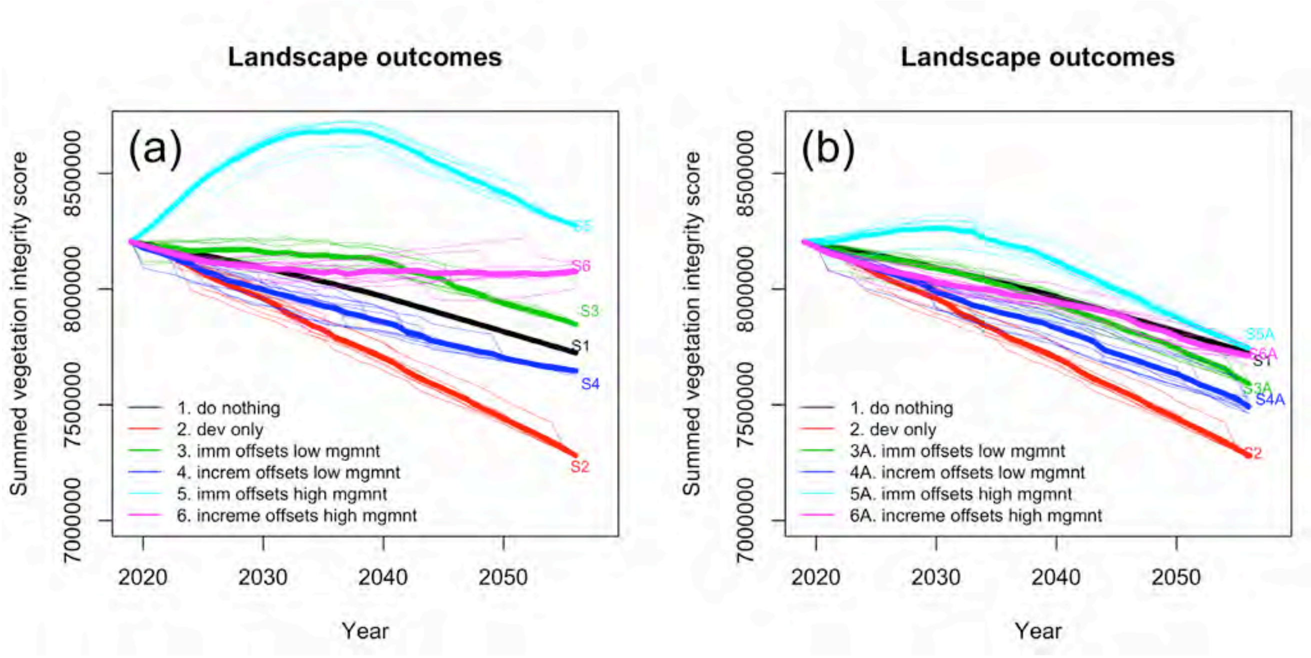

Figure 13. Landscape scale outcomes for 10 realisations of each scenario. The mean of each scenario is shown as the bold line and each individual realization is shown as a thin line. (a) depicts the case where all parcels in the strategic offset region are implemented as offsets, while (b) shows the case where only half of the parcels (randomly selected) in the strategic offset region are implemented as offsets.

Landscape scale ***outcomes*** are shown in Figure 13. When all parcels in the strategic offset area are implemented (Figure 13(a)), all scenarios except S5 result in losses in summed vegetation integrity relative to the initial state. The high intensity management of offsets and their early implementation mean S5 results in initial improvements, however once these gains stop accruing, the ongoing losses in the rest of the landscape result in S5 declining after about 2037, finishing slightly above the initial starting condition. S3 initially outperforms S6, but the high intensity management means that eventually S6 overtakes S3 resulting in a higher summed vegetation integrity score at 2055. The relative ranking of the scenarios is the same for the scenarios where only half the offsets are implemented (Figure 13(b)). However, in this case all scenarios result in ongoing landscape losses except S5A which has small initial gains, which then decline after approximately 2035. In this case, all scenarios end with summed ecological integrity below the current starting state.

Figure 14 shows program scale ***outcomes*** when the vegetation integrity score is summed over the program area (development and offset areas). For the scenarios where only half the parcels in the strategic offset area are implemented (Figure 14(b)), the offset program area is reduced compared to when all parcels in the offset area are implemented as offsets (Figure 14(a)), resulting the plots starting from a lower initial value. Note that in Figure 14(b) there are different starting values for each realization, due to the fact the offset parcels are randomly selected and will have different total area for each realization. When all offsets are implemented (Figure 14(a)), the relative performance of all scenario outcomes at the program scale is similar to the landscape scale outcomes (Figure 13). However, in this case S5 and S6 result in gains relative to the initial starting state, and S3 results in a small gain which eventually declines to approximately the stating state by the end of the simulation, while S4 results in declines relative to the initial state for the duration of the simulation. When half the offsets are implemented (Figure 14(b)), all scenarios result in losses by the end of the simulation relative to the starting state. S5A provides some initial gains but eventually drops below the initial state by the end of the simulation. The difference between each scenario is much more reduced compared to Figure 14(a), with the variation between model realizations providing significant overlaps between the scenarios.

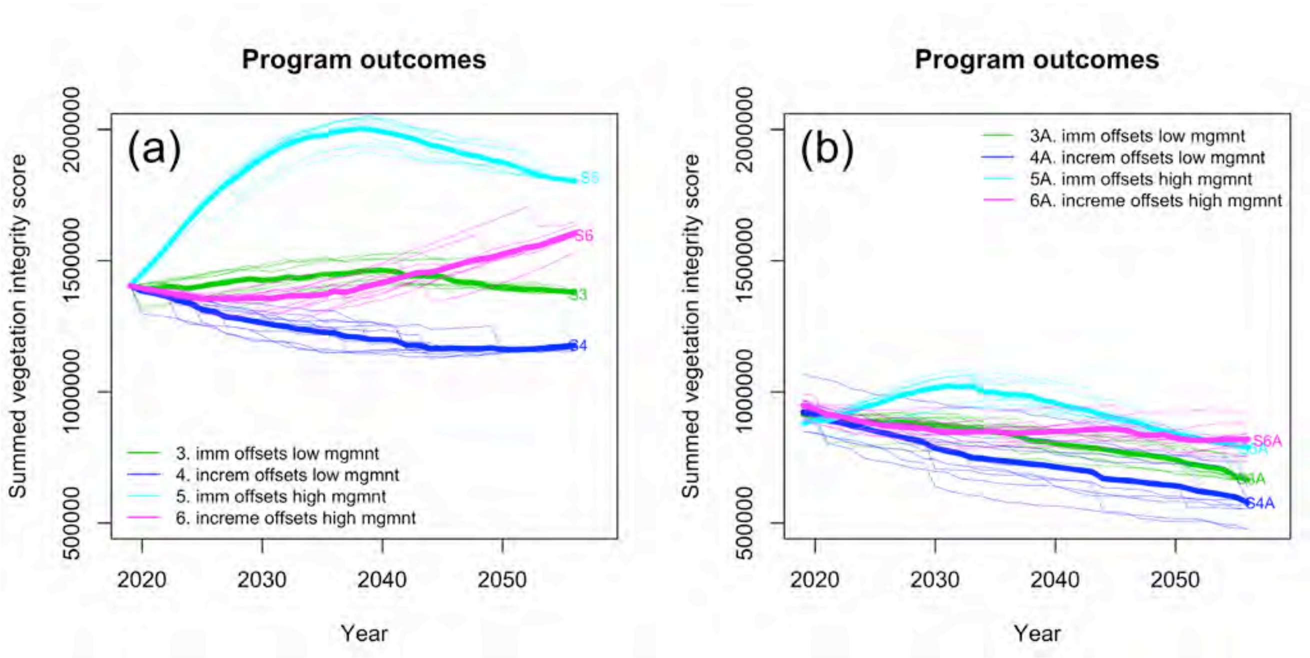

Figure 14. Program scale outcomes for 10 realisations of each scenario, with the mean of each scenario shown as a bold line and each individual realization shown as a thin line. (a) depicts the case where all parcels in the strategic offset region are implemented as offsets, while (b) shows the case where only half of the parcels (randomly selected) in the strategic offset region are implemented as offsets. Note that scenarios 1 and 2 are not shown as these scenarios do not have offsets and thus the 'program scale' (consisting of the offset and development area) is do not have offset areas defined.

The ***impact*** of each scenario is shown in Figure 15, depicting how each scenario performs relative to S1 without any offsets or development. As discussed above, this shows ***the extent to which the development impacts alone are compensated***. When all parcels in the strategic offset area are implemented (Figure 15(a)), S3, S5 and S6 always result in positive impacts, with S6 resulting in initial losses for the first 8 years or so. S3 initially outperforms S6, but the high intensity management of S6 means it eventually overtakes S3. S4 results in initial losses, which then improve but remain negative for the duration of the simulation meaning that low intensity management with offsets implemented incrementally is likely to result in losses relative to no development or offsets (S1). When only half the parcels in the offset area are implemented (Figure 15(b)), gains are significantly reduced for all offset scenarios, with only S6A ending with a value slightly higher than zero but S5A is also very close to zero. This means that when only half the parcels in the strategic offsets area are implemented as offsets, only scenarios with high intensity management (S5A and S6A) compensate for development losses.

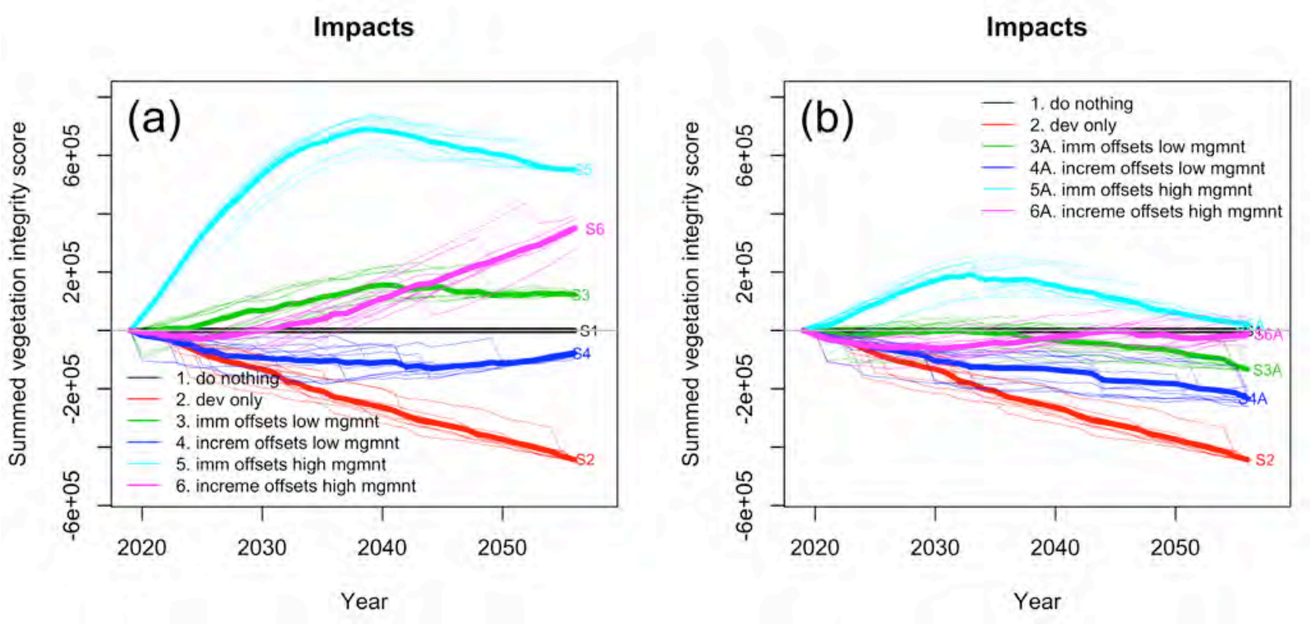

Figure 15. Impacts of the offset and development scenarios, relative to the counterfactual baseline of S1. This shows the performance of each scenario in terms of compensating for development losses alone. Ten realizations of each scenario are shown, with the mean of each scenario depicted as a bold line and each individual realization shown as a thin line. S1 is shown as a horizontal line with impact of zero (a) depicts the case where all parcels in the strategic offset region are implemented as offsets, while (b) shows the case where only half of the parcels (randomly selected) in the strategic offset region are implemented as offsets.

Table 6 summarizes all the results, showing the final summed vegetation integrity score for each scenario at the end of the simulation (year 2056). It also shows the percentage change of each scenario relative to summed vegetation integrity score of S1 on the last time step (middle column) as well as the percentage change relative to initial starting condition of all scenarios at the landscape scale (last column).

Table 6 indicates that under S1, there is a 5.8 % drop in summed vegetation integrity score at the landscape scale due to ongoing private land activities and other degrading process. When development is included, this adds an additional impact of almost the same magnitude (5.78 %) (seen by comparing the percentage change between S1 and S2). Thus, we see the impact of development is almost the same as the projected declines under S1 at the scale of Cumberland subregion from landscape scale threats.

From Table 6 it can also be seen that by the year 2056, only S5 and S6 provide gains at the landscape scale relative to the starting condition, and that S3, S5, S6, S5A and (almost) S6A provide gains, or achieve No Net Loss of summed vegetation integrity relative to do nothing (S1).

Table 6. The percentage change of each scenario relative to Scenario 1 (do nothing) on the last time step of the simulation.

Scenario	Mean summed vegetation integrity score on the last time step and landscape scale	Percentage change relative to value of Scenario 1 on the last time step	Percentage drop relative to starting condition
S1 – Do nothing	7,724,857	0 %	-5.8 %
S2 – Development only	7,281,680	- 5.7 %	-11.2 %
Offsets implemented in all of the parcels in the strategic offset area			
S3 – Imm offsets low management	7,847,765	+ 1.6 %	-4.3 %
S4 – Increm offsets low management	7,646,977	- 1.0 %	-6.8 %
S5 – Imm offsets high management	8,275,312	+7.1 %	+0.86 %
S6 – Increm offsets high management	8,074,270	+ 4.5 %	-1.6 %
Offsets implemented in half of the parcels in the strategic offset area			
S3A – Imm offsets low management	7,591,975	-1.7 %	-7.5 %
S4A – increm offsets low management	7,491,923	-3.0 %	-8.7 %
S5A – Imm offsets high management	7,745,532	+0.27 %	-5.6 %
S6A – Increm offsets high management	7,712,384	-0.16 %	-6.0 %

DISCUSSION

This report presents the results of a trend analysis examining the potential impacts of development and offsetting in the Cumberland subregion on the native vegetation community *Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion* (PCT 849; referred to here as CPW). It consisted of two parts: a formal expert elicitation to gather quantitative knowledge regarding how CPW will change over time under different management scenarios; and quantitative modelling to simulate the urban development within designated Growth Areas, compensation via managing areas as biodiversity offsets in a strategically defined offset region, and the ecological response of CPW over the whole Cumberland subregion. The main points that can be concluded from the trend analysis results are discussed below.

The landscape scale accounts for all parcels in the whole Cumberland subregion, including the parcels that are not part of the program and subject to ongoing declines due to typical private land activities. At this scale, only one scenario results in a gain of summed vegetation integrity of CPW relative to the current state over the whole Cumberland subregion (Figure 13). The gain occurs when offsets are implemented immediately with high intensity management and all parcels in the strategic offsets area are assumed to be secured. In this scenario, there are initial gains, but by the end of the 37-year time period, scenario 5 has dropped to be just above the initial value of the summed vegetation integrity score.

All other scenarios at the landscape scale result in losses of summed vegetation integrity over the whole Cumberland subregion, right from the start. This is due to the predicted large and ongoing condition declines of all the vegetation left unmanaged on private land, as the Plan only influences a proportion of the subregion. The predicted declines in vegetation integrity for unmanaged areas subject to typical private landholder activities can be seen in Figure 13, with scenario 1 line (black line in figure) showing how this plays out relative to the offset and development scenarios. By comparing Figure 13(a) and 13(b) it is clear that if only 50 % of the parcels in the strategic offset area can be implemented as offsets, CPW declines relative to its current condition will be notably larger by the end of the simulation.

The program scale accounts for only the parcels of land where development and offsetting occurs. At this scale, it is only possible to maintain the current state (or better) if all parcels in the strategic offset area are managed, *and* high intensity management *or* immediate offsets are implemented (scenarios 3, 5 and 6; Figure 14). If only half the offsets in the strategic offset area are implemented, all scenarios eventually fall below the current state (Figure 14(b)).

If all offsets in the strategic offset area are implemented, scenarios 3, 5, and 6 also offer the potential of achieving No Net Loss relative to the do nothing scenario (S1: no offsets or development; Figure 15). However, only scenario 5 can reliably deliver no let loss relative to scenario 1 where only half of the parcels in the offset area are secured (Figure 15(b)). In the case where only half the parcels are secured as offsets, all other scenarios result in losses relative to scenario 1, meaning that, in this case, the net impact of development and offsets results in a net loss.

From these results it is clear that high intensity management and implementing offsets as early as possible are both factors in ensuring offsets deliver the greatest gains. However, the importance of high intensity management relative to implementing offsetting early depends on the time horizon over which gains are evaluated. Implementing all offsets immediately with low intensity management delivers greater gains in the short term (1-2 decades), but the simulations show that implementing offsets incrementally with high intensity management eventually delivers greater gains. Clearly, the best conservation outcomes occur with high intensity management and immediate offsets (scenario 5), which results in notably better performance compared to all other scenarios.

The negative impact of development can be seen by comparing scenarios 1 and 2 in Figure 13 (the black and red lines, respectively) which shows the landscape outcomes of CPW of the whole Cumberland subregion. The only difference between these scenarios is the loss of vegetation due to development. Comparison of these two lines in Figure 13 indicates that development in the Growth Areas is having a large negative impact on CPW, and this impact is of similar in magnitude to the declines occurring over the whole Cumberland subregion (a decline of 5.7% in the summed vegetation integrity score (Table 6)).

The results of the expert elicitation reveal there is significant potential for restoring CPW if high intensity management (as defined in Table 3) is implemented. As shown in Figure 10, the expert elicitation revealed that the vegetation integrity score can be significantly improved under the high intensity management regime, even when starting from the low initial condition state. However, if low intensity management is implemented (as described in Table 2), then the gains are significantly reduced and do not reach the point of plateauing within the 60-year time horizon of the elicitation.

It should be noted that the effects of climate change were *not* included in this analysis. While this was discussed in some detail during the expert elicitation workshop, it was agreed that the other degrading processes considered in the elicitation are likely to have a greater determinantal effect than climate change over shorter time frames. In addition, there is a much greater ability control these processes compared to climate change. These factors, along with the significant uncertainties around the impacts of climate change, led to excluding climate change as a degrading process in the modelling.

