AUGUST 2020

CUMBERLAND PLAIN ASSESSMENT REPORT

PREPARED FOR THE NSW GOVERNMENT DEPARTMENT OF PLANNING, INDUSTRY AND ENVIRONMENT

Contents of the Cumberland Plain Assessment Report

PART 5B: BCAR STAGE 2 (IMPACT ASSESSMENT)

PART 6A: STRATEGIC ASSESSMENT REPORT

PART 6B: STRATEGIC ASSESSMENT REPORT

PART 7: EVALUATION OF THE PLAN

PART 8: SUPPORTING DOCUMENTS

Terms and acronyms used in the Cumberland Plain Assessment Report

Term	Acronym	Description
Action		Activities that directly support the fulfilment of one or more Commitments in the Plan. Actions may be amended using adaptive management throughout the life of the Plan.
Active restoration		When entering a biodiversity stewardship agreement, a landholder can elect to undertake active restoration management actions which generate additional biodiversity credits. They include actions to restore or improve ecological features in a landscape, such as habitat enhancement, targeted supplementary planting to augment habitat and the control of high threat exotic vegetation. See also Required management actions
Adaptive Management		Adaptive management is a structured, iterative approach to help determine how management actions can be most effective in achieving the Plan's outcomes. It allows the implementation of the conservation program to respond to changing circumstances, and ensure the actions are delivering the commitments and meeting the outcomes.
Already Protected Land		Already protected land is used to describe areas with an existing designation of protection from development for environmental reasons, including national parks, nature reserves, biodiversity stewardship sites and other protected lands, such as conservation agreements.
Asset Protection Zone	APZ	An APZ is a buffer zone between a bushfire hazard and buildings. It is managed to minimise fuel loads and reduce potential radiant heat levels, flames, localised smoke and ember attack. The appropriate APZ distance is based on vegetation type, slope and the nature of the development.
Assisted regeneration		Assisted regeneration is the practice of fostering natural regeneration and recolonisation after actively removing ecological impediments (e.g. invasive species, fish barriers) and reinstating appropriate abiotic and biotic states (e.g. environmental flows, fire regimes). See also Ecological restoration, Natural regeneration, Reconstruction
Australian Government Department of Agriculture, Water and the Environment	DAWE	The Australian Government department responsible for environment protection and conservation of biodiversity amongst other things.
Avoidance		An area of land which has been avoided from urban capable land in the biodiversity certification footprint due to its high biodiversity value. Note this is distinct from areas avoided for other reasons such as steep slopes and riparian buffers.
BioBanking agreements		Biobanking agreements were administered under the repealed *Threatened Species Conservation Act 1995*. These agreements are now called biodiversity stewardship agreements (BSAs) under the *Biodiversity Conservation Act 2016*
BioBanking Assessment Method (under the Threatened Species Conservation Act 1997)	BBAM	The BioBanking Assessment Method (BBAM) has been replaced by the Biodiversity Assessment Methodology (BAM) under the *Biodiversity Conservation Act 2016*

Term	Acronym	Description
Biodiversity		Biodiversity is biological diversity - the full variety of living things – referring to plants, animals, fungi and bacteria. It is considered at all scales, from the genetic variation between individuals, to species and the populations they form, and also the complex arrangements of ecosystems.
Biodiversity Assessment Method	BAM	The BAM assesses the impact of actions on threatened species and threatened ecological communities, and their habitats, and the impact on biodiversity values. The BAM provides the processes for identifying biodiversity values, impacts of proposed development and quantifying and describing credits that can be created on BSAs.
Biodiversity certification		Biodiversity certification is a streamlined biodiversity assessment process for areas of land that are proposed for development provided for under the *Biodiversity Conservation Act 2016*. The process identifies areas that can be developed after they are certified and measures to offset the impacts of development. Where land is certified, development may proceed without the usual requirement for site by site assessment of biodiversity impacts.
Biodiversity Certification Area		The land proposed to be biodiversity certified, comprising urban capable lands and transport corridors.
Biodiversity Certification Assessment Report	BCAR	A BCAR is an assessment report done through the Biodiversity Assessment Method that details the types and amounts of impacts from undertaking development actions on a site, including prescribed impacts, avoidance and amelioration. It also identifies opportunities from the development.
Biodiversity Conservation Act 2016	BC Act	The *Biodiversity Conservation Act 2016* establishes the Biodiversity Offset Scheme and allows for the biodiversity certification of land. This is the NSW Act which sets out provisions relating to strategic biodiversity certification, as well as many other issues such as the listing of threatened entities and key threatening processes.
Biodiversity Conservation Regulation 2017	BC Regulation	Provides supporting regulatory detail under the *Biodiversity Conservation Act 2016*
Biodiversity Conservation Trust	BCT	The BCT is a statutory not-for-profit body established under Part 10 of the *Biodiversity Conservation Act 2016*. It was established to encourage and support landholders across NSW to participate in private land conservation.
Biodiversity Development Assessment Report	BDAR	A BDAR is an assessment report prepared by an accredited person that identifies how the proponent proposes to avoid and minimise impacts. It also identifies any potential impact that could be characterised as serious and irreversible according to specified principles, as well as the offset obligation required by the likely impacts on biodiversity of the development or clearing proposal, expressed in biodiversity credits. The BDAR must be provided to the approval authority as part of their development, or a major project proposal, or a clearing application.
Biodiversity Investment Opportunities Map	BIO Map	A map of core areas and corridors identified in western Sydney. Used to calculate impacts to, and protection of, important landscape features and as a surrogate for connectivity

Term	Acronym	Description
Biodiversity Offsets Scheme	BOS	The BOS is a framework to avoid, minimise and offset impacts on biodiversity from development and clearing, and to ensure land that is used to offset impacts is secured in-perpetuity with an appropriate level of funding to ensure management actions identified are implemented.
Biodiversity risk weighting	BRW	The BAM uses a biodiversity risk weighting to evaluate the ecological risks of threatened entities from the biodiversity offsets scheme. The biodiversity risk weighting is comprised of two components: • Sensitivity to loss – this considers the increased threat posed to an entity from offsetting the loss of habitat or population, and • Sensitivity to potential gain – this considers the ability of a species to respond to improvements in habitat condition at an offset site
Biodiversity Stewardship Agreement	BSA	These are agreements are used for landholders wishing to generate and sell biodiversity credits under the Biodiversity Offsets Scheme (BOS)
Biodiversity Stewardship Site	BSS	The site secured under a BSA. Credits generated by establishing a biodiversity stewardship site can be generated and sold through the BOS.
Biodiversity values		Biodiversity values refers to vegetation integrity, habitat suitability and biodiversity-related values such as threatened species abundance, vegetation abundance, habitat connectivity, threatened species movement, flight path integrity and water sustainability as identified in the *Biodiversity Conservation Act 2016* (NSW) and regulations which are considered in the Biodiversity Assessment Method.
Biodiversity Values Map		The Biodiversity Values Map identifies land with high biodiversity value that is particularly sensitive to impacts from development and clearing. The map forms part of the Biodiversity Offsets Scheme Threshold which is one of the triggers for determining whether the Biodiversity Offset Scheme applies to a clearing or development proposal. The map is prepared by the Department of Planning, Industry and Environment under Part 7 of the *Biodiversity Conservation Act 2016* (BC Act) (OEH, 2019).
BioNet Atlas		NSW database managed by EES containing data on species records
BioNet Vegetation Classification		NSW database managed by EES containing data on PCTs
Category 1 matters		Matters that need detailed assessment in the Strategic Assessment Report. These matters are reliant on the Strategic Assessment Area, have some potential to be impacted (directly, indirectly or cumulatively), and are addressed in detail.
Category 2 matters		Matters that do not need further assessment in the Strategic Assessment Report. These matters are not reliant on the Strategic Assessment Area, are subject to no or very low risk of impacts (directly, indirectly or cumulatively), and are not addressed further in the Assessment Report.
Class of action approval		Class of action approval describes the projects covered by the approval that do not need individual referral, assessment or approval under the *Environment Protection and Biodiversity Conservation Act 1999* (Cth) provided they are undertaken in accordance with the endorsed final strategic assessment. See also strategic assessment.
Classes of actions		Classes of actions that are covered by the Plan are: Nominated area development (urban and employment lands), major transport infrastructure, and utilities infrastructure.

Term	Acronym	Description
Commitment		A commitment is a defined milestone in the Plan which is met through the delivery of the actions.
Commitments and actions		The Cumberland Plain Conservation Plan (the Plan) will deliver a range of commitments that will maximise biodiversity conservation outcomes in Western Sydney for threatened species, populations and ecological communities
Connectivity		Connectivity links, as defined by the Biodiversity Assessment Method, are those that connect different areas of habitat, facilitating movement of threatened and more common species across their distribution. The presence of significant biodiversity links on a site contributes to the biodiversity value of that subject land at the landscape scale. Connectivity can be identified at different scales depending on the target species and can include recognised biodiversity corridors, a local corridor identified by a council, flyways for migratory species or a riparian corridor of a stream, wetland or estuary.
Conservation lands		Conservation lands are sites of high biodiversity identified for as potential for reserves or biodiversity stewardship agreements under the Plan, including locations where ecological restoration may also occur.
Conservation Plan		A conservation plan describes how a conservation program will manage and offset the impacts on biodiversity from projected growth, over time and across the Plan Area. The Cumberland Plain Conservation Plan (Plan) will be provided to the NSW Minister for Environment in making an application for strategic biodiversity certification and to the Commonwealth Minister for the Environment for endorsement as part of strategic assessment.
Conservation Priorities Method		The Conservation Priorities Method is a systematic and repeatable method for determining and prioritising new conservation lands. The method was used to determine the strategic conservation area. The method combines detailed spatial information about biodiversity values with an analysis of planning and land use constraint data in order to assess the feasibility of implementing conservation lands as commitments under the Plan.
Conservation program		The conservation program is a package of commitments and actions to offset the residual impact of the proposed development on biodiversity values and to ensure that the Plan's outcomes are delivered.
Cumberland IBRA subregion (or 'Cumberland subregion')		Interim Biogeographic Regionalisation for Australia (IBRA) was developed by the Commonwealth Government as a key planning tool to identify land for conservation. It has since become an improved spatial mapping and information source on vegetation communities and ecosystems across Australia. The Cumberland IBRA subregion is the main focus of this Plan, with most of the Plan Area occurring within this subregion.
Cumberland Plain		The Cumberland Plain is a relatively flat, broad geographic basin located within the Cumberland IBRA subregion, identified by dominant older shale and younger alluvial geology.
Cumberland Plain Assessment Report	CPAR or this Assessment Report	The Cumberland Plain Assessment Report has been prepared to meet the statutory requirements for the strategic assessment and strategic biodiversity certification. It assesses the impacts of proposed development on biodiversity and other values protected under NSW and Australian Government biodiversity legislation.

Term	Acronym	Description
Cumberland Plain Conservation Plan		The Cumberland Plain Conservation Plan (Plan) is a strategic conservation plan being developed to manage and offset the impacts on biodiversity from projected growth in Western Sydney. The Plan will deliver a conservation program to protect and enhance biodiversity at a landscape scale while balancing the future needs of the local community.
Cumulative impacts		Cumulative impacts are those which continue to add to each other as time progresses. Many cumulative impacts can be avoided or minimised through strategic conservation planning.
Derived native grasslands	DNG	Derived native grassland is a "native grassland" remaining after the removal or dieback of previous woody canopy vegetation (shrubs or trees), to a point where woody vegetation has less than 10 per cent cover (Benson, 1996).
Development Control Plan	DCP	A Development Control Plan provides detailed planning and design guidelines to support the planning controls in the Local Environmental Plan developed by a council. Each council is required to publish their Development Control Plan/s on the NSW Planning Portal.
Digital Elevation Model	DEM	A gridded layer of elevation that represents a terrain's surface.
Direct impacts		Direct impacts are those which result in a negative change to biodiversity condition from undertaking an action such as clearing.
District Plan		An integrated land use, transport and infrastructure plan outlining the local priorities and actions for implementing the Greater Sydney Region Plan, A Plan for Growing Sydney. There are five District Plans for the Western City, Central City, Eastern City, North and South districts.
District Plans		District plans are integrated land use, transport and infrastructure plans outlining the local priorities and actions for implementing the Greater Sydney Region Plan, A Plan for Growing Sydney (hyperlink). There are five District Plans for the Western City, Central City, Eastern City, North and South districts.
Ecological function		Ecological function is the potential of an ecosystem to deliver a service that is itself dependent on ecological processes and structures. It considers how species interact with and affect their environment and involves any process or set of processes that can cause change or may be changed by external influences.
Ecological restoration		Ecological restoration is the process of assisting the recovery of an ecosystem that has been degraded, damaged or destroyed through actively managing restoration. It is also sometimes called rehabilitation or revegetation. See also Natural regeneration, Assisted regeneration, Reconstruction.
Ecological Sustainable Development	ESD	Defined as using, conserving and enhancing the community's resources so that ecological processes, on which life depends, are maintained, and the total quality of life, now and in the future, can be increased. Additional definitions can be found under Section 6 of the *Protection of the Environment Administration Act 1991* (NSW) and Section 3A of the *Environment Protection and Biodiversity Conservation Act 1999* (Cth).
Ecosystem Credit Species	ECS	Ecosystem Credit Species under the BAM

Term	Acronym	Description
Ecosystem processes		The numerous interactions between different components (both living and non-living) of an ecosystem that support the biological elements of the system (EPA, 2015).
Environment Protection and Biodiversity Conservation Act 1999 (Cth)	EPBC Act	The EPBC Act is the Australian Government's central piece of environmental legislation, which provides a framework to protect and manage items identified in the nine categories of Matters of National Environmental Significance.
Environmental Planning and Assessment Act 1979 (NSW)	EP&A Act	This is the NSW Act which provides a legal framework for land use planning, how land is to be developed and managed; and provides a framework for the creation of environmental plans. It is administered by the NSW Department of Planning, Industry and Environment.
Environmental Planning Instruments	EPI	Environmental Planning Instrument is the collective name LEPs and SEPPs, not including DCPs.
Environmental zones		Environmental zones or 'E zones' are identified in LEPs and are used to identify land that is of important environmental value. There are four 'E zones' including E1 (National Parks and Nature Reserves), E2 (Environmental Conservation), E3 (Environmental Management) and E4 (Environmental Living).
Excluded land		Land that is already protected or developed for urban and other purposes or, for other reasons, was not considered for inclusion in the biodiversity certification. These lands include: • Existing protected land, including reserves and established offset sites • Commonwealth land, such as Orchard Hills Defence Establishment • Lands already assessed as part of another development approval (Bingara Gorge), lands progressing through an alternate development assessment (Mount Gilead and Menangle Park) • Lands already developed (existing urban areas and urban land zones)
Existing North West and South West Growth Areas		The new term for the North West and South West Growth Centres.
Extent of occurrence	EOO	The area contained within the shortest continuous imaginary boundary which can be drawn to encompass all known, inferred or projected sites of present occurrence of a species or ecological community, excluding cases well outside an entity's normal distribution.
Facilitated impacts		Impacts that result from further actions (including actions by third parties) which are made possible or facilitated by the action
Finalised priority assessment list	FPAL	This is the list of species, ecological communities, and key threatening processes that have been nominated and approved for assessment by the Minister responsible for the EPBC Act
Future Transport Strategy 2056		The Future Transport Strategy is a 40-year strategy which will guide NSW transport investment over the longer term. It is an update of the 2012 Long Term Transport Master Plan for NSW.
Greater Macarthur Growth Area	GMAC	One of the four nominated areas that the NSW Government has identified as the key focus for urban development to 2056 in Western Sydney.

Term	Acronym	Description
Greater Penrith to Eastern Creek Investigation Area	GPEC	One of the four nominated areas that the NSW Government has identified as the key focus for urban development to 2056 in Western Sydney.
Greater Sydney Commission	GSC	The Greater Sydney Commission is leading strategic metropolitan planning for the Greater Sydney region. Their strategic plans serve to make Greater Sydney more productive, liveable and sustainable for future generations.
Greater Sydney Region Plan		A 20-year integrated land use, transport and infrastructure plan outlining the priorities and actions for Greater Sydney.
Greater Sydney Regional Plan		Also known as 'Greater Sydney Region Plan - A Metropolis of Three Cities'. It is a 20-year integrated land use, transport and infrastructure plan outlining the priorities and actions for Greater Sydney.
Important Koala habitat		Important koala habitat is the term used to describe both primary and secondary corridors. It is the area that is critical to the long-term viability of koalas (primary corridors) as well as the areas (if enhanced) that would support the population (secondary corridors).
Important population		Important populations are defined in the Commonwealth's Significant Impact Guidelines (Policy Statement 1.1) (DoE, 2013) as: *"Any population of a vulnerable species which meets the definition of an important population in the Commonwealth's Significant Impact Guidelines (Policy Statement 1.1) as follows:* *'A population that is necessary for a species' long-term survival and recovery. This may include populations identified as such in recovery plans, and/or that are:* • *key source populations either for breeding or dispersal* • *populations that are necessary for maintaining genetic diversity, and/or* • *populations that are near the limit of the species range"* For the purposes of the SAR, important populations are also defined as including any population of an endangered or critically endangered species. Under the EPBC Act, all populations of an endangered or critically endangered species are considered to be important for the survival and recovery of the species.
Indirect and offsite impacts		Indirect and offsite impacts include downstream, downwind, upstream and facilitated impacts e.g. fertilisers washed into river systems, extraction of raw materials and construction of a dam for irrigation water facilitates water use. See Significant Impact Guidelines for more detail
Indirect impacts		Indirect impacts include downstream, downwind, upstream and facilitated impacts e.g. fertilisers washed into river systems, extraction of raw materials and construction of a dam for irrigation water that facilitates water use. See Significant Impact Guidelines for more detail.
Interim Biogeographic Regionalisation for Australia	IBRA	Interim Biogeographic Regionalisation for Australia (IBRA) was developed by the Commonwealth Government as a key planning tool to identify land for conservation. It has since become an improved spatial mapping and information source on vegetation communities and ecosystems across Australia.

Term	Acronym	Description
Knowledge Based Method	KBM	Assumed presence using a knowledge-based method was used to define species polygons for species where expert reports were not prepared or adequate species records were not available to complete a Species Distribution Model (SDM). KBMs mapped species habitat based on vegetation mapping plus additional habitat or geographic elements.
Koala movement corridors		Koala movement corridors are areas of habitat (often but not always linear) which facilitate the movement and dispersal of koalas between habitat patches which would otherwise be disconnected. Koala movement corridors facilitate Koala population dispersal, which protects against localised extinctions, as Koalas require large, connected areas of important habitat for feeding and breeding.
Land Category		The Plan and the spatial viewer identify a number of land categories including: • **Certified** – Urban Capable: Urban capable land is land identified for future development that will seek approval to be both biodiversity certified under the *Biodiversity Conservation Act 2016* (NSW) and strategically assessed under the *Environment Protection and Biodiversity Conservation Act 1999* (Cth). This category identifies where future urban development is likely to occur subject to other approvals. • **Excluded** – Excluded land is land which has been excluded from the Plan and for which NSW strategic biodiversity certification and the Commonwealth strategic assessment will not be sought. • **Non-Certified** – avoided for biodiversity purposes/ avoided for other purposes/ Western Sydney Aerotropolis: Non-certified land has three sub-categories including: o Land that has high biodiversity values to be protected and has been avoided from the urban capable land for this reason o Land that cannot be feasibly developed due to the topography (slope) of the land or having an environmental feature such as a riparian corridor o Land affected by the 1 per cent annual exceedance probability flood and other non-certified land within the Western Sydney Aerotropolis that is not included in the other non-certified categories
Land Use and Infrastructure Implementation Plan	LUIIP	A LUIIP provides an overview of future land uses and the proposed sequence of development to ensure new jobs and homes are delivered in time with infrastructure.
Local Aboriginal Land Council	LALC	A LALC is an autonomous body which is governed by Boards elected by local Aboriginal community members every two years. LALCs were established under the Aboriginal Land Rights Act 1983 as the elected representatives for Aboriginal people in NSW. The Plan Area includes three LALCs: Deerubbin, Tharawal and Gandangara.
Local Environmental Plan	LEP	An LEP is an environment planning instrument that guides planning and development decisions within a local government area in NSW. This is achieved through zoning and development controls, which provide a framework for the way land can be used.

Term	Acronym	Description
Matters of National Environmental Significance	MNES	Matters of national environmental significance are defined under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) as: • Listed threatened species and communities • Migratory species • Wetlands of international importance (listed under Ramsar) • Commonwealth marine environment • World Heritage properties • National Heritage places • The Great Barrier Reef Marine Park • Nuclear actions • A water resource, in relation to coal seam gas development and large coal mining development
Monitoring Evaluation Reporting	MER	MER is the process of tracking and reviewing projects over time to ensure outcomes are met. For the Plan, it will provide assurance that conservation program outcomes and commitments are being satisfied and clarity for delivery partners on how to appropriately measure and report in a coordinated manner.
Native vegetation		Native vegetation is any plant native to NSW prior to European settlement, defined in Part 5A of the Local Land Services Act 2013. It can also include any plant, living or dead, in mapped Category 2-vulnerable land and generally excludes marine vegetation. Native vegetation species when occurring together form native vegetation communities, which in NSW are called Plant Community Types (PCTs).
Natural regeneration		Natural regeneration is an approach to restoration that relies on spontaneous or unassisted natural regeneration as distinct from an 'assisted natural regeneration' approach that depends upon active intervention. See also Assisted regeneration, Ecological restoration, Reconstruction.
Nature Conservation Trust agreements	NCT agreements	Protected land under Nature Conservation Trust agreements
Nominated area		A nominated area is an area in Western Sydney identified for future growth which seek approvals through the Plan under the *Biodiversity Conservation Act 2016* (NSW) and *Environment Protection and Biodiversity Conservation Act 1999* (Cth). These areas include: Wilton Growth Area, Greater Macarthur Growth Area, Western Sydney Aerotropolis, and Greater Penrith to Eastern Creek Investigation Area.
Non-offsettable grassland	NoG	Non-offsettable grassland comprises grassland vegetation zones with a vegetation integrity score of <15 and does not require offsetting for the associated PCT under the BAM
NSW (Mitchell) Landscapes		The Mitchell Landscapes were mapped in 2002 using a combination of landsystems in the west of NSW and geology and Digital Elevation Model (DEM) in the east of NSW. There have been a number of new versions since the original mapping. The most recent is version 3.1 (OEH, 2018).
NSW Environment Energy and Science	EES	The NSW Government department responsible for environment protection and conservation of biodiversity amongst other things. Formerly known as Office of Environment and Heritage (OEH).

Term	Acronym	Description
NSW Government Department of Planning, Industry and Environment		The NSW Government department responsible for effective and sustainable planning and the development of industry to support growth in NSW
NSW Koala Strategy		The NSW Koala Strategy identifies a set of short-term actions as part of a longer-term goal to stabilise and increase koala populations. The strategy encompasses four key pillars: koala habitat conservation, conservation through community action, safety and health of koala populations and building knowledge and education.
NSW listed candidate species		A candidate Species Credit Species required assessment of potential impacts within the nominated areas as part of the BAM assessment, with the results documented in the BCAR
NSW Office of Environment and Heritage		A former office of the NSW Government from 2011 to 2019. Now known as NSW Environment Energy and Science
Outcome		An outcome is a reported or measurable result of a desired goal. In the Plan, it is the intended environmental, economic or social impact or value of delivering the Plan's commitments.
Outer Sydney Orbital	OSO	Outer Sydney Orbital (Stage 1) from Palmyra Avenue to the Hume Motorway and remaining Outer Sydney Orbital 1 provides for a future north south motorway and freight rail line.
Plan Area		The Plan Area covers around 200,000 hectares and includes the Cumberland IBRA subregion and some minor areas of the adjacent Sydney Cataract and Wollemi IBRA subregions. It extends from 10 kilometres north of Windsor to Picton in the south, and from the Hawkesbury-Nepean River in the west to east near Liverpool. It includes sections of eight Local Government Areas – Wollondilly, Camden, Campbelltown, Liverpool, Fairfield, Penrith, Blacktown and Hawkesbury.
Plant Community Type	PCT	PCTs are the community-level grouping used in NSW's planning and assessment tools and vegetation mapping programs. They are identified in the BioNet Vegetation Classification (VIS) database.
Precinct planning		Precinct Planning ensures that nominated areas are strategically planned and infrastructure is delivered in a coordinated manner. The program identifies the development intent and development capacity across an entire precinct, through the allocation of housing choices, built form, infrastructure, and environmental and open space desires.
Prescribed impact		A prescribed impact, in the Biodiversity Offset Scheme, is an impact to a particular factor affecting biodiversity which must be considered. These are: impacts or potential impacts to habitat features (such as caves and cliffs, rocks, man-made structures and non-native vegetation) as well as impacts on habitat connectivity, threatened species movement, water bodies and water-related processes that sustain threatened species.
Primary Koala Corridors		Primary koala corridors are connected areas of koala habitat that are contiguous (gaps between trees less than 100 metres) and greater than 380 hectares in width.
Priority Conservation Lands	PCL	PCLs were identified as part of the Cumberland Plain Recovery Plan methodology report (DECCW, 2010)

Term	Acronym	Description
Protected matters search tool	PMST	The Australian Government PMST identifies whether MNES or other matters protected by the EPBC Act are likely to occur in an area.
Ramsar Wetlands		A list of Wetlands of International Importance, identified in the Ramsar Convention, signed in Ramsar, Iran and maintained by the Commonwealth.
Reconstruction		Reconstruction is an ecological restoration approach where the appropriate biota needs to be entirely or almost entirely reintroduced as they cannot regenerate or recolonise within feasible timeframes, even after expert assisted regeneration interventions. See also Natural regeneration, Assisted regeneration, Ecological restoration.
Required management action		A Required management action is an action for a biodiversity stewardship site required to improve the condition of native vegetation or species habitat. These could include activities such as native vegetation management (restoring native vegetation, retaining and managing regrowth, nutrient control), pest animal control, weed management, among others.
Reserves		Reserves are conservation lands of high biodiversity value typically managed by National Parks and Wildlife Services or council. Reserves can include national parks, nature reserves, regional parks, council reserves and community reserves.
Riparian		Riparian refers to lands that relate to waterways and parts of the landscape influenced by streams and flowing fresh water. The riparian buffer is defined in BAM as being within a certain distance from the top of the bank of a waterway of particular order.
Saving Our Species program	SOS	The Saving Our Species program is an initiative in which the NSW Government is investing $100 million over five years (from 2016 to 2021) to protect threatened species from extinction (OEH, 2016)
Secondary Koala Corridors		Secondary koala corridors are movement corridors that are less than 50 metres wide or not connected at both ends to other koala habitat.
State Environmental Planning Policy	SEPP	A SEPP is an environmental planning instrument that deals with matters of State or Regional environmental planning significance.
Serious and irreversible impacts	SAII	As defined in Guidance to assist a decision-maker to determine a serious and irreversible impact (OEH, 2017a). An SAII is one that: • Will cause a further decline of the species or ecological community that is currently observed, estimated, inferred or reasonably suspected to be in a rapid rate of decline, or • Will further reduce the population size of the species or ecological community that is currently observed, estimated, inferred or reasonably suspected to have a very small population size, or • Impact on the habitat of a species or ecological community that is currently observed, estimated, inferred or reasonably suspected to have a very limited geographic distribution, or • Impact on a species or ecological community that is unlikely to respond to measures to improve habitat and vegetation integrity and is therefore irreplaceable

Term	Acronym	Description
Special Infrastructure Contribution		Levy contributions from developers to fund the delivery of state and regional infrastructure required to support a growing population, such as roads, public transport, health facilities, emergency services, schools, and open space and provide for biodiversity management.
Species Credit Species	SCS	Species Credit Species under the BAM
Species Distribution Model	SDM	SDMs are statistical models used to estimate the relationship between species records at sites and the environmental and/or spatial characteristics of those sites. Once this relationship has been estimated, the SDM can be used to predict other locations in the landscape where the species is likely to occur. Species Distribution Modelling was undertaken for Commonwealth listed Category 1 species within the Cumberland subregion where adequate species records were available to develop a model.
Strategic Assessment		Strategic assessments are landscape-scale assessments under the Commonwealth *Environment Protection and Biodiversity Conservation Act 1999*. Unlike project-by-project assessments, which look at individual actions, they can consider a much broader set of actions over a much larger scale and timeframe, such as a plan, policy or program.
Strategic Assessment Agreement		The strategic assessment agreement is the formal agreement between the Commonwealth Minister for Environment and the State of NSW to enter into the assessment. It is a mandatory requirement under national environment law, and formally establishes the expectations of both parties.
Strategic Assessment Area		The Strategic Assessment Area is the area assessed for impacts to matters protected under Part 3 of the *Environment Protection and Biodiversity Conservation Act 1999* (Cth) from development under the Plan and where conservation outcomes can be achieved. The Strategic Assessment Area is spatially aligned with the Plan Area.
Strategic Assessment Report	SAR	An assessment report done in accordance with the Terms of Reference for the SAR provided under the Part 10 Strategic Assessment Section 146 Agreement between the Commonwealth Minister for the Environment and the State of NSW under the EPBC Act
Strategic biodiversity certification		Strategic biodiversity certification is a form of biodiversity certification available only to planning authorities such as the Department of Planning and Environment, to support significant regional development and planning processes.
Strategic Conservation Area	SCA	The strategic conservation area was determined using the Conservation Priorities Method and represents large remnants of native vegetation with good connectivity, or areas with the potential to enhance connectivity in the Plan Area. The strategic conservation area will be used to identify potential conservation lands for further investigation.
Strategic Conservation Planning		Strategic conservation planning is a landscape-scale approach to assessing and protecting biodiversity upfront in planning for large-scale development. This strategic approach allows for the streamlined delivery of housing and infrastructure while protecting regionally important land for conservation and publicly accessible green space.