There are many uncertainties and assumptions in a modelling exercise such as presented here, which have been detailed throughout the report. They include uncertainties in the model inputs, such as the spatial data characterizing the location and initial condition of CPW, and the expert predictions of how ecological factors of CPW will change over time (which varied considerably between experts in some cases). There are also uncertainties in the assumptions of the structure of the model, for example around management being constant and continuous and equally effective over all parcels being managed. Finally, there are many assumptions built into the scenario definitions, which, as discussed above, represent outer bounds of different realistic options for offsetting. While these assumptions and uncertainties may limit the actual predictive ability of a modelling exercise such as this, it is impossible to model so far into the future and on such as large scale without making a wide range of assumptions.

The utility of an exercise such as this is that it allows the relative performance of different scenarios to explored with respect to a clearly-articulated system model, including its uncertainties and assumptions. Thus, scenarios can at least be evaluated with respect to these system models, providing a transparent set of assumptions as how the evidence underlying mitigation decisions were generated. For evaluating mitigation strategies over such large spatial and temporal scales, there is no other alternative.

OVERALL KEY MESSAGES

The key findings of this analysis for CPW are summarized below.

- Landscape-scale threats across the Cumberland subregion, such as weed invasion, grazing, rubbish dumping, and disturbance from recreational activities are causing significant declines.
- The negative impact of development in the Growth Areas is of a similar scale to ongoing declines from landscape scale threats across the whole Cumberland subregion over 37 years. Landscape scale threats across the subregion are projected to result in a 5.8 % drop in summed vegetation integrity score over 37 years (scenario 1, Table 6). The additional impact of development adds further losses of almost the same magnitude (another 5.78 %; Table 6).
- The Plan is generally unlikely to reverse declines from landscape scale threats across the whole Cumberland subregion because the magnitude of these threats is large and the Plan only influences a proportion of the subregion. The only scenario where declines were always reversed at the landscape scale was scenario 5 (Figure 13, Table 6), where it was assumed that: (i) all parcels in the strategic offset area are implemented as offsets, (ii) all offsets were implemented immediately; and (iii) all offsets had high-intensity management. This comprises the outer bound of the best-case scenario, and may not be feasible to implement.
- In terms of whether the Plan addresses the impacts of development in the Growth Areas alone within the program area (ignoring declines from landscape scale threats), two of the four offset scenarios (scenarios 5 and 6) provided adequate compensation irrespective of whether 100% or 50% of the CPW was secured as offsets in the strategic offset area (Figure 15, S5 and 5A, S6 and 6A). When 100% of the CPW available in the strategic offset area is secured as an offset, three of the four offset scenarios compensate for development impacts (all except scenario 4). When 50% of the CPW available in the strategic offset area is secured as an offset, only two of the four offset scenarios (S5 and S6) provide adequate compensation.
- In terms of whether the Plan addresses the impacts of development in the Growth Areas as well as declines from landscape scale threats within the program area, three of the four offset scenarios (scenarios 3, 5, and 6) compensate for both these impact types when 100% of the CPW in the strategic offset area is secured (Figure 14(a)). However, none of the offset scenarios can compensate for both these impact types in the program area if only 50% of the CPW in the strategic offset area is secured (Figure 14(b)).

- The timing of offset implementation and the level of management intensity make a significant difference to the gains able to be achieved by offsets, with early implementation/high intensity management always performing best.
- The relative benefit of early implementation compared to high intensity management depends on the time period over which gains are evaluated. The results suggest that (Figure 15):
  - Early implementation with low or high intensity management delivers greater gains in the short term (1 to 2 decades).
  - Early implementation with high intensity management delivers the greatest gains in the long term.
- Results of expert elicitation (Figure 10) indicate that high intensity management provides significant potential for providing restoration gains for CPW, even when starting from a low initial condition. However, low intensity management has limited capacity to improve the ecological condition of CPW, especially when starting from a low initial condition.

Care will need to be taken in extrapolating these results to other PCTs. However, it is likely that the overall findings will have relevance and will provide useful context to the discussion of long-term trends in native vegetation change within the Cumberland subregion.

APPENDICES

APPENDIX A – DETAILED RESULTS OF THE EXPERT ELICITATION

Below, the key results of the expert elicitation are summarized. They show the *best estimates* of each expert for how tree richness (Figure A1), grass richness (Figure A2), forb richness (Figure A3), tree cover (Figure A4), and grass cover (Figure A5) change over time. This is presented using four different starting conditions (low; medium 1; medium 2; high) and three management regimes (do nothing; low; and high management)— see main text for details of starting conditions and management. In each of the plots below, the results for each individual expert is shown with a thin, coloured line. The mean over all experts for is shown with a dashed black line. For the results presented in the main report, the mean value is across all experts is used for calculating the vegetation integrity score, as described above.

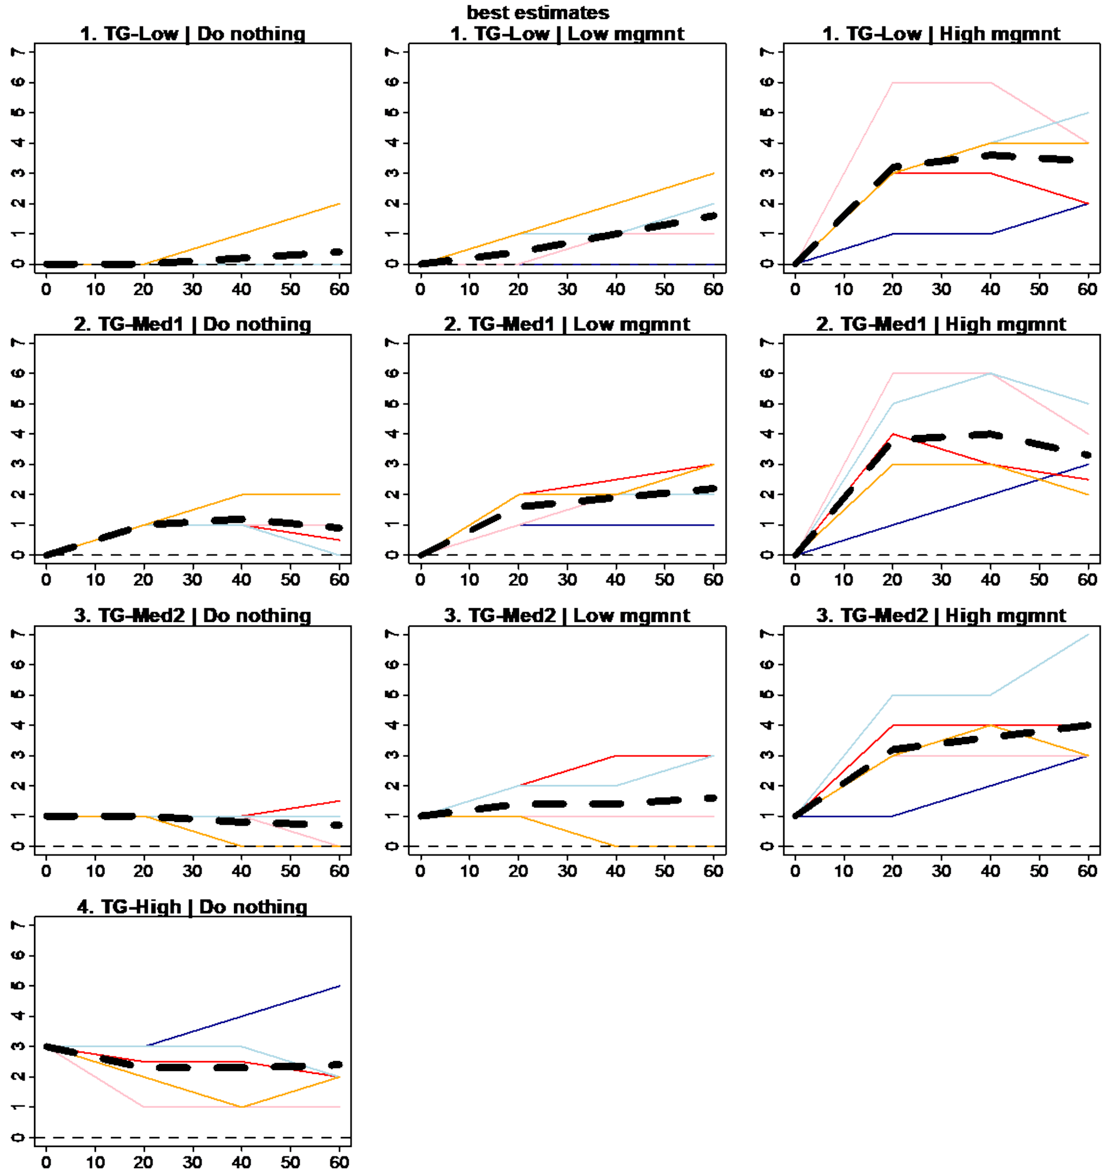

Figure A1. Results of the expert elicitation showing how tree richness (y-axis) for CPW is predicted to change over time (x-axis) for different initial conditions and management regimes in 20-year increments. The left column shows results for the do-nothing management scenario, while the middle and right columns show results for the low and high management regimes, respectively. The top row shows results for vegetation starting in the low condition, the second and third rows show results for vegetation starting in the medium 1 and medium 2 condition, respectively. The bottom plot shows results for vegetation starting in the high condition under do-nothing. Note, results were not elicited for vegetation starting in the high condition under high or low management, as it was assumed that with management, it would retain its richness score. Y-axis value on all plots is the count of species of trees in a notional 20 m x 20 m plot. X-axis (time) values were identified at t=0, t=20, t=40 and t=60.

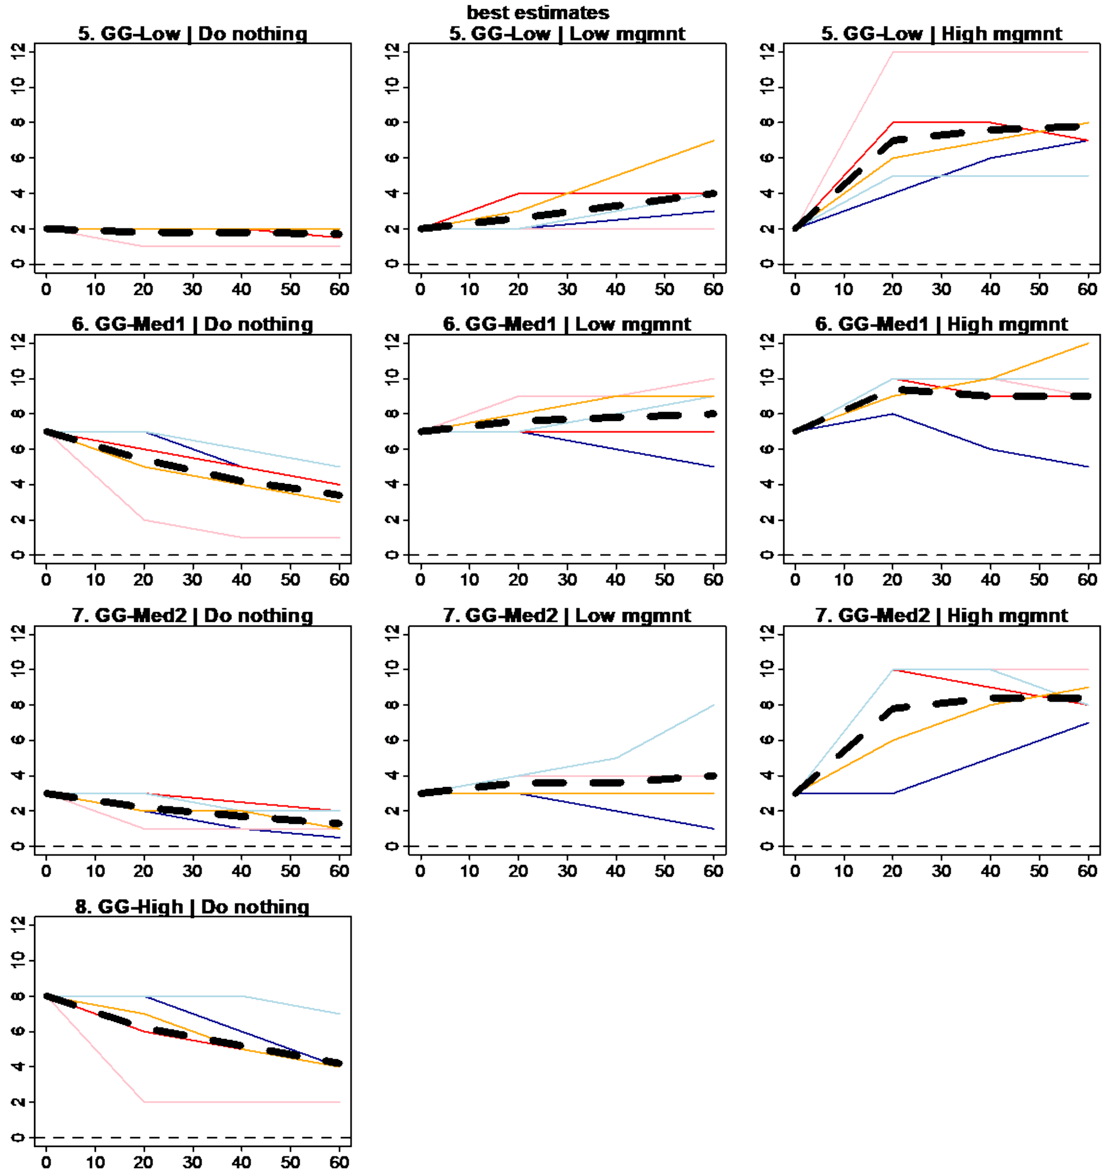

Figure A2. Results of the expert elicitation showing how grass-growth-form-group species richness (y-axis) for CPW is predicted to change over time (x-axis) for different initial conditions and management regimes in 20-year increments. The left column shows results for the do-nothing management scenario, while the middle and right columns show results for the low and high management regimes, respectively. The top row shows results for vegetation starting in the low condition, the second and third rows show results for vegetation starting in the medium 1 and medium 2 condition, respectively. The bottom plot shows results for vegetation starting in the high condition under do-nothing. Note, results were not elicited for vegetation starting in the high condition under high or low management, as it was assumed that with management, it would retain its richness score.

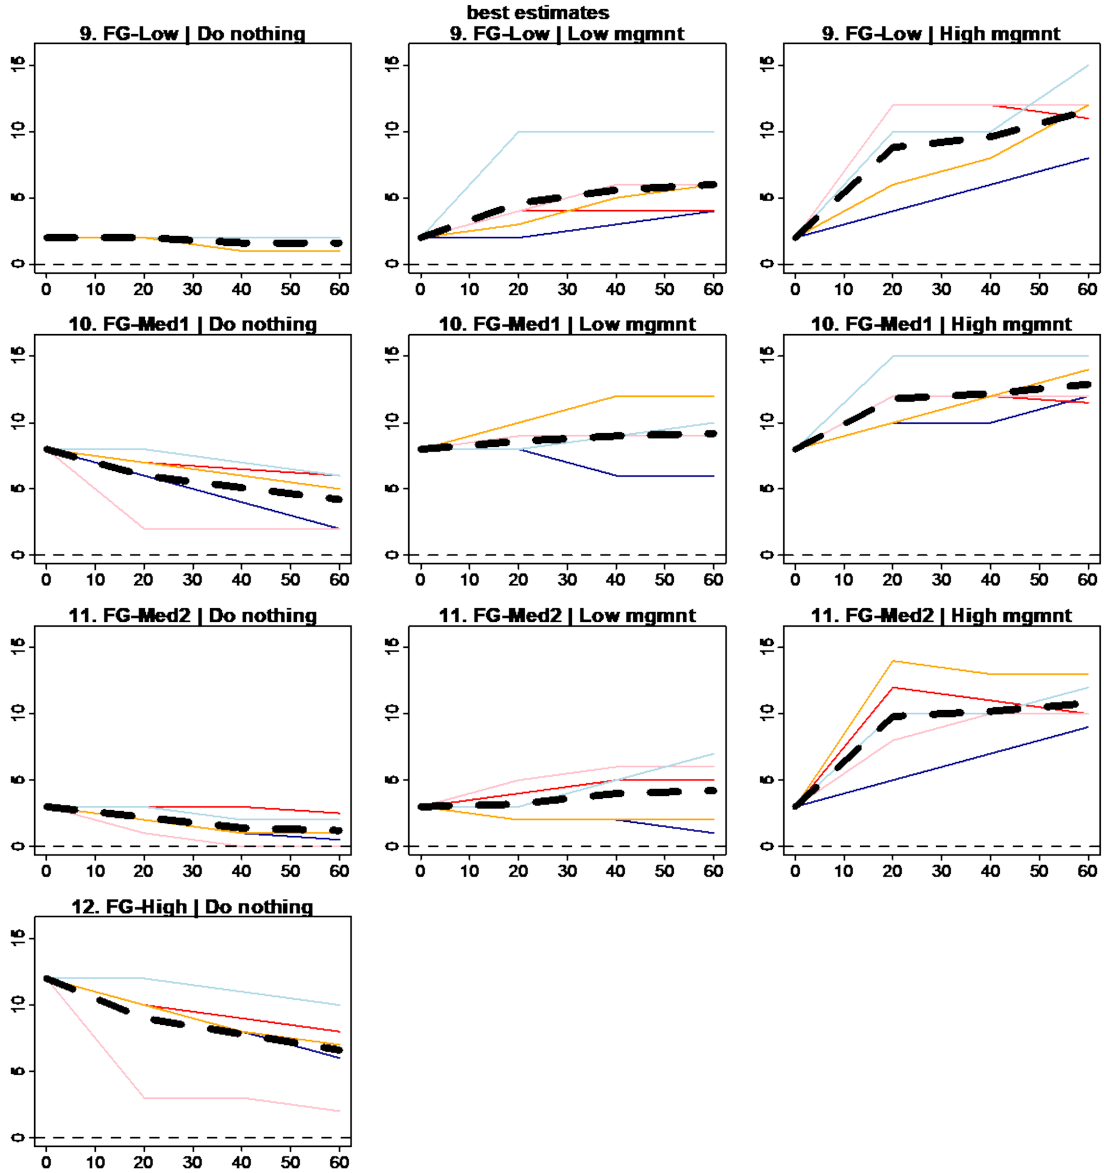

Figure A3. Results of the expert elicitation showing how <u>forb species richness</u> (y-axis) for CPW is predicted to change over time (x-axis) for different initial conditions and management regimes in increments of t=20. The left column shows results for the do-nothing management scenario, while the middle and right columns show results for the low and high management regimes, respectively. The top row shows results for vegetation starting in the low condition, the second and third rows show results for vegetation starting in the medium 1 and medium 2 condition, respectively. The bottom plot shows results for vegetation starting in the high condition under do-nothing. Note, results were not elicited for vegetation starting in the high condition under high or low management, as it was assumed that with management, it would retain its richness score.