Term	Acronym	Description
Strategic Environmental Assessment	SEA	A Strategic Environmental Assessment (SEA) is prepared as part of the process of identification and protection of Transport Corridors. It provides an assessment of the environmental, economic and social impacts of reserving the corridor. SEAs are non-statutory documents that assist in the planning and decision making process for the community and Government. They are subject to public consultation and include justification for a preferred corridor alignment and provide information on the assessment of alternative corridor alignments
Structured decision-making		The Department applied a structured decision-making process during early development of the Plan to define a high-level biodiversity outcome for the Cumberland subregion that set the context and direction for the development of the Plan. The SDM was one of the first steps in a comprehensive conservation planning process for the Plan.
Structure Plan		A Structure Plan is a spatial representation of high-level land uses, environmental assets and transport infrastructure within a nominated area. It includes overarching planning principles, distribution of land uses, the phasing of precincts and identification of a high-level transport framework, the Blue–Green Grid and other key infrastructure.
Sub-Plan A		Sub-Plan A of the Cumberland Plain Assessment Report: Conservation Program and Implementation
Sub-Plan B		Sub-Plan B of the Cumberland Plain Assessment Report: Koalas
Subject Land		The Plan Area for the Biodiversity Certification Assessment Report, comprising the nominated areas and their urban capable lands. The BAM uses the term Subject Land to mean land to which the BAM is applied in Stage 1 to assess the biodiversity values of the land, including land within urban capable lands or proposed for biodiversity certification. For the Assessment Report, the terms 'nominated areas' and 'urban capable lands' are used instead of the term Subject Land.
Terms of Reference	ToR	Terms of Reference are a requirement under the *Environment Protection and Biodiversity Conservation Act 1999* (Cth) for undertaking a strategic assessment and are prepared in accordance with the Strategic Assessment Agreement. Terms of Reference outline the requirements for the Strategic Assessment Report, including how impacts to MNES should be assessed and how the overall outcomes of the Plan have been evaluated.
The assessor		A BCAR can only be prepared by a person accredited under the accreditation scheme developed under Section 6.10 of the BC Act. Throughout this report, an accredited person is referred to as 'the assessor'.
Threatened Biodiversity Data Collection	TBDC	The Threatened Biodiversity Data Collection is maintained in the NSW BioNet Atlas database and consists of profiles for threatened species, populations and ecological communities that occur in NSW.
Threatened Ecological Community	TEC	An ecological community may be listed as vulnerable, endangered or critically endangered under the *Biodiversity Conservation Act 2016* and/or *Environment Protection and Biodiversity Conservation Act 1999* depending on the level of threat and risk of its collapse.

Term	Acronym	Description
Threatening processes		A process is defined as a threatening process under the EPBC Act if it threatens or may threaten the survival, abundance or evolutionary development of a native species or ecological community. The EPBC Act enables the listing of key threatening processes. A threatening process may be added to the list of key threatening processes in several circumstances, including where it could cause a native species or an ecological community to become eligible for listing under the EPBC Act as threatened.
Transport corridors		The transport corridors are part of the NSW Government's planning for the long-term transport needs of Western Sydney by identifying and protecting corridors of land that can be used to deliver road and rail infrastructure when needed in the future. The transport infrastructure will be constructed and delivered to 2056.
Urban capable land		Not all parts of the nominated areas are proposed for urban development. Urban capable lands are the areas directly impacted by the proposed urban and agricultural development. This refers to the areas within the nominated areas where the NSW Government has streamlined the delivery of priority housing and infrastructure through the biodiversity certification process.
Vegetation integrity score	VI score	A measure of vegetation condition. When scores for composition, structure and function are combined into a vegetation integrity score, they provide the rigour and transparency needed to make site-scaled comparisons and inform natural resource management decision making tools such as the BAM (OEH, 2017b)
Vegetation zones		A vegetation zone is an area of native vegetation that is the same PCT and has a similar broad condition state.
Western City District Plan		The Western City District Plan aligns with the Greater Sydney Region Plan, and provides more details regarding targeted planning objectives for the District, with associated actions to be undertaken to achieve the outlined objectives.
Western Parkland City		The Western Parkland City is one of the three proposed conglomerate cities which would make up Greater Sydney in the GSC's vision of a metropolis of three cities. The Western Parkland City would contain metropolitan clusters located around Greater Penrith, the Western Sydney Airport, Campbelltown-Macarthur and Liverpool. It includes areas across six Local Government Areas – Blacktown, Camden, Campbelltown, Fairfield, Liverpool and Penrith.
Western Sydney		A major region of Sydney comprised of 12 local government areas: Blacktown, Canterbury-Bankstown, Camden, Campbelltown, Cumberland, Fairfield, Hawkesbury, Liverpool, Parramatta, Penrith and Wollondilly.
Western Sydney Aerotropolis	WSA	One of the four nominated areas that the NSW Government has identified as the key focus for urban development to 2056 in Western Sydney.
Western Sydney City Deal		The City Deal is a 20-year agreement to deliver a transformation of Sydney's outer west. The Commonwealth and NSW Governments, together with eight local governments of Western Sydney, signed the Western Sydney City Deal on 4 March 2018.

Term	Acronym	Description
Western Sydney Parklands Trust		The Western Sydney Parklands Trust is a self-funded Government agency. Maintaining and expanding the Parklands' facilities is an important aspect of the Trust's core business. Business hubs, generally located on the perimeter of the Parklands, provide the sustainable funding base.
Wilton Growth Area	Wilton	One of the four nominated areas that the NSW Government has identified as the key focus for urban development to 2056 in Western Sydney.
Working group		Working groups will be established under the Plan to determine priorities and support delivery of the Plan’s commitments to meet outcomes for a specific area of focus. They will comprise relevant stakeholders and experts as required. Four working groups are proposed to be established under the Plan: compliance, koalas, weed control and pest and animal control.

Part 1 List of Figures

Part 1 List of Tables

1 Introduction

The NSW Government has identified four areas for urban growth and other development ('nominated areas') and a series of transport corridors within and outside the nominated areas to support the future growth of Western Sydney for the next 36 years. These initiatives are identified under two key planning strategies:

- *A Metropolis of Three Cities - The Greater Sydney Region Plan* (Greater Sydney Commission, 2017)
- *Future Transport 2056* (Transport for NSW, 2018)

The nominated areas program represents the strategic prioritisation and delivery of new development as part of the long-term growth of Greater Sydney provided under the Greater Sydney Region Plan. The nominated areas are the key focus for development until 2056 and will be the centres of economic activity in Western Sydney.

The transport corridors are part of the NSW Government's planning for the long-term transport needs of Western Sydney by identifying and protecting corridors of land that can be used to deliver road and rail infrastructure when needed in the future. The transport infrastructure will be constructed and delivered over the next few decades.

The nominated areas program is administered by the NSW Department of Planning, Industry and Environment (the Department). The transport corridors program is administered by Transport for NSW, who are a major project partner.

The Department is progressing the approvals required for the development. As part of the biodiversity approvals required, the Department is preparing the Cumberland Plain Conservation Plan (the Plan) to provide long-term certainty for biodiversity and development in Western Sydney. The Plan sets out:

- Proposed development under the Plan
- A conservation program to achieve the Plan's objective and outcomes and offset the impacts of development on biodiversity values
- How the Plan will be implemented

The Plan will support two separate statutory approvals processes under State and Commonwealth laws required to address the impacts of the proposed development on biodiversity values, in accordance with:

- Strategic biodiversity certification under Part 8 of the *Biodiversity Conservation Act 2016* (BC Act)
- Strategic assessment under Part 10 of the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act)

This Cumberland Plain Assessment Report (Assessment Report) assesses the potential impacts of the proposed development under the Plan on biodiversity values regulated under the BC Act and EPBC Act.

The strategic biodiversity certification and strategic assessment processes aim to reduce the costs and timeframes associated with regulation of the proposed development under the BC Act and EPBC Act and more effectively manage the biodiversity impacts of planned growth and improve biodiversity outcomes in the long term by:

- Removing duplication between NSW and Commonwealth biodiversity laws
- Replacing site by site assessments and approvals for individual projects that would generally be needed under both the BC Act and EPBC Act for the proposed development with a single and strategic approval approach

1.1 DESCRIPTION OF THE PLAN

The purpose of the Plan is to establish long-term certainty for biodiversity conservation and development in Western Sydney. The Plan supports the delivery of infrastructure, housing and jobs for Western Sydney in a planned and strategic way that also protects and maintains key biodiversity values of Western Sydney.

The Plan includes a conservation program of commitments and actions that seeks to improve ecological function and resilience in the Cumberland Plain and provide an enduring conservation legacy for Western Sydney.

The Plan comprises an overall Plan and a series of sub-plans that cover three key elements:

- Development – this covers the urban and industrial, infrastructure, agribusiness, and transport development under the Plan, including the scope and location of the development
- Conservation – this covers the conservation program and set of commitments to achieve the Plan's objective and to offset the impacts of the development on biodiversity values
- Implementation framework – this covers how the Plan will be implemented

The Plan is described in detail in Part 2.

1.2 PLAN TIMING

The Plan will be implemented over the period to 2056 and the Department is seeking that the approvals for the Plan have effect until this date. This timing aligns with implementation of the *Greater Sydney Region Plan: A Metropolis of Three Cities* (GSC, 2018) and the *Future Transport Strategy 2056* (Transport for NSW, 2018).

1.3 THE PLAN AREA

The Plan Area is shown in Figure 1-1.

The Plan Area is primarily within the Interim Biogeographic Regionalisation for Australia (IBRA) Cumberland subregion of the Sydney Basin Bioregion. It also includes some minor areas of the adjacent Sydney Cataract subregion. The area covered is approximately 200,000 hectares (see Figure 1-1).

The Cumberland subregion is a broad geographic feature bounded by the elevated lands of the Hornsby Plateau in the north, the base of the Blue Mountains to the west, the Woronora plateau in the south, and the Sydney CBD to the east.

The Plan Area for this project lies generally within the Western part of the subregion and extends from about 10 km north of Windsor south to Tahmoor (south of Picton), and from approximately Silverdale eastwards to Liverpool, and includes all or part of eight Local Government Areas (LGAs), being:

- Camden Council
- City of Blacktown
- City of Campbelltown
- City of Fairfield
- City of Hawkesbury
- City of Liverpool
- City of Penrith
- Wollondilly Shire

The vast majority of the proposed development occurs in the Cumberland subregion. Small parts of two of the nominated areas (Wilton and GMAC) occur in the Sydney Cataract subregion but are not in the areas intended for development.

The assessment areas differ for the Strategic Assessment Report (SAR) and Biodiversity Certification Assessment Report (BCAR) components of the report:

- For the SAR, the assessment area is called the Strategic Assessment Area and covers the area of the Plan
- For the BCAR, the assessment area is called the Subject Land and covers the nominated areas

1.4 PURPOSE OF THIS REPORT

The Assessment Report assesses the potential impacts of the proposed development under the Plan on biodiversity values and other matters regulated under the BC Act and EPBC Act. The Assessment Report is a single report prepared to meet the statutory requirements for both:

- A BCAR prepared in accordance with the Biodiversity Assessment Method (BAM) in accordance with the BC Act

- A SAR prepared in accordance with the Terms of Reference (ToR) for the SAR provided under the Part 10 Strategic Assessment Section 146 Agreement between the Commonwealth Minister for the Environment and the State of NSW under the EPBC Act (see Supporting Document A)

1.4.1 PURPOSE OF BCAR COMPONENT OF THE REPORT

The purpose of the BCAR component of this Assessment Report is to provide an assessment of the proposed development taken under the Plan in accordance with stages 1 and 2 of the BAM, including:

- Identifying and assessing the biodiversity values of the area covered by the proposed development
- Quantifying the impacts on biodiversity values of the proposed development
- Describing the commitments and actions to offset the impacts of the development, including the number and classes of biodiversity credits that would be required to be retired if the offset rules under the Biodiversity Conservation Regulation 2017 (BC Regulation) applied

As the proposed development has been determined by the NSW Environment Minister to be considered for approval under a ‘strategic biodiversity certification’, the offset rules under the BC Regulation do not apply and the Minister can determine any measure to be a conservation measure (see Section 2.1).

The BCAR component of this Assessment Report will be considered by the NSW Minister for the Environment in deciding to confer strategic biodiversity certification for the proposed development under the BC Act.

1.4.2 PURPOSE OF SAR COMPONENT OF THE REPORT

The purpose of the SAR component of this Assessment Report is to address the ToR and assess the impacts of the proposed development taken under the Plan on all matters protected by Part 3 of the EPBC Act (protected matters).

The SAR component of this Assessment Report will be considered by the Commonwealth Environment Minister in deciding to endorse the Plan under the EPBC Act. If the Plan is endorsed by the Minister, the Minister may subsequently consider approval of the proposed development in accordance with the endorsed Plan.

1.5 SCOPE OF THE DEVELOPMENT

The scope of the proposed development broadly comprises:

- Urban and industrial development within urban capable land in the nominated areas
- Infrastructure within urban capable land in the nominated areas, as well as ‘essential’ infrastructure in limited cases within avoided lands in the nominated areas
- Agribusiness within agribusiness lands in the Western Sydney Aerotropolis (WSA)
- Western Sydney Major Infrastructure Corridors (transport corridors) within and outside the nominated areas

Figure 1-1 shows the location of the four nominated areas and the transport corridors.

The nominated areas comprise:

- Greater Macarthur Growth Area (GMAC)
- Greater Penrith to Eastern Creek Investigation Area (GPEC)
- Western Sydney Aerotropolis (WSA) (excluding where there is overlap with the existing South West Growth Area)
- Wilton Growth Area (Wilton)

Not all parts of the nominated areas are proposed for development. The proposed development will occur within specified urban capable lands within each nominated area. These are shown in Figure 1-1.

Further details of the proposed development are provided in Part 2.

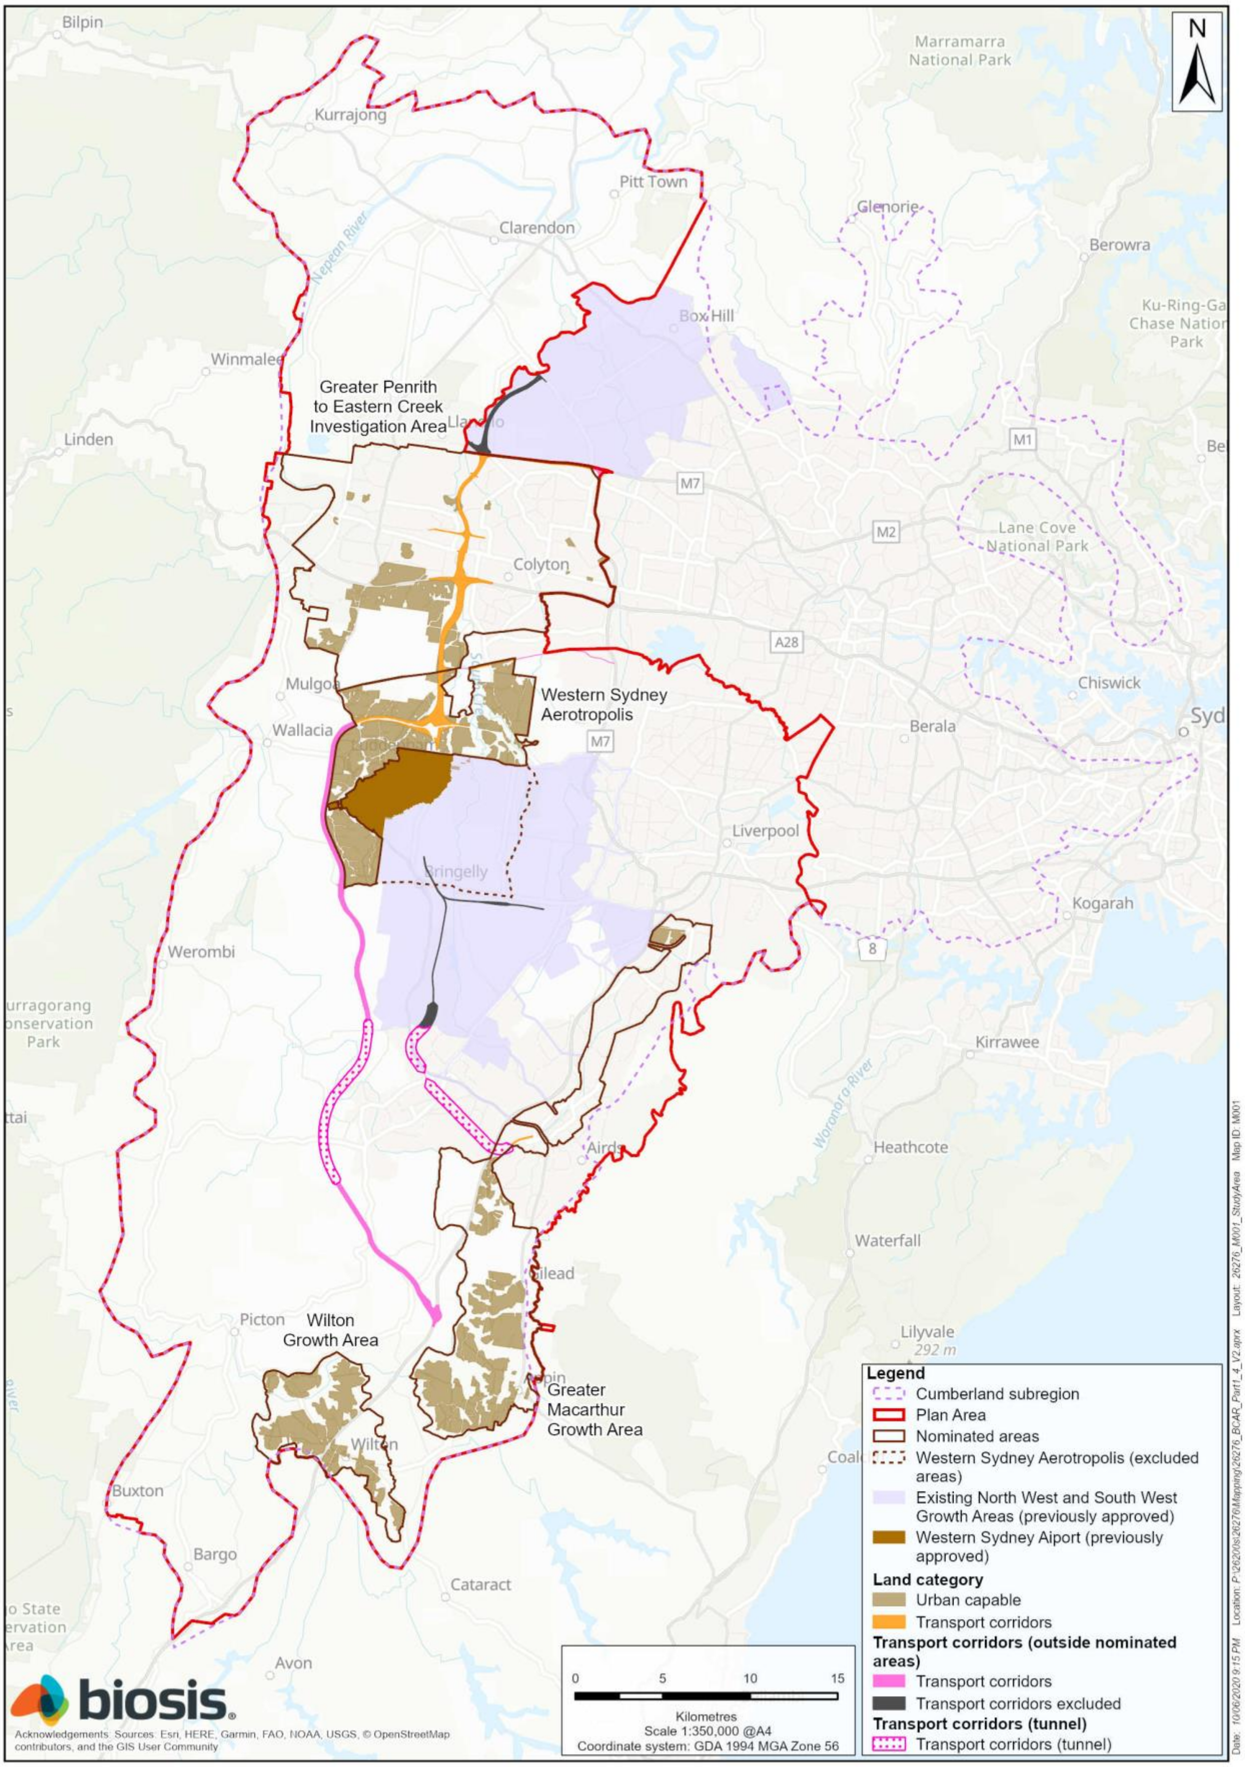

Figure 1-1: The Plan Area and location of nominated areas and transport corridors

1.6 APPROVALS BEING SOUGHT

The Department is seeking two separate statutory approvals for the impacts of the development on biodiversity values:

- Strategic biodiversity certification under Part 8 of the BC Act
- Approval under Part 10 of the EPBC Act

Table 1-1 shows what development is subject to assessment and approval under the BC Act and EPBC Act.

Table 1-1: Development being assessed for approval under the BC Act and the EPBC Act

Development	Biodiversity certification under BC Act	Approval under Part 10 of EPBC Act
The following development within the nominated areas: • Urban and industrial development • Infrastructure • Agribusiness • Transport corridors	✓	✓
Transport corridors outside the nominated areas*	-	✓

* Biodiversity certification may be sought for the transport corridors outside the nominated areas at a later date, and may be included as a modification or series of modifications to this biodiversity certification

Table 1-2 identifies the boundaries of the approval areas under the BC Act and EPBC Act and the effect of the approvals should they be granted.

Table 1-2: General boundaries of the approval areas under the BC Act and EPBC Act and effect of the approvals

	General boundaries of approval area	Effect of the approval
Biodiversity certification under BC Act	Land within the boundaries of the urban capable land and transport corridors within the nominated areas shown in Figure 1-1 Land that is avoided or excluded (see Chapter 14) is not included in the land proposed to be biodiversity certified	Development can proceed in these areas without further approval under the BC Act Development must be undertaken in accordance with any conditions of the biodiversity certification under the BC Act Any other necessary approvals must also be obtained for the development, including development consent under the *Environment Planning and Assessment Act 1979* (EPA Act)
Approval under Part 10 of EPBC Act	Land within the boundaries of the urban capable land and transport corridors within and outside the nominated areas shown in Figure 1-1, as well as 'essential' infrastructure within avoided lands in the nominated areas	Development can proceed in these areas without further approval under the EPBC Act Development must be undertaken in accordance with the Plan and any conditions of the Part 10 approval under the EPBC Act

1.7 WHO PREPARED THIS REPORT

The Department commissioned a project team to prepare the Assessment Report and undertake data collection on biodiversity values within the Plan Area. The project team preparing this Assessment Report is comprised of:

- Open Lines – Responsible for preparing this Assessment Report, particularly the SAR component of the report
- DAJ Environmental – Part of the Open Lines team responsible for preparing this Assessment Report
- Biosis – Responsible for:
  - Preparing the BCAR component of this Assessment Report

  - Leading the collection of data to meet the requirements of the BAM and ToR
  - Developing the native vegetation, Threatened Ecological Communities (TEC) and species maps of the Plan Area
  - Undertaking all BAM calculations to determine:
    - Amount of native vegetation, TECs and species habitat avoided and impacted
    - Number and class of biodiversity credits that would be required to be retired
- Ecoplanning – Provided support to Biosis in collecting field data to meet the requirements of the BAM and ToR

1.7.1 ACCREDITED ASSESSOR

A BCAR can only be prepared by a person accredited under the accreditation scheme developed under Section 6.10 of the BC Act. Throughout this report, an accredited person is referred to as 'the assessor'.

The BCAR component of this Assessment Report has been prepared by Jane Raithby-Veall from Biosis. Jane is a BAM accredited assessor (BAAS18134) taking the lead assessor role for the project. In preparing the BCAR, Jane has:

- Lead the development of the BCAR to ensure that it meets the requirements of the BAM
- Reviewed and approved all of the data that is part of the BAM process
- Reviewed and approved all components of the BCAR

Given the size and complexity of the project, Jane was supported by a range of people in preparing the BCAR component of this Assessment Report. They include:

- Accredited BAM assessors/ecologists and GIS operators within Biosis
- Accredited BAM assessors/ecologists within Ecoplanning
- Impact assessment specialists within Open Lines and DAJ Environmental
- Technical staff within the Department's Conservation and Sustainability Branch

1.8 IMPLICATIONS OF 2019/2020 BUSHFIRES

NSW experienced extensive bushfires throughout the spring and summer of 2019-20. As of 3rd February 2020, the fires had burnt 5.37 million hectares of land (approximately 7 per cent of NSW). This includes (DPIE, 2020):

- 37 per cent of the national park estate, including 81 per cent of the Greater Blue Mountains World Heritage Area
- 42 per cent of state forests
- 52% of heathland, 50% of wet sclerophyll and 37% of rainforest vegetation formations in NSW
- 25% of the most suitable koala habitat in eastern NSW (moderate, high and very high suitable habitat), particularly areas on the north coast, central and southern tablelands, central coast and the south coast

The full impact of the fires will not be understood for some time (EES, 2020).

Given the significance of these events, an initial assessment of the implications of the bushfires for the Cumberland Plain Conservation Plan and this Assessment Report was undertaken and is provided at Supporting Document G.

2 Regulatory context

This Chapter provides an overview of the key steps in the legislative processes for:

- Strategic biodiversity certification under Part 8 of the BC Act
- Strategic assessment under Part 10 of the EPBC Act

The key steps in the regulatory processes are shown in Figure 2-1.

These two processes are similar but differ in some respects. Both remove the need for site by site biodiversity assessment and approval of individual development actions. A key difference between the two processes is that:

- The EPBC Act process approves specific actions or classes of actions undertaken in accordance with an endorsed policy, plan or program that do not need further approval of biodiversity impacts
- The BC Act process approves a specific area of land that does not need further approval of biodiversity impacts

2.1 BIODIVERSITY CONSERVATION ACT 2016

Under Part 8 of the BC Act, individuals and planning authorities can seek strategic biodiversity certification from the NSW Minister for the Environment over areas of land. The biodiversity certification process requires that biodiversity values are assessed, and areas of high biodiversity value are identified and protected for conservation. Development can proceed in nominated areas with any remaining impacts on biodiversity offset through conservation measures.

Development on land that is biodiversity certified does not need further approval from planning authorities for impacts on biodiversity under the EP&A Act. In particular:

- The environmental assessment requirements for the approval of State Significant Infrastructure under Part 5.1 of the EP&A Act do not require an assessment of the impact on biodiversity
- An assessment of the likely impact on biodiversity of development is not required under Part 4 of the EP&A Act
- A consent authority is not required to take into consideration the likely impact on biodiversity when determining a development application under Part 4 of the EP&A Act
- An activity under Part 5 of the EP&A Act is taken to be an activity that is not likely to significantly affect any threatened species or ecological community under the BC Act, or its habitat
- A determining authority under Part 5 of the EP&A Act is not required to consider impacts on biodiversity

Impacts to biodiversity values on the land proposed for biodiversity certification, as well as the biodiversity benefits of the conservation program, are assessed through a BCAR. The BCAR is prepared by an accredited person in accordance with the BAM. The BCAR must be released for public comment prior to the Minister conferring biodiversity certification.

The Environment Minister may confer biodiversity certification if satisfied that the 'approved draft conservation measures' under the biodiversity certification adequately address the likely impacts on biodiversity values of the biodiversity certification, having regard to the BCAR. If the Minister is of the opinion that the biodiversity certification is likely to have serious and irreversible impacts on biodiversity values, the Minister must take those impacts into consideration and determine whether there are any additional measures that can minimise those impacts.

In determining the approved draft conservation measures under the biodiversity certification (including the number of credits that may be required to be retired), the Minister must have regard to the BCAR, but is not bound by the BCAR.

Planning authorities can apply to the Environment Minister to declare an application for biodiversity certification to be a 'strategic application'. Strategic biodiversity certification supports significant regional development and planning processes and provides an opportunity for impacts on biodiversity to be addressed at the landscape scale.