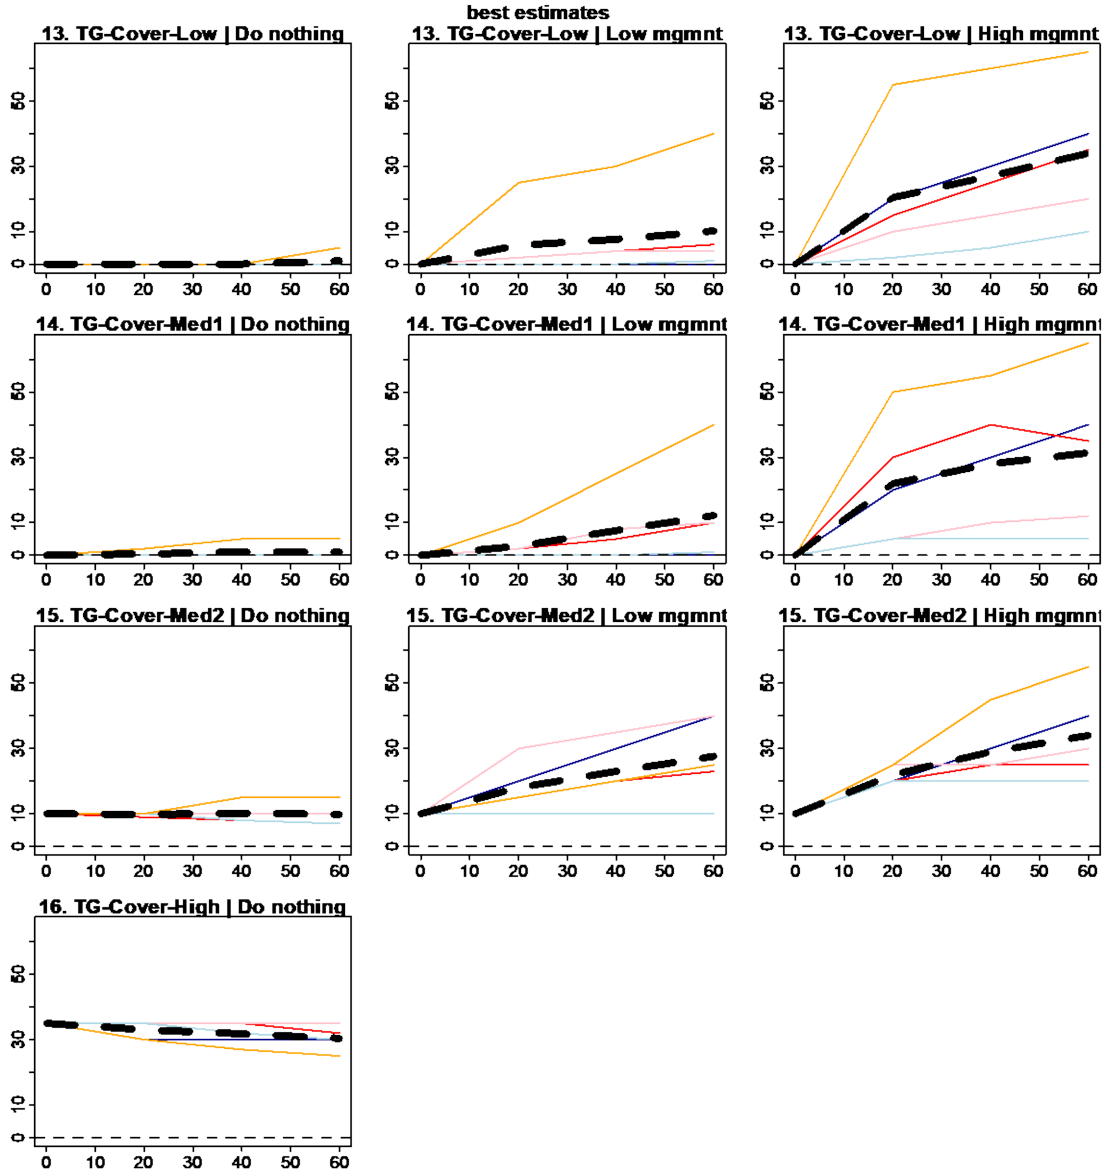

Figure A4. Results of the expert elicitation showing how tree crown cover (y-axis) for CPW is predicted to change over time (x-axis) for different initial conditions and management regimes in increments of t=20. The left column shows results for the do-nothing management scenario, while the middle and right columns show results for the low and high management regimes, respectively. The top row shows results for vegetation starting in the low condition, the second and third rows show results for vegetation starting in the medium 1 and medium 2 condition, respectively. The bottom plot shows results for vegetation starting in the high condition under do-nothing. Note, results were not elicited for vegetation starting in the high condition under high or low management, as it was assumed that with management, it would retain its cover score.

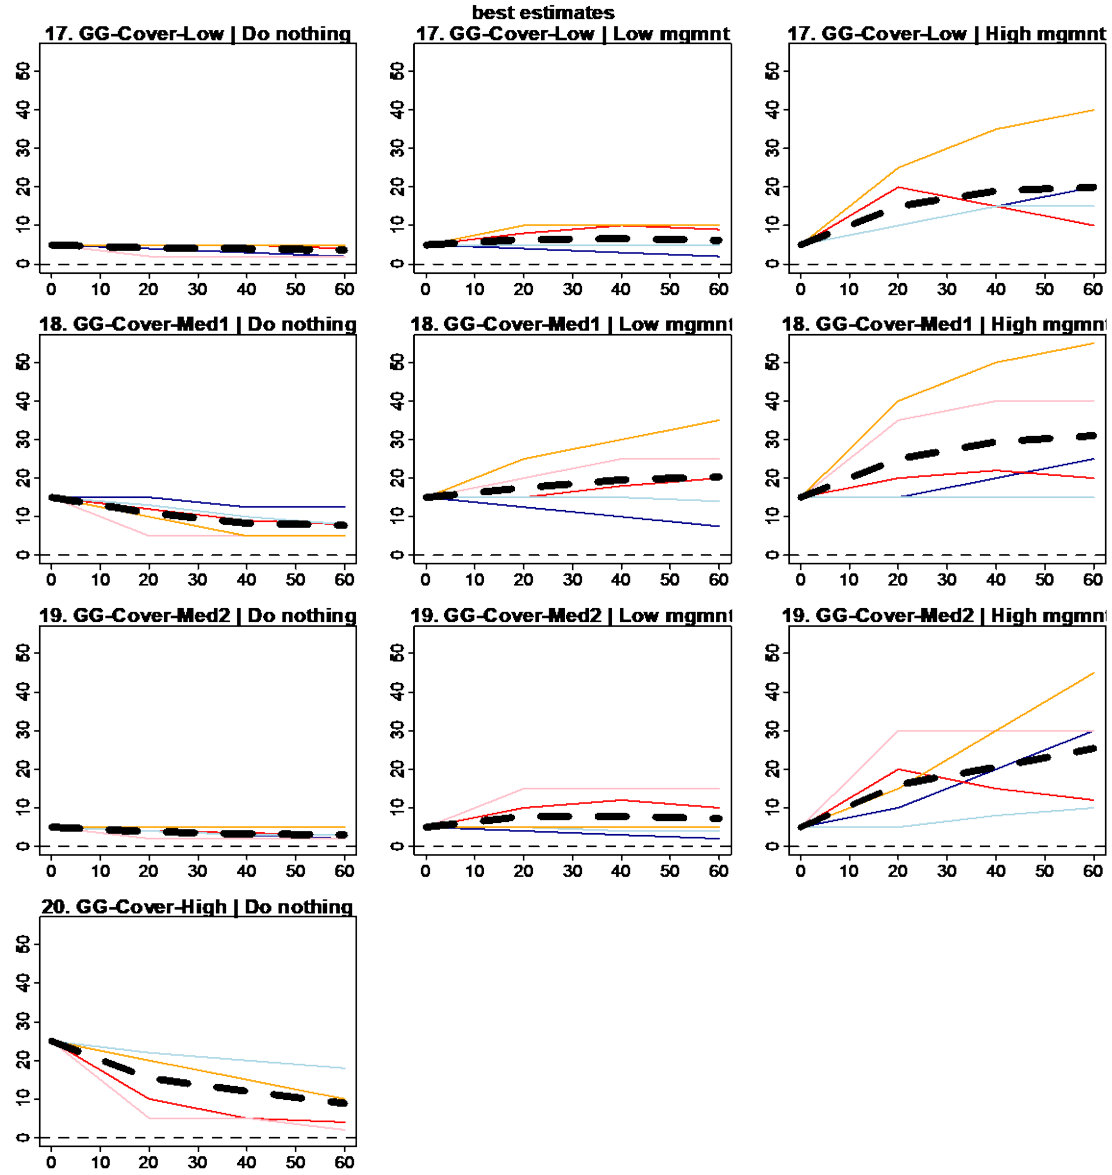

Figure A5. Results of the expert elicitation showing how <u>grass crown cover</u> (y-axis) for CPW is predicted to change over time (x-axis) for different initial conditions and management regimes in increments of t=20. The left column shows results for the do-nothing management scenario, while the middle and right columns show results for the low and high management regimes, respectively. The top row shows results for vegetation starting in the low condition, the second and third rows show results for vegetation starting in the medium 1 and medium 2 condition, respectively. The bottom plot shows results for vegetation starting in the high condition under do-nothing. Note, results were not elicited for vegetation starting in the high condition under high or low management, as it was assumed that with management, it would retain its cover score.

Biodiversity credit report – GPEC

BAM Credit Summary Report

Proposal Details

Assessment Id	Proposal Name	BAM data last updated
00013050/BAAS18134/18/00013054	Western Sydney Strategic Biodiversity Certification - Greater Penrith to Eastern Creek	18/06/2020
Assessor Name	**Report Created**	**BAM Data version ***
Jane Raithby-Veall	24/06/2020	29
Assessor Number	**BAM Case Status**	**Date Finalised**
BAAS18134	Open	To be finalised
Assessment Revision	**Assessment Type**	
3	Biocertification	

* Disclaimer: BAM data last updated may indicate either complete or partial update of the BAM calculator database. BAM calculator database may not be completely aligned with Bionet.

Ecosystem credits for plant communities types (PCT), ecological communities & threatened species habitat

Zone	Vegetation zone	Vegetation	Area (ha)	Constant	Species sensitivity to gain class (for BRW)	Biodiversity	Potential	Ecosystem credits

Biodiversity credit report – WSA

BAM Credit Summary Report

Proposal Details

Assessment Id	Proposal Name	BAM data last updated *
00013050/BAAS18134/18/00013053	Western Sydney Strategic Biodiversity Certification - Western Sydney Aerotropolis	18/06/2020
Assessor Name	**Report Created**	**BAM Data version ***
Jane Raithby-Veall	01/07/2020	29
Assessor Number	**BAM Case Status**	**Date Finalised**
BAAS18134	Open	To be finalised
Assessment Revision	**Assessment Type**	
3	Biocertification	

* Disclaimer: BAM data last updated may indicate either complete or partial update of the BAM calculator database. BAM calculator database may not be completely aligned with Bionet.

Ecosystem credits for plant communities types (PCT), ecological communities & threatened species habitat

Zone	Vegetation zone	Vegetation	Area (ha)	Constant	Species sensitivity to gain class (for	Biodiversity	Potential SAII	Ecosystem credits

About the Authors

Ascelin Gordon is an RMIT University Vice Chancellor's Senior Research Fellow within the ICON Science research group that sits within the Centre for Urban Research, in the School of Global Urban and Social Studies. He undertakes research on a range of conservation problems with a particular focus on ecological modelling, decision making for conservation, and biodiversity offsetting.

Vira Koshkina is undertaking a PhD at RMIT University in mathematical sciences within the School of Science. Her PhD focuses on developing new approaches for species distribution modelling that integrates different data sources and can better account for spatial correlations.

Acknowledgments

A range of people have been invaluable in pulling together the data required for this study and providing expert advice on species focussed on here. In particular we would like to thank: Tom Holden, Steve Douglas, Peter Hemphill, Rebecca Dwyer, Paul Burcher, Greg Steenbeeke, Enhua Lee, and Darren James.

Summary

The NSW Government is planning for the future growth of Sydney, and as part of the planning process the Department of Planning and Environment are preparing the Western Sydney Strategic Sustainability Plan (WSSSP). The WSSSP includes a conservation plan for the Cumberland Subregion (IBRA 7), and within this, habitat mapping is being undertaken for all Category 1 EPBC Act listed species. This report details the process to develop species distribution models (SDMs) for 19 EPBC listed species (6 fauna species and 13 flora species), which were deemed suitable for this approach.

Occurrence data for the species were obtained from BioNet, and 21 spatial predictors layers were selected to as likely covariates that could be used to develop models to predict the likelihood of occurrence of the species. SDMs were developed using the software 'Maxent'.

An approach was developed to account for the different levels of bias likely present in the species occurrence records from BioNet. This resulted in three maps with different assumptions regarding bias in the occurrence data, depicting the likelihood of occurrence for each species. These maps were then combined to produce a single risk-based SDM with three classes of occurrence for each species: "unlikely to occur" - none of the SDMs showed the species occurring; "potential to occur"- at least one on the SDMs showed the species occurring; and "likely to occur" - all 3 of the SMDs showed the species as occurring.

Results for all species are presented, and the limitations of the approach are discussed in detail. Options for improving the resulting SDMs also presented. Software to undertake the analysis was developed in R, and is available via GitHub. All SDMs produced are available for download as raster files for use in subsequent analysis, and the predictor layers used in generating the SDMs are also available.

Introduction

The NSW Government is planning for the future growth of Sydney to provide new jobs, homes, services and transport links in the West and South West Districts of Western Sydney. As part of the planning process, priority growth areas (PGAs) have been defined, and the NSW Department of Planning and Environment (DPE) is preparing the Western Sydney Strategic Sustainability Plan (WSSSP).

The WSSSP will provide an overarching strategy for managing environmental and development outcomes in the West and South West Districts of Western Sydney and will consist of three components: (i) a strategic conservation plan (ii); a green infrastructure plan; and (iii) an urban sustainability plan. The strategic conservation plan will be utilized to support strategic avoidance and mitigation of development impacts, and also to increase persistence of biodiversity values in Western Sydney through identifying the most suitable patches of native vegetation for protection. The plan will be assessed strategically at both the NSW and Commonwealth level through:

- Biodiversity certification under the NSW Biodiversity Conservation Act 2016 (BC Act);

- A strategic assessment under the Commonwealth's Environment Protection and Biodiversity Conservation Act 1999 (EPBC Act).

As part of the conservation plan, DPE is undertaking habitat mapping across the Cumberland Subregion (IBRA 7) for all Category 1 EPBC Act species. This is being done through one of two methods: (i) species distribution models (SDMs; the focus of this report); and (ii) an expert knowledge-based approach (where SDMs are not possible), undertaken by Biosis (not dealt with any further here). In addition to the subregion mapping, detailed mapping is being undertaken within the PGAs as part of the NSW Biodiversity Assessment Methodology (BAM) process.

SDMs are statistical models used to estimate the relationship between species records at sites and the environmental and/or spatial characteristics of those sites (Franklin 2010). Once this relationship has been estimated, the statistical model can be used to predict other locations in the landscape where the species is likely to occur. Thus, SDMs are useful as they can provide estimates over large areas of where a species (or its habitat) is likely to occur. SDMs are used in broad range of applications including the management of threatened species, conservation planning, predicting the impacts of threatening processes such as development or climate change and to manage landscapes (Guillera-Arroita et al. 2015).

In this context of the WSSSP, it is envisaged that SDMs will be used in three ways:

1. They will provide context for the detailed impact analysis being undertaken within the PGAs. For example, they will provide information about the relative importance of habitat within the PGAs compared to the rest of the Cumberland Subregion;

2. They will enable an indicative impact assessment for transport corridors. Transport corridors will be intersected with the SDM predictions to provide an indication of possible impacts on Matters of National Environmental Significance. It is critical to note the transport corridors will be surveyed in detail as part of future NSW biodiversity approvals process, and that the SDM outputs are for indicative impact assessment only;

3. They will help evaluate proposed conservation measures by providing indicative information about the amount of habitat available for biodiversity offsetting. It is critical to note that any sites proposed for offsets or other measures will be surveyed prior to being secured. Thus, the SDM outputs are for indicative evaluation of offsets or other conservation measures.

Undertaking species distribution modelling to produce accurate predictions regarding where a species, or its habitat, is likely to occur can be challenging for a number of reasons. Firstly, the species occurrence data used for modelling is often highly biased (Elith et al. 2006). In regions where there are no species occurrences, it's often not clear whether the species really doesn't occur there, or whether no one has looked. Secondly, spatial data capturing appropriate predictors that are driving the species occurrences needs to be available. Thirdly detectability may be an issue, where if a species is present, it may be less likely to be seen in some parts or its range than in others, further biasing the presence records (Guillera-Arroita 2016). Finally, a species may not occur in every location where its environmental niche is present, due to interactions with other species, or historical accidents.

On top this, SDMs are more challenging in human dominated regions such as the Cumberland Plain. This landscape has a long history of human use that has resulted in it becoming increasing modified, and placing great importance on the remaining biodiversity values. These landscape modifications mean that there are a range of additional anthropogenic other factors driving where species currently occur, such as land clearing and invasive species. The species occurrence records in the Cumberland Plain may be driven by all the above factors. This means the predictions derived from SDMs will be predicting some combination of where species originally occurred, and where it is now due to current anthropogenic threats.

Given the limitation of this approach, SDMs should be supplemented with expert derived methods. However, the advantage of this approach is that it is data-driven, systematic, repeatable, and easily able to be updated once further data on species locations is gathered or improved predictor layers becomes available.

Species distribution models using 'Maxent'

Developing a species distribution model starts with collecting observations of species occurrences and data on environmental factors that are thought to affect the occurrence of the species. The locations are then linked to the values of the environmental predictors, and the values of the predictors at the locations of the specific observations are extracted to a table along with the results of the survey. A statistical, machine learning, or another type of model describing the relationship between species occurrence and environmental data is then fitted to the data. The model coefficients that are estimated during the model fitting process are then applied to the environmental data to produce a prediction map of the species habitat (Franklin 2010). There are two common types of species occurrence data which can be used to build SDMs: presence-background data and site-occupancy data (Phillips et al. 2006).

The two types differ by the collection method and have various levels of reliability. *Site - occupancy data i*s collected during a planned survey, when the researchers split the geographical domain of interests into fixed sized areas called survey sites. The sites are then inspected looking for the species of interest and either the presence or absence of the species is recorded. In many cases, researchers conduct repeated surveys to ensure that the individuals present at the site have been detected. Critically the absence of a species at a location is also available from this type of data.

Presence-background (PB) data consists of "presence-only" data which comprises a set of locations where individuals of the species under investigation have been observed, combined with some background points selected from the areas where the species has not been detected. The presence only data is often collected opportunistically from surveys and is usually added to online publicly accessible databases which aggregate presence only data from multiple sources. To use this data in modelling, "background points" are needed and these are randomly selected from the area where predictions are to be made (Merow et al. 2013). There are multiple ways that points can be sampled to generate the background data. Due to being the most widely available, presence-background data is the most common data used in SDMs.

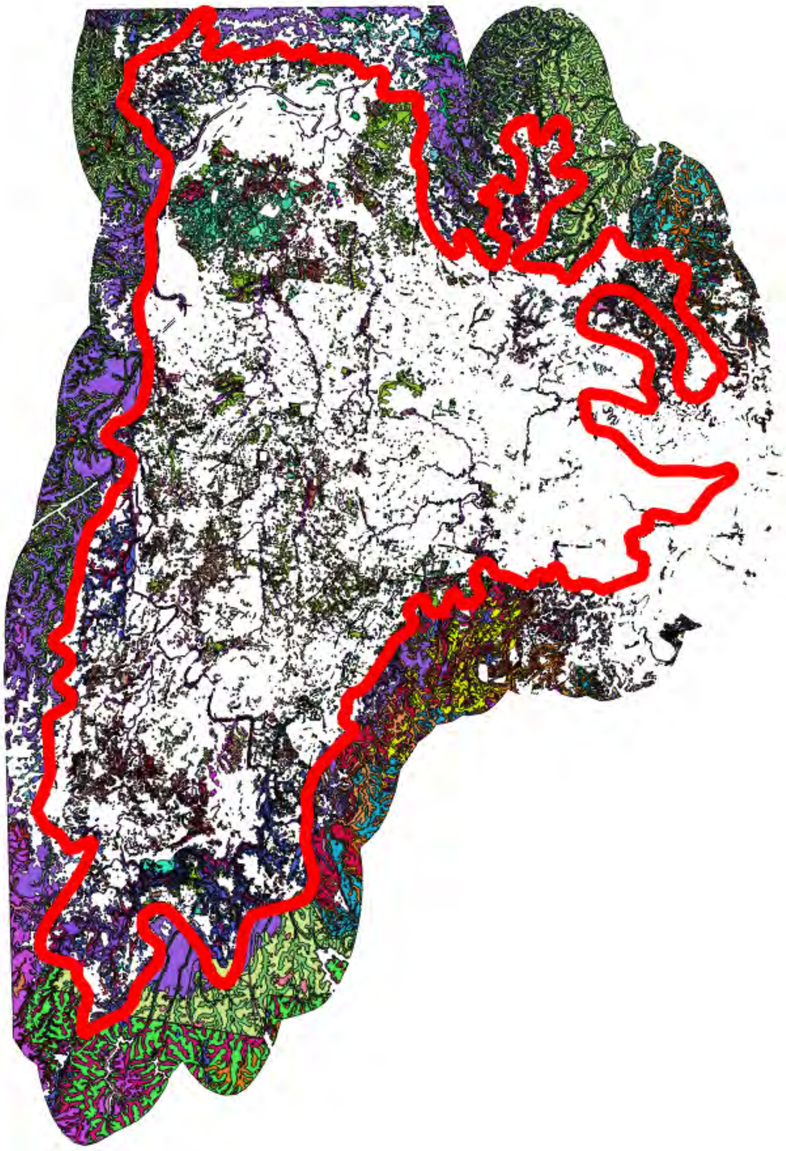

Figure 1 The map of the study area: a 10 km buffer around was placed around the Cumberland Subregion (the Cumberland Subregion outline is shown as a red line). A map of native vegetation is overlaid. The vegetation is classified by Plant Community Type. Areas the north and south-west are visible where the buffer was reduced due to limited data.

While PB data is pervasive, it can have high levels of bias since the observations are done in non-structured fashion and locations of species detections are likely to correlate with the areas that are more accessible by humans (Phillips and Dudík 2008a). Using this data without accounting for these biases can lead to a model that predicts the probability of a species being detected by humans rather than the likelihood of a species being present in the area. This effect is called overfitting, meaning that while the model is doing an excellent job at fitting the coefficients that explain the observed presence data, it does a poor job of predicting the probability of a species being present at other locations. To avoid overfitting, ecologists choose background points in the PB data according to the bias that is present in the presence records (Elith et al. 2011). This is described further below.

All the models presented here were built using Maxent, which is a free software that has been widely used and evaluated in the peer reviewed literature, and is accepted as a powerful method for generating SDMs with PB data (Phillips and Dudík 2008b; Elith et al. 2011; Merow, Smith, and Silander 2013; Phillips et al. 2017). It estimates the probability of the species presence in each point of the landscape based in the environmental parameters of that point relative to the values of the same parameters in locations where the species is known to occur.

Maxent estimates species distribution by trying to achieve the most uniform distribution (i.e maximum entropy) of the parameters in the predicter areas of likely occurrence, while obeying the constraints that the expected number of species in each location closely matches the observed presences (Phillips et al 2006). To do that, the method heavily relies on the background points selected from the study area in the locations where the species has not been observed.

In this report we present the results of using Maxent with PB data for 19 EPBC-listed species in the Cumberland Subregion consisting of 6 fauna species and 13 flora species.

Methods

Study area

For the study area we chose an area that includes a 10 km buffer around the Cumberland (IBRA 7) Subregion (Figure 1). The study area does not include the full 10km buffer around the all areas of the Cumberland Subregion due to some areas in the buffer lacking appropriate vegetation and soil data. Thus, the buffer is reduced in areas to the north and south west of the Cumberland Subregion (Figure 1).

Species occurrence data

Occurrence data used in the analysis was obtained from BioNet, a repository for biodiversity data products managed by the NSW Office of Environment and Heritage (http://www.bionet.nsw.gov.au). The BioNet Atlas application contains data collections comprising (i) species sightings; (ii) systematic surveys; (iii) threatened biodiversity; and (iv) species names. The initial list of species considered for the modelling is shown in Table 1, and BioNet sighting records were extracted for a 100km buffer around the Cumberland Subregion for initial analysis.

Scientific name	Common name	Order	Kingdom
Acacia pubescens	Downy Wattle	Flora	Plantae
Persoonia nutans	Nodding Geebung	Flora	Plantae
Pimelea spicata	Spiked Rice-flower	Flora	Plantae
Phascolarctos cinereus	Koala	Diprotodonta	Animalia
Pultenaea parviflora	NA	Flora	Plantae
Pteropus poliocephalus	Grey-headed Flying-fox	Chiroptera	Animalia
Eucalyptus benthamii	Camden White Gum	Flora	Plantae
Casuarina glauca	Swamp Oak	Flora	Plantae
Grevillea parviflora subsp. parviflora	Small-flower Grevillea	Flora	Plantae
Persoonia bargoensis	Bargo Geebung	Flora	Plantae
Micromyrtus minutiflora	NA	Flora	Plantae
Litoria aurea	Green and Golden Bell Frog	Anura	Animalia
Acacia bynoeana	Bynoe's Wattle	Flora	Plantae
Lathamus discolor	Swift Parrot	Psittaciformes	Animalia
Melaleuca deanei	Deane's Paperbark	Flora	Plantae
Chalinolobus dwyeri	Large-eared Pied Bat	Chiroptera	Animalia
Pomaderris brunnea	Brown Pomaderris	Flora	Plantae
Petauroides volans	Greater Glider	Diprotodonta	Animalia
Commersonia prostrata	Dwarf Kerrawang	Flora	Plantae
Pommerhelix duralensis	Dural Woodland Snail	Eupulmonata	Animalia
Persoonia hirsuta	Hairy Geebung	Flora	Plantae
Allocasuarina glareicola	NA	Flora	Plantae
Dasyurus maculatus	Spotted-tailed Quoll	Dasyuromorphia	Animalia
Syzygium paniculatum	Magenta Lilly Pilly	Flora	Plantae
Botaurus poiciloptilus	Australasian Bittern	Ciconiiformes	Animalia
Anthochaera phrygia	Regent Honeyeater	Passeriformes	Animalia
Persoonia mollis subsp. maxima	NA	Flora	Plantae
Cynanchum elegans	White-flowered Wax Plant	Flora	Plantae
Persoonia glaucescens	Mittagong Geebung	Flora	Plantae
Pimelea curviflora var. curviflora	NA	Flora	Plantae
Pterostylis saxicola	Sydney Plains Greenhood	Flora	Plantae
Darwinia biflora	NA	Flora	Plantae
Leucopogon exolasius	Woronora Beard-heath	Flora	Plantae
Heleioporus australiacus	Giant Burrowing Frog	Anura	Animalia
Lasiopetalum joyceae	NA	Flora	Plantae
Acacia gordonii	NA	Flora	Plantae
Rostratula australis	Australian Painted Snipe	Charadriiformes	Animalia
Eucalyptus camfieldii	Camfield's Stringybark	Flora	Plantae
Genoplesium baueri	Bauer's Midge Orchid	Flora	Plantae
Haloragodendron lucasii	NA	Flora	Plantae
Macquaria australasica	Macquarie Perch	Perciformes	Animalia

Isoodon obesulus obesulus	Southern Brown Bandicoot (eastern)	Peramelemorphia	Animalia
Thesium australe	Austral Toadflax	Flora	Plantae
Hoplocephalus bungaroides	Broad-headed Snake	Squamata	Animalia
Pterostylis gibbosa	Illawarra Greenhood	Flora	Plantae
Eucalyptus sp. Cattai	NA	Flora	Plantae
Haloragis exalata subsp. exalata	Square Raspwort	Flora	Plantae
Trachystoma petardi	Pinkeye Mullet; Fresh Water Mullet	Mugiliformes	Animalia
Hibbertia spanantha	Julian's Hibbertia	Flora	Plantae
Acacia terminalis subsp. terminalis	Sunshine Wattle	Flora	Plantae
Prostanthera marifolia	Seaforth Mintbush	Flora	Plantae
Caladenia tessellata	Thick Lip Spider Orchid	Flora	Plantae
Leptospermum deanei	NA	Flora	Plantae
Thelymitra kangaloonica	Kangaloon Sun Orchid	Flora	Plantae
Hibbertia sp. Bankstown	NA	Flora	Plantae
Deyeuxia appressa	NA	Flora	Plantae
Rhizanthella slateri	Eastern Australian Underground Orchid	Flora	Plantae
Prototroctes maraena	Australian Grayling	Osmeriformes	Animalia

Table 1. The initial list of species considered for modelling.

Species were then excluded due to a range of factors. This included having a small number of records (in general more than 50 occurrences was required for modelling, though an indicative SDM has been produced for the White-flowered Wax Plant (Cynanchum elegans) with only 23 records—see below) and the fact they were generalist species for which appropriate predictor layers were not available to predict occurrence. It was also found that some candidate species were considered based on erroneous records, so that after a manual review of the records (see below) very few legitimate records remained. Table 2 shows the final species for which SDMs were undertaken using Maxent.

The data extracted from Bionet included records up until the 14 August, 2018. Records were filtered so that only records with a spatial accuracy of 100m or less were retained. No filter was applied to exclude records older than a specified date, as it was deemed that the 100m accuracy filter would remove all old records with low accuracy.

It was found that there were various errors in the species occurrence data derived from BioNet. To address this, external consultants were contracted to undertake a manual review of the occurrence records for all records up until 14 Aug 2018. Steve Douglass (Ecological Surveys & Planning) reviewed the flora records, and Paul Burcher (Aquila Ecological Surveys) reviewed the fauna records.

Scientific name	Common name	Order	Kingdom
Acacia bynoeana	Bynoe's Wattle	Fabaceae (Mimosoideae)	Flora
Acacia pubescens	Downy Wattle	Fabaceae (Mimosoideae)	Flora
Botaurus poiciloptilus	Australasian Bittern	Ardeidae	Fauna

Cynanchum elegans	White-flowered Wax Plant	Apocynaceae	Flora
Darwinia biflora	NA	Myrtaceae	Flora
Eucalyptus benthamii	Camden White Gum	Myrtaceae	Flora
Grevillea parviflora subsp. parviflora	Small-flower Grevillea	Proteaceae	Flora
Heleioporus australiacus	Giant Burrowing Frog	Myobatrachidae	Fauna
Litoria aurea	Green and Golden Bell Frog	Hylidae	Fauna
Micromyrtus minutiflora	NA	Myrtaceae	Flora
Persoonia bargoensis	Bargo Geebung	Proteaceae	Flora
Persoonia hirsuta	Hairy Geebung	Proteaceae	Flora
Persoonia nutans	Nodding Geebung	Proteaceae	Flora
Phascolarctos cinereus	Koala	Phascolarctidae	Fauna
Pimelea spicata	Spiked Rice-flower	Thymelaeaceae	Flora
Pomaderris brunnea	Brown Pomaderris	Rhamnaceae	Flora
Pommerhelix duralensis	Dural Woodland Snail	Camaenidae	Fauna
Pteropus poliocephalus	Grey-headed Flying-fox	Pteropodidae	Fauna
Pultenaea parviflora	NA	Fabaceae (Faboideae)	Flora

Table 2. The final list of species for which SDMs were undertaken.

The data review process involved a manual review of occurrence records, and updating information associated with species occurrence records, or removing the record as appropriate. The process consisted of:

- addressing erroneous records which could occur through
    - misidentification;
    - data entry error (wrong species input);
    - incorrect spatial data (co-ordinates and/or location description);
    - inappropriate spatial accuracy assignment (too coarse, too fine, depending on data quality);
    - plantings or naturalisations
- for some of the very old records, there was sufficient information to allow them to be located with high accuracy in remnant habitats (such as urban bushland) in highly developed suburbs, in these cases the records were kept and the locations and accuracy records were updated.

The fauna data cleaning also involved marking records as to whether or not they should be counted as 'informative' or not for the modelling. This was based on whether the record was in breeding habitat for the species, or whether it was likely to in foraging habitat, or in locations of where the species was dispersing outside its habitat (or possibly road kill). Specifically:

- for the Grey-headed Flying-fox (*Pteropus poliocephalus*), only records associated with roosts where retained;
- for the Koala (*Phascolarctos cinereus*), only records associated with native vegetation were retained, due to the male koalas being known to disperse through non-native habitat after the breeding season;

- for Australasian Bittern, records were only retained if they were in or close to appropriate mapped native vegetation, and records associated with open water were excluded.

The number of records for each of the species being modelled is displayed below in Table 3, including a breakdown the proportion of records overlapping native vegetation and the number within the Cumberland Subregion.

Scientific name	Common name	Total number of presences in study area	Number of presences in Cumberland	Percentage of presences in areas with native vegetation (%)
Litoria aurea	Green and Golden Bell Frog	13496	12587	0.6
Acacia pubescens	Downy Wattle	5344	5138	85
Phascolarctos cinereus	Koala	3983	1191	76.9
Pteropus poliocephalus	Grey-headed Flying-fox	2590	1639	54.6
Persoonia nutans	Nodding Geebung	1559	1511	88.6
Pimelea spicata	Spiked Rice-flower	1312	1312	93.5
Grevillea parviflora subsp. parviflora	Small-flower Grevillea	1292	1089	97.3
Pultenaea parviflora	NA	1221	1211	79.4
Darwinia biflora	NA	1181	27	11.1
Eucalyptus benthamii	Camden White Gum	582	577	72.3
Persoonia hirsuta	Hairy Geebung	503	38	68.4
Persoonia bargoensis	Bargo Geebung	390	271	80.4
Acacia bynoeana	Bynoe's Wattle	268	113	77
Micromyrtus minutiflora	NA	190	188	66.5
Heleioporus australiacus	Giant Burrowing Frog	134	13	30.8
Pommerhelix duralensis	Dural Woodland Snail	79	16	87.5
Pomaderris brunnea	Brown Pomaderris	75	71	88.7
Botaurus poiciloptilus	Australasian Bittern	56	34	44.1
Cynanchum elegans	White-flowered Wax Plant	23	23	82.6

Table 3. Number of occurrence records in BioNet for each species after the data cleaning was completed. For each species, the total number of records in the study area is shown, the number within the Cumberland Subregion, and the percentage of the records that overlap with native vegetation.

Environmental predictors

Through discussions with a range of experts on the flora and fauna of the Cumberland Plain, and drawing on similar studies utilizing SDMs in NSW (Kujala at al. 2016) a range of potential predictors layers were selected. The experts providing feedback into the selection of predictors included staff members of NSW Government Departments (OEH and DPE) as well as a range of consultants involved in WSSSP. The list of the initial 37 predictors considered in the analysis is shown in Table 4.

Predictor code	Predictor description
vegetation	Native vegetation
ct_temp_maxsum	Average daily max temperature - Summer
ct_tempannrnge	Temperature Annual Range: difference between bio5 and bio6 (bio7)
cw_precipann	Annual Precipitation (bio12)
gp_k_fillspl	filtered potassium (K), gaps filled in using geograhically weighted regession model and spline function
lf_aspect_tr	Beer's Apsect- transformation of aspect to a continuous scaled variable. Changed for the southern hemisphere by setting maximum value (2) to SE slopes (coolest) and minimum (0) to NW slopes (warmest).
lf_cti	Compound topographic index or CTI also known as wetness index, topographic wetness index. Based on DEM-H (for flow direction and accumulation)
lf_rough0100	Neighbourhood topographical roughness based on the standard deviation of elevation in a circular 100 m neighbourhood. Derived from DEM-S
lf_tpi0120	Topographic position index using neighbourhood of 120m radius
dl_lat_grid	Latitude (surrogate for location, disperal, isolation)
dl_long_grid	Longitude (surrogate for location, dispersal, isolation)
ce_radhp	Highest Period Radiation (bio21)
ce_radlp	Lowest Period Radiation (bio22)
ct_frostdays_lt2	Number of days/annum with minimum temperature less than 2 degrees
ct_temp_maxwin	Average daily max temperature - Winter
ct_temp_minsum	Average daily min temperature - Summer
ct_temp_minwin	Average daily min temperature - Winter
ct_tempdiurn	Mean Diurnal Range (Mean(period max-min)) (bio2)
ct_tempmtcp	Min Temperature of Coldest Period (bio6)
ct_tempmtwp	Max Temperature of Warmest Period (bio5)
cw_etaaann	Average areal actual evapotranspiration - Annual
cw_etapann	Average areal potential evapotranspiration - Annual
dl_strmdstge2	Euclidean distance to 2nd order streams and above
dl_strmdstge4	Euclidean distance to 4th order streams and above
dl_strmdstge6	Euclidean distance to 6th order streams and above
gp_u_fillspl	filtered uranium (U), gaps filled in using geograhically weighted regession model and spline function
lf_rough0500	Neighbourhood topographical roughness based on the standard deviation of elevation in a circular 500 m neighbourhood. Derived from DEM-S
ct_tempann	Mean annual temperature (ANUCLIM)
ct_tempmtcp	Mean temperature of the coldest period (ANUCLIM)
ct_tempmtwp	Mean temperature of the hottest period (ANUCLIM)
cw_precipann	Mean annual rainfall (ANUCLIM)
cw_precipseas	Precipitation of Seasonality: Coefficient of Variation (ANUCLIM)

ce_radann	Mean annual solar radiation (ANUCLIM)
DEM	The altitude of a cell above sea level
lf_slope_deg	The slope of a cell (derived from Altitude)
lf_rough1000	Topographic ruggedness (standard deviation in altitude) in a 1000 metres m radius (derived from Altitude)
lf_cti	Compound topographic index (derived from Altitude)

Table 4. List of the predictors recommended by experts considered for modelling.