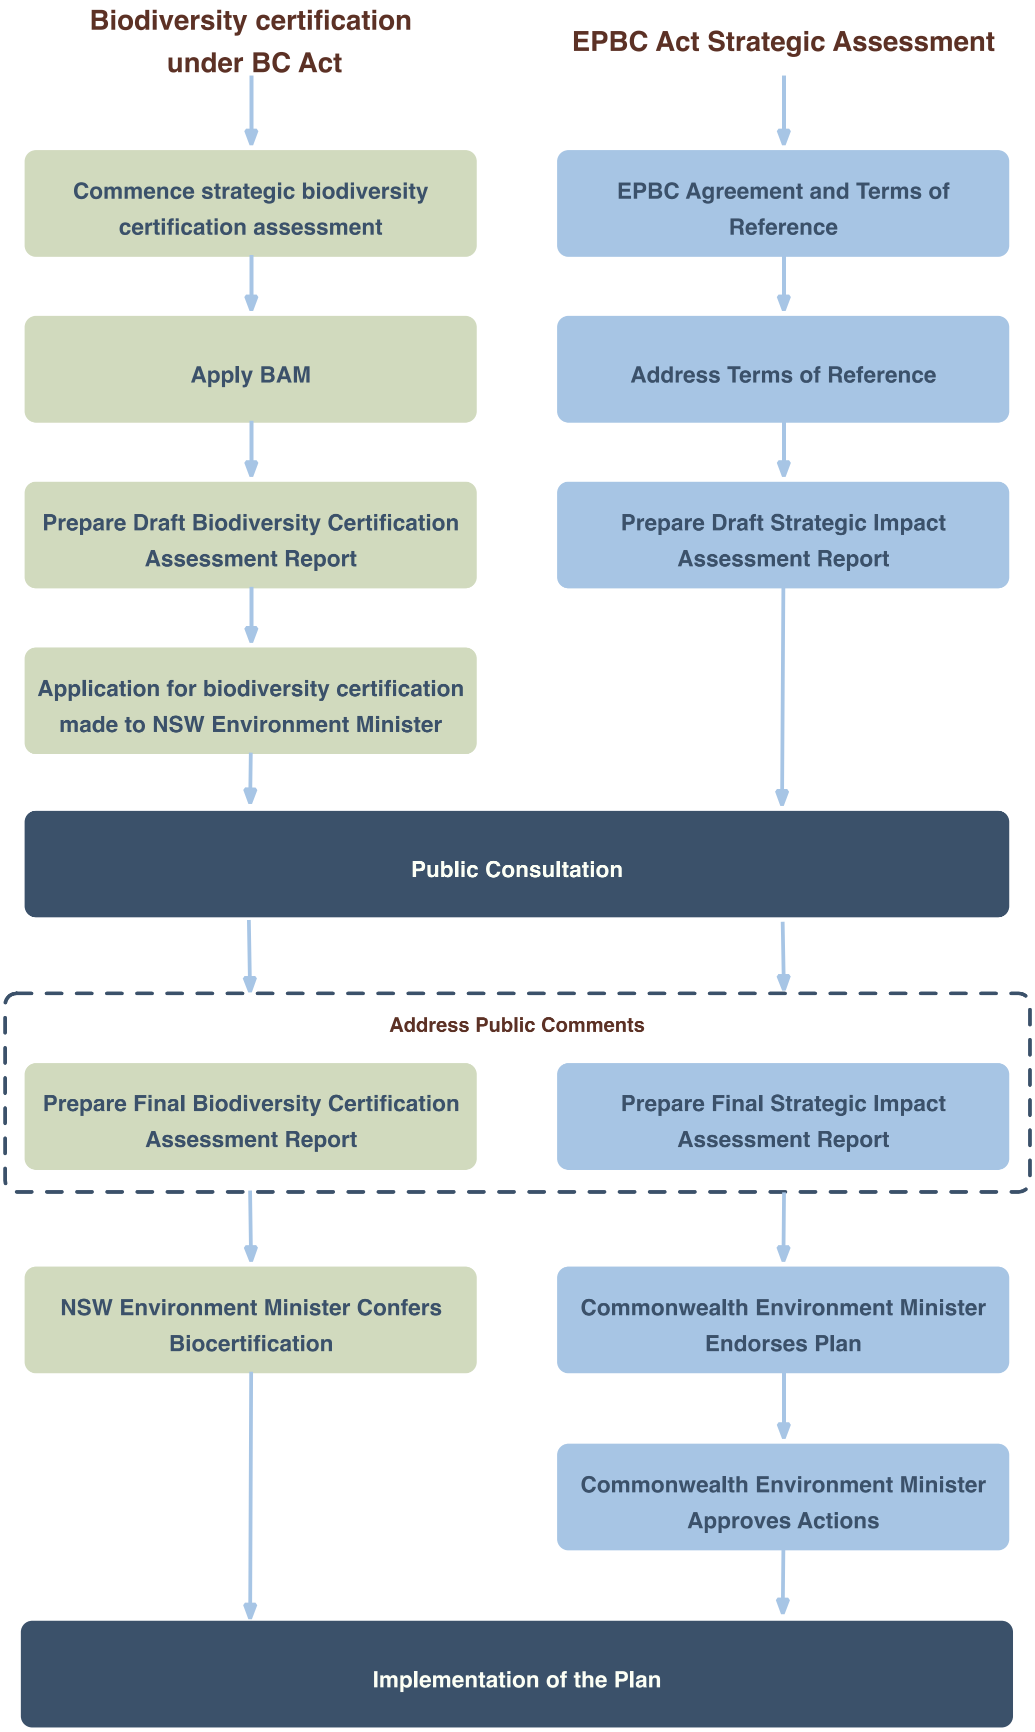

Figure 2-1: Key steps in the regulatory processes

In recognition of this, a wider range of conservation and other measures are available to proponents for strategic biodiversity certification to offset impacts on biodiversity values than for standard certification. A strategic biodiversity certification may propose a mix of conservation measures that includes credits to be retired, as well as:

- Reservation of land under the *National Parks and Wildlife Act 1974* (NPW Act)
- Adoption of development controls (or State infrastructure contributions) under the EP&A Act that conserve or enhance the natural environment
- Any other measures declared by the regulations to be approved conservation measures
- Any other measure that the Minister determines to be a conservation measure

The Minister is to take into account criteria in Clause 8.3 of the BC Regulation when declaring that an application for strategic biodiversity certification is a strategic application. The criteria are:

1. The size of the area of the land
2. Any regional or district strategic plan under the EP&A Act that applies to the area in which the land is situated
3. Advice provided by the Minister for Planning regarding the proposed biodiversity certification
4. The economic, social or environmental outcomes that the proposed strategic biodiversity certification could facilitate

The Environment Minister declared on 16 January 2019 that the project is a strategic biodiversity certification.

Under Section 8.22 of the BC Act, modifications may be made to a biodiversity certification once it has been conferred. Modifications can be made to the period of certification, the description of land that is biodiversity certified by extending or limiting biodiversity certification, as well as to conservation or other measures. Unless a BCAR is not required, an application for modification of a biodiversity certification is to be accompanied by a revised BCAR.

2.2 ENVIRONMENT PROTECTION AND BIODIVERSITY CONSERVATION ACT 1999

The EPBC Act is Australia's key piece of legislation to protect and manage Australia's nationally and internationally important flora, fauna, ecological communities and heritage places. The objectives of the EPBC Act include:

- Providing for the protection of the environment (especially matters of national environmental significance)
- Conserving Australian biodiversity
- Providing a streamlined national environmental assessment and approvals process
- Promoting Ecological Sustainable Development (ESD) through the conservation and ecologically sustainable use of natural resources.

Under Part 10 of the EPBC Act, the Commonwealth Minister for the Environment can agree to undertake a strategic assessment of the impacts of a policy, plan or program on matters protected under the EPBC Act.

The Agreement to undertake the strategic assessment was signed by the NSW Minister for Environment and Commonwealth Minister for the Environment on 12 November 2018 (see Supporting Document A)

The agreement must provide for a ToR to guide the preparation of an Assessment Report on the impacts of the policy, plan or program. The Assessment Report must be released for public comment. The ToR outlines what the Assessment Report must contain to allow the Commonwealth Minister to endorse the Plan.

Actions undertaken in accordance with a policy, plan or program endorsed by the Environment Minister do not require further assessment and approval for impacts on protected matters under the EPBC Act.

The Environment Minister may endorse a policy, plan or program if satisfied that the Cumberland Plain Assessment Report adequately addresses the impacts on protected matters to which the agreement relates (s 146(2)(f)) and that any recommended modifications to the policy, plan or program by the Minister have been made (s 146 (2f(ii))).

The agreement between the Commonwealth Environment Minister and the State of NSW provides that, in determining whether or not to endorse the Plan, the Minister may consider the extent to which the commitments for the protection and management of protected matters are enforceable and achievable over the life of the Plan.

The draft agreement also provides that, in determining whether this Assessment Report adequately addresses the impacts, the Commonwealth Environment Minister must have regard to the extent to which the Plan meets the objectives of the EPBC Act, including how the Plan:

- Protects the environment, especially protected matters under Part 3 of the EPBC Act
- Promotes ESD through the conservation and ecologically sustainable use of natural resources
- Promotes the conservation of biodiversity
- Provides for the protection and conservation of heritage
- Promotes a cooperative approach to the protection and management of the environment
- Assists in the co-operative implementation of Australia's international environmental responsibilities

Following endorsement, the Environment Minister may approve the taking of actions in accordance with the endorsed policy, plan or program subject to a range of general considerations (s 146F) and constraints on decision making (s 146G-M), including to not act inconsistently with a recovery plan or threat abatement plan for a protected matter (s 146K).

2.3 OTHER APPROVALS REQUIRED FOR THE PROPOSED DEVELOPMENT

A range of other planning and environmental approvals may be required for the proposed development, including:

- Planning approvals under the EP&A Act
- Aboriginal cultural heritage approvals under the *National Parks and Wildlife Act 1974*
- Built heritage approvals under the *Heritage Act 1977*
- Noise, water, air pollution approvals under the *Protection of the Environment Operations Act 1997*
- Water management approvals under the *Water Management Act 2000*

The proposed development will be implemented through a range of existing legislative and planning frameworks, particularly the EP&A Act. Implementation arrangements are described in Part 2.

3 Overview of environment within the Plan Area

This Chapter provides a brief overview of the environment within the Plan Area, including historical land-uses. A more detailed description of the environment within the Plan Area in accordance with Section 3.1 of the ToR, including the extent and quality of native vegetation and threatening processes, is provided in Chapter 28.

3.1 HISTORICAL LAND-USES

The Cumberland subregion has been greatly affected by historical and ongoing land-uses and land management practices. This is mainly due to topographic and geological characteristics that meant the subregion could support much greater agricultural and urban development than the surrounding sandstone areas.

Before European settlement, the subregion supported diverse native vegetation, including extensive grassy open forests, ironbark and turpentine forests, dry rainforests and floodplain forest, and wetland communities. Mammals such as echidnas, quolls, phascogales, bandicoots, koalas, gliders, and bettongs would have been common, along with many woodland birds such as the Hooded Robin, Brown Treecreeper, Speckled Warbler and Diamond Firetail (DECCW, 2011).

Hundreds of records of Aboriginal sites have been found across the Cumberland subregion, suggesting the subregion was an important area for Aboriginal people materially, socially and spiritually (DECCW, 2011). Records suggest Aboriginal occupation of the Sydney region occurred for at least 20,000 years, and possibly 40,000 years (Nanson, Young et al., 1987; Stockton, 2009; Stockton & Holland, 1974). There is evidence of extensive use of fire by Aboriginal people to manage the landscape, including to establish mosaics of native vegetation to facilitate hunting (Gammage, 2011).

European agricultural land practices were established by settlers in 1792, and by the middle of the 19th century most of the Cumberland subregion was either being grazed or cultivated (Tozer, 2003). Significant clearing for urban development, including residential, commercial and industrial land-uses, followed.

3.2 BIODIVERSITY VALUES

The biodiversity values of many parts of the Plan Area, particularly within the Cumberland subregion, have been lost or degraded as a result of both historical and ongoing patterns of land-use and land management practices.

The existing native vegetation communities in the Plan Area are shown in Figure 3-1. Existing native vegetation comprises 39 Plant Community Types (PCTs). Remaining areas are often of high conservation value. Much remaining native vegetation comprises TECs or habitat for species listed under the BC Act and EPBC Act.

Remaining native vegetation is also highly fragmented. In 2010, an estimated 2,446 individual remnants remained in the Cumberland subregion, ranging from less than one hectare to 3,598 hectares (DECCW, 2011). The eighty one largest patches (greater than 50 hectares) represent 51 per cent of the remaining native vegetation community extent (DECCW, 2011). While some flora and fauna species will persist in small native vegetation patches with active management, evidence is that larger patches have a better prospect for long-term survival (DECCW, 2011).

Evidence indicates that biodiversity loss significantly increases once habitat fragmentation by clearing exceeds 70 per cent of the landscape. This threshold has already been passed in the Cumberland subregion (DECCW, 2011). Only approximately 13 per cent of the pre-1970 extent of native vegetation in the subregion remains intact, with an additional 12 per cent occurring as heavily degraded communities (e.g. scattered trees) in disturbed areas (DECCW, 2011).

The vast majority (greater than 75 per cent) of the remaining native vegetation within the Cumberland Plain is privately owned. At 2011, approximately 8 per cent of native vegetation was protected in existing formal reserves (DECCW, 2011).

3.3 KEY THREATS

A principal threat to the biodiversity values of the Cumberland subregion is the further loss and fragmentation of habitat from clearing for urban development and agricultural land uses (DECCW, 2011), including illegal clearing.

Historial clearing has led to increasingly isolated and small remnants of native vegetation that are more susceptible to degradation, and provide less habitat values and support fewer species (DECCW, 2011).

The *Cumberland Plain Recovery Plan* (DECCW, 2011) identifies several other key threats, including:

- Weed invasion particularly by African olive, African lovegrass, and bridal creeper
- Altered fire regimes, particularly too frequent fire caused by arson
- Runoff of high-nutrient and turbid water from urban and agricultural areas

The ecological communities of the Cumberland Plain are particularly vulnerable to weed invasion due to their grassy understorey, relatively fertile soils and past agricultural uses. Weeds such as African olive (*Olea europaea* subsp. *cuspidata*), African lovegrass (*Eragrostis curvula*) and bridal creeper (*Asparagus asparagoides*) are well established, which displaces native plants and affects the regeneration of communities (DECCW, 2011).

Stormwater carrying high nutrient and sediment loads from impermeable surfaces such as roads may runoff into areas of native vegetation, which can encourage weed invasion in addition to the soil erosion issues.

Other threats identified in the Recovery Plan (DECCW, 2011) include:

- Impacts from recreational use of areas of native vegetation
- Grazing and mowing
- Altered hydrology
- Sedimentation and erosion
- Salinity
- Impacts of climate change

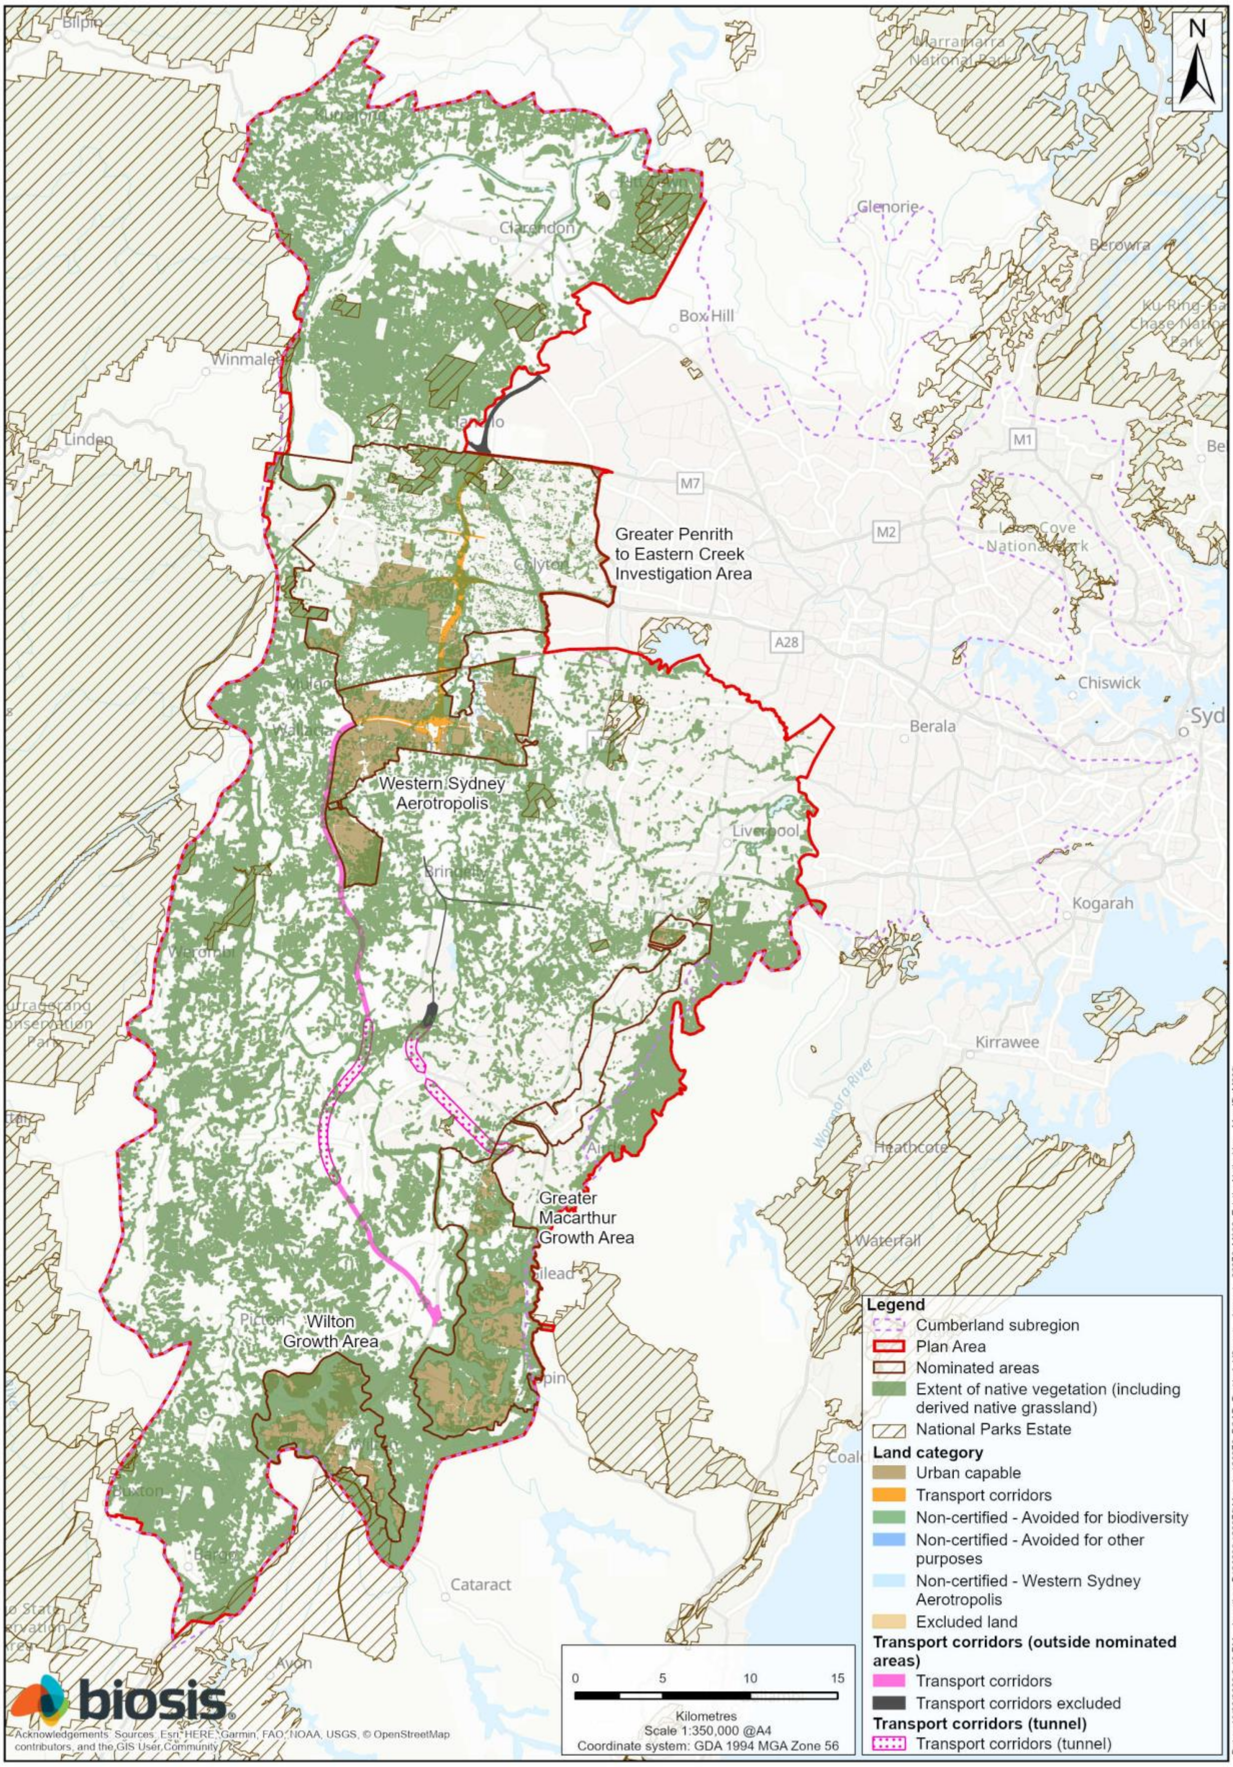

Figure 3-1: Existing native vegetation communities in the Plan Area

4 How to read this Assessment Report

4.1 COMPONENTS OF THE REPORT

This Assessment Report comprises both a BCAR prepared in accordance with the BAM under the BC Act and a SAR prepared in accordance with the ToR under the Part 10 Strategic Assessment Agreement of the EPBC Act.

The BCAR is mostly covered in Part 5, and the SAR part is mostly covered in Part 6. Where the requirements for preparing a BCAR and SAR are the same or similar, these requirements have been addressed jointly in a single part of this Assessment Report to avoid repetition and confusion.

Table 4-1 shows each main component of this Assessment Report and whether it forms part of the BCAR or SAR or both.

Table 4-1: Parts of this Assessment Report that comprise the BCAR or SAR or both

Report part	Description	BCAR	SAR
Part 1: **Overview**	Provides a general introduction to the project, this Assessment Report and the regulatory context. Includes details of the accredited assessor (as per BC Regulation clause 6.9 (f))	✓	✓
Part 2: **Description of the Cumberland Plain Conservation Plan**	Describes the Plan, including its development and conservation elements, and how it will be implemented	✓	✓
Part 3: **Assessment approach**	Provides details of the assessment approach, including methods for identifying relevant biodiversity values that need assessing in this Assessment Report and the methods for mapping native vegetation, TECs and species habitat	✓	✓
Part 4: **Minimising impacts**	Provides details of the processes and actions taken to avoid and minimise impacts, an assessment of indirect impacts, and how the Plan will approach adaptive management	✓	✓
Part 5A: **BCAR Stage 1 (biodiversity assessment)**	Covers the requirements of Stage 1 of the BAM (existing biodiversity values) not already covered in Parts 1, 3, and 4	✓	-
Part 5B: **BCAR Stage 2 (impact assessment)**	Covers the requirements of Stage 2 of the BAM (assessment of impacts) not already covered in Parts 1, 3, and 4	✓	-
Part 6A: **Strategic Assessment Report** **Part 6B:** **Strategic Assessment Report**	Covers the requirements of the ToR relating to identifying existing biodiversity values and assessing the impacts of the Plan on protected matters not already covered in Parts 3 and 4	-	✓
Part 7: **Evaluation of the Plan**	Evaluates the adequacy of the conservation commitments and actions (as per BC Act section 8.7 and EES draft *Guidelines for planning authorities for proposing conservation measures in strategic applications for biodiversity certification* (EES, 2019) and sections 4.6, 4.7, 5 and 6 of the ToR	✓	✓

4.2 HOW THIS REPORT ADDRESSES REGULATORY REQUIREMENTS

4.2.1 REQUIREMENTS FOR PREPARING A BCAR

The key requirements for preparing a BCAR under the BC Act are set out under:

- Part 8 of the BC Act
- Section 6.9 of the BC Regulation
- Appendix 10 of the BAM

Table 4-2 provides the key requirements for preparing a BCAR and identifies where each of these requirements are addressed in this Assessment Report, and specifically the BCAR component of this Assessment Report.

Table 4-2: Where requirements for preparing a BCAR are addressed in this Assessment Report

Minimum information requirements for a BCAR (taken from Appendix 10 of the BAM)	Maps and data requirements	Chapter of Assessment Report
Stage 1 biodiversity assessment		
Introduction		
Introduction to the biodiversity assessment: • Identification of urban capable lands • General description of development • Sources of information used in the assessment	• Site map • Location map	Chapter 7 Chapter 13 Chapter 18
Landscape context		
Identification of landscape features at the development site: • Bioregions and subregions, NSW landscape region and area • Native vegetation extent in the buffer area • Cleared areas • Rivers and streams classified according to Strahler stream order • Wetlands within, adjacent to and downstream of the site • Connectivity features • Areas of geological significance and soil hazard features • Site context components	• Site and Location maps showing landscape features	Chapter 18
Native vegetation		
Identify native vegetation extent within the development site, including cleared areas and evidence to support differences between mapped vegetation extent and aerial imagery	• Native vegetation extent, including cleared areas	Chapter 19
Describe PCTs within the development site: • Vegetation class and type • Area (ha) for each vegetation type • Species relied upon for identification of vegetation type and relative abundance • Justification of evidence used to identify a PCT • TEC status • Per cent cleared value of PCT	• Native vegetation extent map • PCTs map • Plot locations relative to PCTs map • TECs map • Plot field data • Plot field data sheets	Chapter 19 Chapter 20

Minimum information requirements for a BCAR (taken from Appendix 10 of the BAM)	Maps and data requirements	Chapter of Assessment Report
Vegetation integrity assessment of the development site: • Mapping vegetation zones • Patch size • Assessing vegetation integrity using benchmark data • Survey effort (number of plots) • Determining the vegetation integrity score	• Table of current vegetation integrity scores for each vegetation zone in development site • Patch size of intact native vegetation	Chapter 11 Chapter 19
Where use of local data is proposed: • Identify relevant vegetation type • Identify source of information for local benchmark data • Justify use of local data in preference to database values		N/A
Threatened species and habitat		
Identify ecosystem credit species associated with PCTs on development site, including: • List of species • Justification for exclusion of any ecosystem credit species	• Table of habitats/habitat components and sensitivity classes • Table of biodiversity risk weighting for species on site	Chapter 11 Chapter 21
Identify species credit species on development site, including: • List of candidate species • Justification for inclusions and exclusions of species credit species based on habitat features • Indication of presence based on targeted survey or expert report • Details of targeted survey technique, effort, timing and weather • Species polygons • Biodiversity risk weighting for the species • Threatened species survey	• Table of list of species credit species and presence status on site as determined by targeted survey, expert report or assumed presence • Species credit species polygons map • Table of species and habitat feature/ components and abundance on site • Table of biodiversity risk weighting for species on site	Chapter 11, including Attachment A Chapter 21
Where use of local data is proposed: • Identify relevant species • Identify aspect of species data • Identify source of information for local data • Justify use of local data in preference to database values		N/A

Minimum information requirements for a BCAR (taken from Appendix 10 of the BAM)	Maps and data requirements	Chapter of Assessment Report
Where expert reports are used in place of targeted survey: • Identify the relevant species • Justify the use of an expert report • Indicate and justify the likelihood of presence of the species and information considered in making this assessment • Estimate the number of individuals or area of habitat for the development site, and how the estimate was made • Identify the expert and their expert credentials	• Expert reports	Chapter 11 Chapter 21 Supporting Document C
Stage 2 Impact Assessment – Biodiversity values		
Avoid and minimise impacts		
Demonstration of efforts to avoid and minimise impact on biodiversity values in accordance with Chapter 8	• Table of measures to be implemented to avoid and minimise the impacts, including action, outcome, timing and responsibility • Urban capable land and transport corridor map	Chapter 14
Assessment of direct and indirect impacts unable to be avoided at the development site, including type, frequency, intensity, duration and consequence of impact	• Maps demonstrating indirect impact zones where applicable	Chapter 15 Chapter 23
Details of the adaptive management strategy proposed to monitor and respond to impacts on biodiversity values that are uncertain	N/A	Chapter 16
Impact summary		
Identification and an assessment of the impacts which are potential serious and irreversible impacts	• Map showing location of serious and irreversible impacts • Table of SAII considerations	Chapter 25
Identification of impacts requiring offset	• Map of impacts requiring offset	Chapter 26
Identification of impacts not requiring offset	• Map of impacts not requiring offset	Chapter 26
Identification of areas not requiring assessment	• Map of areas not requiring assessment	Chapter 26

Minimum information requirements for a BCAR (taken from Appendix 10 of the BAM)	Maps and data requirements	Chapter of Assessment Report
Ecosystem credits and species credits that measure the impact of the development on biodiversity values, including: • Future vegetation integrity score for each vegetation zone at the development site • Change in vegetation integrity score • Number of required ecosystem credits for the impact of development on each vegetation zone at a development site • Number of required species credits for each threatened species that is impacted on by development	• Table of PCTs requiring offset and the number of ecosystem credits required • Table of threatened species requiring offset and the number of species credits required • Submitted proposal in the Credit Calculator	Chapter 26
Biodiversity credit report		
Credit classes for ecosystem credits and species credits at the development site	• Table of credit class matching credit profile	Supporting Document E

4.2.2 REQUIREMENTS FOR PREPARING A SAR

The requirements for preparing a SAR are set out under the ToR under the Part 10 Strategic Assessment Agreement.

Table 4-3 provides the key requirements for preparing a SAR and identifies where each of these requirements are addressed in this Assessment Report, and specifically the SAR component of this Assessment Report.