The vegetation layer used as a predictors consisted of data from the Sydney Metropolitan Area vegetation mapping "SydneyMetroArea_v2_0_2013_E_3817" (see https://www.environment.nsw.gov.au/-/media/OEH/Corporate-Site/Documents/BioNet/bionet-vegetation-map-data-release-notes-170144.pdf) and the 2013 update to the western parts of the Remnant Vegetation of the Cumberland Plain "CumberlandPlainWest_2013_E_4207" (see https://datasets.seed.nsw.gov.au/dataset/e0bed919-8e8b-45a0-803d-bcfb2a2d47e3). In addition, vegetation mapping from the PGAs undertaken by Biosis was also included in the analysis. The original vegetation maps are shape files, and the analysis used the Plant Community Type (PCT) attribute in the shape file to convert merge the above layers and convert them to a single raster layer.

The soil data used was from the NSW Soil Conservation Services 1:100,000 map series, sourced from eSpade (https://www.environment.nsw.gov.au/eSpade2Webapp). See Appendix 4 for a description of the numerical codes used for the modelling for each soil type. The soil type map was originally a shape file, and was converted to a raster file based on the soil type. Detailed consideration was given to the appropriateness of using the soil data in the modelling due to it known to be relatively coarse, and to contain some errors. On balance, it was decided the importance soil as predictor means the models are likely to be better with soil data included, compared to leaving it out.

All other predictors were provided by the NSW Department of Planning and Environment and were already in raster format.

The predictor layers were rasterized to 27m meter resolution (matching the resolution of many of the existing predictor layers) for subsequent use in the analysis, and cropped to the study area.

Checking for collinearity

Multicollinearity of predictors is a term that refers to a situation when two or more covariates are strongly correlated (Farrar and Glauber 1967). These strong correlations can have a negative effect on coefficient estimates during modelling. It can lead to situations where small changes in the data may cause large changes in estimated coefficients, resulting unreliable predictions of species occurrence (Renner and Warton 2013; Dormann et al. 2013).

The correlation coefficients for all combinations of potential predictors were calculated (see Appendix 3 for details of the correlations between predictor pairs). The correlations between predictors were estimated using the Pearson correlation, except for categorical variables, where Goodman and Kruskal's tau measure was used (Appendix 3).

If two predictors had a correlation coefficient larger than 0.8, one of them was removed. To select which predictor to remove, the following procedure was used: (i) the predictors were ranked based on the number of other predictors they are correlated with; (ii) the predictors with the highest ranks were then removed until all the remaining predictors had a correlation of less than 0.8.

After this process was completed, there were 21 predictor layers remaining, which are listed in Table 5.

Predictor code	**Predictor description**
ce_radann	Annual Mean Radiation
ce_radhp	Highest Period Radiation
ce_radlp	Lowest Period Radiation
ct_frostdays_lt2deg_1	Number of days/annum with minimum temperature less than 2 degrees
ct_tempann_1	Mean annual temperature
ct_tempseas_1	Temperature of Seasonality: Coefficient of Variation
cw_precipseas	Precipitation of Seasonality: Coefficient of Variation
DEM_c	The altitude of a cell above sea level
dl_lat_grid	Latitude (surrogate for location, disperal, isolation)
dl_strmdstge2	Euclidean distance to 2nd order streams and above
dl_strmdstge4	Euclidean distance to 4th order streams and above
dl_strmdstge6	Euclidean distance to 6th order streams and above
gp_k_fillspl	filtered potassium (K), gaps filled in using geograhically weighted regession model and spline function
lf_aspect_tr	Beer's Apsect
lf_slope_deg_c	The slope of a cell (derived from Altitude)
lf_cti	Compound topographic index
lf_rough0100	Neighbourhood topographical roughness based on the standard deviation of elevation in a circular 100 m neighbourhood.
lf_tpi0120	Topographic position index using neighbourhood of 120m radius

soil	Soil type (see Appendix 4 for correspondence between numerical codes and soil code
vegitation_pct_b	Native vegetation (PCT)

Table 5. The final list of predictor layers used in the analysis.

SDM approach

Maxent requires as inputs a list of the species presences and a set of spatial predictor layers. The after running, the software produces its spatial layers depicting likelihood of species occurrence, and also returns the value for the contributions for each of the environmental predictors used for model fitting. The higher the value of the contribution the more important the predictor is fitting the model to the data, and therefor for predicting the species occurrence.

For the categorical variables (vegetation and soil type) the software returns the contribution of the individual categories. For example, for the vegetation the output is the contribution of each individual PCT, depicting which PCTs are most strongly associated with the locations of the species.

Modelling

The full inputs required for Maxent are (i) the locations of the presence and background points used for model training, (ii) the location of the presence and background points that are to be used for model validation and (iii) the spatial layers of the environmental covariates that are thought to explain species occurrences (Phillips et al., 2006).

The main output of Maxent is a spatial layer of the predicted likelihood of occurrence. Each point in this layer is assigned a value between 0 and 1 that represent the likelihood of the species being present there. Note that this is the *relative likelihood* and not a probability of occurrence, meaning it is just an estimate of how likely the species is to occur there, relative the other locations in the study area and not an absolute probability of the species being present (Phillips and Dudík 2008b; Elith et al. 2011). These values can then thresholded to obtain a binary map of likely and unlikely occurrence areas. There are multiple ways to select a threshold values (Liu, White, and Newell 2013). The threshold value was selected so the sum of the sensitivity (i.e. the true positive rate) and specificity (i.e. the true negative rate) is highest, as this has been shown to perform well compared to other approaches (Liu, White, and Newell 2013).

When running Maxent, all presence records for each species were split in 2 parts: 80% of the points were used in the modelling process to fit the modes (‘training data’), and 20% was used as ‘testing data’. The test data was used to evaluate the performance of the model by understanding how well it predicts data points it hasn’t been trained on.

The models were evaluated using ROC curves, a commonly used approach for evaluating the performance of models for binary data (Franklin 2010) . The ROC curve plots the true positive rate (correctly identified presences) against the false positive rate for different threshold (cut off) settings (Liu et al. 2016). The accuracy of the model prediction can then be measured by the *Area under the ROC curve (AUC)* metric, where a value of 1 implies a model perfectly predicts presences and absences, and the lower the value the worse the model performance.

The AUC metric was originally utilized for the site-occupancy data, to determine how well the model could predict presences and absences in data it hadn’t been trained on. In cases of PB data, AUC uses background points instead of absences and compares presences to background data. Therefore, it provides a measure for how well the model is predicting the presences locations not used to train the model.

Predictor selection

To select the predictor layers to use for the SDMs for each species a model selection process was used. Model selection starts with the list of the final environmental predictors shown in Table 5. An automated variable selection process was then undertaken for each of the species individually which consisted of the following steps:

1. The model is fitted to the training data using all the covariates in Table 5
2. The AUC for the model and the covariates contributions are calculated
3. Covariates with the lowest contribution (less than 0.02) are removed from the predictor list

4. The model is refitted with the updated predictor list and new AUC and variable contribution are calculated
5. If the AUC of the new model has either increased, or has not become lower by more than 0.05, then a new iteration starting at step 3 is undertaken to remove another predictor
6. If the AUC has decreased by more than 0.05, then the final model is selected using the predictors from the previous iteration before the AUC decreased
7. However, if there are no covariates with contribution less than 0.02 the final model is selected from this iteration

This process results in a set of predictors that unique to each species, that allows Maxent predictions that are most accurate in predicting the 20% of data that was not used in training the maxent model.

Dealing with biases in the occurrence data

Background and summary of the problem

When using PB data in the modelling, we need to compare the set of recorded presences with a set of points selected from the area where the species has not been detected.

The approach Maxent uses is randomly selecting "background points" from throughout the study area where species occurrence is to be predicted. If the presence points are unbiased (meaning people just looked in random locations and reported the species when they saw it), then this approach works well and with enough presences, can give a good prediction of the species locations.

However, the occurrence data is not unbiased as the locations where species are recorded are not randomly selected. This is due to a combination of many factors: they may be close to roads or in more easily accessible locations, they can result from targeted surveys undertaken where the species is thought likely to occur, there may be far more records on public land than on private land, etc.

Maxent provides a method to help account for these potential biases in the occurrence data. It allows users to provide a spatial layer (called a "bias layer") describing the bias in where the species locations are recorded. It tells Maxent that in certain locations, no one ever looked for the species. Maxent then uses this bias layer to select its background points. If the bias layer is known correctly, then including the bias layer can greatly improve the SDM predictions. The problem is that while it's likely that the occurrence records for each species in Cumberland Subregion are biased, we don't exactly how they are biased, and the bias may be different for each species.

Using multiple bias layers

Our proposed solution to this problem was to undertake three models for each species, each with different assumptions regarding the potential bias in the records:

1. *Bias layer 1*: assumes the records are unbiased and that the species was searched for at random locations in the landscape with only presences recorded. Thus, the bias layer is the whole study area.

2. *Bias layer 2*: assumes that there are biases in where the species were searched for, but that it is the same for all species. It aggregates the records of all species together,

buffers them, and assumes this provides a good description of the bias in where species were searched for.

3. *Bias layer 3*: assumes there are biases in where the species where searched for, but that this may vary between species. It generates a separate bias layer for each species, by buffering just presence locations of the species being modelled, and assumes this is a good description of where the species was searched for.

While none of these bias layers are going be an accurate description of where the species was searched for, our assumption is that for each species, one of these bias layers is going to be a reasonable approximation in describing the biases in the presence records. Thus, our approach is to run 3 maxent models, with each of the 3 bias layers above. Though it should be noted, that the model selection process as described above was used to select the predictors for each species using *bias layer 1*. These same selected predictors were then used in generating the models with *bias layer 2* and *bias layer 3*. Thus, the three different SDMs all had the same set of predictors, making comparing and summarizing the predictor contributions more appropriate across the three SDMs.

For each of these SDMs, generated with a different bias layer, were then converted into a binary presence-absence layer (using maxent's build-in method that selects a threshold based on getting the same rate of false presences and false absences; see above). This produced 3 binary layers which can be aggregated into to a single layer with 3 possible values:

0 ("***unlikely to occur***") - locations where none of the binary maps showed the species occurring

1 ("***potential to occur***") - locations where at least one on the maps showed the species occurring

3 ("***likely to occur***") - locations where all 3 of the maps showed the species to occur

Interpretation

"Unlikely to occur" areas are where none of the binary maps predicted that the species is likely to be present. "Potential to occur" is a conservative estimate showing everywhere the species could potentially occur, accounting for the different plausible assumptions about how we could approximate the biases in the data. "Likely to occur" shows only areas that were predicted to be habitat under all 3 assumptions regarding how the data would be biased. This is likely to miss some locations where the species occurs, but as these areas always come up no matter what we assume regarding the biases, they can more robustly be assumed to capture the presence of the species.

This can also be seen as a risk-based approach where (subject to model assumptions), "potential to occur" minimizes the risk of missing an area where the species occurs, and "likely to occur" minimizes the risk of selecting an area where the species doesn't occur. Thus "potential to occur" is more appropriate for assessing the impacts on species, while "likely to occur" is more appropriate targeting conservation actions such as offsets.

Source code and data availability

The analysis was undertaken using open source statistical programming language R (version 3.5.1), and utilized the following packages:

- rJava version 0.9-10
- caTools version 1.17.1.1
- ENMeval version 0.3.0

- dismo version 1.1-4
- maptools version 0.9-4
- raster version 2.6-7
- rgdal version 1.3-4
- sp version 1.3-1
- knitr version 1.20

The knitr_1.20 package was used to generate the automated reports presented in Appendices 1 and 2.

All the source code to undertake the analysis is available via Github at: https://github.com/thekoshkina/WSSSP-Modelling/tree/master/SDM

The spatial layers for the covariates used in the analysis are available at: http://glass.eres.rmit.edu.au/tzar_input/sydney-cumberland-plain-SDM/covariates.zip

Results

The full results for all species are presented in Appendix 1 and 2. Appendix 1 contains the SDMs produced by Maxent for each species with each of the three different bias layers. For each of 19 species, the Appendix 1 presents:

- Summary information for the species
- A table with the predictor layers used for the species (the three SDMs with the different bias layer all use the same predictors)
- Maps of the Maxent output for the each of the three bias layers showing:
    - The relative likelihood of occurrence map produced for the species, and then this map thresholded into a binary presence/absence map such that false presence absence and false presence rates are the same
    - The AUC value for the SDMs
    - These two maps are shown with and without the species presences overlaid as blue dots
- The contribution of each predictor layer for each the three SDMs with different bias layers
- For layers where the categorical variables of soil and vegetation are used, the contributions of each of the soil and vegetation categories are given.

Appendix 2 then presents the single SDMs for each species aggregated from the SDMs generated with the three bias layers, as described above. For each of the 19 species, the Appendix 2 shows:

- Summary information for the species, and
- A table with the predictor layers used for the species
- A table with average contribution of each predictors across the 3 SDMs with the different bias layers, and the 3 highest contributing soil types and PCTs for across the 3 SDMs (where vegetation and soil type were included as predictors)
- The three-category risk-based occurrence map for the species, both with and without the species occurrences overlaid

Figure 2 – Figure 4 show example output SDMs for *Pultenaea parviflora* for the three different bias layers, with the occurrences of the species shown as blue points. The SDM results for bias layers 1 and 2 are similar (Figure 2 and Figure 3), however using bias layer 3 (where the background points are chosen from the areas around the recorded presences the species), results in a significantly different SDM with areas of higher likelihood of occurrence spread over a much larger area (Figure 4). This trend of the bias layers 1 and 2 producing more similar results and bias layer 3 producing a significantly different result was a common result across most of the species modelled (Appendix 1). However, for the Grey-headed Flying-fox (*Pteropus poliocephalus*) all three bias layers resulted in more similar results (Appendix 1) and for the Australasian Bittern (*Botaurus poiciloptilus*), bias layer 2 resulted in a significantly different result, while bias layers 1 and 3 were more similar (Appendix 1).

The results from the three bias layers are then combined to produce the three-category risk-based map shown in for the example of *Pultenaea parviflora* (Figure 5). In this case, the areas depicted where the species are “most likely to occur” overlaps the vast majority of the species occurrences.

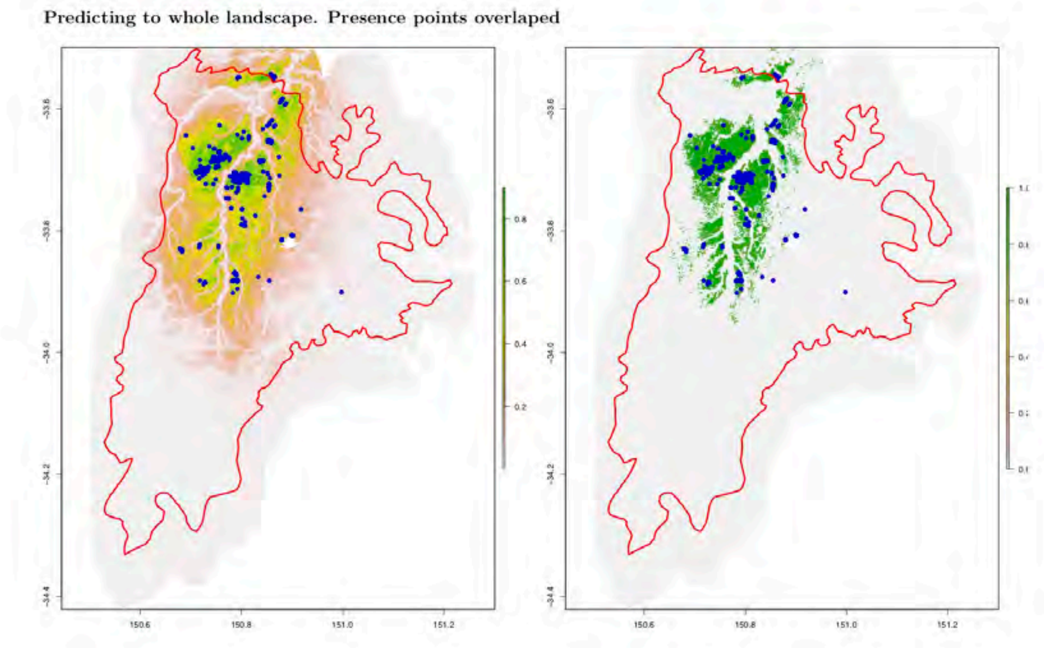

Figure 2 Predicted likelihood of occurrence map generated by Maxent for *Pultenaea parviflora* using bias layer 1. The left figure shows the raw likelihood of occurrence map generated by Maxent, the right figure shows the version of the map where it has been thresholded to produce a binary map of predicted presence/absence of the species based on selecting a threshold level such that false presence and false absence rate are the same. Occurrences of the species are shown as blue points.