Table 4-3: Where requirements for preparing a SAR are addressed in this Assessment Report

Section	ToR requirement	Chapter of Assessment Report
1. Purpose of the Strategic Impact Assessment Report	1.1 The purpose of the Report is to assess the impacts of actions taken under the Cumberland Plain Conservation Plan (Plan) on all matters protected by Part 3 of the EPBC Act ('protected matters')	Chapter 1
2. Description of the Plan being assessed	2.1 The Report must describe the Plan	Part 2
	2.1.1 The Report must provide a summary outlining its overall purpose, key elements, spatial extent, and timeframes, including how long the Plan will be in effect	Chapter 1 Part 2
	2.1.2 The Report must provide details about the key elements, including: a. The conservation commitments and outcomes to be delivered for protected matters b. The actions likely to be taken under the Plan over the short, medium and long term c. The legal and administrative frameworks to implement the Plan and the persons and authorities responsible for implementation	Chapter 7 Chapter 8 Chapter 9
	2.1.3 The Report must describe the need and justification for the Plan including the environmental, social and economic drivers for its development	Chapter 6
	2.1.4 The Report must describe the decision-making framework used in considering alternatives and developing conservation outcomes of the Plan. It should identify where alternative options that have been evaluated to reach	Chapter 6

Section	ToR requirement	Chapter of Assessment Report
	the final Plan have been published	
	2.1.5 The Report must describe how the principles of ESD (as set out in section 3A of the EPBC Act) are considered and promoted in the development of the Plan	Chapter 40
3. Description of the protected matters impacted by the Plan	3.1 The Report must describe the nature of the environment within the Strategic Assessment Area, and other areas outside the Strategic Assessment Area that may be impacted by actions taken under the Plan. This must include (at a minimum):	Chapter 28
	• 3.1.1 A description of historical and current land use.	Chapter 28
	• 3.1.2 The extent and quality of native vegetation present including detailed mapping of ecological communities and habitat for threatened species listed under the EPBC Act	Chapter 28 Chapters 29 to 31
	• 3.1.3 The nature of the environment, including ecosystem processes and threatening processes	Chapter 28
	• 3.1.4 A description of the landscape context for key environmental matters, including connectivity, habitat fragmentation and ecological processes	Chapter 28 Chapters 29 to 31
	• 3.1.5 A spatial map of areas that are already protected for environmental purposes, including Biobanking and Biodiversity Stewardship sites	Chapter 28
	3.2 The Report must identify and describe each protected matter that may be impacted directly, indirectly and cumulatively by actions taken under the Plan, including (at a minimum):	Chapters 29 to 35
	• 3.2.1 Key sites, and where relevant, key habitats for protected matters	
	• 3.2.2 Important populations of protected matters, including the consideration of the importance of both small and large areas of habitat, and their position within the landscape	
	• 3.2.3 Areas likely to be important for maintaining ecological processes (for example, habitat connectivity) for protected matters	
	• 3.2.4 Condition of protected matters, including where relevant, seasonal and annual variability, and their likelihood to alter over time	
	• 3.2.5 Key threatening processes	
4. Assessment of the impact of the Plan on protected matters	4.1 The Report must describe and assess the likely impacts of actions taken under the Plan on all protected matters	Chapters 29 to 35
	4.2 The Report must describe the method used to understand likely impacts on all protected matters of actions taken under the Plan. The level of the assessment will be proportionate to the level of likely risk to each protected matter. The method must:	Chapter 11
	• 4.2.1 Be appropriate for assessment at a strategic scale	
	• 4.2.2 Rely on the best available information	
	• 4.2.3 Discuss uncertainty, including reference to the technical data and information relied upon	Chapter 11 Chapter 13
	4.2 The Report must identify the data used in the assessment, any limitations it may have, where (or if) the data is available and where it can be accessed, including publicly accessed	Chapter 11 Chapter 13

Section	ToR requirement	Chapter of Assessment Report
	4.3 Describe and assess separately the likely impacts (if any) of actions taken under the Plan on the environment on Commonwealth land (as defined in section 528 of the EPBC Act)	Chapter 35
	4.4 The Report may also consider protected matters that are potentially eligible for listing as a result of inclusion in a final priority assessment listing held by the Commonwealth, or a recommendation to the Commonwealth Minister for listing by the Threatened Species Scientific Committee prior to the Report being submitted	Chapters 29 to 31
	4.5 The Report must include an analysis of the likely adverse impacts of actions of the Plan on protected matters. This must include (at a minimum) consideration of:	
	• 4.5.1 Information on the following: o Number and size of populations/important populations. o Extent (in hectares) of suitable habitat. o Extent (in hectares) and condition of protected matters. o Landscape connectivity and ecological processes. o Heritage listing and values	Chapters 29 to 35
	• 4.5.2 How impacts on protected matters will be avoided through land use planning and other measures, and what mitigation measures will be implemented to reduce impacts, including a description of the mitigation measures and how unavoidable impacts will be offset	Chapter 14 Chapters 29 to 35
	• 4.5.3 Potential indirect and cumulative impacts	Chapter 15 Chapters 29 to 35 Chapter 38
	4.6 The Report must include an analysis of the conservation benefits (beneficial impacts) of the Plan, including:	Chapter 8 Chapter 41
	• 4.6.1 How protected matters will be conserved, protected and managed within the Strategic Assessment Area and other areas related to the Plan	
	• 4.6.2 The adequacy of the commitments and actions under the Plan in protecting and managing protected matters, including the effectiveness of implementation and funding arrangements and who will be responsible for delivering on commitments	Chapters 29 to 35 Chapter 41
	• 4.6.3 How proposed commitments and actions involving environmental offsets meet the principles of the *Environment Protection and Biodiversity Conservation Act, Environmental Offsets Policy*, 2012 (DSEWPC, 2012)	Chapter 41
	• 4.6.4 How landscape connectivity has been maintained and improved, which may include opportunities for strategic ecological restoration of key corridors and areas adjacent to sites with high biodiversity values	Chapters 29 to 35 Chapter 41
	• 4.6.5 How adaptation to reasonable climate change scenarios has been considered	Chapter 41
	4.7 The Report must consider the extent to which the impacts on protected matters of actions taken under the Plan meet legislative obligations under the EPBC Act, including but not limited to:	
	• 4.7.1 Consistency with Australia's international obligations, including the Ramsar Convention	Chapter 33

Section	ToR requirement	Chapter of Assessment Report
	• 4.7.2 Consistency with recovery plans (section 146K of the EPBC Act)	Chapters 29 to 31
	• 4.7.3 Regard to objectives, conservation actions and other relevant information in conservation advices (section 146K of the EPBC Act)	Chapters 29 to 31
	• 4.7.4 Consistency with World Heritage management plans (sections 316 and 321 of the EPBC Act) and National Heritage place management plans (sections 324S and 324X of the EPBC Act)	Chapter 34
	4.7 The Report may also consider other Commonwealth policy guidelines on protected matters	Chapters 29 to 35
	4.8 The Report must include justification for key methods used in the assessment, including summaries of independent peer review processes and where the review/s are available to the public	Chapter 11
5. Evaluation of the overall outcomes of the Plan	5.1 The Report must evaluate the overall commitments and outcomes for protected matters taking into account likely impacts on protected matters from actions taken under the Plan	Chapters 29 to 35 Chapter 41
	5.2 The evaluation must include:	
	• 5.2.1 The extent to which protected matters are represented in areas to be protected or managed under the Plan or in existing protected areas in the bioregion/subregion	
	• 5.2.2 The extent to which the areas to be protected or managed under the Plan or existing protected areas in the bioregion/subregion will ensure the long-term viability of each protected matter	
	• 5.2.3 Whether there will be serious and irreversible impacts on any protected matter	
	• 5.2.4 An assessment of how the Plan meets the endorsement criteria set out in the Agreement at clause 8	
	5.3 The evaluation may also include consideration of:	
	• 5.3.1 The extent to which the commitments and actions under the Plan facilitate adaptation of biodiversity to climate change and address any significant vulnerabilities of protected matters under reasonable climate change scenarios	
	• 5.3.2 The likely effectiveness of the commitments and actions under the Plan in protecting and managing protected matters and risks and uncertainties	
6. Addressing uncertainty and adaptive management	6.1 The Report must identify key uncertainties and risks associated with implementing the Plan, responses to these and proposed adaptations to changing circumstances. Key uncertainties may include:	Chapter 16 Chapter 41
	• 6.1.1 Knowledge gaps in scientific understanding and responding to new knowledge	
	• 6.1.2 Assumptions made in assessing potential impacts and benefits	
	• 6.1.3 How changes to State and Commonwealth legislation, policies, plans and advice is to be accounted for in the management of the areas impacted by the Plan	
	• 6.1.4 Effectiveness or capacity to ensure the Plan is implemented	

<table>

Part 2 List of Tables

5 Introduction

The NSW Department of Planning, Industry and Environment (the Department) has prepared the Cumberland Plain Conservation Plan (Plan) to establish long-term certainty for biodiversity conservation and development in Western Sydney. This Part describes the Plan, including:

- Planning context and need for the Plan (see Chapter 6)
- Development under the Plan (see Chapter 7)
- Conservation program of the Plan (see Chapter 8)
- Implementation framework for the Plan (see Chapter 9)

A summary of the Plan, including its purpose, key elements, and vision and objectives, is provided in Part 1.

This Chapter provides an introduction to the Plan, including:

- Purpose of the Plan
- Vision and objectives of the Plan
- Key elements of the Plan
- Structure of the Plan
- How the Plan was developed

5.1 PURPOSE OF THE PLAN

The purpose of the Plan is to establish long-term certainty for biodiversity conservation and development in Western Sydney. The Plan supports the delivery of infrastructure, housing and jobs for Western Sydney in a planned and strategic way that also protects and maintains Western Sydney's key native flora and fauna.

The Plan includes a conservation program of commitments and actions that seeks to improve ecological function and resilience in the Cumberland Plain and provide an enduring conservation legacy for Western Sydney.

5.2 VISION AND OBJECTIVES OF THE PLAN

The Plan provides a high-level vision and objective and defines a set of outcomes and commitments that aim to achieve the Plan's objective and meet regulatory requirements under the NSW *Biodiversity Conservation Act 2016* (BC Act) and Commonwealth *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act).

The NSW Government's vision for the Plan is to "support Western Sydney's biodiversity and growth".

The objective of the Plan is to:

> *"Deliver biodiversity outcomes and support the ecological function of the Cumberland Plain, improving liveability and facilitating urban development in Western Sydney"*

5.3 KEY ELEMENTS OF THE PLAN

The Plan includes three key elements:

- Development – this covers the urban and industrial, infrastructure, agribusiness, and transport development under the Plan, including the scope and location of the development
- Conservation – this covers the conservation program and set of commitments to achieve the Plan's objective and offset the impacts of the development on biodiversity values
- Implementation framework – this covers how the Plan will be implemented

The key elements of the Plan are described in detail in Chapters 7, 8 and 9 respectively.

5.4 STRUCTURE OF THE PLAN

The Plan comprises an overall Plan and two Sub-Plans.

The overall Plan describes how the development will occur and how impacts to biodiversity values and other protected matters will be addressed through the Plan's conservation program and implementation framework, including a set of commitments to address the impacts.

The Sub-Plans contain more details on how the overall Plan will be implemented, including sets of actions for each commitment that set out how the commitment will be delivered. The Sub-Plans are:

- Sub-plan A – details the conservation program and its implementation, including the evaluation program
- Sub-plan B – details how Koalas will be protected under the Plan

5.5 HOW THE PLAN WAS DEVELOPED

5.5.1 PROGRAM LOGIC UNDERPINNING THE PLAN

The Plan was prepared on the basis of a program logic. The program logic describes how the vision, objective, outcomes, commitments and actions of the Plan link together:

- Outcomes – These are the environmental, social and economic outcomes of the Plan
- Commitments – These set out how the outcomes are going to be delivered
- Actions – These describe what will be done to deliver the commitments

The program logic underpinning the Plan is shown in Figure 5-1.

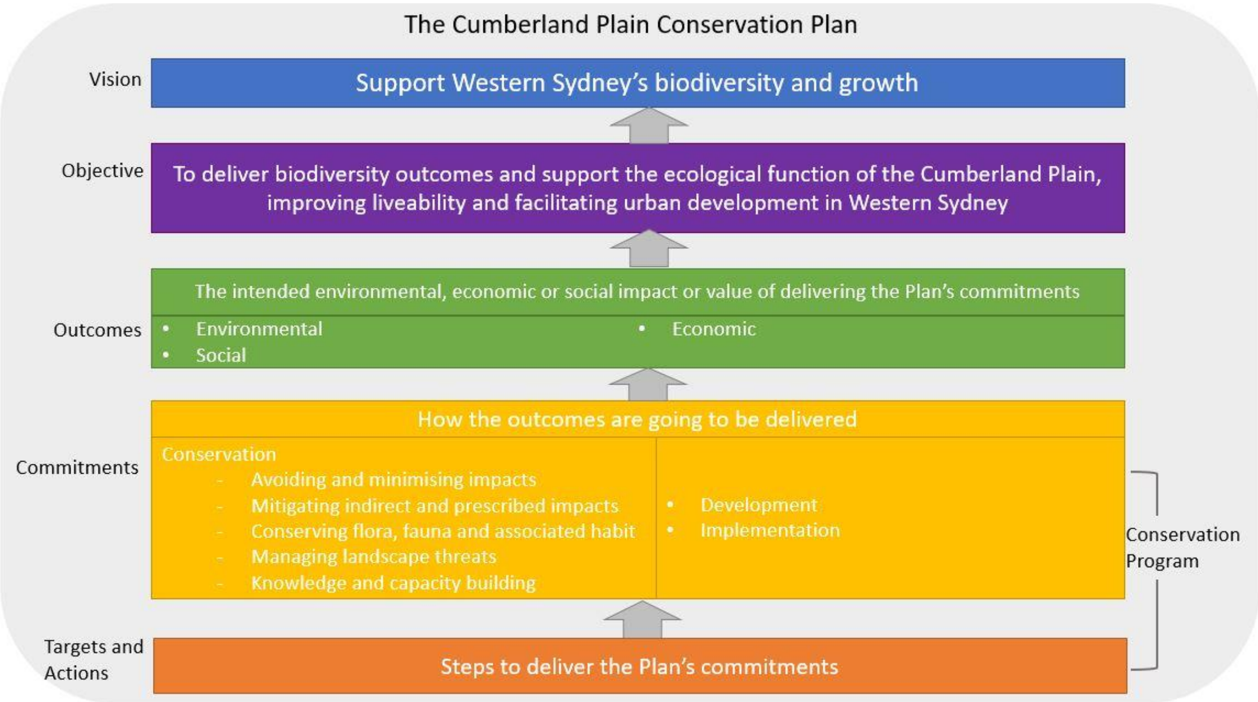

Figure 5-1: Program logic underpinning the Plan

5.5.2 COMMUNITY CONSULTATION ON THE PLAN

The Department has undertaken several community engagement processes to inform the Plan, including:

- Establishment of a People's Panel in 2018 comprising of 18 community members, with at least two representatives from each of the LGAs in the Strategic Assessment Area. The Panel participated in a series of workshops on the Plan

- Establishment of a Community Reference Group comprising non-government organisations, academic and key industry stakeholders in the biodiversity conservation sector. In 2019, the Community Reference Group provided a set of comments and recommendations that were considered in developing the Plan
- Targeted engagement with the Aboriginal community to seek early feedback on the Plan
- Six months of early engagement on the Plan with the Western Sydney community and key stakeholders between July and December 2019. This was done to inform stakeholders and seek preliminary feedback to support development of the Plan before it is released for public exhibition

6 Planning context and need for the Plan

6.1 INTRODUCTION

The Plan has been prepared as part of a broader and complex long-term planning process for Western Sydney that aims to address a range of key planning challenges facing Greater Sydney, such as population growth and housing affordability.

This Chapter sets out:

- Key planning challenges for Western Sydney
- Planning context for Western Sydney
- Need and justification for the Plan
- Alternatives to the Plan

6.2 PLANNING CHALLENGES FOR GREATER SYDNEY

Greater Sydney is subject to several key planning challenges, including relating to:

- Population growth and housing needs, including housing affordability and choice
- Job opportunities
- Access to transport
- Protecting the natural environment and amenity

6.2.1 POPULATION GROWTH AND HOUSING NEEDS

Sydney's continued rapid growth presents a substantial challenge to urban planners. Sydney is predicted to grow by an additional 1.7 million people by 2036 (GSC, 2018a). Residents already face significant barriers to home ownership because of issues around housing affordability. In 2018, Sydney was the third least affordable major housing market for middle incomes globally, with median house prices over 11 times the median household income (Cox & Pavletich, 2019).

To accommodate this growing population, 725,000 new homes will be needed, including approximately 210,000 homes in the Western Parkland City at the centre of the Western Sydney Aerotropolis (WSA).

6.2.2 JOB OPPORTUNITIES

Sydney is predicted to have an additional 817,000 jobs by 2036. Currently there is an imbalance in the distribution of workplaces within the city, with a significant number of jobs being located within the CBD of Eastern Sydney. The concentration of jobs in one location increases the costs associated with obtaining and operating commercial premises and increases barriers to setting up or expanding business operations in Sydney (GSC, 2018a).

6.2.3 ACCESS TO TRANSPORT

The suburban layout of Sydney encourages car use over alternative transport options, such as public transport or cycling. The concentration of jobs in Eastern Sydney also means that many residents in Western Sydney are subject to long commutes. Increased travel times and heavy reliance on cars for commuting decreases the quality of life of residents by decreasing accessibility to employment and services and increasing the costs of commuting. This impacts air quality and decreases opportunities to participate in social and recreational activities (GSC, 2018a).

6.2.4 NATURAL ENVIRONMENT AND AMENITY

The natural environment and built heritage of Western Sydney provides important social, cultural, aesthetic, economic, historic and environmental values within the Sydney region. The environment of Western Sydney is under significant pressure from historical and proposed new land uses (see Part 1) and balancing the protection of the environment and heritage with other urban development objectives is a significant planning challenge.

6.3 PLANNING CONTEXT FOR WESTERN SYDNEY

The NSW Government has prepared several strategies and plans to address the key planning challenges facing Greater Sydney in a coordinated and strategic manner. The key strategies and plans that form part of this planning framework, and their relationship to each other and the Plan, are discussed below.

6.3.1 WESTERN SYDNEY CITY DEAL

The Western Sydney City Deal is the single largest planning, investment and delivery partnership in the history of Australia, and involves the Australian and NSW Governments and eight local Councils in Western Sydney (GSC, 2018b). The Deal supports additional jobs, housing and liveability improvements in Western Sydney.

Under the City Deal, the NSW Government has committed to publish 5-year and 20-year housing targets for each local government area to deliver 185,000 new homes needed in the next 20 years.

The City Deal supports the delivery of the Western City District Plan that covers the nominated areas, and includes a commitment to conduct a strategic assessment under the EPBC Act to protect the environment and streamline environmental approvals for development in Western Sydney (DIRDC & DPC, 2018).

This Plan provides a mechanism to undertake this strategic assessment.

6.3.2 GREATER SYDNEY REGION PLAN

The Greater Sydney Region Plan is a 40-year vision for a global metropolis of three cities incorporating land use planning, transport planning and infrastructure planning. The Region Plan sets out a plan to manage urban growth by establishing a 'metropolis of three cities': Western Parkland City, Central River City, and Eastern Harbour City.

The Region Plan supports the delivery of the Western Parkland City by facilitating the nominated areas and transport corridors. The Region Plan also includes an action (number 72) to deliver strategic conservation planning and develop a conservation plan for Western Sydney. This Plan delivers on that action.

The Region Plan is guided by 10 overarching directions and 40 objectives for liveability and sustainability, productivity and infrastructure in Greater Sydney and includes a target that all homes will be within 30 minutes' access to jobs, schools, and health care (GSC, 2018a). Two core directions address sustainability:

- A cool and green parkland city in the Wianamatta (South Creek) corridor (Objective 26)
- Biodiversity is protected, urban bushland and remnant vegetation is enhanced (Objective 27)

The Region Plan is supported by a series of five 20-year District Plans. These District Plans provide greater detail regarding planning, development and conservation objectives for each district of Sydney.

By supporting the delivery of the Western Parkland City, this Plan will contribute to the wider objective to develop Sydney as a 'polycentric city' and therefore help address many key planning challenges outlined in Section 6.2. Monocentric cities that experience growth can suffer from increasing business costs, increased housing and living costs, increased labour costs and reduced labour supply, and social segregation, congestion, air quality problems, heat island effects and spatial polarisation (GSC, 2018a). Major cities are responding to planning challenges associated with city growth through promoting the development of polycentric city structures (GSC, 2018a).

6.3.3 WESTERN SYDNEY DISTRICT PLAN

The relevant District Plan for the area covered by this Plan is the Western City District Plan. The Western City District Plan aligns with the Greater Sydney Region Plan, and provides more details regarding targeted planning objectives for the District, with associated actions to be undertaken to achieve the outlined objectives.

This Plan supports the implementation of Western City District Plan's planning priorities for:

- Creating a Parkland City urban structure and identity, with Wianamatta (South Creek) as a defining spatial element (Priority W13)
- Protecting and enhancing bushland and biodiversity (Priority W14)
- Protecting and enhancing scenic and cultural landscapes (Priority W16)

6.3.4 FUTURE TRANSPORT STRATEGY 2056

The Future Transport Strategy 2056 is an overarching strategy to achieve a series of objectives for the NSW transport network (Transport for NSW, 2018). The Transport Strategy will be implemented by a suite of plans, including the Greater Sydney Services and Infrastructure Plan (Transport for NSW, 2018).

The Future Transport Strategy 2056 supports the development of Sydney as a polycentric city by developing an integrated network of transport corridors to support connectivity and liveability within Sydney.

The Transport Strategy identifies a range of transport initiatives for investigation, including the Outer Sydney Orbital identified under this Plan (Transport for NSW, 2018).

This Plan supports the delivery of these transport initiatives in Western Sydney.

6.3.5 NSW KOALA STRATEGY

The NSW Koala Strategy aims to stabilise and then increase Koala numbers, ensuring genetically diverse and viable populations of Koalas in NSW in the longer term (OEH, 2018).

The Koala Strategy identifies a series of actions to be implemented from 2018 to 2021. Actions fall under the following categories: Koala habitat conservation, conservation through community action, safety and health of Koala populations and building knowledge and education (OEH, 2018). The NSW Government has committed approximately $45 million to implementing the Koala Strategy (OEH, 2018).

This Plan supports the delivery of the Koala Strategy in Western Sydney.

Koala habitat has been significantly impacted by the 2019/20 bushfires in NSW. This is further discussed in Supporting Document G.

6.4 NEED AND JUSTIFICATION FOR THE PLAN

This Section addresses section 2.1(3) of the ToR, which requires the report to '…describe the need and justification for the Plan including the environmental, social and economic drivers for its development'.

The Plan is needed for the following four key reasons:

- Supports the delivery of the nominated areas program and transport corridors
- Supports the delivery of key planning strategies and plans
- Provides a mechanism to address conservation challenges for the Cumberland subregion
- Supports NSW Government priorities

6.4.1 SUPPORTS THE DELIVERY OF THE NOMINATED AREAS PROGRAM AND TRANSPORT CORRIDORS

This Plan supports the delivery of the NSW Government nominated areas program and the development of major transport infrastructure to meet the long-term transport needs of Western Sydney.

The nominated areas program represents the strategic prioritisation and delivery of new development as part of the long-term growth of Greater Sydney and to meet key social and economic objectives identified under the Greater Sydney Region Plan. The program will consolidate future development needs across Western Sydney by establishing four new nominated areas. The nominated areas are the key focus for urban development over the coming decades and will be the centres of economic and social activity in Western Sydney.

Future Transport 2056 identifies a series of major infrastructure corridors for the coming decades. For Western Sydney, major transport infrastructure is planned to be delivered to respond to the economic and social needs of Western Sydney over the next 40 years. This Plan includes key Western Sydney transport corridors to facilitate infrastructure projects that will generate economic activity and support employment opportunities in the region.

6.4.2 SUPPORTS DELIVERY OF KEY PLANNING STRATEGIES AND PLANS

The Plan supports the delivery of key planning strategies and plans for Western Sydney, as well as the Western City Deal. By supporting the delivery of these, the Plan is directly helping to address key environmental, social and economic planning challenges facing Greater Sydney outlined in Section 6.2.

The key plans and strategies that this Plan is supporting, and how the Plan supports their delivery, are outlined in Section 6.3. In summary, the Plan is needed to support implementation of:

- Western Sydney City Deal – by providing the mechanism to conduct a strategic assessment under the EPBC Act to protect the environment and streamline environmental approvals for development in Western Sydney
- Greater Sydney Region Plan, by supporting the delivery of:
  - Western Parkland City
  - Key objectives of the Region Plan, including:
    1. A cool and green parkland city in the Wianamatta (South Creek) corridor (Objective 26)
    2. Biodiversity is protected, urban bushland and remnant vegetation is enhanced (Objective 27)
- Western City District Plan, by supporting the delivery of planning priorities:
  - Creating a Parkland City urban structure and identity (Priority W13)
  - Protecting and enhancing bushland and biodiversity (Priority W14)
  - Protecting and enhancing scenic and cultural landscapes (Priority W16)
- NSW Koala Strategy in Western Sydney

6.4.3 PROVIDES A MECHANISM TO ADDRESS CONSERVATION CHALLENGES FOR CUMBERLAND SUBREGION

Conservation planning in the Cumberland subregion is challenging and complex. Biodiversity in the subregion has suffered significant disturbance, and the subregion is one of the most threatened regions in NSW (DEC, 2005). Many ecological communities and species are listed as threatened under both NSW and Commonwealth legislation. Areas of remaining native vegetation are often of high conservation value. At the same time, the population of Sydney is growing, housing affordability is a priority and the cost of land across the region is very high.

These issues make it challenging to identify options that satisfy regulatory and community expectations around biodiversity conservation while also addressing the need for cost effective development.

Strategic assessment processes provide significant opportunities to address the key conservation challenges in the Cumberland subregion while facilitating cost effective development.

Strategic assessments can have the following benefits:

- Streamline the assessment and approval process and reduce duplication between regulatory requirements
- Enable effort to be focused on the highest biodiversity value areas of the landscape
- Address ecological function and landscape-scale ecological processes, such as habitat connectivity
- Manage threats at a landscape scale that can maximise benefits to multiple species
- Be designed and implemented strategically, such as by consolidating offsets into large and more viable patches
- Be implemented ahead of impacts occurring from development, to help reverse any trend of decline

6.4.4 SUPPORTS NSW GOVERNMENT PRIORITIES

The Plan supports NSW Government priorities and in particular, the Premier's Priorities. The Premier has prioritised making housing more affordable, delivering infrastructure and creating jobs for the people of NSW.

The Plan supports these priorities by:

- Supporting the delivery of key planning strategies and plans that help address these priorities
- Providing a mechanism to deliver development through a streamlined assessment and approval process and by reducing duplication between NSW and Commonwealth regulatory requirements.

6.5 ALTERNATIVES TO THE PLAN

This section addresses section 2.1(4) of the ToR, which requires the report to '…describe the decision-making framework used in considering alternatives and developing conservation outcomes of the Plan. It should identify where alternative options that have been evaluated to reach the final Plan have been published'.

Alternatives can be discussed in terms of different:

- Approaches to urban development
- Conservation outcomes
- Locations of the urban capable lands and transport corridors

6.5.1 ALTERNATIVE APPROACHES TO URBAN DEVELOPMENT

The nominated areas program involves the identification of large areas for greenfield development in high-level strategic planning documents. The nominated areas represent a planned approach to land release for which the NSW Government takes a lead role in setting objectives, planning, and co-ordinating the delivery of development.

Developing nominated areas provides the most effective approach to address the key planning challenges facing Sydney as it provides for a considered and strategic approach to the location of urban and transport infrastructure. A planned approach to land release through nominated areas also allows for:

- Co-ordinated precinct structure planning and better integration of land use and transport to maximise social and economic benefits, including employment areas, schools, hospitals, transport precincts, and open space
- More effective investment by infrastructure agencies when planning for services
- Better co-ordination and alignment between the objectives of different government agencies
- Better direction for the development industry about where future development will occur and greater certainty for landowners about the future use of their land
- A co-ordinated approach to development contributions to help fund the delivery of key infrastructure
- A more efficient use of government resources in responding to development proposals

The alternative to developing nominated areas is a larger number of smaller urban precincts that are separately identified and planned by different planning authorities across a broader region. This approach does not provide the benefits that come with the co-ordinated planning and consolidated development within nominated areas.

6.5.2 ALTERNATIVE CONSERVATION OUTCOMES

The Department applied a structured decision-making process during early development of the Plan to define a high-level biodiversity outcome for the Cumberland subregion that set the context and direction for the development of the Plan. The structured decision-making was one of the first steps in a comprehensive conservation planning process for the Plan. Other planning processes included a process to avoid impacts to biodiversity values (see Chapter 14) and a method to identify high value conservation lands within the Cumberland subregion for offsets that best support an ecologically-functioning, connected landscape (called the Conservation Priorities Method – see Sub-Plan A).

The structured decision-making process provides a systematic method to identify and compare a range of conservation options available to the NSW Government, taking into account social, economic and environmental considerations.

The structured decision-making process involves five steps:

1. Understanding the decision/s that need to be made
2. Identifying what is important when making those decision/s
3. Developing a range of alternatives to compare
4. Understanding the performance of different alternatives
5. Comparing options and selecting a preferred alternative

The key decision relevant to the structured decision-making work was:

> *"What is the optimal biodiversity outcome for Western Sydney that will enable planned and existing development (including both in and beyond the nominated areas in the Cumberland Plain) to proceed in an affordable and sustainable way?"*

The structured decision-making process was based around four decision making criteria and six performance measures across environmental, social and economic themes. The criteria were:

- Maximise conservation of biodiversity
- Minimise the costs of delivering the biodiversity outcome
- Ensure the biodiversity outcome is feasible
- Maximise public amenity

The process looked at four different models to provide funding for the biodiversity outcome, examined twenty alternative biodiversity outcomes, modelled the performance of each alternative and compared the twenty alternatives under various scenarios to reach conclusions about the optimal approach.

The process found that the best approach to achieving the optimal biodiversity outcome with the available funding is to apply a broad mix of commitments and actions to maximise the biodiversity values that are protected, maximise certainty of delivery and alleviate the pressure on offset supply and demand.

The best mix of approaches includes:

- Securing one or more new national parks in the Plan Area
- Investing in biodiversity stewardship in the best remaining vegetation in the Plan Area
- Restoring key parts of the landscape within the Plan Area
- Providing dedicated funding for a set of actions to protect Koalas
- Investing a smaller proportion of the funding on biodiversity stewardship outside the Plan Area, within the allowable variation rules under the BC Regulation

This mix of approaches is reflected in the conservation program for the Plan (see Chapter 8).

6.5.3 ALTERNATIVE LOCATIONS OF URBAN CAPABLE LANDS AND TRANSPORT CORRIDORS

PROCESSES TO LOCATE THE URBAN CAPABLE LAND

The urban capable land was identified in three phases:

- Strategic planning to locate the nominated areas
- Initial development of footprints through Land Use and Infrastructure Implementation Plans
- Iterative refinement of the footprints through development of the Plan and assessment of impacts

The initial development and refinement of the urban capable land footprints is described in Chapter 14.

Strategic planning to locate the nominated areas

The broad location of the nominated areas was determined through various strategic planning strategies and investigations over many years. Two key planning strategies that informed the location of the nominated areas were:

- *A Plan for Growing Sydney* (DPE, 2014) – this identified the general location of Wilton Growth Area (Wilton) and Greater Macarthur Growth Area (GMAC) and the Badgerys Creek Airport precinct, which was subsequently refined further by the Department to become WSA
- *A Metropolis of Three Cities* (GSC, 2017) – this identified the general location of Greater Penrith to Eastern Creek Investigation Area (GPEC) and establishes a 40-year vision for Sydney as a global metropolis of three cities, including the Western Parkland City covering the nominated areas

The nominated areas were located based on a broad range of strategic planning considerations, including:

- Proximity to current and planned locations of employment
- The cost of infrastructure provision including roads, water, sewerage, public transport, schools and health facilities
- The economic and social cost to communities of having poor access to employment and services, including transport
- Environmental constraints, including biodiversity values

Action 2.4.2 of *A Plan for Growing Sydney* (DPE, 2014) aimed to develop a long-term framework for the identification of new nominated areas to improve the management of future land release in Sydney. In preparing a framework for the identification of nominated areas, Action 2.4.2 indicates that a range of issues should be considered, including:

- The value of land for drinking water supply, agriculture, environmental management and other purposes
- Constraints to development, including environmental constraints and natural hazards

The Department undertook investigations into the location of the nominated areas in accordance with Action 2.4.2.

PROCESSES TO LOCATE THE TRANSPORT CORRIDORS

The process for identifying, selecting and designing future corridors and transport projects involves a detailed set of steps and processes to ensure optimum infrastructure, environmental, social and economic outcomes are achieved. The *Planning guideline for Major Infrastructure Corridors* (DPE, 2016) sets out the recommended processes for infrastructure agencies to follow through the different phases of corridor planning.

The guideline provides advice in relation to the three broad phases:

- Strategic planning – identification
- Corridor planning and selection
- Infrastructure delivery

The first two phases lead to the identification and protection of transport corridors. As part of this process, a Strategic Environmental Assessment (SEA) is prepared which provides an assessment of the environmental, economic and social impacts of reserving the corridor. SEAs are non-statutory documents that assist in the planning and decision-making process for the community and Government. They are subject to public consultation and include justification for a preferred corridor alignment and provide information on the assessment of alternative corridor alignments.

In making decisions on corridor selection, infrastructure agencies undertake a constraints analysis and multi-criteria comparison of options. These include consideration of a wide range of factors including:

- Aboriginal heritage
- Biodiversity
- Costs
- Engineering and construction limitations
- Land use and property impacts
- Landscape character and visual amenity
- Noise and vibration
- Non-Aboriginal heritage
- Socio-economic considerations
- Soils, geology and contamination
- Transport planning
- Water quality and hydrology

Box 1 provides an example of the process used to locate the Outer Sydney Orbital (OSO) (AECOM, 2018).

BOX 1: PROCESS USED TO LOCATE THE OUTER SYDNEY ORBITAL

The Draft SEA for the OSO (AECOM, 2018) sets out the process that was followed to locate that transport corridor. Transport for NSW commissioned the OSO study "to identify the most appropriate location for the corridor and to protect land within that corridor for the future provision of critical road and freight rail infrastructure". The method for identifying the corridor involved (AECOM, 2018):

- *Identifying a study area – investigations commenced with a broad OSO study area to identify high-level constraints and opportunities*
- *Understanding constraints and opportunities – an analysis of constraints and opportunities within the study area included prioritisation of constraints as well as identification of key areas and values to avoid during corridor design development*
- *Developing guiding principles – a list of guiding principles was developed to inform the selection of a long list of corridor options. These principles followed the hierarchy of 'avoid, minimise, and mitigate impacts', to allow for the creation of a series of options*
- *Identifying corridor options – a range of tools, including computer software and specialist advice, was used to identify a long list of corridor options*
- *Evaluating corridor options – this included specialist investigations of identified options, comparative assessment and multi-criteria analyses*
- *Selecting a recommended OSO corridor – a continuation of the evaluation process where selection and refinement of a recommended corridor involved multi-criteria assessment, targeted stakeholder consultation and design development*
- *Consulting with the public on the recommended corridor – to obtain feedback on the recommended OSO corridor*

Potential impacts to biodiversity were a key consideration (amongst a range of considerations) in the SEA and the ultimate selection of the corridor. A similar process was followed for the other transport corridors.

7 Development under the Plan

7.1 INTRODUCTION

This Chapter describes each of the development elements of the Plan in detail.

An overview of the development under the Plan is provided in Part 1. Part 1 also describes the scope and boundaries of the approvals being sought by the Department for the development under the BC Act and EPBC Act.

7.1.1 DEVELOPMENT UNDER THE PLAN

The Plan provides for the following development:

- Urban and industrial development within urban capable land in nominated areas
- Infrastructure within urban capable land in nominated areas, as well as 'essential' infrastructure in limited cases within avoided lands in the nominated areas
- Agribusiness within agribusiness lands in the Western Sydney Aerotropolis
- Western Sydney Major Infrastructure Corridors (transport corridors) within and outside the nominated areas

Each type of development is described in detail in sections 7.2 to 7.5. The development is described in terms of actions that are to be included in an approval of a class of actions pursuant to section 146 of the EPBC Act.

7.1.2 MAJOR DEVELOPMENT NOT PART OF THE PLAN

The following major urban and transport development occur within the Plan Area but are not part of this strategic biodiversity certification and strategic assessment process as they have been previously assessed and approved, or are currently being assessed and considered for approval, under NSW and Commonwealth laws:

- Existing North West and South West Growth Areas (previously assessed and approved)
- Western Sydney Airport (previously assessed and approved)
- Sydney Metro Stage 1 (currently being assessed and approved)

The location of these developments is shown in Part 1.

7.2 URBAN AND INDUSTRIAL DEVELOPMENT

The Plan provides for urban and industrial development in four nominated areas:

- Wilton Growth Area (Wilton)
- Greater Macarthur Growth Area (GMAC)
- Western Sydney Aerotropolis (WSA) (excluding where there is overlap with the existing South West Growth Area)
- Greater Penrith to Eastern Creek Investigation Area (GPEC)

The nominated areas are shown in Figure 7-1 to Figure 7-4.

Not all parts of the nominated areas are proposed for development. The proposed development will occur within specified urban capable lands within each nominated area. Other areas of land within the nominated areas include:

- Land covered by the transport corridors
- Land avoided for development because of its biodiversity value (see Chapter 14)
- Land avoided for development for other reasons (e.g. because it is unsuitable for development)
- Land that is already protected or developed, or otherwise not included in the Plan (excluded land)

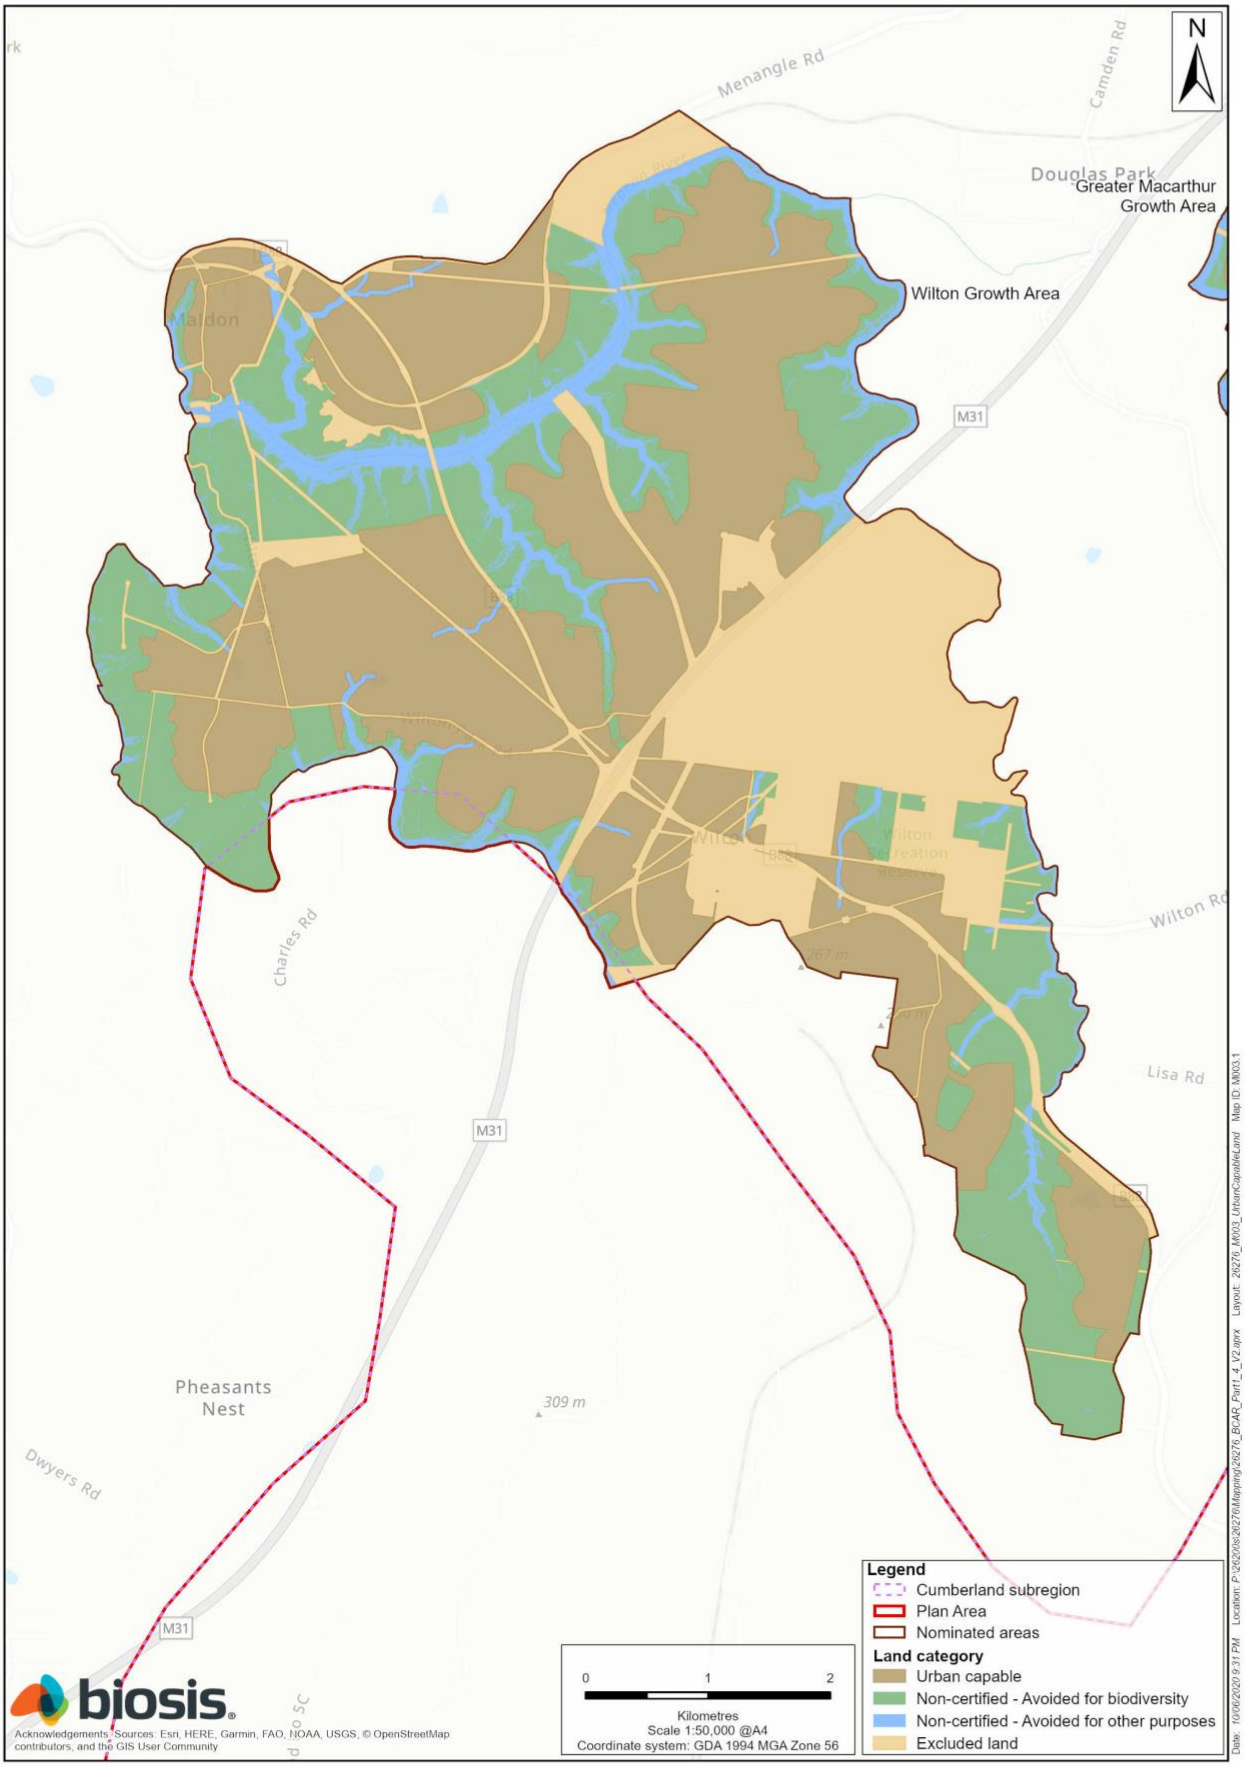

Figure 7-1: Wilton Growth Area and urban capable land

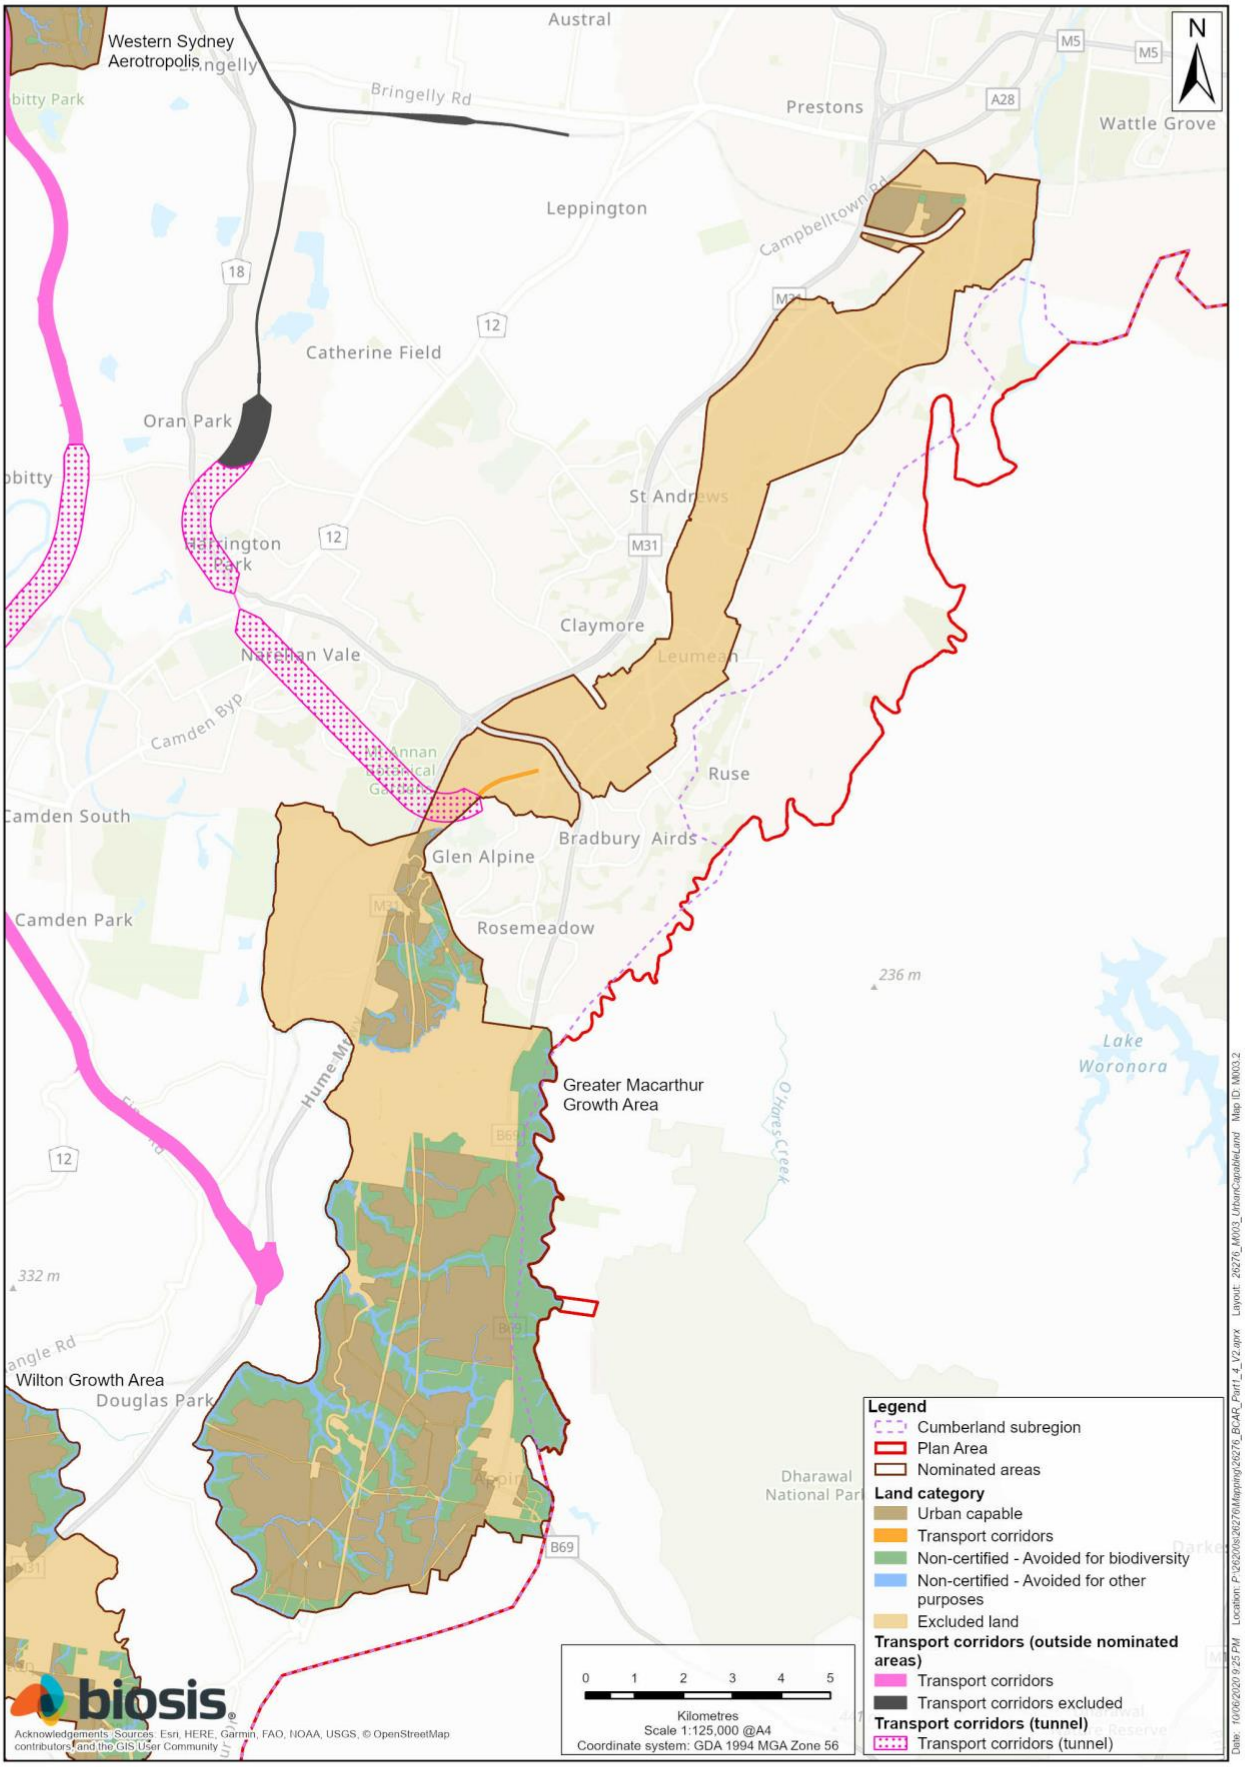

Figure 7-2: GMAC and urban capable land

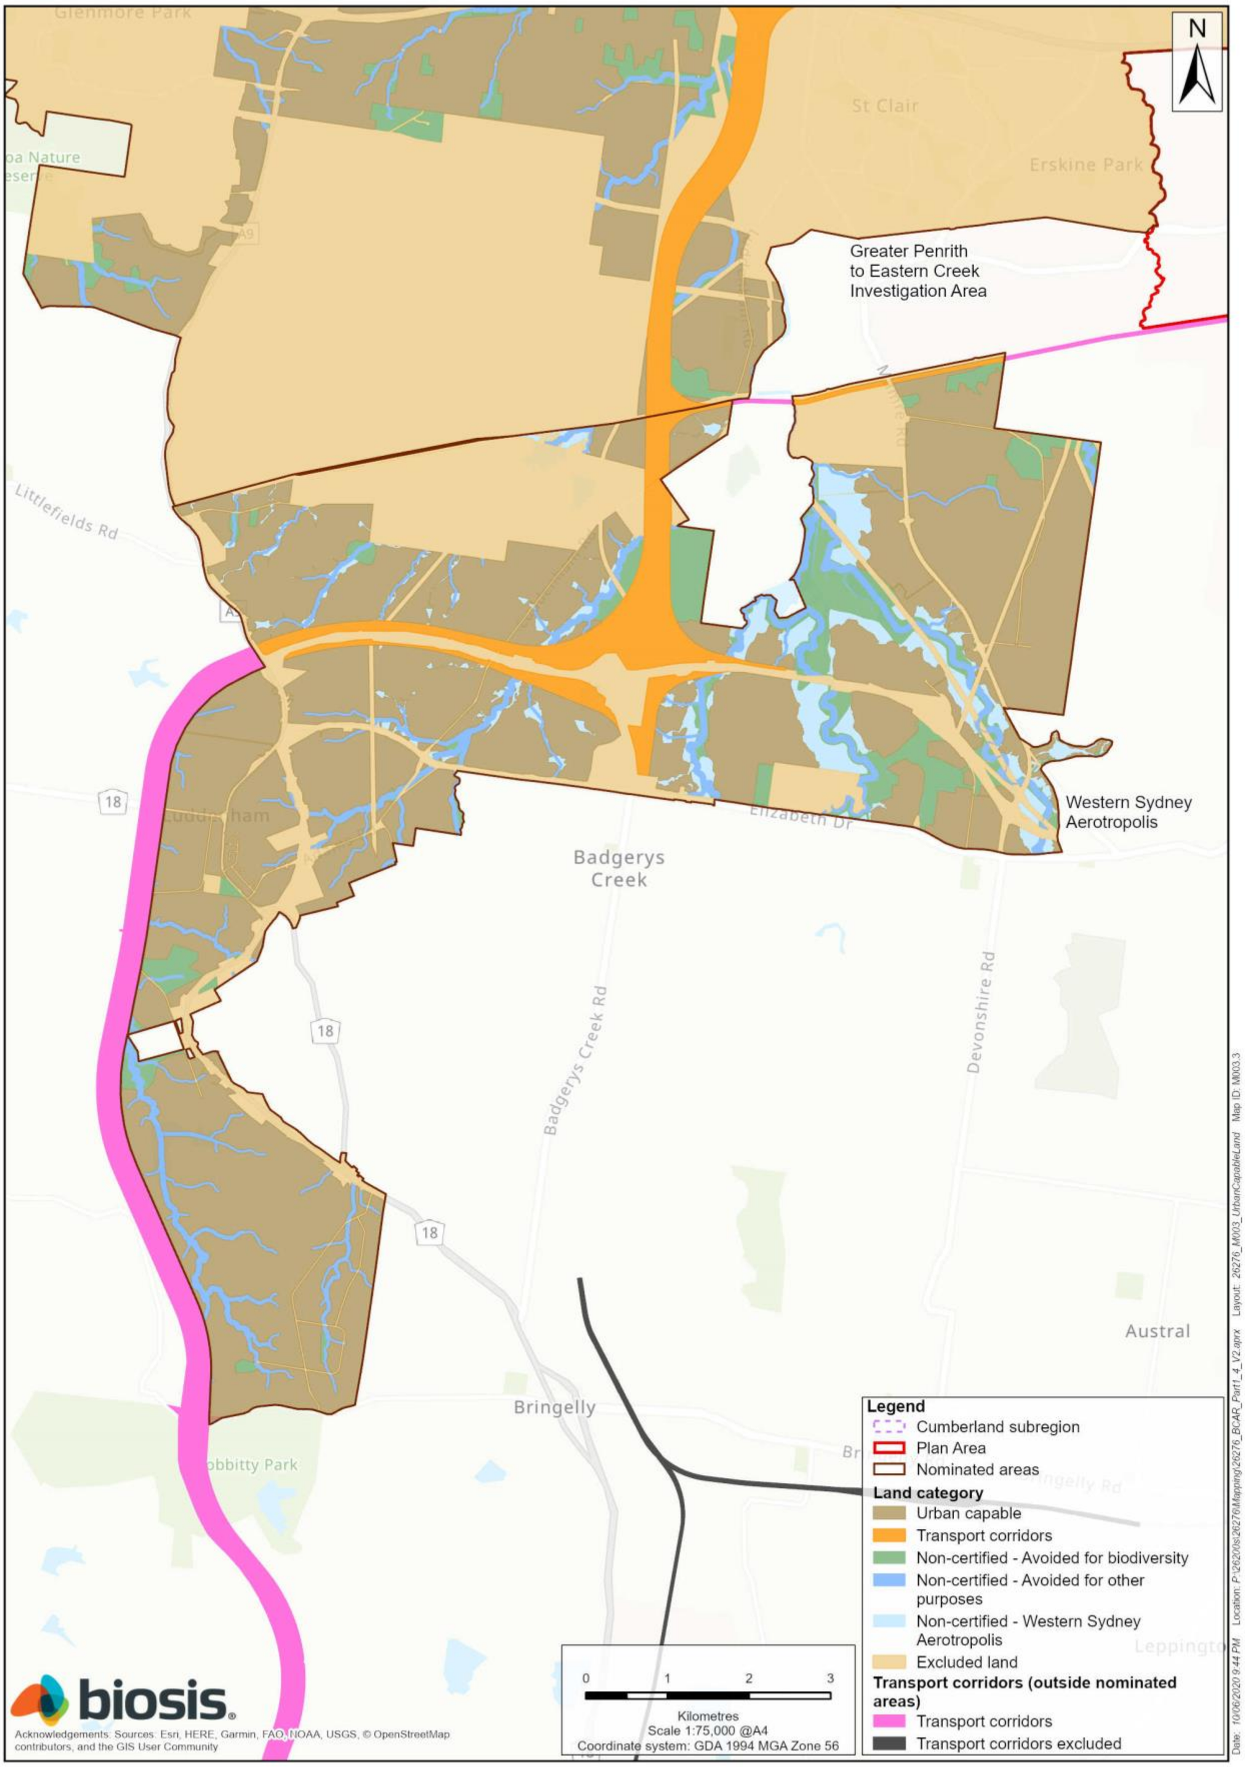

Figure 7-3: WSA and urban capable land

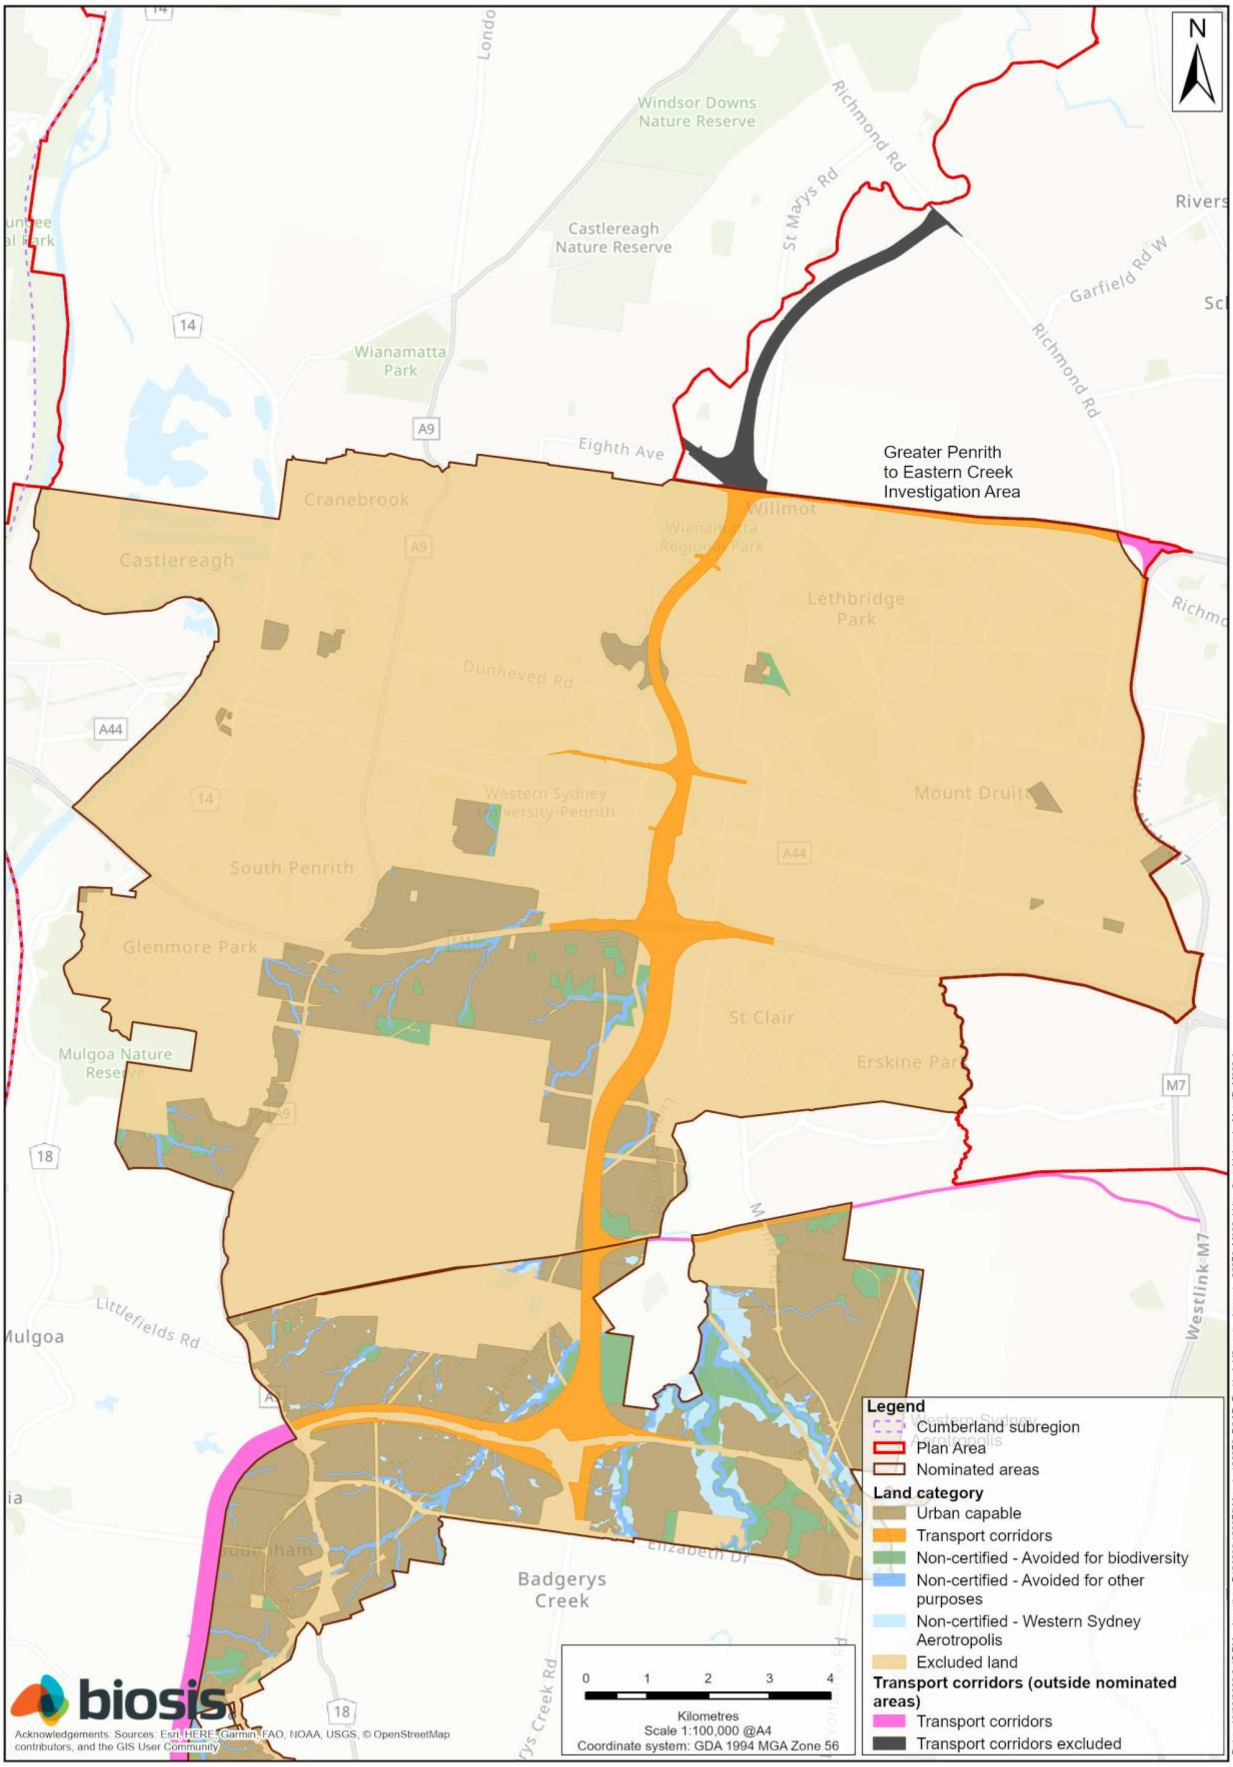

Figure 7-4: GPEC and urban capable land

Urban and industrial development will be confined to the urban capable lands within the nominated areas and includes any development permitted through residential, business, or industrial zones, consistent with the structure plan and precinct plans for each nominated area. Urban and industrial development includes:

- Mixed residential, commercial and industrial development
- Major town centres
- Social infrastructure, such as education facilities and child care services
- Essential services, such as health and emergency services facilities
- General industrial facilities, such as retail outlets and manufacturing industries
- Warehouse, freight and logistics including distribution centres
- Airport and ancillary uses to support the delivery and operation of the Western Sydney Airport
- Related, supporting development, provided they do not produce unforeseen impacts on MNES

Structure plans and precinct plans will be prepared for each nominated area and map the boundaries of the urban capable land and the intended land use zones. Structure plans and precinct plans will be made by the relevant planning authority under the *Environmental Planning and Assessment Act 1979* (EP&A Act). The NSW Government will amend the relevant State Environmental Planning Policy to attach the structure plans and precinct plans before development under the Plan commences.

Relevant planning authorities will rezone the land over time. A Ministerial Direction under section 9.1 of the EP&A Act will be made to require that any planning proposals to rezone the land must be consistent with the intended land use zones structure plan and precinct plans attached to the State Environmental Planning Policies (SEPPs).

7.3 INFRASTRUCTURE

Infrastructure development will generally be limited to urban capable land within the nominated areas and includes:

- Electricity transmission or distribution networks
- Gas pipelines
- Road or road infrastructure facilities, including public transport facilities (this is limited to local roads)
- Water reticulation systems, water storage facilities, water treatment facilities, or water supply systems
- Telecommunications facilities or telecommunication networks
- Stormwater management systems
- Resource recovery facility, waste disposal facility, waste or resource management facility and transfer stations
- Organic waste and composting facilities
- Supporting infrastructure for parks and public reserves (environmental facility, information and education facility, kiosk, recreation area, recreation facilities (outdoor), water recreation structure, road)

Certain essential infrastructure may be carried out by or on behalf of a public authority on land outside the urban capable land (not including excluded land) within the nominated areas (i.e. on avoided land) provided the 'guidelines for development' in the Plan are followed. The guidelines limit the scope of infrastructure development within these areas and aim to ensure development avoids and mitigates and offsets any impacts to biodiversity values.

The guidelines specify a range of requirements to achieve this outcome, including that:

- The environmental impacts of the projects are considered under the EP&A Act
- An 'avoid and mitigate' process is applied as part of this assessment process
- Any relevant MNES-specific requirements of the Plan are applied

The guidelines for development are described and evaluated in Chapter 37.

7.4 AGRIBUSINESS

The Western Sydney airport presents an opportunity to invest in agriculture and agribusiness industries. The Agribusiness Precinct within WSA occurs on the northern and western edges of the airport and supports the long-term retention and growth of agriculture and agribusiness in the Western Parkland City.

Agribusiness will be confined to within the Agribusiness Precinct within WSA (see Figure 7-5) and includes existing, new and proposed agricultural areas to support the nominated areas program. Agricultural production will be confined within the agriculture or agribusiness lands within WSA. However, it is possible that associated development related to agribusiness, wholesale markets, manufacturing and logistics may occur in other precincts.

Agriculture development may include:

- Intensive plant agriculture, including protective structures used for production of fruit, vegetables or flowers
- Agribusiness – businesses associated with the production, processing, marketing and distribution of agricultural products, such as biotechnology research and development, food processing and export enabling infrastructure
- Advanced food manufacturing and logistics
- Wholesale markets, such as retail, distribution centres, cold stores, ripening rooms, and treatment facilities

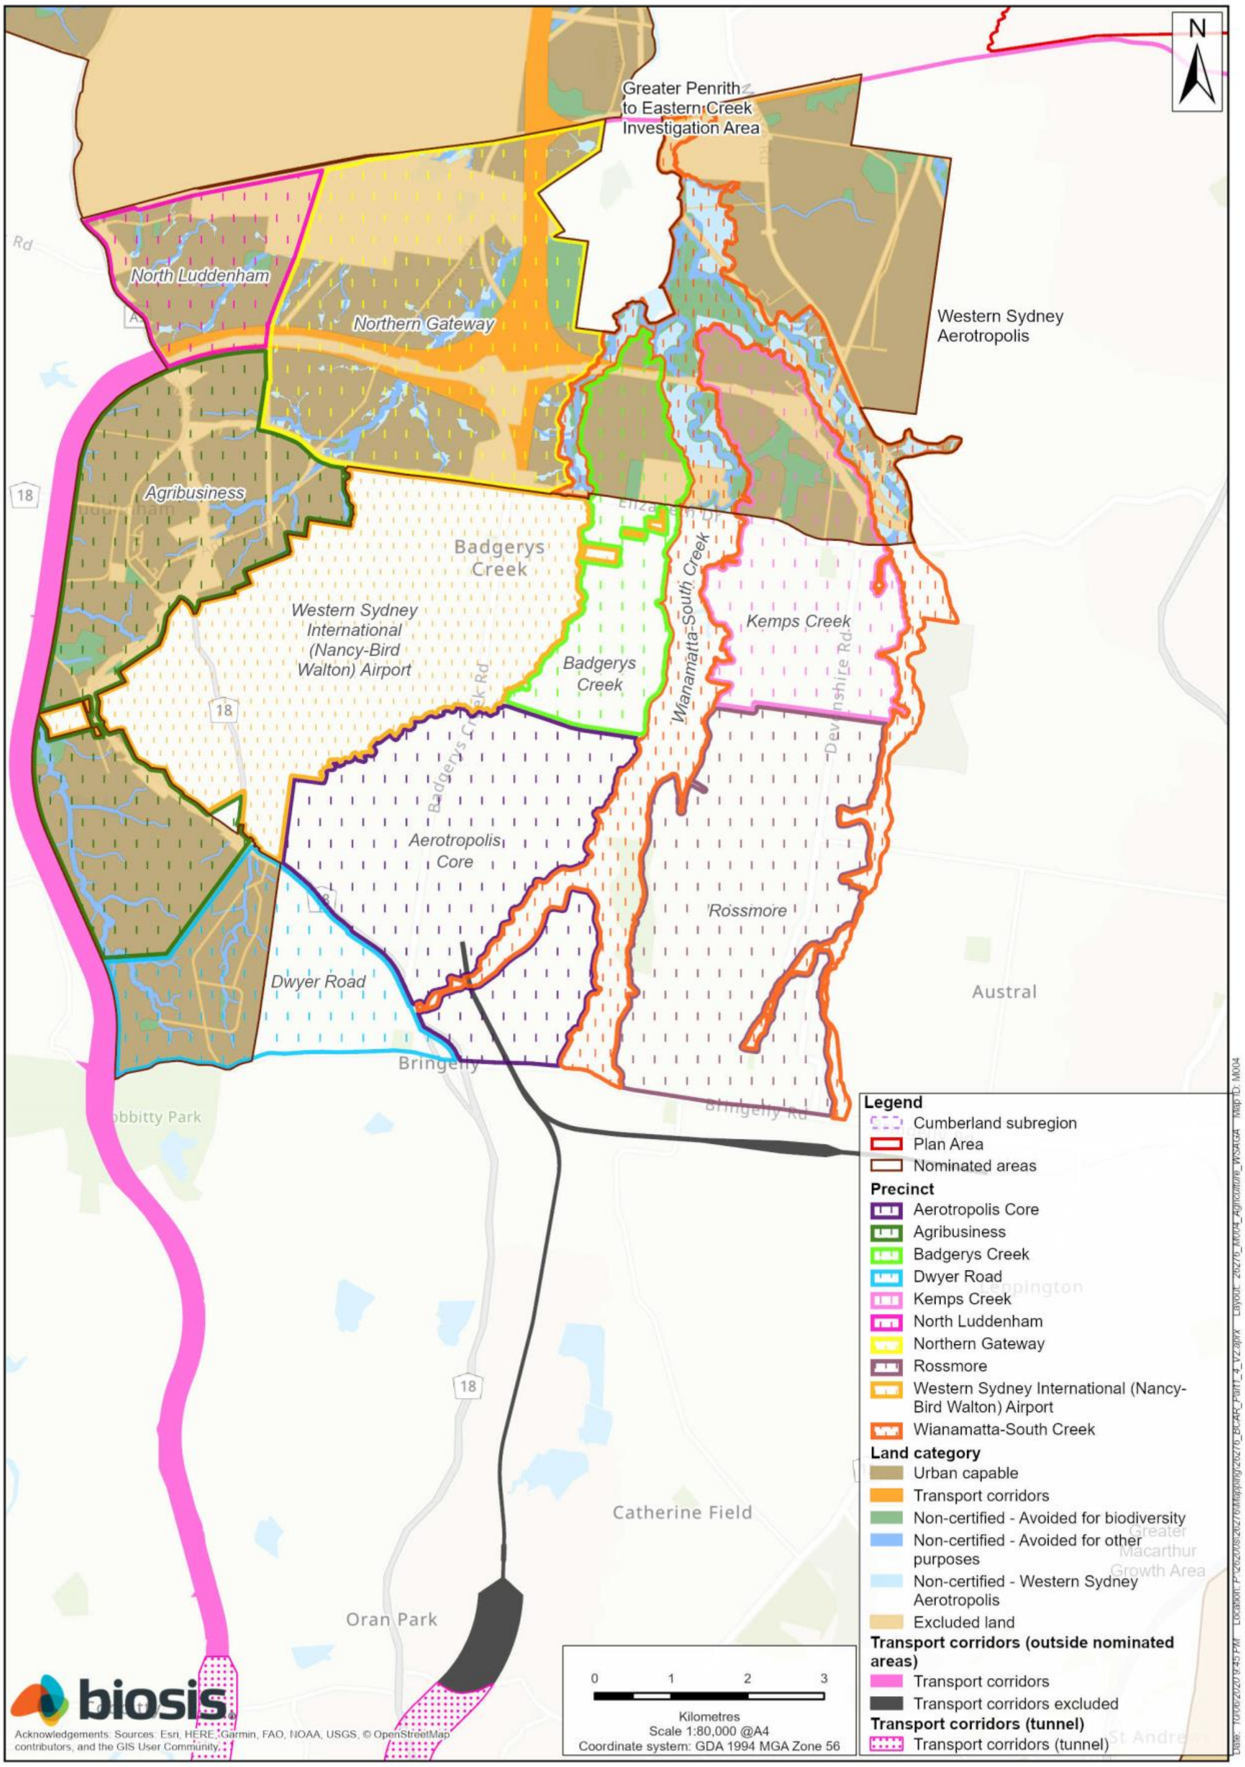

Figure 7-5: Agriculture and Agribusiness Precinct of WSA

7.5 TRANSPORT CORRIDORS

The NSW Government is finalising long term major infrastructure corridors for Western Sydney by identifying and protecting corridors that can be used to deliver the major components of the future transport network. These corridors will facilitate the delivery of major transport infrastructure to meet the long-term needs of Western Sydney, as outlined in the Future Transport Strategy 2056 (Transport NSW, 2017) and the Greater Sydney Region Plan.

For Western Sydney, the transport corridors are planned to be delivered over the next 40 years. The delivery and timing of the major transport infrastructure within the corridors is subject to future NSW Government decisions. The responsibility for delivery of the transport infrastructure rests with Transport for NSW.

The transport corridors and the indicative timing for investigating the delivery of these corridors are identified in Table 7-1. The indicative locations of the transport corridors are shown in Figure 7-6. Parts of the transport corridors are located within GPEC, WSA and GMAC. There are no transport corridors identified within Wilton.

Table 7-1: Transport corridors for investigation

<table>
<tr><th>Project</th><th>Description</th><th>Timing for investigation</th></tr>
<tr><td>Sydney Metro Greater West south from Western Sydney Aerotropolis to Macarthur (except for those areas within the existing South West Growth Area)</td><td>Provides for a commuter railway line</td><td>0 to 10 years</td></tr>
<tr><td>Western Sydney Freight Line corridor</td><td>Provides for a future freight rail line to connect Port Botany and Western Sydney</td><td rowspan="2">10 to 20 years</td></tr>
<tr><td>Outer Sydney Orbital (Stage 1) from Palmyra Avenue to the Hume Motorway</td><td rowspan="2">Provides for a future north south motorway and freight rail line</td></tr>
<tr><td>Remaining Outer Sydney Orbital 1</td><td rowspan="2">20 or more years</td></tr>
<tr><td>M7/Ropes Crossing Link Road</td><td>Provides for a future east-west motorway linking the M7 to the future Outer Sydney Orbital at Ropes Crossing</td></tr>
</table>

Development under the transport class of action includes all activities associated with the design, construction, and operation of the major road or rail projects. This includes any development on land within the transport corridors shown in the Plan (see Figure 7-6) or on any other land required for the transport project along these general alignments, as identified under the NSW environmental assessment and approval process for each project current at the time the project is brought forward (this is currently the State Significant Infrastructure approval process).

The transport activities included under the Plan include, but are not limited to:

- Vegetation clearing
- Earthworks
- Utility works
- Landscaping
- Erosion and sediment control
- Laydown areas
- Road and rail construction
- Tunnel construction
- Construction of supporting infrastructure such as stations, car parks and pedestrian access
- Electricity infrastructure
- Site offices and access roads
- Dust and noise suppression

- Stormwater management (including detention basins, ponds and dams)
- Vehicle and train movements
- Maintenance and upgrade activities
- Installation and maintenance of traffic control and safety infrastructure

As each transport project is brought forward for investigation, the project will be subject to:

- A process of strategic planning and detailed design, which will determine the final alignment of each transport project that will generally occur within each transport corridor
- NSW environmental assessment and approval process for each project current at the time the project is brought forward (this is currently the State Significant Infrastructure approval process).

The transport projects included in the Plan have not finalised implementing a process to avoid biodiversity values as the alignment for the corridors are not currently certain. Additional areas will be avoided as designs for the transport projects are determined. The Plan includes commitments for further avoidance and minimisation of impacts to biodiversity values related to the transport corridors (see Chapter 36).

It is important to note that sections of a number of the transport corridors occur within the existing North West and South West Growth Areas. These sections already have EPBC Act approval under the previous Part 10 strategic assessment for the growth areas and are therefore not further considered in this Assessment Report.

TUNNELS

Development under the transport class of action includes tunnel construction and operation. Sections of two of the transport corridors are proposed to include tunnels. These are:

- Outer Sydney Orbital – Cobbitty to Cawdor
- Metro Rail Future Extension tunnel – Oran Park to Narellan, and Narellan to Macarthur

The location of the tunnels are shown in Figure 7-6.

The activities associated with tunnelling may include but are not limited to the matters shown in Table 7-2.

Table 7-2: Construction activities and operational infrastructure associated with transport corridor tunnels

Project phase	Activities
Construction activities	• Site establishment and enabling work, including but not limited to utility work, fencing and hoarding, construction ancillary facilities and access, demolition of buildings and structures and clearance of vegetation where required • Erection of acoustic sheds (where relevant) over the temporary access tunnels and to contain noise and dust from tunnelling operations • Construction of temporary access tunnels • Construction of main tunnels, including but not limited to entry and exit ramps and associated tunnelled infrastructure • Spoil management and haulage • Finishing work in tunnel and provision of permanent tunnel services, including but not limited to mechanical and electrical fit out • Drainage work, including permanent water treatment facilities
Operational infrastructure	• Utilities infrastructure (including adjustments to, or relocation of, existing utilities infrastructure), electronic tolling facilities, signage, ventilation systems, emergency systems, systems for the control and management of roads, and tunnel control centre facilities • Entry and exit ramps (tunnel portals) • Connection to power, including construction of or connection to electrical substations • Connection and tie in with existing surface roads and infrastructure

Project phase	Activities
	• Pedestrian and cyclist facilities • Drainage work, pavement and finishing work (including landscaping and urban design treatments)

As for the other parts of the transport corridors, development for the tunnels will generally occur within the footprints of the tunnels shown in Figure 7-6. In some circumstances development activities may be necessary adjacent to the footprint.

The impacts of tunnels are assessed separately (see Chapter 36) to the rest of the transport corridors as only small areas of the footprints will be disturbed and impacts have not been included in the impact statistics for transport corridors in the assessments for Commonwealth-listed species and Threatened Ecological Communities (TECs) (see Chapters 29 to 31).

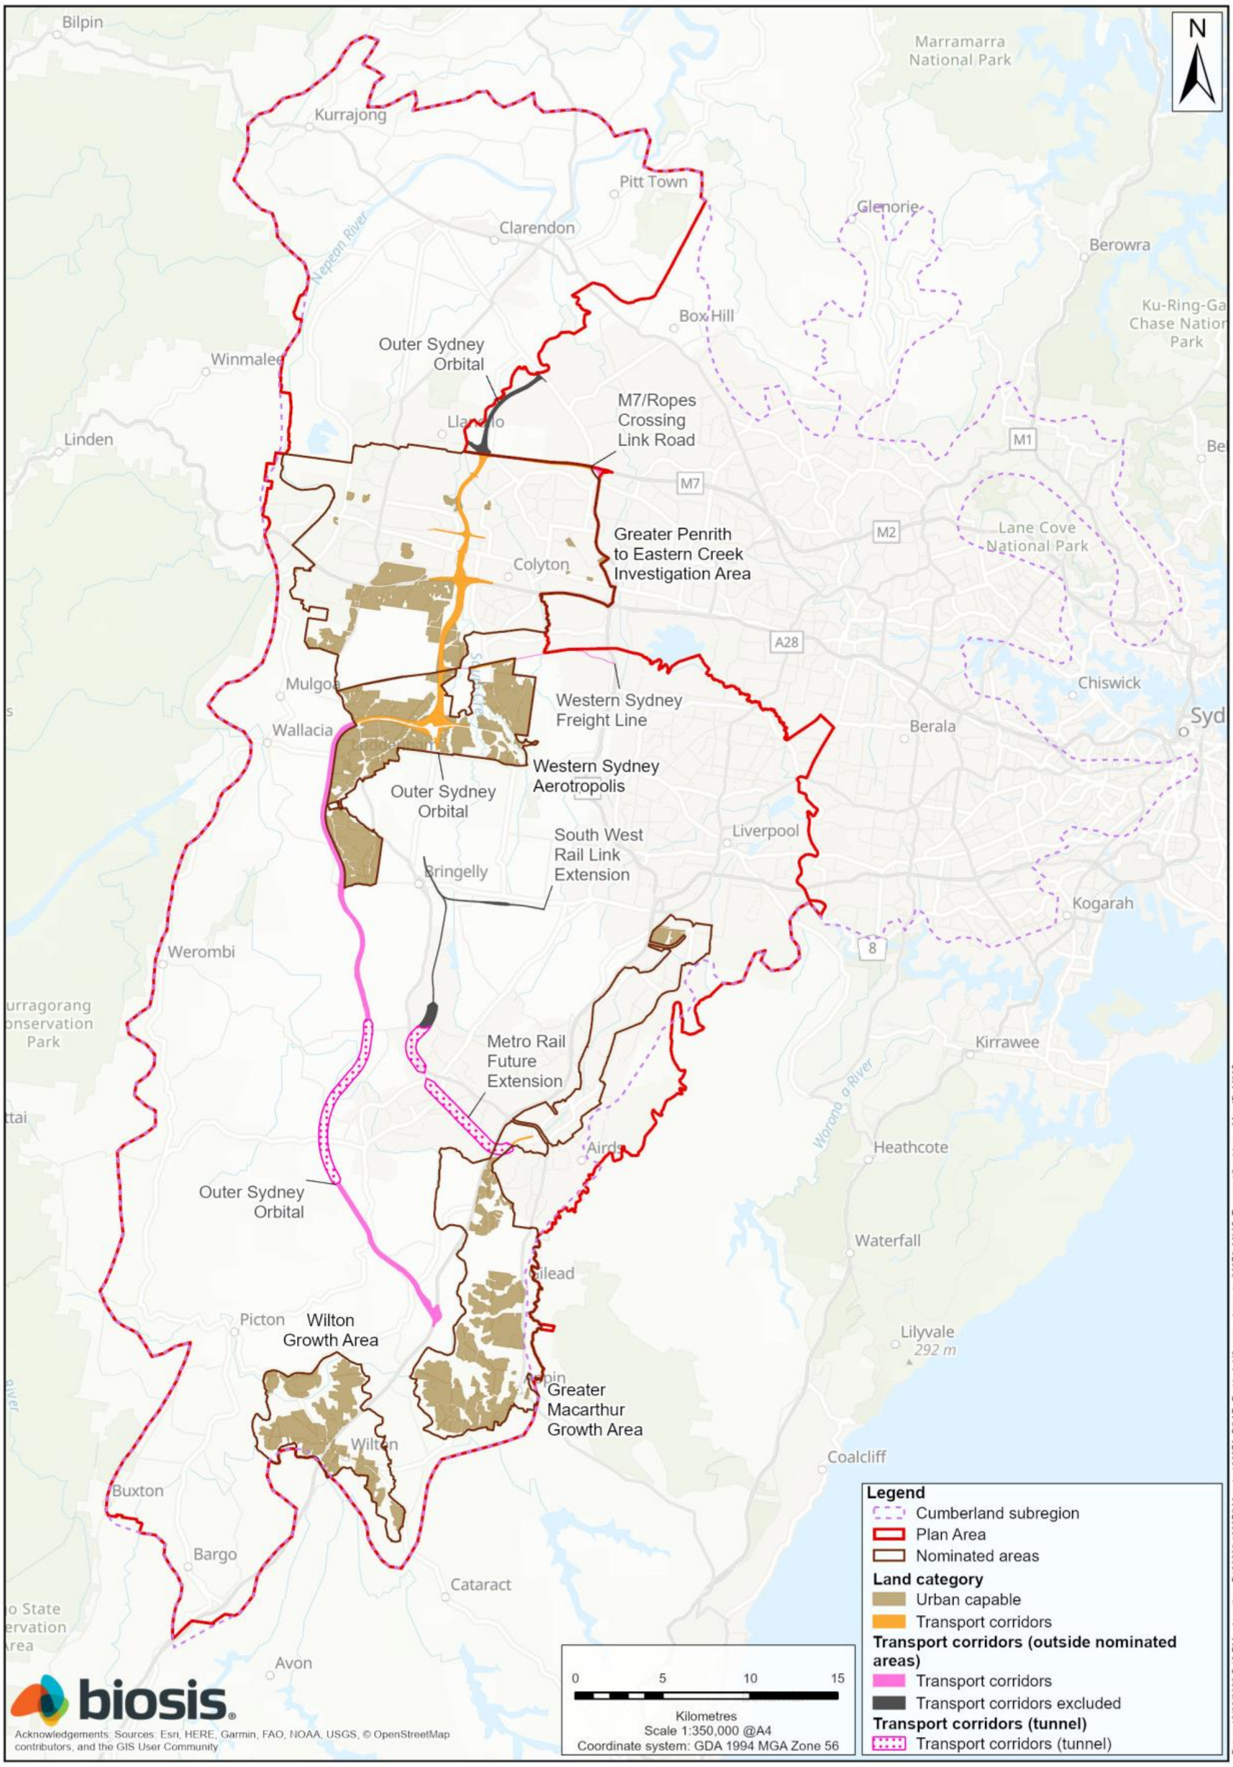

Figure 7-6: Indicative locations of transport corridors

8 Conservation program of the Plan

8.1 INTRODUCTION

The Plan includes a conservation program to achieve the Plan's objective to "deliver biodiversity outcomes and support the ecological function of the Cumberland Plain…" and offset the impacts of the development on biodiversity values.

This Chapter describes the conservation program under the Plan, including:

- Overview of the conservation program
- Commitments and actions to deliver the conservation program
- Koala conservation program
- Development of the conservation program

The conservation program is supported by an implementation framework which sets out how the Plan will be delivered. Chapter 9 provides an overview of the implementation framework.

Part 7 provides a detailed evaluation of the adequacy of conservation program.

8.2 OVERVIEW OF THE CONSERVATION PROGRAM

8.2.1 PURPOSE OF THE CONSERVATION PROGRAM

The purpose of the conservation program is to achieve the Plan's objective and conservation outcomes and offset the impacts of the development on biodiversity values. The conservation program has been designed to maximise ecological function and resilience at the landscape scale in the Cumberland subregion (see Section 8.5).

8.2.2 ELEMENTS OF THE CONSERVATION PROGRAM

The conservation program has five key elements:

1. Avoiding and minimising impacts
2. Mitigating indirect and prescribed impacts
3. Conserving flora and fauna and habitat
4. Managing landscape threats
5. Building knowledge and capacity

The key focus of the conservation program is conserving flora and fauna and habitat by securing priority conservation areas in the Cumberland subregion to offset the impacts of the development on biodiversity values and maximise ecological function and resilience at the landscape scale.

The elements of the conservation program are shown in Figure 8-1.

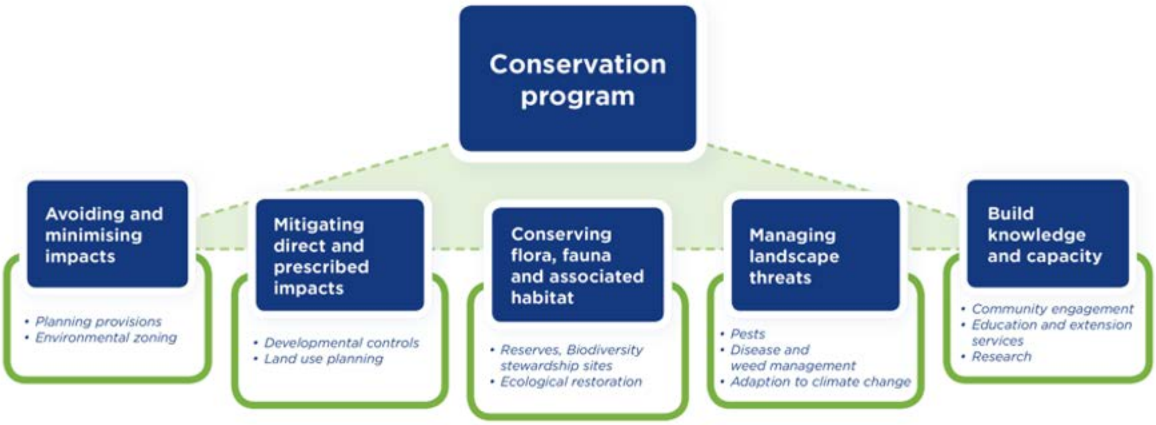

Figure 8-1: Key elements of the conservation program

8.2.3 OUTCOMES

The outcomes of the Plan deliver the Plan's vision and objective. The outcomes of the Plan include economic, social and environmental outcomes. The environmental outcomes of the Plan are:

- Extent and condition of native vegetation increases and improves within areas in the Cumberland subregion most likely to support long-term viability and ecological connectivity
- TECs persist and their condition improves within areas in the Cumberland subregion most likely to support long-term viability
- Populations of targeted threatened species persist and the condition of suitable habitat improves within areas in the Cumberland subregion most likely to support long-term viability
- Condition of riparian corridors within the nominated areas improves

8.2.4 COMMITMENTS

Commitments are what will be done to deliver the Plan's outcomes. The Plan includes commitments relating to each element of the conservation program. The commitments will be implemented over the life of the Plan.