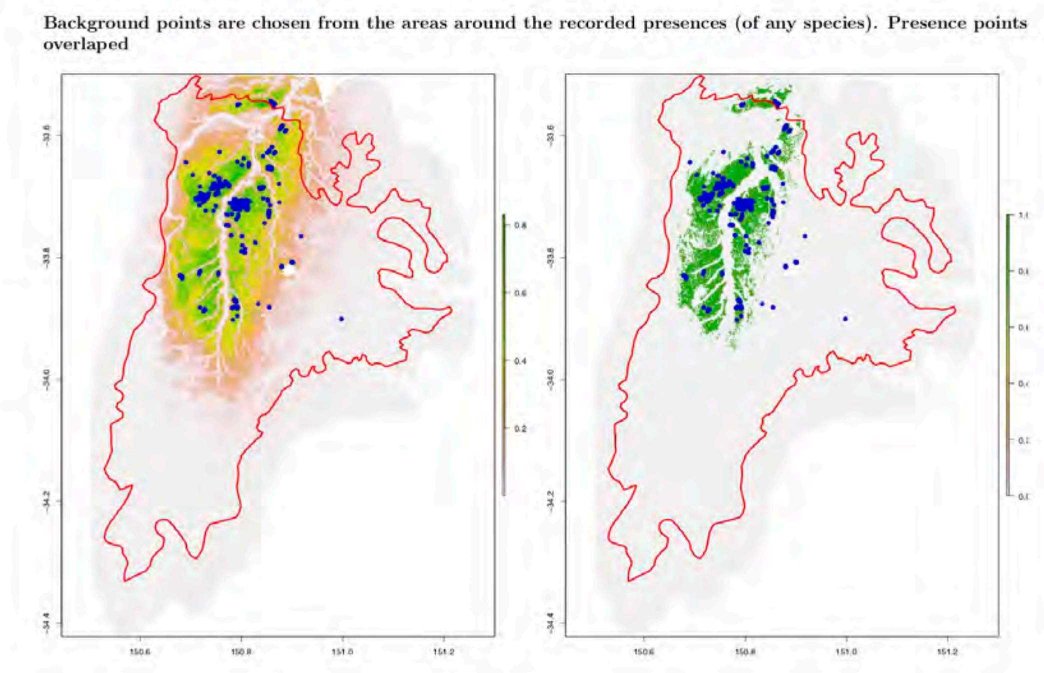

Figure 3 Predicted likelihood of occurrence map generated by Maxent for *Pultenaea parviflora* using bias layer 2. The left figure shows the raw likelihood of occurrence map generated by Maxent, the right figure shows the version of the map where it has been thresholded to produce a binary map of predicted presence/absence as described in Figure 2. Occurrences of the species are shown as blue points.

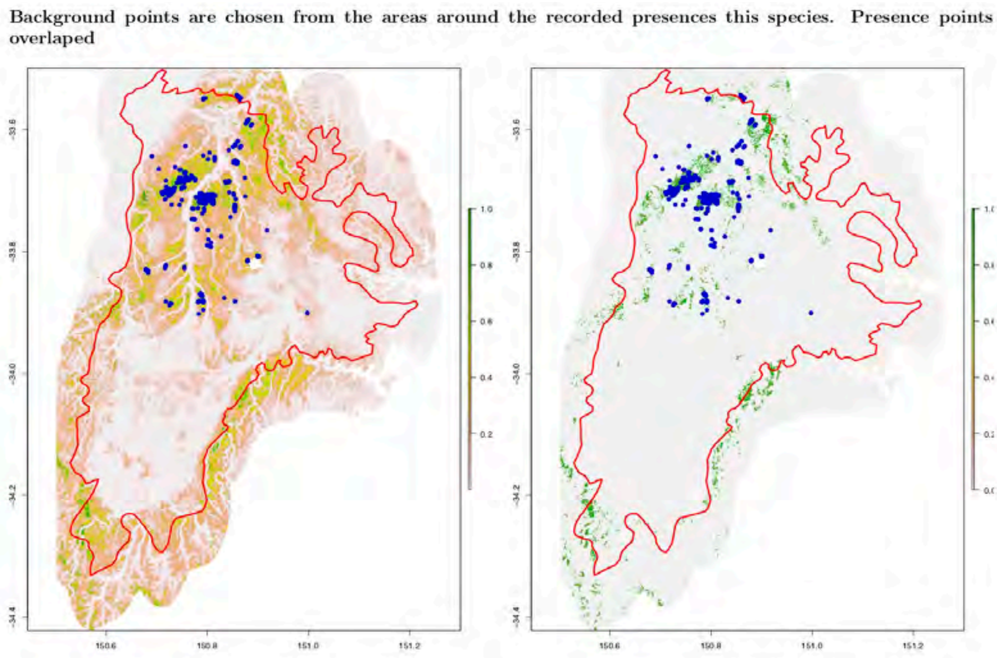

Figure 4 Predicted likelihood of occurrence map generated by Maxent for *Pultenaea parviflora* using bias layer 3. The left figure shows the raw likelihood of occurrence map generated by Maxent, the right figure shows the version of the map where it has been thresholded to produce a binary map of predicted presence/absence as described in Figure 2. Occurrences of the species are shown as blue points.

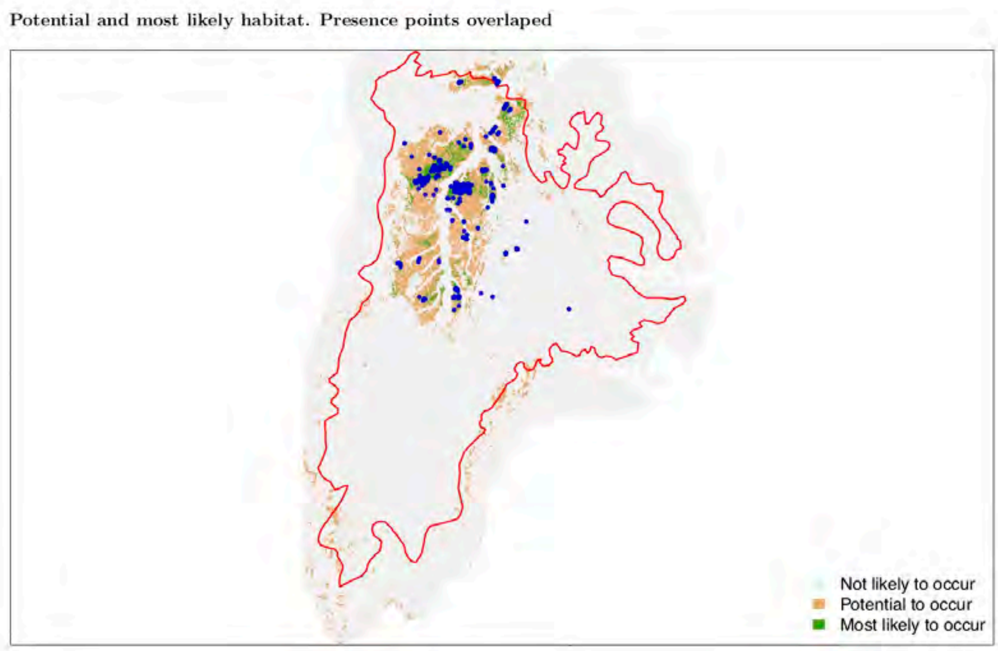

Figure 5 The final risk-based likelihood of occurrence map for *Pultenaea parviflora*. This is generated from maps in the three previous figures as described in the methods, and indicates areas where the species is "not likely to occur" (none of the previous three maps thresholded maps predicted occurrence), has "potential to occur" (at least one of the previous three maps thresholded maps predicted occurrence) and is "most likely to occur" (all three of the previous thresholded maps predicted occurrence). Occurrences of the species are shown as blue points.

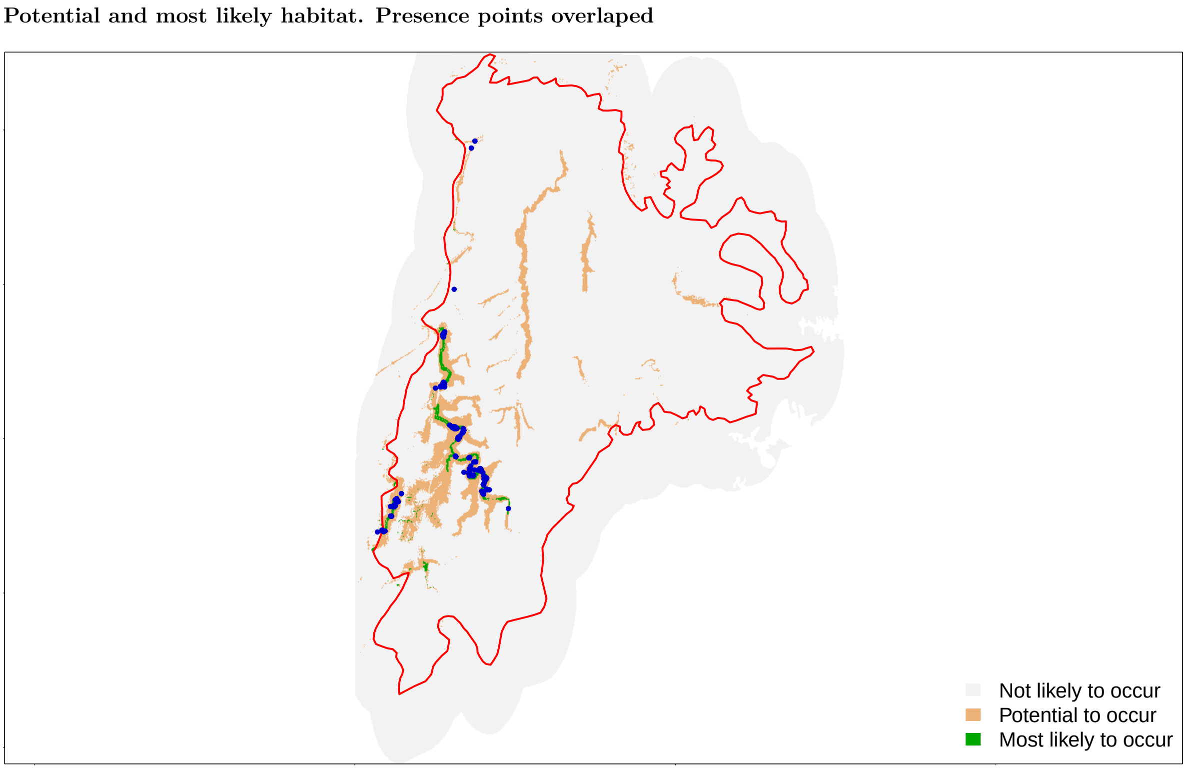

Figure 6 The risk-based SMD output for the Camden White Gum (*Eucalyptus benthamii*). Occurrences of the species are shown as blue points.

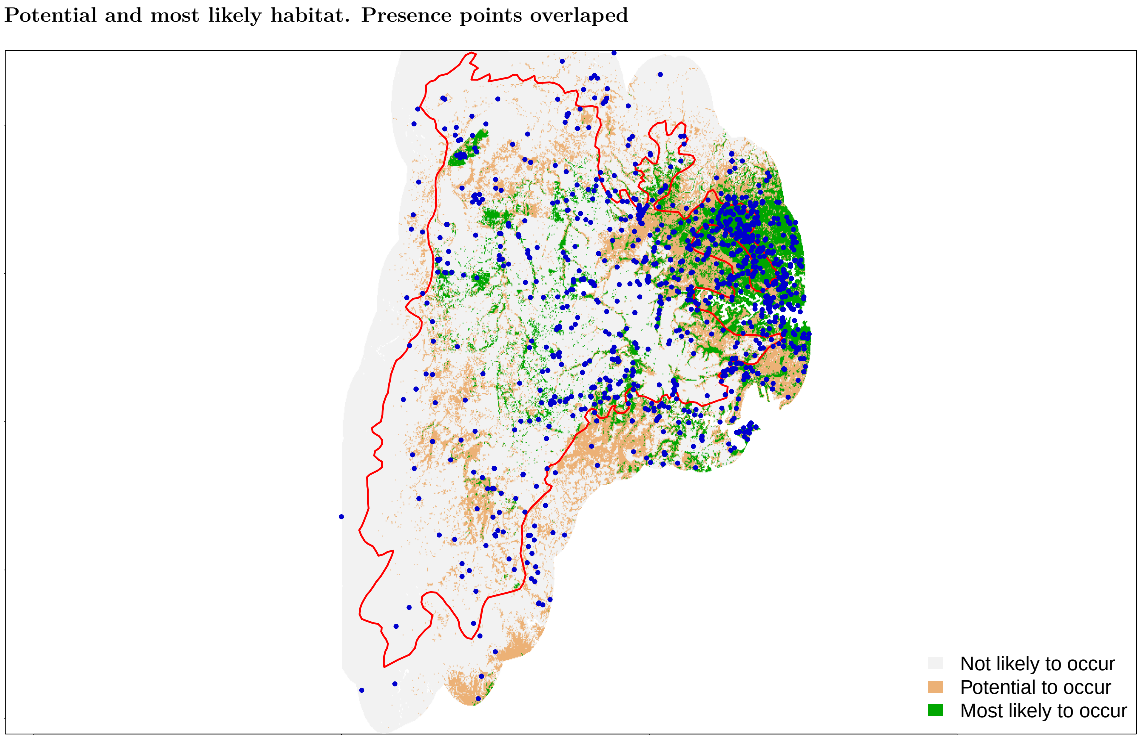

Figure 7 The risk-based SMD output for the Grey-headed Flying-fox (*Pteropus poliocephalus*). Occurrences of the species are shown as blue points.

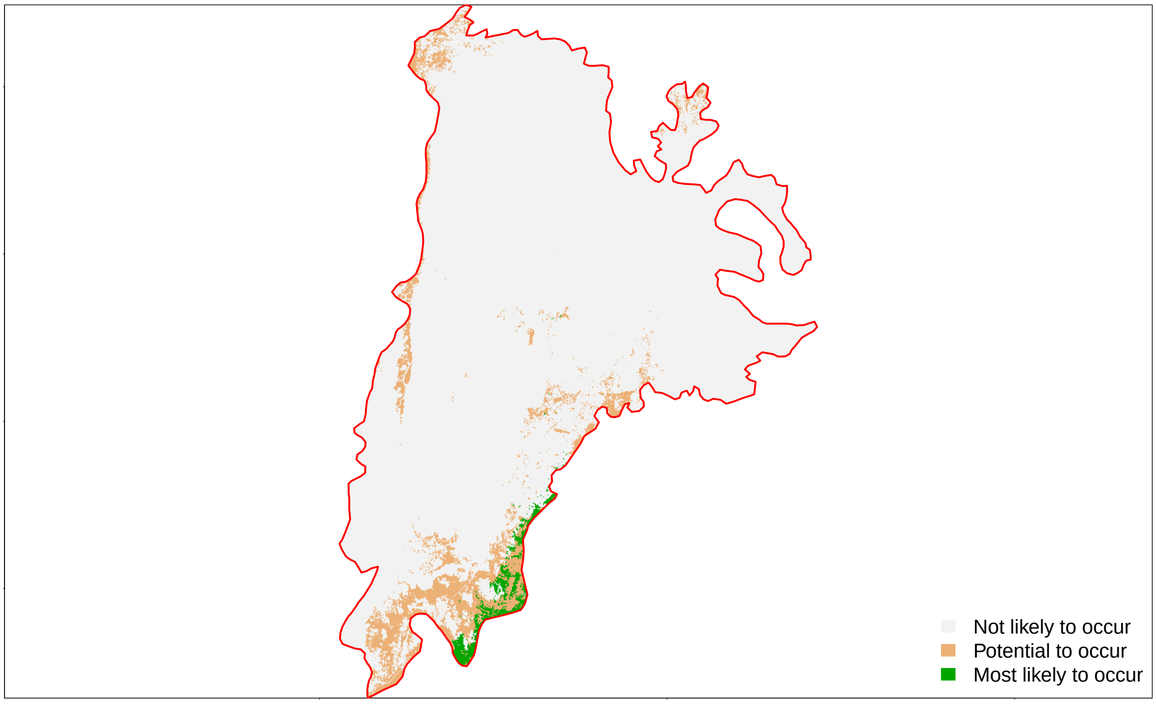
Potential and most likely habitat



Potential and most likely habitat. Presence points overlaped

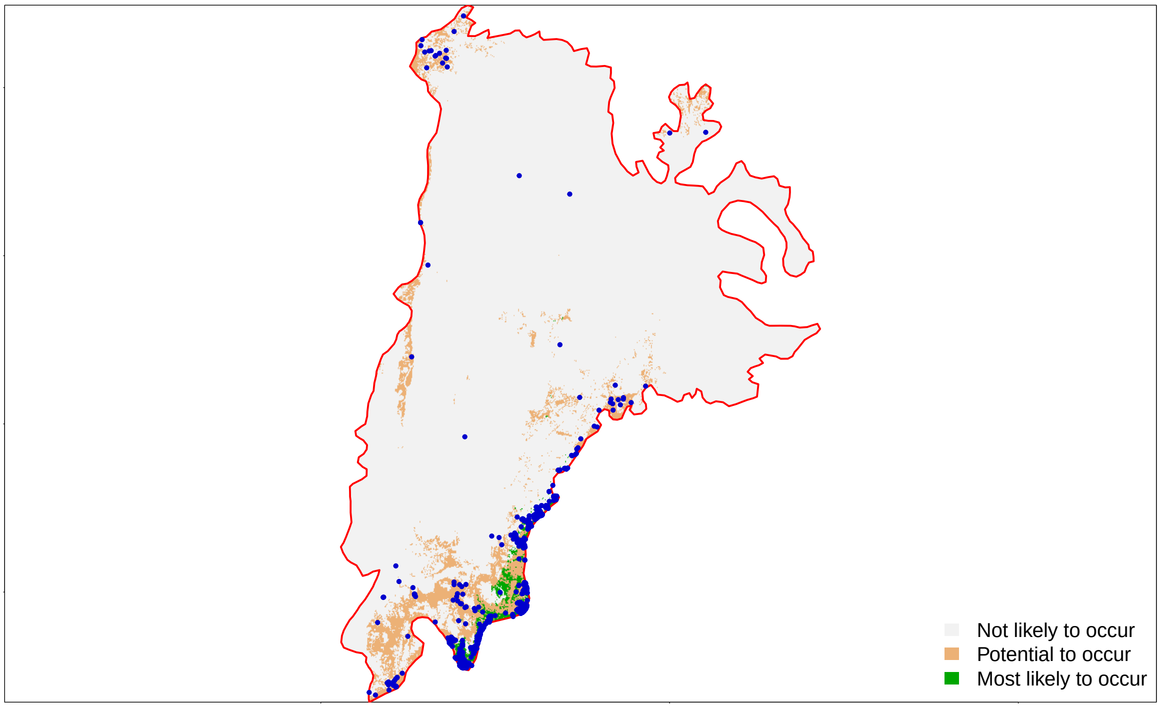


Figure 8 The risk-based SMD output for the Koala (Phascolarctos cinereus). For clarity the SDM outputs are presented with (bottom plot) and without (top plot) the occurrences of the species (shown as blue points).