8.2.5 ACTIONS

Actions are what will be done to deliver the commitments. Each commitment has a set of actions associated with it. Actions are set out in the Sub-Plans and may be subject to change following approval of the Plan.

8.3 COMMITMENTS AND ACTIONS TO DELIVER THE CONSERVATION PROGRAM

This Section provides a summary of the key commitments and actions to deliver the conservation program. Further details of the commitments and actions to deliver the conservation program are provided in the Plan.

8.3.1 AVOIDING AND MINIMISING IMPACTS

The Plan includes a commitment (Commitment 2) to avoid and minimise impacts from urban and industrial, and infrastructure development, to at least 4,315 hectares[1] of land within the nominated areas. This includes

- Avoiding 3,670 hectares of native vegetation comprising:
    - 2,735 hectares of native vegetation because of its biodiversity value
    - 935 hectares of riparian corridors and steep land
- Avoiding specific amounts of habitat for Commonwealth and NSW listed TECs
- Limiting cumulative direct impacts from essential infrastructure within non-certified land to the Commonwealth listed Shale Sandstone Transition Forest TEC and prioritising the avoidance of impacts from this infrastructure to specific known populations of flora species and important Koala corridors (see Chapter 37)

This commitment will be delivered through several actions, including:

- Introducing a planning provision to require that the urban capable lands in the precinct plans are consistent with the areas of certified land and avoided lands identified in the Plan
- Applying environmental protection zoning to avoided lands
- Applying further planning controls through the NSW planning system if the avoidance targets are not being met

The Plan includes commitments (Commitment 3 and Commitment 4) for further avoidance and minimisation in relation to the transport corridors, including the tunnel sections of the transport corridors.

Further avoidance in relation to the transport corridors will be undertaken through:

- A process of strategic planning and detailed design, which will determine the final alignment of each transport project that will generally occur within each transport corridor
- NSW environmental assessment and approval process for each project current at the time the project is brought forward (this is currently the State Significant Infrastructure approval process)

8.3.2 MITIGATING INDIRECT AND PRESCRIBED IMPACTS

The Plan includes several commitments (Commitment 5, Commitment 6, and Commitment 7) related to mitigating indirect and prescribed impacts. The commitments are to mitigate indirect and prescribed impacts:

- On species and TECs from development, to best practice standards
- On species from transport corridors
- On Koala to best practice standards and in line with the Chief Scientist Koala Report

Sub-plan A identifies actions to deliver these commitments, including:

- Preparing Development Control Plans for each nominated area setting out the development controls to be addressed by neighbourhood plans and development applications to mitigate indirect and prescribed impacts
- Applying the environmental assessment and approval process for each transport project current at the time the project is brought forward (this is currently the State Significant Infrastructure approval process)
- A range of mitigation measures for Koala, including:
    - Constructing exclusion fencing between important Koala habitat and urban capable land in Wilton and GMAC
    - Applying development controls within 60 m of Koala habitat in accordance with the *Koala Habitat Protection Guideline* (DPIE, 2020) (made under State Environmental Planning Policy (Koala Habitat Protection) 2019)

[1] Note that the total area of avoided land at the start of the Plan is 4,795 hectares. The avoidance target has reduced this figure by 10 per cent to allow for potential future development of essential infrastructure in non-certified land

8.3.3 CONSERVING FLORA AND FAUNA HABITAT

This category of commitments is the key focus of the conservation program (see Figure 8-1). The key commitment of the Plan to offset the impacts of the development on biodiversity values is to protect a minimum of 5,475 ha of impacted native vegetation communities in the Cumberland subregion to conserve biodiversity values in perpetuity.

As part of this commitment, the Plan has committed to:

- Securing specific minimum amounts of Commonwealth and NSW-listed TECs
- Securing populations of species considered at risk of notable impacts
- Undertaking ecological restoration of priority areas
- Securing priority habitat corridors to support connectivity for TECs and species
- Establishing a Georges River Koala Reserve to secure a Koala movement corridor along the Georges River
- Establish at least two new reserves in addition to the Georges River Koala Reserve to protect TECs and species habitat that are targeted for protection under the Plan

PRIORITY AREAS FOR CONSERVATION

The Department has identified Strategic Conservation Areas (SCAs) within the Cumberland subregion within which the commitment to secure 5,475 ha of native vegetation will be prioritised. The SCAs are shown in Figure 8-2.

SCAs represent the areas in the Cumberland subregion containing habitat for biodiversity values impacted by the development that are considered most likely to be viable in the long-term and maximise ecological function and connectivity across the landscape. The process to identify the SCAs is described in Section 8.5.

The Department has developed several approaches to oversee, track and establish conservation lands as offsets over the life of the Plan. These are:

- A series of principles and steps to guide the selection of conservation lands
- A reconciliation accounting process to reconcile offsets acquired through the Plan (including conservation lands) with development impacts throughout the life of the Plan to 2056

The Department will also develop a Conservation Lands Implementation Strategy that will include:

- Priorities for establishing conservation lands
- Targets and timeframes for establishing conservation lands
- Proposed mechanisms for securing each area of priority conservation land
- Suitable land managers for each area of priority conservation land

Other key actions to deliver the offset targets in the Plan include:

- Undertaking surveys prior to securing land for conservation to confirm biodiversity values
- Entering into written agreements with delivery partners to set out the arrangements to secure land for conservation
- Establishing an engagement program to inform landholders about conservation opportunities under the Plan

MECHANISMS TO SECURE CONSERVATION LAND

Land will be secured for conservation in perpetuity through two programs:

- A reserve program to create reserves through acquisition of land
- A Biodiversity Stewardship Agreement (BSA) program to establish BSAs with landholders

The Department may also seek to purchase biodiversity credits from landholders who have already established BSAs to help deliver the offset targets, particularly the species offset targets.

Reserves

Reserves provide the highest level of in-perpetuity biodiversity protection and a range of social benefits not provided by the other commitments, such as public access to natural areas and open space.

There are a range of reserve types proposed under the Plan, including: National Park, Nature Reserve, State Conservation Area, Regional park, Council reserve and community-based reserves. Reserve managers will depend on the type of reserve, and will be determined during implementation of the Plan.

Office of Strategic Lands (OSL) will be responsible for securing land for reserves. Land may be secured through:

- Market purchase (a voluntary negotiated sale with the landholder)
- Owner-initiated acquisition of privately-owned land (where OSL has the right to purchase the land first)
- Active acquisition (where OSL actively engage with the landowner to purchase their land)
- Compulsory acquisition in limited circumstances

Within the first five years of the Plan's implementation, the NSW Government will prioritise the establishment of new public reserves to deliver upfront strategic offsets to protect TECs and species habitat. These are:

- The Georges River Koala Reserve – This is the most important north–south Koala movement corridor along the Georges River between Appin and Kentlyn. In addition to protecting important Koala habitat, the proposed reserve contains around 1,500 hectares of native vegetation, including approximately 375 hectares of Shale Sandstone Transition Forest and 60 hectares of Cumberland Plain Woodland
- The Gulguer Reserve Investigation Area – This investigation area covers about 1,800 hectares and is located in the Warragamba area in the Wollondilly LGA. A reserve in this area will support the east-west connection between Burragorang State Conservation Area and Gulguer Nature Reserve. TECs include approximately 600 hectares of Shale Sandstone Transition Forest and 200 hectares of Cumberland Plain Woodland
- The Confluence Reserve Investigation area – This investigation area lies in the Hawkesbury LGA in the north of the Plan Area, to the east of Londonderry and covers about 600 hectares. It has been identified as a potential area for conservation and ecological restoration efforts due to its proximity to several existing nature reserves

These reserve locations are not final and are likely to be refined. Other areas within the SCAs have also been identified for further investigation as future reserves to provide greater landscape connectivity, such as the Bargo area.

Biodiversity Stewardship Agreements

BSAs are voluntary cooperative agreements between a private landholder and the NSW Government. BSAs are registered on the title of a property to provide in-perpetuity protection of biodiversity values. Landholders are responsible to ongoing management of the land using funding provided via developers.

The Biodiversity Conservation Trust (BCT) will be responsible for overseeing the delivery of the BSA program under the Plan and ensuring compliance with BSAs.

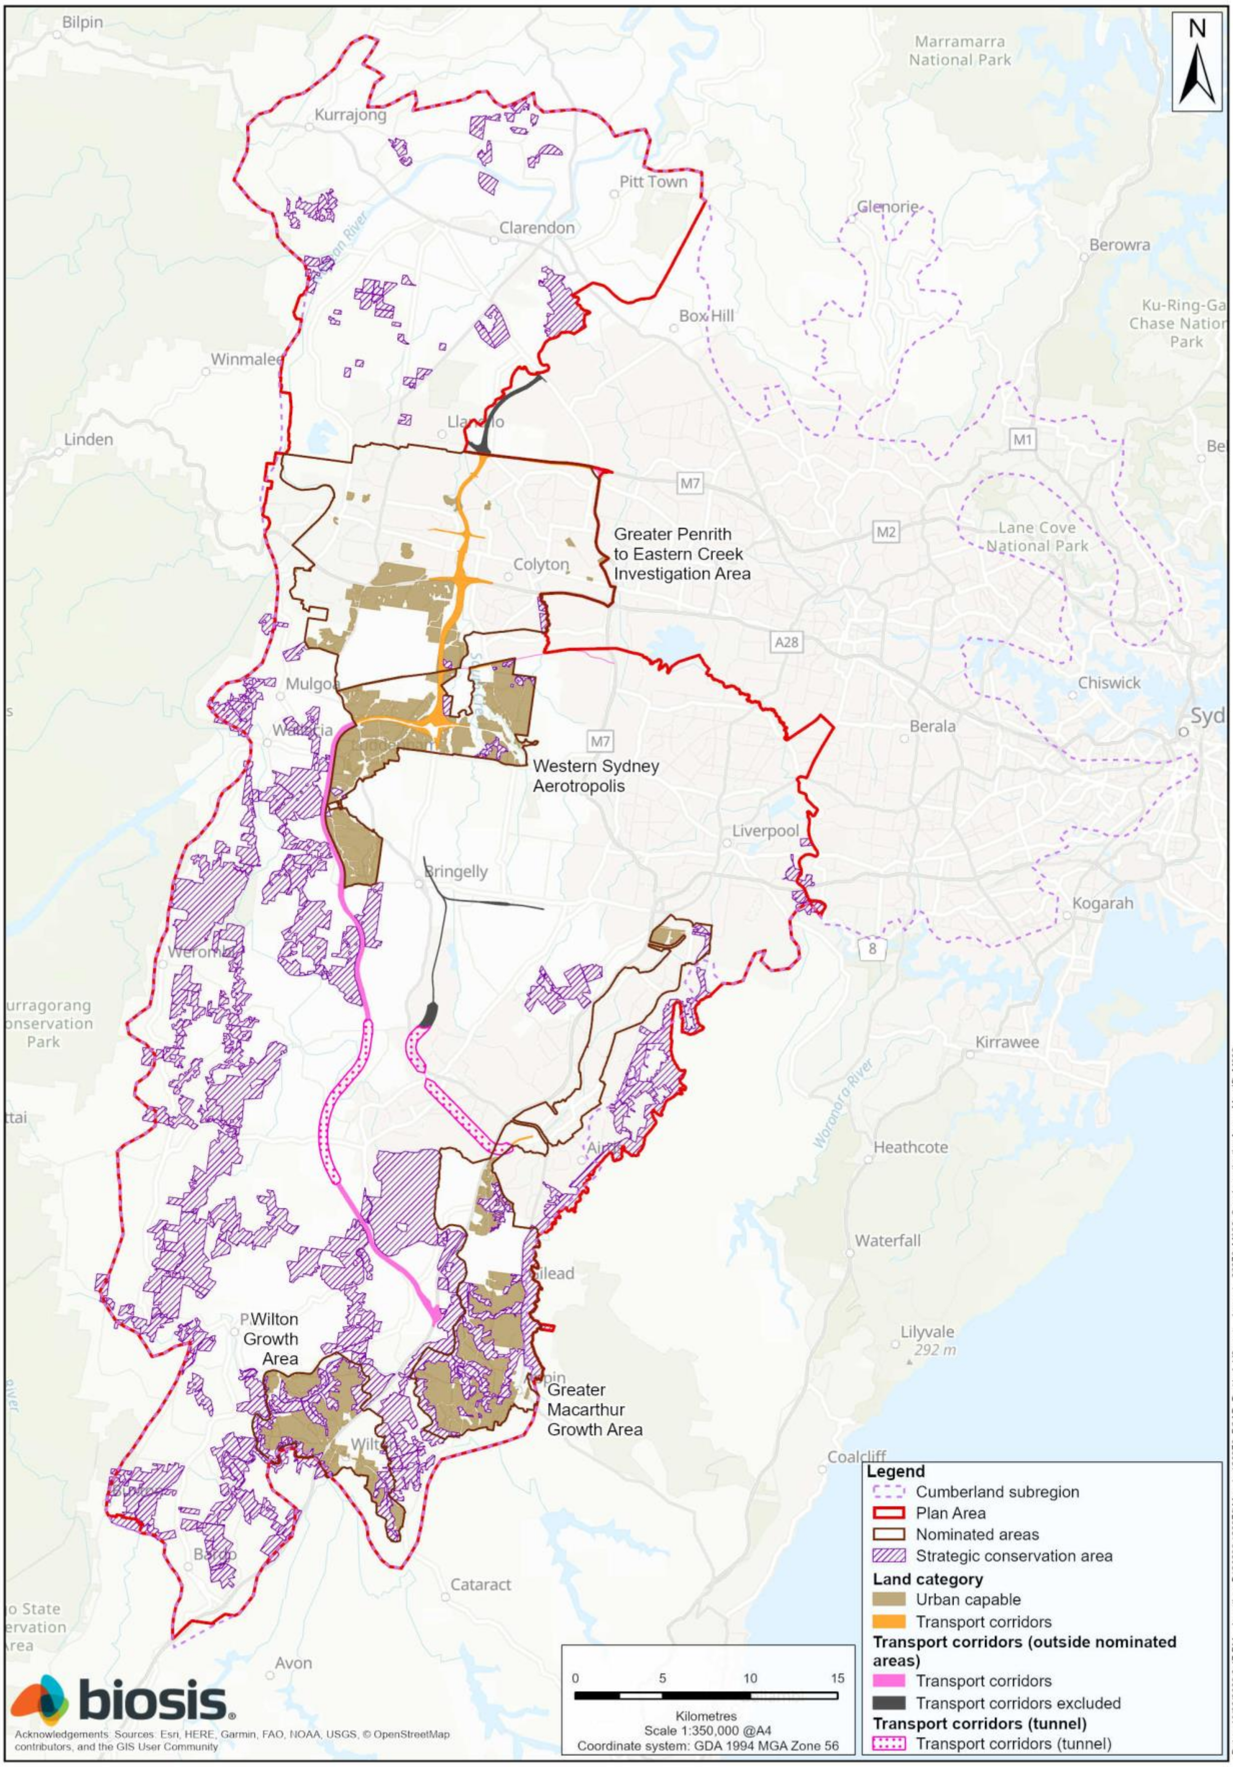

Figure 8-2: Location of Strategic Conservation Areas

RESTORATION OF LAND

As part of the commitments to secure 5,475 ha of native vegetation (Commitment 8) and undertake ecological restoration of priority areas (Commitment 13), there is a target to restore up to 25 per cent of the native vegetation through the ecological restoration of land. A key action to deliver this target includes developing a Restoration Implementation Strategy in consultation with key delivery partners to guide restoration priorities.

Ecological restoration works are intended to be carried out early in the life of the Plan to maximise conservation benefits. Restoration on BSA sites will be overseen by the BCT and undertaken in accordance with BCT guidelines.

INTERIM PROTECTION OF CONSERVATION LAND

The Plan includes a commitment to minimise impacts to biodiversity values on land within SCAs prior to securing land for conservation (Commitment 14). Several actions will be implemented as part of this commitment, including implementing planning controls and preparing a Ministerial Direction to strengthen consideration of biodiversity impacts when planning authorities consider development applications and rezoning applications in these areas.

Planning controls will be applied across the SCAs except for land owned by Local Aboriginal Land Councils (LALCs) or under claim by LALCs. Deerubbin owned land has been excluded from the SCAs at their request. Other LALC owned land and land under claim represents 1,700 ha of the 28,300 ha in the SCAs.

8.3.4 MANAGING LANDSCAPE THREATS

The Plan includes a range of commitments to manage threats to biodiversity in strategic locations in the Cumberland subregion to reduce threats to land secured within SCAs, including:

- Deliver weed and pest control programs (Commitment 16 and Commitment 17) to manage weeds and pests in strategic locations in the Cumberland subregion to reduce threats to conservation lands under the Plan
- Support disease control programs (Commitment 19) to better manage disease affecting fauna within the Cumberland subregion
- Fire management in strategic locations (Commitment 18) to support the maintenance of biodiversity values in conservation lands under the Plan
- Funding for research on biodiversity and climate adaptation in the Cumberland subregion

Actions under these commitments include to:

- Establish working groups for weeds and pest animals to advise on threat management
- Develop more detailed implementation strategies for weeds and pests and in consultation with the working groups and other key stakeholders, including delivery partners, to set out:
  - Priorities for management of the threat
  - Guidance on management approaches
  - Any research needs
  - Delivery arrangements, including the provision of funding under the Plan

The Plan identifies a range of delivery partners to support implementation of these commitments and actions.

8.3.5 BUILDING KNOWLEDGE AND CAPACITY

The Plan includes a range of commitments and actions to build capacity and support stakeholders in relation to biodiversity conservation in the Cumberland subregion, including:

- Providing opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation, including Koala conservation (Commitment 21)
- Providing opportunities for Aboriginal communities in Western Sydney to participate in biodiversity conservation and related economic opportunities arising from the Plan (Commitment 22)
- Providing extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land (Commitment 23)

- Investing in research that will help to secure threatened species and increase understanding of threats and land management issues (Commitment 24)
- Supporting rehabilitation measures to help maintain Koala health and welfare (Commitment 25)

The Plan identifies a range of delivery partners to support implementation of these commitments and actions.

8.4 KOALA CONSERVATION PROGRAM

The Koala is one of Australia's most iconic species and the Plan includes a specific set of commitments and actions to ensure the long-term protection of Koala in the Cumberland subregion.

The key commitment for Koala is to establish a reserve to secure a Koala movement corridor along the Georges River (Commitment 10) between Appin and Kentlyn. Key actions associated with this commitment include to:

- Protect up to 700 hectares of land between Appin and Kentlyn that is currently in ownership of NSW Government as the first stage in establishing the Georges River Koala Reserve
- Protect an additional 430 hectares of land between Appin and Kentlyn through the acquisition of land for the Georges River Koala Reserve
- Protect up to 755 hectares of land between Kentlyn and Long Point as future additions to the Georges River Koala reserve
- Restore up to 200 hectares of cleared land within the Georges River Koala reserve to strengthen the north-south Koala movement corridor

The Plan also includes a commitment relating to supporting habitat connectivity for TECs and species, including Koala (Commitment 12). Actions under this commitment relevant to Koala include:

- Protecting avoided Koala habitat through environmental conservation zoning in potential east-west Koala movement corridors between the Georges River and the Nepean River
- Through restoration, ensuring at least one north-south corridor (the Georges River Koala Reserve) and one east-west corridor are each at least 390m wide, for Koala viability and movement
- Facilitating Koala movement for at least one east-west corridor by constructing a Koala crossing at Appin Road
- Constructing a Koala passage under Kings Fall Bridge to support north-south Koala movement from the Georges River Koala Reserve to the southern Koala habitat

The Plan also includes commitments or actions to:

- Mitigate indirect and prescribed impacts from the development on the Southern Sydney Koala population to best practice standards and in line with the Chief Scientist Koala Report (Commitment 7)
- Investing in the NSW Koala Strategy (OEH, 2018) (under Commitments 21 and 25) to:
  - To implement the Koala health and welfare program in South Western Sydney
  - Raise awareness of the Southern Sydney Koala population

Koala movement corridors are shown in Figure 8-3.

Further details on the Koala conservation program are provided in Sub-Plan B.

8.5 DEVELOPMENT OF THE CONSERVATION PROGRAM

The conservation program was informed by two key processes to identify priority areas for conservation and establish offset targets that will adequately offset the impacts of the development on biodiversity values.

- A method to identify SCAs (called the Conservation Priorities Method)
- Establishment of offset targets

8.5.1 CONSERVATION PRIORITIES METHOD

The SCAs were identified through a Conservation Priorities Method. The method combines detailed spatial information about biodiversity values with an analysis of constraints and opportunities to identify an optimal mix of potential conservation sites to offset the impacts of the development on biodiversity values.

The method builds on the significant amount of strategic conservation planning that has occurred in the Cumberland subregion over the last decade, including the Cumberland Plain Recovery Plan (DECCW, 2011) and Biodiversity Investment Opportunities Map (OEH, 2015).

The method is summarised in Box 2 (taken from Sub-Plan A).

Box 2: Summary of Conservation Priorities Method

The Method uses multi-criteria analysis to achieve a ranking of conservation priorities, using three stages:

Stage 1 – Ecological assessment

The first stage identifies the areas of highest biodiversity value based on an ecological assessment of remaining vegetation patches and their proximity to key features and applying a set of criteria that would either constrain or permit that area to be used as an offset

Thresholds for the minimum area of offset required for each target Plant Community Type (PCT) were identified based on impact, predicted offset required and the amount of each PCT remaining in the landscape after the application of phase '0' constraints

Offset requirements were determined by applying a matrix that applies an offset ratio to all impacted entities based on their conservation status and condition. In accordance with the matrix, the offset ratio increases both as conservation significance increases and as the condition of vegetation improves

Phase 2 – Constraints Assessment

The remaining vegetation and species habitat available for potential offset is assessed for further constraints that could challenge the implementation of commitments

Stage 3 - Conservation priorities assessment & offset selection method

The final stage identifies suitable conservation areas based on Stages 1 and 2 using vegetation and species offset selection methods (noting that the selection of suitable offset areas is done from the ground up', i.e. from PCT and threatened species habitat to the landscape scale)

The SCAs will be updated over the life of the Plan using up to date information on biodiversity values, constraints and opportunities. A program of ground-truthing will be undertaken to confirm the biodiversity values of the SCAs consisting of desktop and aerial assessment (using satellite imagery) and on-ground surveys.

The Conservation Priorities Method will be reviewed in line with the Plan's 5-yearly review process.

8.5.2 DEVELOPMENT OF OFFSET TARGETS

The conservation program includes commitments to secure 5,475 ha of native vegetation in conservation lands. As part of this commitment, the Plan establishes offset targets for specific biodiversity values to ensure that the commitment addresses the biodiversity values being impacted. Offset targets have been developed for:

- Each impacted Commonwealth-listed TEC
- Each impacted NSW-listed TEC
- Commonwealth and NSW-listed species likely to be at risk of residual adverse direct impacts

An analysis of how the conservation program and offset targets meets the principles of the EPBC offsets policy (DSEWPC, 2012) is provided in Part 7.

Threatened ecological community offset targets

The Department developed an approach for defining offset targets to ensure that the commitments address the biodiversity values being impacted. The offset target method determined offset targets on the basis of the amount (ha) of each impacted matter, the conservation status of the impacted matter and the condition of the impacted matter.

This approach is explained in detail in the Conservation Priorities Method that supports the Plan.

Table 8-1 identifies the offset targets for each impact TEC.

Table 8-1: Offset targets for threatened ecological communities

Matter	Offset target
Commonwealth-listed TECs	
Shale Sandstone Transition Forest	715 ha
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest	575 ha
Coastal floodplain eucalypt forest of eastern Australia (subject to listing)	575 ha
Cooks River Castlereagh Ironbark Forest	105 ha
Coastal Swamp Oak Forest	5 ha
NSW-listed TECs/PCTs	
Cumberland Plain Woodland	3,170 ha
Shale Sandstone Transition Forest	1,540 ha
River-flat Eucalypt Forest	450 ha
Shale Gravel Transition Forest	150 ha
Cooks River Castlereagh Ironbark Forest	110 ha
Swamp Oak Floodplain Forest	50 ha
Freshwater Wetlands on Coastal Floodplains	5 ha
Moist Shale Woodland	0.2 ha

Species offset targets

Species offset targets were developed for each Commonwealth and NSW-listed species likely to be at risk of residual adverse impacts from the direct impacts of development under the Plan.

The determination of what species need offsets was based on:

- Commonwealth-listed species – assessments of the level of risk of residual adverse impacts as a result of the direct impacts of development under the Plan undertaken for each species in Chapter 29 and 30
- NSW-listed species – a set of criteria that aims to address the risk of residual adverse direct impacts

This risk-based approach was undertaken because the spatial and temporal scale of the Plan means that there is an inherent level of uncertainty in the baseline data (both for species habitat and records). In particular, the potential habitat mapping for the majority of species is highly precautionary and does not necessarily indicate with great certainty if a species will occur in an area impacted by the development. It is critical therefore to understand the level of risk to each species rather than take a simplistic view of direct impacts to potential habitat as presented in the impact numbers.

The approach to determining risk for Commonwealth and NSW-listed species was different because of the different methods used to assess impacts on these species used in the Assessment Report.

Species offset targets for Commonwealth and NSW-listed species are identified in Table 8-2.

Table 8-2: Offset targets for species

Species	Cth status	NSW status	Offset target
Cynanchum elegans	E	E	2 offset locations
Dillwynia tenuifolia	-	V	3 offset locations
Epacris purpurascens var. *purpurascens*	-	V	1 offset location
Grevillea juniperina subsp. *juniperina*	-	V	3 offset locations
Hibbertia fumana	-	CE	1 offset location
Hibbertia puberula	-	E	1 offset location
Koala	V	V	610 ha of important habitat
Marsdenia viridiflora subsp. *viridiflora*	-	E	1 offset location
Meridolum corneovirens	-	E	3 offset locations
Persoonia nutans	E	E	2 offset locations
Pimelea spicata	E	E	3 offset locations
Pultenaea parviflora	V	E	2 offset locations
Pultenaea pedunculata	-	E	1 offset location
Southern Myotis	-	V	2 offset locations
Swift Parrot	CE	E	4,470 ha of potential foraging habitat

Commonwealth-listed species

The determination of what Commonwealth-listed species need offsets was based on assessments of the level of risk of residual adverse direct impacts undertaken for each species in Chapter 29 and 30. A detailed description of the risk framework applied to assess each Commonwealth-listed species is provided in Chapter 29 and 30.

Risk is generally considered to be the combination of the likelihood and consequence of an event occurring. In summary, the risk framework involved consideration of:

- Likelihood that a species will be directly impacted due to impacts to populations and/or potential habitat, taking into account records and potential habitat mapping, as well as level of confidence in these
- Consequence of the direct impacts, taking into account conservation status, SAII entities, endemicity, and thresholds that were specified for the amount of direct impact on populations and potential habitat due to the development

The risk framework also included an assessment of the likelihood and consequence of impacts due to fragmentation, as well as an amended approach to determining risk for wide-ranging fauna (such as Swift Parrot).

The species considered to require offsets were those with a high or medium risk of residual adverse impacts. These were:

- *Cynanchum elegans*
- Koala
- *Persoonia nutans*
- *Pimelea spicata*
- *Pultenaea parviflora*
- Swift Parrot

Offsets were not considered necessary for species which are considered to be at low or very low risk.

Species offset targets are specified under the Plan in terms of:

- Number of ‘offset locations’

- Hectares of foraging habitat for Swift Parrot
- Hectares of important habitat for Koala

An 'offset location' is a site where one or more populations and habitat of the species has been confirmed through surveys or an expert report as being present. Offset location sites may be reserves or BSA sites (see Section 8.3.3).

Specifying offset targets in terms of number of 'offset locations' rather than amounts of potential habitat was considered the most robust approach. This is because it ensures known habitat and populations will be secured and managed in perpetuity, rather than merely potential habitat with no certainty that the species will benefit from the offset.

For Swift Parrot, 'potential foraging habitat' was used as the offset target. This species is a species credit species for 'important habitat' under the BAM, however, only potential foraging habitat will be impacted by the development.

For Koala, 'important habitat' (defined as primary and secondary corridors – see Part 3) was used as the offset target as this has been mapped in the Plan Area and will be impacted by the development.

The method to determine the 'offset location' targets for each species was based on a combination of the identified level of risk of residual adverse direct impacts (high or medium) and conservation status. Consistent with the approach for determining offset targets for TECs, Swift Parrot, and Koala, species with a higher conservation status (as well as a higher risk of residual adverse direct impacts) required larger offset targets. This is shown in Table 8-3.

Table 8-3: Method to determine offset targets for species with offset locations targets

Risk of residual adverse direct impacts	Conservation status		
	V	E	CE
High	2 offset locations	3 offset locations	4 offset locations
Medium	1 offset locations	2 offset locations	3 offset locations

Offset targets for Swift Parrot and Koala were determined by applying an approach developed by the Department consistent with the approach for determining TEC targets. As for TECs, targets were determined on the basis of the amount (ha) of habitat of each matter impacted by the development, and were driven by two key principles:

- Impacts to higher conservation status matters require more offsets that lower status matters
- Impacts to higher condition habitat require more offsets than lower condition habitat

This approach is explained in detail in the Conservation Priorities Method that supports the Plan.