Figures 6–Figure 8, show three additional examples of the risk-based SDMs for the Camden White Gum, the Grey-headed Flying-fox and Koala, respectively. These show a SDM outputs for a more localised species (Camden White Gum; Figure 6), compared to the wide spread presence sighting of the Grey-headed Flying-fox (Figure 7). For the Grey-headed Flying-fox, only records associated with colonies were used and for this species it's clear that a greater proportion of the records do overlap the potential or likely to occur areas in the risk-based SDM. Figure 8 shows the results for the Kola. Due to the large number of presence records (915 used in the modelling), the SDM is shown for clarity both with and without the Koala presences overlaid. It should be noted that unlike the other species the Koala SDM was only undertaken for the Cumberland Subregion, excluding the buffer (see Discussion). For the Koala, only records associated with native vegetation were used, to exclude records associated with dispersing males outside their habitat. In this case almost all of the records overlapped areas of potential and most likely habitat.

The predictors with the highest contributions varied for each species, and while the same predictors were used in the SDMs for each of the three bias layers, their relative contributions are often differed between the SDMs with the three different bias layers. The number of predictors used for each species could also vary, due to the model selection process (described above). Species had as low as 5 predictors (e.g. the Bargo Geebung *Persoonia bargoensis*) or as many as 15 (e.g. the Giant Burrowing Frog *Heleioporus australiacus*) (see Appendix 2). While soil type and vegetation were important predictors for many of the species they were not always the ones with the largest contributions.

Figure 9 shows the AUC values for SDMs produced for each species, with the AUC values for each of the bias layers shown in a different colour. In general, SDMs with bias layer 3 tended to have lower AUC scores. There is only one poor performing model, which is for the Australasian Bittern (*Botaurus poiciloptilus*), when using bias layer 3 (results in an AUC score of 0.57; Figure 9). All other SDMs across species and bias layers have AUC scores greater than 0.7, with the majority of them having AUC score greater than 0.9 (Figure 9).

Results availability online

The full results presented here are available by contacting the authors or online as follows.

Pdf documents containing all risk-based maps are available here:

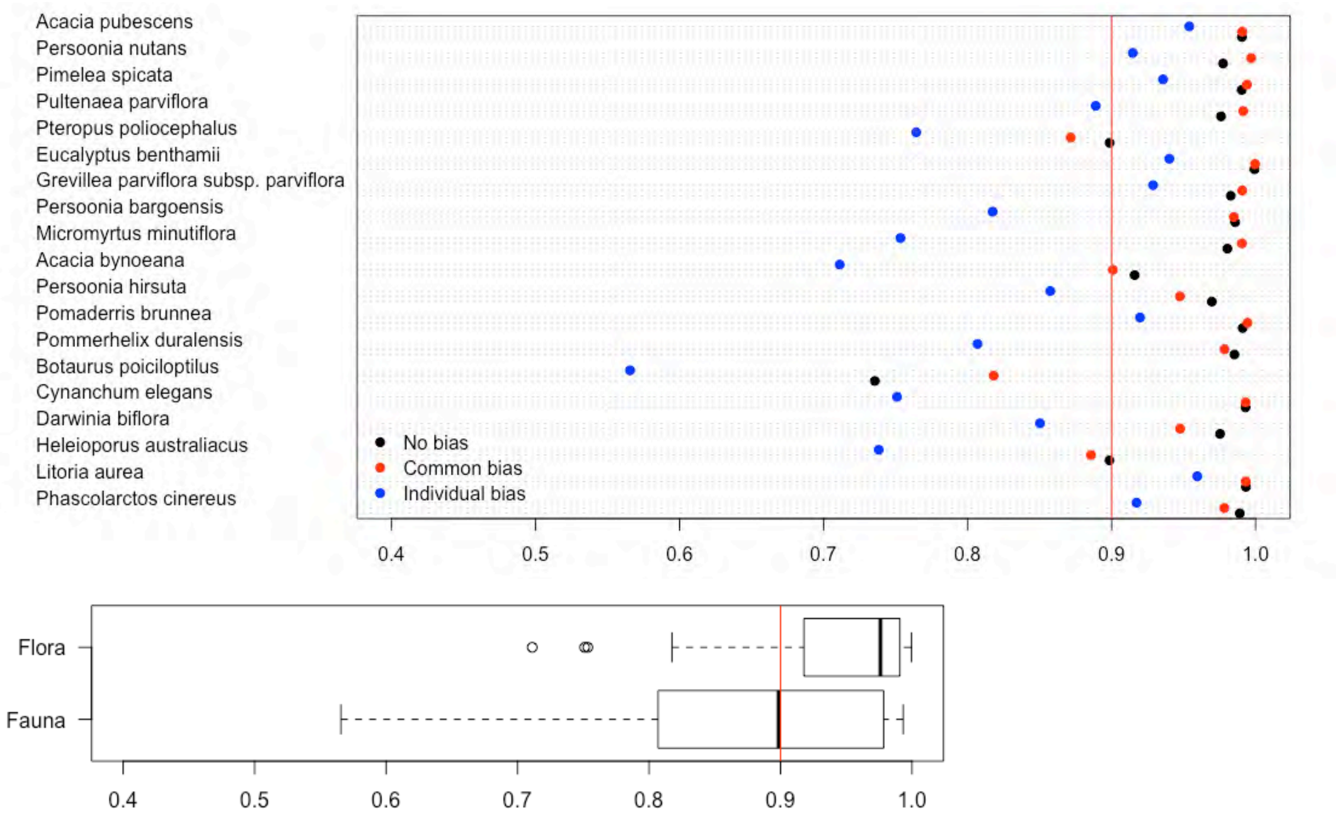

Figure 9 The AUC values for the SDMs for all species. The results for the 3 bias layers are shown in black (bias layer 1–no bias), red (bias layer 2–common bias) and blue (bias layer 3–individual bias). The lower plot shows the distribution of AUC scores for all flora and all fauna, as box plots.

Discussion

We have presented SDMs for 13 flora species and 6 fauna species for the Cumberland Subregion (IBRA 7). Using the risk-based approach we have produced maps using the Maxent species distribution modelling package that depict where a species is likely to occur using three classes of: “unlikely to occur”, "potential to occur" and "likely to occur".

Species maps

All the resulting SDMs tended to have high AUC scores (the majority of them were over 0.9 with only one model less than 0.7; Figure 9). This means that in most cases the resulting models accurately predicted the locations of records that were not used to train the model. However, a high AUC score does not necessarily mean it should be concluded that the resulting SDM is an accurate representation of the true species likelihood of occurrence. It just means that it is an accurate representation of the presence records used to train the model. If these species records are highly biased, an SDM output may have a high AUC score and still provide a highly biased result. We have tried to control for bias in the occurrence data by using different bias layers in Maxent as described above.

In general, the approach to generating SDMs may over-predict the habitat for species. This may be partly due to anthropogenic factors limiting the current distribution of species, and the fact that predictors capturing these factors were not incorporated due to lack of available data. In other cases, errors in the occurrence data and/or covariate layers (particularly vegetation and soil) mean that Maxent may pick up associations between species and PCTs or soil types that are artefacts. However, the "likely to occur" regions of the SDMs are significantly reduced compared to the "potential to occur" regions and thus are less likely to involve over-predictions.

It should be noted that risk-based SMD results do not always predict regions for "likely to occur" and "potential to occur" that overlap every single species presence record used in the modelling. There can be numerous reasons for this. However, the general point is that Maxent is designed to produce a probability layer that does not "overfit" the data (see methods). A model that is overfitted produce an SDM that predicts to all occurrences used to train the model accurately, while predicting to locations not used to train the model poorly. The result of not overfitting (achieved through using the "maximum entropy distributions") is that while most species occurrences will be located in predicted and likely/potential to occur areas, not all presences will be in these areas.

Below we discuss some of the SDMs for specific species.

Fauna

The koala is a difficult species to model, and more detailed modelling of its potential feed trees is being undertaken by OEH. The SDM presented here results from the records used from BioNet (which may be highly biased away from the heavily cleared and fragmented parts of Cumberland Plain) and their associations with the available predictors. As discussed above, records not associated with native vegetation were excluded from the model, as it was hypothesized that in many cases these would correspond to dispersing male koalas (a known behaviour after breeding) and would not be associated with breeding habitat. In addition, it's important to note the SDM here differs from the other SDMs in that we exclude the 10km buffer around the Cumberland Plain when modelling this species, and only use the records within the Cumberland Subregion. The reason for this was that there were a large number of additional Koala records located in the buffer region (>2700 records). This large number of records outside the Cumberland Subregion, skewed the model to predict only a small amount of habitat within the Cumberland Subregion, compared to modelling the species just with the Cumberland Subregion. While the model trained just on the presences for the Cumberland Subregion, predicts a greater amount of koala habitat, it still predicts an absence of koala occurrence on most of the Cumberland Plain. While there may not be koalas in many of these areas now due to fragmentation and anthropogenic threats, there may much more theoretically sound potential habitat on the plain in terms of PCTs on the Cumberland Plain then is currently depicted by the SDM produced here.

After some consideration it was decided to undertake an SDM for the Green and Golden Bell Frog (*Litoria aurea*). However, the resulting predictions should be used with some caution as there are important factors driving its distribution for which appropriate predictors were not available. For example, Chytridiomycosis is known to impact where the species occurs. In addition, the Green and Golden Bell Frog is known not to be restricted to areas surrounded by native vegetation and has been found in quarries, constructed ponds, and small bodies of the water on the ground (Enhua Lee, OEH, personal communication).

As the Grey-headed Flying-fox (Pteropus poliocephalus), forages widely, it was decided to exclude foraging records and only use those associated with colonies, as otherwise without this constraint, the whole region may be potential foraging habitat for the species. In the resulting SDMs, there is more habitat than expected, so the model may be over predicting slightly (Paul Burcher, personal communication).

Further the SDM for Dural Woodland Snail may have overestimated most ‘potential to occur’ habitat as the species is thought to be restricted to the northern margins of the sub-region at the shale/sandstone interface (Paul Burcher, personal communication).

Plants

The White-flowered Wax Plant (*Cynanchum elegans*) has 23 records that were used for the modelling. Due to the small number of records, the SDM resulting from this species should be treated with some caution.

Hairy Geebung (*Persoonia hirsute*), and *Darwinia biflora* have a small proportion of their records within the Cumberland Subregion (most records being in the 10km buffer region) and the resulting SDMs estimate that a small proportion of their habitat occurs inside the Cumberland subregion.

Several of the SDM layers are expected to over-predict the likely areas where the species occur. While this may be acceptable from a precautionary approach, in some cases the models are predicting likely occurrences beyond the range where the species is known to occur. For example, the *Persoonia nutans*, the habitat map predicts the potential for the species to occur in too far south and to the northeast. It has never been known to occur in the Hornsby Plateau, and is confined to the Cumberland Plain except for an outlier in the North West, and an outlier in the South, both in close proximity to the Plain (Steve Douglas, personal communication). Likewise, the model for *Acacia pubescens* likely over-predicts potential habitat and the model for *Acacia bynoeana* may also predict more potential habitat than would be expected based on soils and PCTs (Steve Douglas, personal communication).

Limitations

As discussed earlier in this report, there are multiple factors that limit the SDM approach for the fauna and flora species in the Cumberland Subregion.

Firstly, for some of the species, this study area only involves a small part of the species range, in which case we may be missing parts of species’ niche and making poor predictions. Initially this project planned to model species within a 100km buffer of the Cumberland Subregion, however at the time undertaking this analysis, vegetation maps containing PCT information was not available for all of this region. There was also not full coverage of this region for soil data (see https://www.environment.nsw.gov.au/eSpade2Webapp). Thus, we limited the study area to a 10 km buffer around the Cumberland Subregion (constrained to where PCT information was available). For these wider ranging species, modelling over a great proportion of their range may result in improved SDMs. However, the ranges of some of the other species modelled here are very range restricted and are limited to within or near the Cumberland Subregion. This species also pose other challenges to model as historical accidents and competition with other species could be driving their current locations, both factors that are unaccounted for in most SDMs (however see Pollock et al. 2014).

The highly-modified landscapes with the Cumberland Subregion mean that in many areas there are high level of fragmentation and anthropogenic threats. This may result in the standard assumptions regarding a species occupying its niche not to apply, meaning that large areas of previous potential habitat may no longer be occupied.

As discussed there is an unknown but potentially large amounts bias in the occurrence records. Here we have first to cleaned the data, and then used multiple bias layers in an attempt to deal with different amount of bias.

Another point to note is that the analysis presented her should be considered purely as attempting to model where the species are *likely to occur*. It does not attempt to model the most effectively locations to conserve the species in the Cumberland Subregion. To do this would require multiple additional factors to be incorporated, including connectivity between locations where the species is likely to occur, and other factors known to affect the viability of the species such as the size of habitat patches, the surrounding landuses and the presence of threats to the species. To undertake this type of analysis there are a range of spatial prioritization tool that can be used such as Zonation (Gordon et al. 2009), however such an analysis is beyond the scope is this project.

Other issues that may also limit or confound the outputs of the SDMs are:

- The fact that detectability may be an issue for some species, meaning they are more likely to be observed in some locations than others (Guillera-Arroita 2016)
- Although we used the best available soil mapping, it is known to be relatively coarse and to contain some errors
- For some of the species, there may be false associations between records and PCTs. This due to spatial errors in the point locations and and/or the PCT maps (Steve Douglas, personal communication)

Extensions of this work

This work could be extended in several ways to improve the predictions produced by the Maxent SDMs. When PCT information is available for all of NSE, it will be possible to model many of the species over a greater area. This may result in improved predictions within the Cumberland Subregion.

For some flora species, there are survey results that incorporate both presence and absence of the species. Having presence and absence data can result in more accurate SDM predictions and there are now approaches where models can be fit with presence-absence data and presence only data simultaneously, making better use of all available data (Koshkina et al. 2017).

It is likely that some of the SDMs presented here over-predict the locations of species beyond their known range. One solution to this issue would be to use expert-derived estimates of the predicted range of the species and then only use SDMs to make predictions to areas within the this predicted range. These range maps would likely capture all the presence records of the species, and constrain the SDM predictions reducing the amount they over-predict.

Appendix 1 - Maxent model results for all species and all bias layers

All maps and tables are contained in the supporting document "full-SDMs-for-all-spp.pdf" supplied with this report. This file is also available by contacting the authors or from http://glass.eres.rmit.edu.au/tzar_input/sydney-cumberland-plain-SDM/full-SDMs-for-all-spp.pdf. Summary information supplied in this document:

- A table with the predictor layers used for the species (the three SDMs with the different bias layer all use the same predictors)
- Maps of the Maxent output for the each of the three bias layers showing:
    - The relative likelihood of occurrence map produced for the species, and then this map thresholded into a binary presence/absence map such that false presence absence and false presence rates are the same
    - The AUC value for the SDMs
    - These two maps are shown with and without the species presences overlaid as blue dots
- The contribution of each predictor layer for each the three SDMs with different bias layers
- For layers where the categorical variables of soil and vegetation are used, the contributions to the of each of the soil and vegetation categories are given.

Appendix 2 - Risk-based 3-category SDMs for each species

All maps and tables are contained in the supporting document "risk-based-occurence-maps.pdf" supplied with this report. This file is also available by contacting the authors or from http://glass.eres.rmit.edu.au/tzar_input/sydney-cumberland-plain-SDM/risk-based-occurence-maps.pdf. Summary information supplied in this document:

- Summary information for the species, and a table with the predictor layers used for the species
- A table with average contribution of each predictors across the 3 SDMs with the different bias layers, and the 3 highest contributing soil types and PCTs for across the 3 SDMs (where vegetation and soil type were included as predictors)
- The three-category risk-based occurrence map for the species, both with and without the species occurrences overlaid.

Appendix 3 - Correlations between predictor variable

The correlations between predictors were estimated using the Pearson correlation, except for categorical variables, where Goodman and Kruskal's tau measure was used. Figure A3.1 shows the correlations between the categorical predicators. Table A3.1 shows the Person correlation between all other predictors.

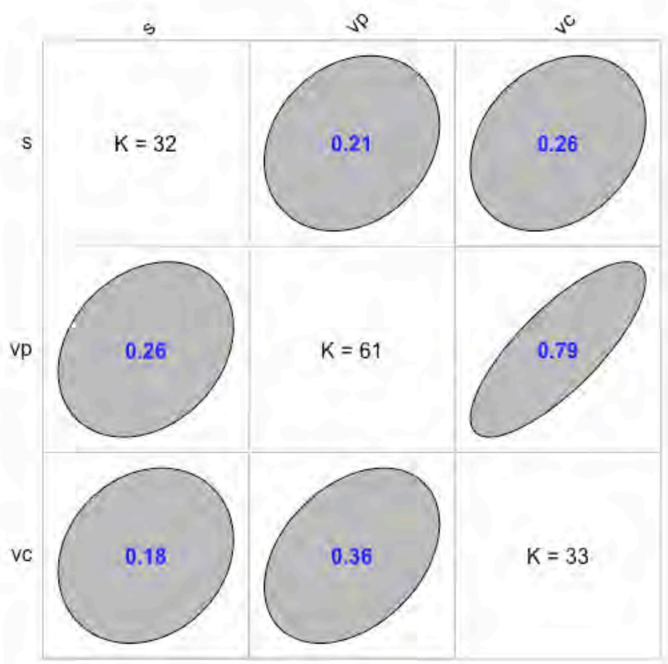

Figure A3.1 TS – The correlations between the categorical predictor layers used in the analysis. In this plot, S is soil, Vp is vegetation PCT, Vc, vegetation community. K is the number of categories in of the categorical predictors.

1 Introduction

NSW experienced extensive bushfires throughout the spring and summer of 2019-20. As of 3rd February 2020, the fires had burnt 5.37 million hectares of land (approximately 7 per cent of NSW). This includes (DPIE, 2020):

- 37 per cent of the national park estate, including 81 per cent of the Greater Blue Mountains World Heritage Area
- 42 per cent of state forests
- 52% of heathland, 50% of wet sclerophyll and 37% of rainforest vegetation formations in NSW
- 25% of the most suitable koala habitat in eastern NSW (moderate, high and very high suitable habitat), particularly areas on the north coast, central and southern tablelands, central coast and the south coast

Of the fire affected national parks, 23 per cent were subject to full canopy damage, 36 per cent had partial canopy damage, and for 27 per cent the canopy was unburnt. Note that areas where the canopy was unburnt may have been affected by fire through the understorey (DPIE, 2020).

The fires also affected large areas of species habitat where species have been recorded and are known to occur. A total of 680 threatened flora species have records within fire affected areas. Of these:

- 61 species (approximately 9 per cent) have more than 80 per cent of their records within fire affected areas, including 19 with more than 30 per cent of records in areas where the canopy was fully damaged
- 37 species have 50 to 80 per cent of records within fire affected areas

A total of 293 threatened fauna species have records within fire affected areas. Of these:

- 5 species have more than 80 per cent of records within fire affected areas, including:
  - *Petaurus australis* (Yellow-bellied Glider) endangered population on Bago Plateau
  - *Petauroides volans* (Greater Glider) endangered population in Eurobodalla
- 99 species have more than 10 per cent of records within fire affected areas

The long-term survival of flora and fauna after fire is complex and the full impact of the fires on biodiversity will not be understood for some time (EES, 2020). Fauna recovery depends on factors such as access to food, water and habitat recovery, which depend on fire severity and future weather conditions. Flora recovery depends on drought, fire frequency and severity, and impacts from pest animals, weeds and pathogens on regrowth (EES, 2020).

Because the extent and intensity of the 2019-20 fires in NSW were so substantial, ultimate recovery of some species impacted by the fires is uncertain and could be affected. This means that:

- The fires may increase the significance of the impacts of the development under the Plan for some species
- Additional commitments under the Plan may be needed for some species to help address the impacts of the fires

An initial assessment of the implications of the fires for the Plan has been undertaken based on available information. The assessment will be reviewed as further information on the impacts of the fires becomes available.

The initial assessment did not address TECs as TECs potentially impacted by the Plan are generally restricted to the Cumberland subregion or surrounding areas and were not broadly affected by the fires. In addition, the mapping of many of the TECs (as PCTs) beyond the nominated areas is of varying and inconsistent quality.

2 Purpose of initial assessment

The purpose of the initial assessment was to identify species where:

- A high percentage (>10 per cent) of NSW records have been affected by fires of the 2019-2020 period, and
- The Cumberland subregion is already important for species persistence in NSW and/or has the potential to become more important for persistence because of the impacts of the fires to other areas of habitat, and
- The Plan has known or likely impacts to the species

Where these three criteria are met, the implication of the fires in relation to the Plan, including the need for commitments to address impacts, should be considered. The rationale for this approach is that:

- Where a species is not reliant on the Cumberland subregion, the Plan has limited opportunity to help address the impacts of the fires on the species or influence conservation outcomes for the species
- Where a species is not being impacted by development under the Plan, the impacts of the fires and consideration of the need for commitments specific to the species, is not directly relevant to the Plan

3 Approach to initial assessment

The approach to the initial assessment involved:

- Identifying each listed threatened species potentially impacted by the Plan (these are Category 1 Commonwealth-listed species and NSW-listed candidate species-credit species and ecosystem-credit species – see Chapter 11)
- Determining the percentage of NSW records within fire-affected areas. This was done by:
  - Obtaining spatial data on fire extent over the 2019-20 period from the GEEBAM dataset available on SEED (DAWE, 2020)
  - Obtaining species records from NSW BioNet (under a licenced extract to get as-held data)
  - Overlaying fire extent with species records and analysing the data using GIS. All records within 100 m of the fire footprint boundary were included as impacted by the fire to account for level of record accuracy and fire-ground extent accuracy
- Determining the percentage of total records in NSW that occur within the Cumberland subregion. This provides an indication of the importance of the subregion for persistence of the species in NSW, although the data density is skewed towards the greater Sydney area due to opportunity for observation and high survey effort
- Identifying whether each species has life-history traits that make the species more susceptible to fire or relies on habitat features that are likely to be affected by fires. This was done based on existing knowledge and/or information in literature or government databases, such as BioNet species profiles

Data was also obtained from the Commonwealth Department of Agriculture, Water and the Environment (DAWE) on the estimated extent of fire impacts on the known or predicted distribution of Commonwealth listed species at a national scale.

The importance of the Cumberland subregion for species persistence was estimated on the basis of record counts. Where the subregion has greater than 10 per cent of existing total NSW records, it was considered that the subregion:

- Is already important for species persistence, and/or
- Has the potential to become more important as a result of the impacts of the fires on the species habitat elsewhere (as it is likely that a reasonable amount of suitable habitat exists in the subregion for the species)

A relatively high figure of 10 per cent was chosen for this threshold because the Cumberland subregion is well surveyed compared to other parts of NSW, meaning that the relative importance of the records as an indicator of the importance of a subregion for persistence increases in distance from Sydney. Using a high percentage recognises that the likelihood of having a record from the Cumberland subregion is higher than for any other subregion, and considers the relative area of the subregion as a proportion of the state (0.3 per cent by area).

4 Limitations

The key limitations of the initial assessment are:

- Reliance on records and record accuracy to provide an indication of species distribution and reliance on the subregion. Records are often only an indicator of survey effort relating to development assessments and ease of accessibility, and are likely to be bias towards iconic and more observable species, in particular birds and mammals
- No age cut-off was applied to the records despite increasing spatial inaccuracy for older records
- Each record may relate to one individual or a much larger population, so the overall significance of a record being impacted by the fires is difficult to quantify

- Impacts within the fire extent are likely to be variable and uneven, and to include areas of low intensity and less damaging burns, small refugia and patches of unburnt habitat
- Treating all of the populations in NSW as a single entity and not recognising bioregional or genetic separations in determining the impact upon a species by the fires

5 Results of initial assessment

The results of the initial assessment are summarised in Table 1. The table shows:

- Species assessed under the Plan with greater than 10 per cent of NSW records affected by fires. It is ordered to show the species with the greatest proportion of NSW records affected to the least
- Percentage of total NSW records for the species that occur in the Cumberland subregion

Species with both greater than 10 per cent of records affected by fires in NSW and greater than 10 per cent of total NSW records within the Cumberland subregion are highlighted in blue. For these species, further comment is made about:

- The risk of impacts of the Plan on the species, drawing on the assessments in this Assessment Report
- The significance of the impacts of the fires on the species
- The adequacy of the commitments in the Plan to helping address the impacts of the fires

These species are:

- *Scoteanax rueppellii* (Greater Broad-Nosed Bat)
- *Grevillea parviflora* subsp. *parviflora* (Small-flower Grevillea)
- *Pomaderris brunnea* (Brown Pomaderris)
- *Persoonia bargoensis* (Bargo Geebung)
- *Acacia bynoeana* (Bynoe's Wattle)
- *Eucalyptus benthamii* (Camden White Gum)
- *Commersonia prostrata* (Dwarf Kerrawang)
- *Myotis macropus* (Southern Myotis)

Koala did not have both greater than 10 per cent of records affected by fires in NSW and greater than 10 per cent of total NSW records within the Cumberland subregion. However, further comment was made about Koala because of the importance of the population in the subregion and the known impacts of the fires on Koala habitat across eastern NSW.

Table 1: Analysis of implications of fires for species relevant to the Plan with greater than 10% of records affected

Scientific name	Common name	Cth status	NSW status	Records/habitat affected by fires			Comments on implications of the fires for the Plan
				Species with > 10% of NSW records affected	% of NSW records that occur in the Cumberland subregion	% distribution affected by fires at national scale	
Petauroides volans	Greater Glider	V	-	82.28%	0.16%	10-30%	-
Petaurus australis	Yellow-bellied Glider	-	V	59.49%	0.1%	No data	-
Persoonia hirsuta	Hairy Geebung	E	E	57.28%	7.2%	30-50%	-
Calyptorhynchus lathami	Glossy Black-cockatoo	-	V	49.20%	0.5%	No data	-
Falsistrellus tasmaniensis	Eastern False Pipistrelle	-	V	45.96%	4.9%	No data	-
Tyto novaehollandiae	Masked Owl	-	V	42.83%	1.4%	No data	-
Dasyurus maculatus maculatus (SE pop)	Spotted-tailed Quoll	E	V	40.27%	0.5%	10-30%	-
Callocephalon fimbriatum	Gang-gang Cockatoo	-	V	36.63%	1.8%	No data	-
Ninox strenua	Powerful Owl	-	V	31.08%	6.6%	No data	-
Maundia triglochinoides		-	V	30.04%	0.4%	No data	-
Persoonia glaucescens	Mittagong Geebung	V	E	28.75%	2.1%	30-50%	-

Scientific name	Common name	Cth status	NSW status	Records/habitat affected by fires: Species with > 10% of NSW records affected	% of NSW records that occur in the Cumberland subregion	% distribution affected by fires at national scale	Comments on implications of the fires for the Plan
Hoplocephalus bungaroides	Broad-headed Snake	V	E	27.19%	1.3%	50-80%	-
Petroica boodang	Scarlet Robin	-	V	26.38%	1.9%	No data	-
Scoteanax rueppellii	Greater Broad-Nosed Bat	-	V	25.41%	11.1%	No data	The species is an ecosystem credit species that is examined in this Assessment Report in terms of impacts to associated PCTs (see Chapter 21). It is predicted to occur in Wilton and GMAC only. The species generally roosts in tree hollows and is more common in tall wet forests. These areas are generally limited within the nominated areas to avoided lands along the edges of Wilton and through the edges and middle of GMAC (associated with gullies and waterways) and will not generally be impacted under the Plan While no species-specific offset is provided for this species under the Plan, the Plan includes commitments (through offset targets for each impacted PCT/NSW TEC) to protect land within the SCAs that contains substantial areas of potential habitat for the species Given the Plan has a low likelihood of impacts to the species and will lead to the protection of substantial areas of potential habitat, the Plan is considered to adequately address impacts to this species in the context of the fires
Grevillea parviflora subsp. *parviflora*	Small-flower Grevillea	V	V	23.98%	21.3%	No data	The risk of residual adverse direct impacts on this species from the Plan is low (see Chapter 29). The area of potential habitat impacted is a small proportion of available habitat for the species in the Plan Area and no records are directly impacted or fragmented While no species-specific offset is provided for this species under the Plan, the Plan includes commitments to protect land within the SCAs that contains 2,975 ha of potential habitat for the species Given the Plan will only have a low risk of impacts on the species and will lead to the protection of substantial areas of potential

Scientific name	Common name	Cth status	NSW status	Records/habitat affected by fires			Comments on implications of the fires for the Plan
				Species with > 10% of NSW records affected	% of NSW records that occur in the Cumberland subregion	% distribution affected by fires at national scale	
							habitat, the Plan is considered to adequately address impacts to this species in the context of the fires
Chalinolobus dwyeri	Large-eared Pied Bat	V	V	23.83%	4.3%	10-30%	-
Petroica phoenicea	Flame Robin	-	V	21.32%	0.6%	No data	-
Cynanchum elegans	White-flowered Wax Plant	E	E	21.02%	4.9%	30-50%	-
Cercartetus nanus	Eastern Pygmy-possum	-	V	20.99%	0.9%	No data	-
Miniopterus schreibersii oceanensis (= M. orianae oceanensis)	Large (Eastern) Bent-winged Bat	-	V	20.78%	9.2%	No data	-
Miniopterus australis	Little Bent-winged Bat	-	V	19.07%	1.8%	No data	-
Pomaderris brunnea	Brown Pomaderris	V	E	18.64%	64.4%	50-80%	The risk of residual adverse direct impacts on this species from the Plan is low (see Chapter 29). The area of potential habitat impacted is a small proportion of available habitat for the species in the Plan Area and no records are directly impacted or fragmented The species occurs within the footprint of the OSO and Metro Rail Future Extension tunnels. The Plan contains a species-specific commitment (Commitment 4.1) to avoid and minimise impacts to this species as a result of tunnel construction, which is considered adequate to protect the individuals within the footprint While no species-specific offset is provided for this species under

Scientific name	Common name	Cth status	NSW status	Records/habitat affected by fires			Comments on implications of the fires for the Plan
				Species with > 10% of NSW records affected	% of NSW records that occur in the Cumberland subregion	% distribution affected by fires at national scale	
							the Plan, the Plan includes commitments to protect land within the SCAs that contains 7,605 ha of potential habitat for the species. Furthermore, three known populations of the species occur within the proposed Georges River Koala Reserve Given the Plan will only have a low risk of impacts on the species and will lead to the protection of substantial areas of potential habitat and several populations, the Plan is considered to adequately address impacts to this species in the context of the fires
Daphoenositta chrysoptera	Varied Sittella	-	V	17.93%	5.9%	No data	-
Persoonia bargoensis	Bargo Geebung	V	E	17.86%	70.9%	10-30%	The risk of residual adverse direct impacts on this species from the Plan is low (see Chapter 29). The area of potential habitat impacted is a small proportion of available habitat for the species in the Plan Area and no records are directly impacted or fragmented While no species-specific offset is provided for this species under the Plan, the Plan includes commitments to protect land within the SCAs that contains 5,174 ha of potential habitat for the species Given the Plan will only have a low risk of impacts on the species and will lead to the protection of substantial areas of potential habitat, the Plan is considered to adequately address impacts to this species in the context of the fires
Heleioporus australiacus	Giant Burrowing Frog	V	V	17.10%	1.2%	30-50%	-
Glossopsitta pusilla	Little Lorikeet	-	V	16.88%	4.0%	No data	-
Varanus rosenbergi	Rosenberg's Monitor	-	V	16.27%	1.4%	No data	-

Scientific name	Common name	Cth status	NSW status	Records/habitat affected by fires			Comments on implications of the fires for the Plan
				Species with > 10% of NSW records affected	% of NSW records that occur in the Cumberland subregion	% distribution affected by fires at national scale	
Acacia bynoeana	Bynoe's Wattle	V	E	15.73%	16.4%	10-30%	The risk of residual adverse direct impacts on this species from the Plan is very low (see Chapter 29). The area of potential habitat impacted is a small proportion of available habitat for the species in the Plan Area and no records are directly impacted or fragmented While no species-specific offset is provided for this species under the Plan, the Plan includes commitments to protect land within the SCAs that contains 5,842 ha of potential habitat for the species Given the Plan will only have a very low risk of impacts on the species and will lead to the protection of substantial areas of potential habitat, the Plan is considered to adequately address impacts to this species in the context of the fires
Ninox connivens	Barking Owl	-	V	15.13%	1.7%	No data	-
Eucalyptus benthamii	Camden White Gum	V	V	13.73%	84.1%	30-50%	The risk of residual adverse direct impacts on this species from the Plan is low (see Chapter 29). The area of potential habitat impacted is a small proportion of available habitat for the species in the Plan Area and no records are directly impacted, although a small area of potential habitat connected to records will be fragmented The species occurs within the footprint of the OSO and Metro Rail Future Extension tunnels. The Plan contains a species-specific commitment (Commitment 4.1) to avoid and minimise impacts to this species as a result of tunnel construction, which is considered adequate to protect the individuals within the footprint While no species-specific offset is provided for this species under the Plan, the Plan includes commitments to protect land within the SCAs that contains 1,495 ha of potential habitat for the species Given the Plan will only have a low risk of impacts on the species and will lead to the protection of substantial areas of potential habitat, the Plan is considered to adequately address impacts to this species in the context of the fires

Scientific name	Common name	Cth status	NSW status	Records/habitat affected by fires: Species with > 10% of NSW records affected	Records/habitat affected by fires: % of NSW records that occur in the Cumberland subregion	Records/habitat affected by fires: % distribution affected by fires at national scale	Comments on implications of the fires for the Plan
Petaurus norfolcensis	Squirrel Glider	-	V	13.00%	0.8%	No data	-
Commersonia prostrata	Dwarf Kerrawang	E	E	12.94%	12.4%	No data	There is no risk of residual direct impacts on this species from the Plan (see Chapter 29). There will be no direct impacts or fragmentation of potential habitat for the species As there are no risks of impacts to the species, the impacts of the fires on this species are not relevant to the Plan
Myotis macropus	Southern Myotis	-	V	11.53%	10.7%	No data	Many records for the species occur in the Plan Area and relatively large areas of potential habitat are impacted by the Plan (see Chapter 23), including water bodies (see Chapter 24) While the fires have affected large areas of habitat containing records, it is important to note that high record density for the species in the Cumberland subregion is likely to be a result of high survey effort rather than an indication of substantial reliance on the subregion The Plan recognises the potential impacts to this species from development under the Plan and includes several commitments to reduce these impacts. These commitments include a species-specific offset to secure 2 offset locations for the species, as well as several other measures to minimise impacts to habitat features that the species relies on (see Chapter 8 and Chapter 15) Furthermore, the Plan includes other commitments to protect land within the SCAs that contain substantial areas (5,475 ha) of potential habitat for the species These commitments are substantial and are considered to adequately address impacts to this species in the context of the fires
Melithreptus gularis gularis	Black-Chinned	-	V	10.95%	2.6%	No data	-

Scientific name	Common name	Cth status	NSW status	Records/habitat affected by fires			Comments on implications of the fires for the Plan
				Species with > 10% of NSW records affected	% of NSW records that occur in the Cumberland subregion	% distribution affected by fires at national scale	
	Honeyeater						
Anthochaera phrygia	Regent Honeyeater	CE	CE	10.94%	5.2%	10-30%	-
Pseudophryne australis	Red-crowned Toadlet	-	V	10.91%	3.6%	No data	-
Phascolarctos cinereus	Koala	V	V	10.32%	2.7%	10-30%	The impacts of the fires on this species are likely to be significant, particularly to populations on the north coast, central and southern tablelands, central coast and the south coast (DPIE, 2020) The fires also increase the significance of the impacts of the Plan on this species. The Southern Sydney Koala population is now likely to be the only population in NSW currently largely unaffected by disease that also remains unaffected by the fires The Plan already recognises the significance of the Southern Sydney Koala population and includes a broad range of commitments to ensure the population persists and the condition of habitat improves in the areas within the Cumberland subregion most likely to support long-term viability (see Sub-Plan B, and Chapter 31). These commitments include: • Avoiding the vast majority (92%) of important Koala habitat (primary and secondary corridors) within the nominated areas • Establishing a large reserve specifically for Koala to secure the north-south movement corridor along the Georges River between Appin and Kentlyn • Funding to plant 100,000 trees as part of ecological restoration of Koala habitat including within the Koala reserve • 120 km of Koala exclusion fencing within Wilton and GMAC to protect Koalas from vehicle strike and dog attacks

Scientific name	Common name	Cth status	NSW status	Records/habitat affected by fires			Comments on implications of the fires for the Plan
				Species with > 10% of NSW records affected	% of NSW records that occur in the Cumberland subregion	% distribution affected by fires at national scale	
							• A range of other measures to manage threats These commitments are substantial and are considered to adequately address impacts to this species in the context of the fires A detailed assessment of the adequacy of the commitments under the Plan for Koala is provided in Chapter 30