NSW-listed species

As the method to assess impacts to NSW-listed species is different to Commonwealth-listed species and does not involve an assessment of risk around residual direct impacts, NSW-listed species needing offset targets were considered to be candidate species credit species directly impacted by the development in relation to:

- Species populations, or
- Habitat for highly restricted species (endemic or largely endemic to the Cumberland Plain) that was considered likely to contain the species (records not present), based on advice of the ecological consultants, or
- Priority management sites for site-managed species under the SOS program

Consistent with the BAM, offsets for ecosystem credit species are addressed through NSW TEC/PCT offsets.

Note that where a NSW-listed species met these criteria but was assessed under the Commonwealth approach (as it was also a Commonwealth-listed species), the determination of whether the species needed an offset target, and the offset target required, was based on the approach to Commonwealth-listed species. For example, there are direct impacts to records of Green and Golden Bell Frog, Grey-headed Flying Fox, and *Grevillea parviflora* subsp. *parviflora*, however, these species were not determined to have a high or medium risk rating under the risk framework.

There were also direct impacts to habitat for Little Eagle and White-bellied Sea Eagle where prior records exist. These species are Serious and Irreversible Impact entities and have been assessed in detail in Chapter 25. Impacts to breeding habitat for these species was not considered to be significant and no specific offsets for these species were considered to be needed.

Table 8-4 identifies the NSW only-listed species (not Commonwealth-listed) that meet the above criteria.

Table 8-4: NSW only-listed species (not Commonwealth-listed) considered to need offset targets

Species	Status	Rationale
Dillwynia tenuifolia	V	Direct impacts to records
Epacris purpurascens var. *purpurascens*	V	Priority management site under the SOS program occurs within urban capable land in the southern part of Wilton
Grevillea juniperina subsp. *juniperina*	V	Direct impacts to records
Hibbertia fumana	CE	Direct impacts to habitat considered likely to contain the species (records not present), based on advice of the ecological consultants
Hibbertia puberula	E	Direct impacts to habitat considered likely to contain the species (records not present), based on advice of the ecological consultants
Marsdenia viridiflora subsp. *viridiflora*	E	Direct impacts to habitat considered likely to contain the species (records not present), based on advice of the ecological consultants
Meridolum corneovirens	E	Direct impacts to records
Pultenaea pedunculata	E	Direct impacts to records
Southern Myotis	V	Direct impacts to records

Because the potential habitat mapping for the majority of species is highly precautionary and is not an appropriate basis for determining offset targets, a method was developed to refine the habitat mapping for each species in Table 8-4. The purpose of this was to determine the area of habitat for each species where there is a higher level of certainty that impacts will occur to the species from the development under the Plan. This refined mapping was done using records and the native vegetation mapping prepared for this Assessment Report and by:

- Collating species records from the NSW BioNet and project surveys
- Identifying all vegetation zones that intersected with the collated species records or a 30 m buffer surrounding the records (the entire vegetation zone was selected where an intersect occurred)
- Combining the habitat model for the species with the vegetation zones selected above, leaving only areas common between the two data sets

Consistent with the approach for TECs, offset targets were derived based on the refined area of habitat for each species impacted by the development under the Plan and the conservation status of the species.

The number of offset locations was then calculated as follows:

- Area of refined habitat impacted of 0 – 50 ha – 1 offset location
- Area of refined habitat impacted of 50 – 100 ha – 2 offset locations
- Area of refined habitat impacted of 100 + ha – 3 offset locations

For the *Hibbertia* and *Epacris* species where no habitat areas containing prior records are impacted, a refined area of habitat was not able to be determined. The target for these species was determined to be one offset location on the basis that impacts are not certain and few populations of *Hibbertia* species are known to occur (particularly *Hibbertia fumana*).

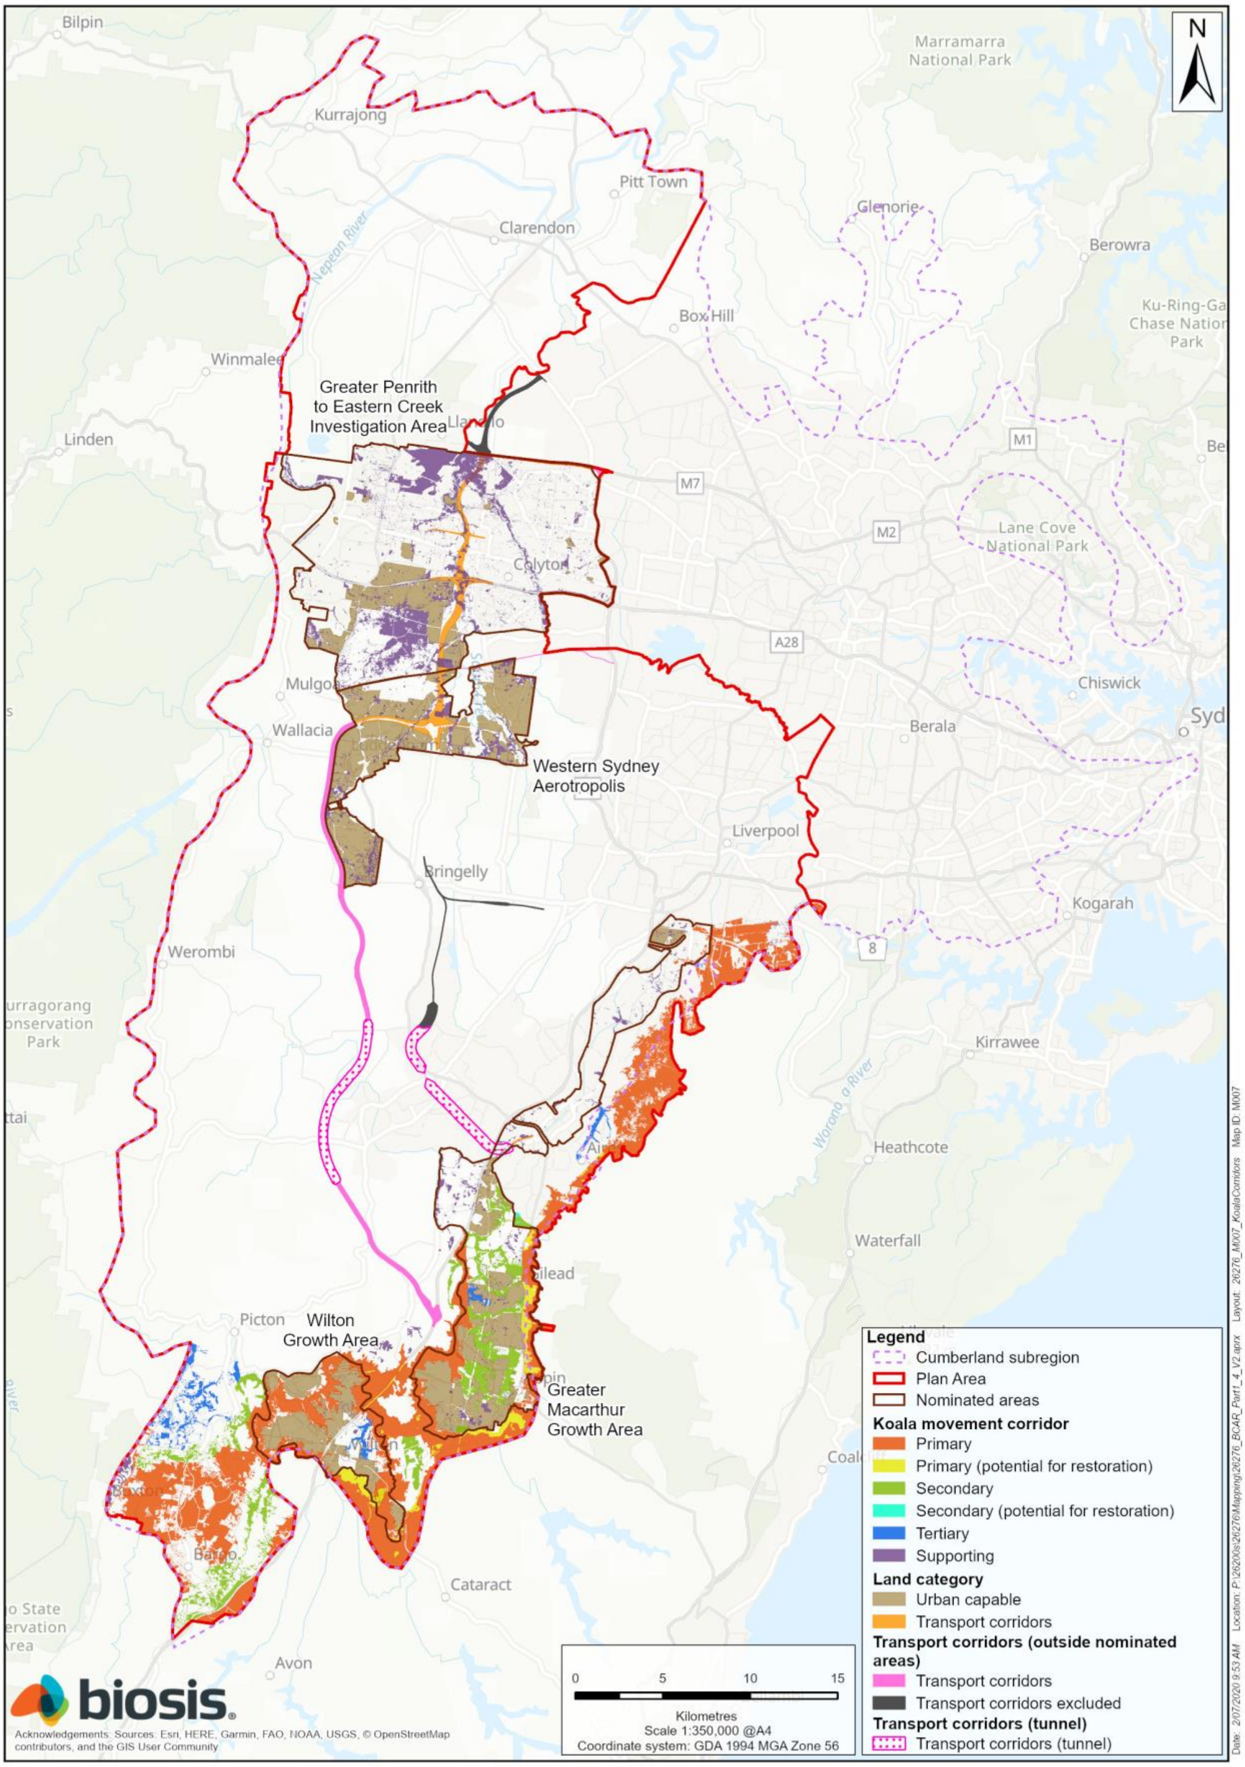

Figure 8-3: Key Koala movement corridors within the Plan Area

9 Implementation framework for the Plan

9.1 INTRODUCTION

The Plan includes an implementation framework to ensure successful delivery of the Plan and provide assurance to approval bodies that the Plan is being delivered in accordance with conditions of approval.

This Chapter describes the implementation framework for the Plan, including:

- Delivery mechanisms
- Roles and responsibilities
- Funding
- Monitoring, evaluation and reporting and adaptive management
- Compliance

This chapter provides an overview of each element of the implementation framework.

9.2 DELIVERY MECHANISMS

9.2.1 NSW PLANNING SYSTEM

Implementation of the Plan will be supported by the NSW planning system.

The Department has committed under the Plan to undertake urban and industrial, infrastructure, agribusiness and transport development in accordance with the Plan and any conditions of approval. Sub-Plan A includes an action to integrate the Plan into the planning delivery framework for the nominated areas through planning mechanisms including zoning, development controls, ministerial directions and development guidelines.

PROPOSED STATE ENVIRONMENTAL PLANNING POLICY

The Department is proposing a new State Environmental Planning Policy (SEPP) for strategic conservation planning to implement the Plan's strategic conservation planning requirements. The objectives of the proposed SEPP include to:

- Ensure development in the nominated areas is consistent with NSW Government and Australian Government biodiversity approvals
- Facilitate appropriate development on biodiversity certified areas
- Identify and protect areas of high value biodiversity in the nominated areas
- Identify areas across the Plan Area that have high-value biodiversity and/or strategic biodiversity values that can support the ecological function of the Cumberland subregion, including threatened ecological communities and species, and areas with important connectivity or ecological restoration potential
- Minimise impacts from future development on biodiversity values in areas of high-value biodiversity
- Support the acquisition of priority areas of high-value biodiversity in the Cumberland subregion as conservation lands in perpetuity
- Minimise impacts to biodiversity values on land secured for conservation from adjoining land uses

The proposed SEPP will include:

- Environmental conservation (E2) zoning that will be applied to areas that are identified in the Plan as non-certified because they are avoided for biodiversity purposes, or other purposes (riparian corridors, steep land). Note that avoided land will have environment (E2) conservation zoning applied except for land owned by LALCs or under claim by LALCs. LALC owned land and land under claim represents 90 ha of the 4,795 ha of avoided land[2]

- Planning controls for the SCAs to minimise impacts from development on areas of high biodiversity value, improve the management of biodiversity and help protect TECs and species in these areas. Note that planning controls will be applied across the SCAs except for land owned by LALCs or under claim by LALCs. Deerubbin owned land has been excluded from the SCAs at their request. Other LALC owned land and land under claim represents 1,700 ha of the 28,300 ha of the SCAs
- Consistency clause for urban development to ensure consistency between the urban capable land identified in precinct plans and areas of urban capable land identified by the Plan, to contain urban development to the urban capable lands and ensure avoided lands remain outside the development areas
- Acquisition clauses that allow the relevant acquisition authority to secure lands suitable for public reserves, such as national parks and council reserves

OTHER PARTS OF THE PLANNING SYSTEM

The other key parts of the planning system that will be used to implement the Plan are shown in Table 9-1.

Table 9-1: Key parts of the planning system and relationship with the Plan

Planning mechanism	Description and relationship to Plan
Strategic plans, such as Land Use and Infrastructure Implementation Plans (LUIIPs)	LUIIPs are high-level strategic plans that set the vision and strategic direction of each nominated area, consistent with the Greater Sydney Region Plan and District Plans LUIIPs will include the boundaries of urban capable lands identified for development through this Plan, and identify as potential environmental or conservation areas high biodiversity land avoided by the Plan
Precinct plans	Precinct plans identify land uses, development and infrastructure for each precinct and are prepared consistent with the relevant strategic plan/LUIIP Precinct Plans will be required to be consistent with the biodiversity approvals under the Plan, and specifically to identify the urban capable land as the certified land mapped by the Plan
Neighbourhood plans	Neighbourhood plans show the detailed structure of a future neighbourhood, including lot yields, residential densities, movement networks, open space, and environmentally sensitive land Neighbourhood plans must be generally consistent with a Precinct Plan and address the controls in the Development Control Plan, and are approved prior to the approval of Development Applications Neighbourhood plans include development requirements that apply at a neighbourhood level, and must include plans for: • Water management, including stormwater drainage and riparian corridors. • Open space, including retention of trees and native vegetation • Protection of environmentally sensitive areas

[2] The total area of avoided land at the start of the Plan is 4,795 hectares. The avoidance target of 4,315 hectares has reduced this figure by 10% to allow for potential future development of essential infrastructure in non-certified land

Planning mechanism	Description and relationship to Plan
Development Control Plans (DCPs)	DCPs include detailed planning and design requirements, objectives and additional development controls that apply at a neighbourhood and lot level to be considered by consent authorities in assessing and determining development applications A DCP is a planning policy that supplements development standards and provisions within environmental planning instruments. DCPs support the implementation of planning controls in the SEPP, Local Environmental Plans (LEPs), or precinct or neighbourhood plan DCPs may include planning principles, as well as objectives, requirements and development standards that address biodiversity and mitigate indirect and prescribed impacts
Development applications	Subdivision and development in the nominated areas will require development consent, as well as appropriate approvals covering any further environmental assessment required under other legislation (not biodiversity) Development applications in nominated areas will need to be consistent with the biodiversity approvals under the Plan, and will need to occur within the certified land mapped by the Plan
Environmental protection zoning	Environmental conservation (E2) zoning will be applied to areas that are identified in the Plan as non-certified because they are avoided for biodiversity purposes, or other purposes (riparian corridors, steep land) Note that avoided land will have environment (E2) conservation zoning applied except for land owned by LALCs or under claim by LALCs. LALC owned land and land under claim represents 90 ha of the 4,795 ha of avoided land
Ministerial Directions	The Department proposes to introduce a Ministerial Direction under section 9.1 of the EP&A Act. The direction will apply to avoided land and the SCAs as mapped in the proposed SEPP. It will restrict the ability to rezone avoided land, increase development or intensify land uses in the SCAs, and require a relevant planning authority to ensure any planning proposals consider the land use objectives that apply to avoided land and, for the SCAs, the matters for consideration in the planning controls that apply to the area Note that planning controls will be applied across the SCAs except for land owned by LALCs or under claim by LALCs. Deerubbin owned land has been excluded from the SCAs at their request. Other LALC owned land and land under claim represents 1,700 ha of the 28,300 ha of the SCAs

9.2.2 IMPLEMENTATION DOCUMENTS

The Plan includes several actions that provide for the preparation of detailed implementation documents that will support the implementation of the Plan. Key implementation documents include:

- Conservation Lands Implementation Strategy to guide the securing of land for conservation (see Chapter 8)
- Restoration Implementation Strategy (see Chapter 8)
- Weed and pest animal control implementation strategies to guide delivery of the weed and pest programs
- Reconciliation accounting process to track progress in meeting offset targets
- Written agreements with delivery partners to set out delivery arrangements
- Compliance strategy

9.3 ROLES AND RESPONSIBILITIES

The Department is the responsible agency for implementing the Plan and meeting regulatory requirements as the party to strategic biodiversity certification under section 8.9 of the BC Act, and is the approval holder under section 146B of the

EPBC Act. The NSW Minister for Planning is the applicant for strategic biodiversity certification and strategic assessment approval. The transport corridors program is administered by Transport for NSW.

The governance framework for the Plan is shown in Figure 9-1.

Roles and responsibilities for implementing the Plan fall under the following categories:

- Oversight bodies
- Co-ordinating bodies
- Delivery partners
- Agency partners

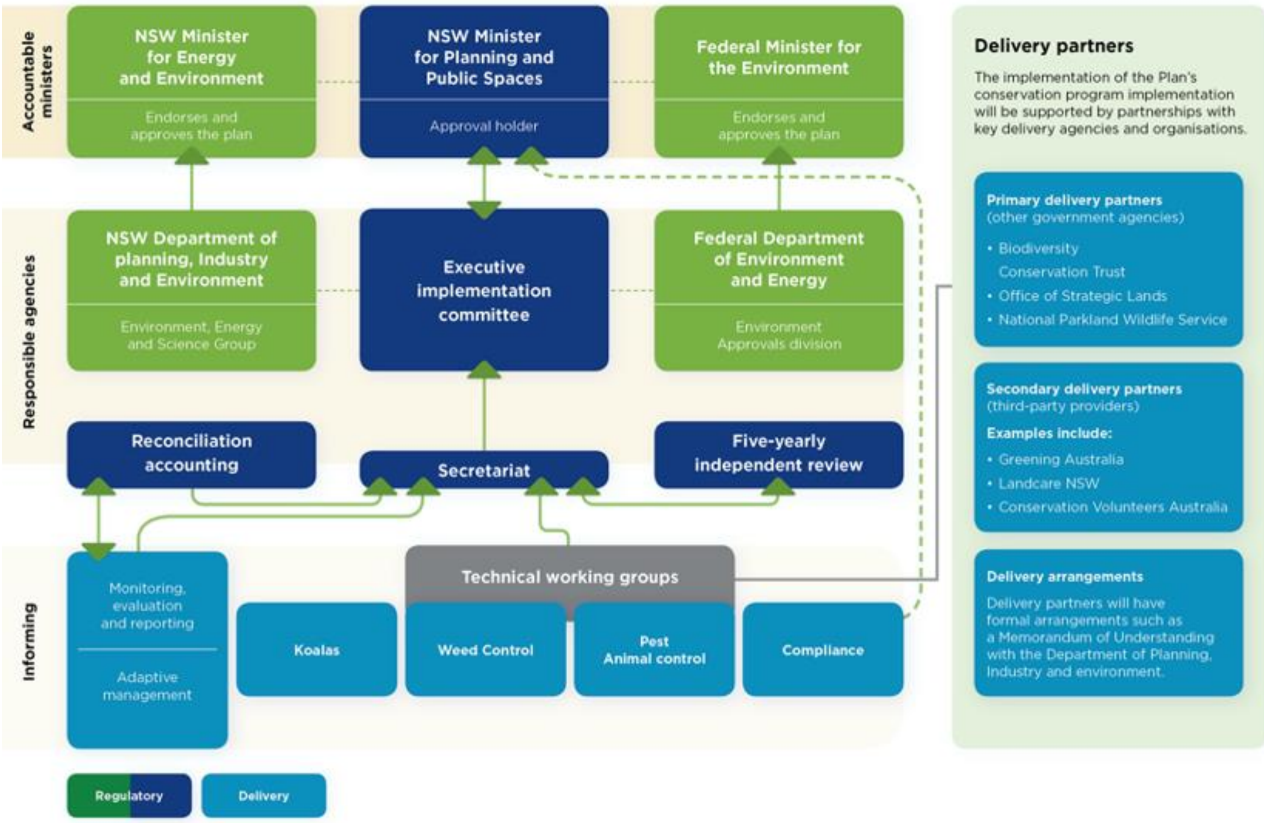

Figure 9-1: Governance framework for the Plan

9.3.1 OVERSIGHT BODIES

An executive implementation committee will be established under the Plan that includes executive level representatives from the Department, approval bodies and partner agencies to act as a steering committee for the Plan.

The executive committee will be the key decision-making authority to determine the appropriate course of action on matters raised, or whether issues need to be escalated for ministerial attention.

9.3.2 CO-ORDINATING BODIES

The Department is the responsible agency for implementing the Plan and meeting regulatory requirements as the party to strategic biodiversity certification under the BC Act, and is the approval holder under the EPBC Act.

The Department's roles will include:

- Reporting to the Minister and preparing progress reports on the implementation and performance of the Plan

- Central coordination of the Plan, through:
  - Steering committees and associated sub-groups and committees
  - Coordinating delivery partners including setting delivery/reporting requirements
  - Contract/grant management
  - Ensuring reports from delivery partners/other relevant agencies feed into Plan's reporting framework
- Overseeing compliance with the Plan

9.3.3 DELIVERY PARTNERS

A range of delivery partners will be responsible for delivering programs under the Plan, including:

- NSW Government bodies, such as:
  - Office of Strategic Lands – key responsibilities include acquisition of reserves under the reserve program
  - National Parks and Wildlife Service – key responsibilities include long-term management of reserves established under the *National Parks and Wildlife Act 1974*
  - Biodiversity Conservation Trust – key responsibilities include delivering the BSA program
- Councils – key responsibilities include administering planning controls and management of council reserves
- Community organisations – key responsibilities include management of smaller community reserves

Service level agreements or memorandums of understanding will be prepared as part of the process of engaging delivery partners to clarify the roles and responsibilities of each delivery partner and to ensure accountability.

9.3.4 AGENCY PARTNERS

Agency partners are involved with planning, delivery and oversight of transport infrastructure, in addition to avoiding, mitigating and offsetting transport environmental impacts. The key agency partner is Transport for NSW.

9.4 FUNDING

The NSW Government will establish a conservation fund to implement the conservation program under the Plan, including the securing of reserves and BSA sites for conservation in perpetuity.

The final Plan will include a commitment for upfront funding to deliver conservation priorities in the first five years of the Plan, including the three new priority reserves (see Chapter 8).

Funding is proposed to be secured using a public-private funding model. The model involves upfront investment from the government and partial cost-recovery from industry through the biodiversity component of a Special Infrastructure Contribution (SIC) levy imposed on housing development in the nominated areas.

Cost recovery from industry will ensure developers contribute to the cost of infrastructure, including the offsetting of biodiversity impacts. Developer contributions will increase annually in line with the medium-term average of the Producer Price Index to ensure industry contributions broadly align with the costs of production.

To establish the funding arrangements, the NSW Government will:

- Establish a biodiversity component of the SIC levy to be applied to developers within the nominated areas
- Establish a Trust to administer funds on behalf of the Department
- Prepare a funding framework in consultation with the Trust to set out details of the cost recovery model and how funding decisions will be made and administered

9.5 MONITORING, EVALUATION, REPORTING AND ADAPTIVE MANAGEMENT

The Plan commits to implementing a monitoring, evaluation and reporting (MER) program over the life of the Plan. Details of the MER framework are provided in Sub-Plan A. The MER framework provides for:

- Monitoring of the delivery of actions and commitments and achievement of outcomes
- Evaluation of the Plan to inform adaptive management responses

- Public reporting on progress in delivering the Plan

The MER framework has been developed on the basis of the program logic underpinning the Plan (see Chapter 5). The key elements of the MER framework are outlined in Figure 9-2.

An MER plan will be prepared during implementation to support the MER framework, including to:

- Identify key performance indicators for biodiversity conservation and report on actions and commitments
- Set out monitoring and data collection procedures
- Identify the scope and frequency of evaluations and key evaluation questions
- Describe how monitoring and evaluation will be used to adaptively manage implementation of the Plan, including defining the scope of potential changes

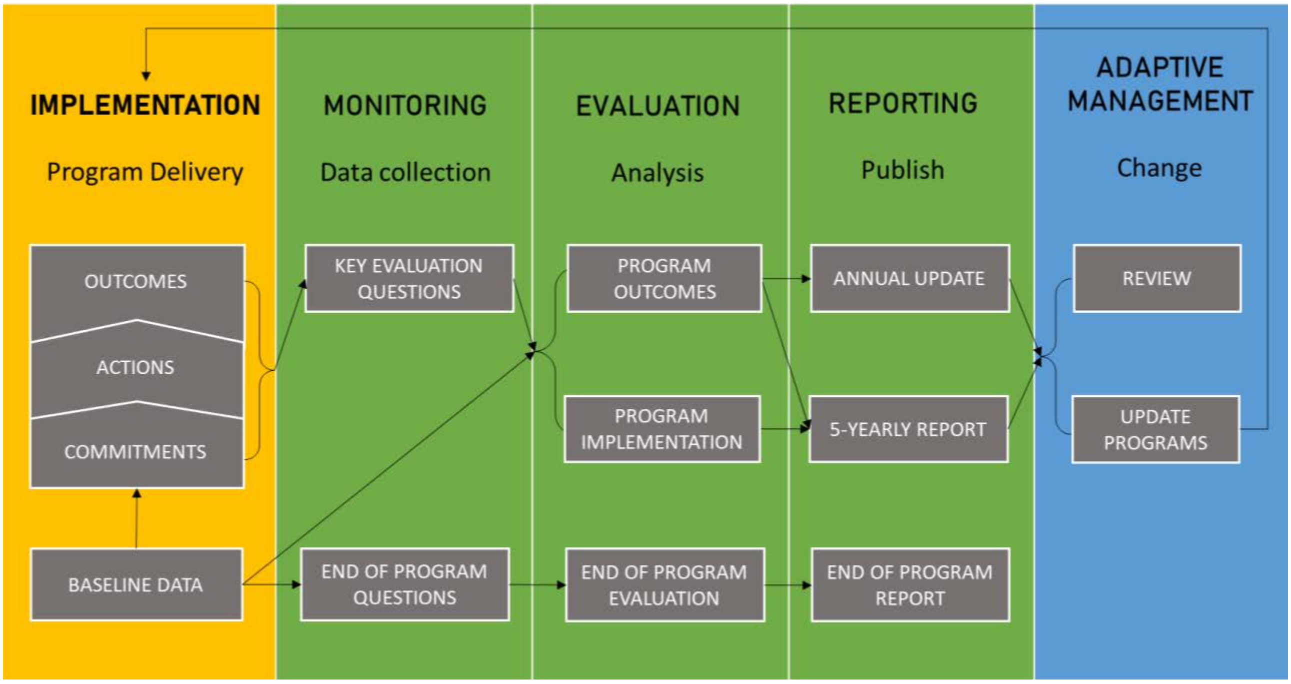

Figure 9-2: Key elements of the MER framework

MONITORING

Monitoring will be designed to inform the evaluations and Key Evaluation Questions and will include:

- Monitoring of the delivery of commitments and actions
- Monitoring of the achievement of the Plan's outcomes

The Department will establish a process to identify what monitoring data is already collected and what further data needs to be collected to establish baselines and support monitoring needs.

Formal agreements will be established with delivery partners and include detailed data collection, management and sharing arrangements and reporting templates. This will streamline data collation and reporting processes for the Plan and feed directly into the adaptive management process.

EVALUATION

Evaluations will be undertaken regularly throughout the implementation of the Plan.

The evaluations will aim to:

- Determine the effectiveness of actions, targets and commitments to deliver outcomes

- Reconsider assumptions made as part of the program logic
- Determine the influence of external factors outside the control of the Plan
- Inform any necessary adaptive management decisions to the implementation of the Plan

Two types of evaluations will be done:

- Evaluation of deliverables – this will evaluate the delivery of commitments and actions
- Evaluation of program – this will evaluate the efficiency and effectiveness of delivery and achieving the outcomes of the Plan, including evaluation of the Plan's success in terms of impact, appropriateness of design and logic, resource efficiency and any external factors that may have contributed to results

The evaluations will be done on the basis of Key Evaluation Questions. The evaluation questions will be designed to measure the Plan's progress and the effectiveness of delivering its commitments and outcomes by asking questions that will reveal the cause of any shortfall or prompt adaptive management for a more effective result.

PUBLIC REPORTING

The Department will prepare an annual update on the delivery of the Plan's commitments and actions. The annual updates will include information from the Key Evaluation Questions and include reporting on program revenue and expenditure. The NSW Government will also collate finer scale program and project reporting from the relevant delivery partners more frequently to support adaptive management over the life of the Plan.

The Department will prepare a fire-yearly report on the status of the Plan, its delivery and interim outcomes. The report will be approved by the NSW Minister for Planning and provided to the NSW and Australian Government Environment Ministers.

The annual update and the five-yearly report as well as other relevant data and information will be made publicly available via the Department's website and published in accordance with the NSW Government's accessibility requirements. They will remain available throughout the life of the Plan.

ADAPTIVE MANAGEMENT

The Plan will be implemented adaptively to ensure the commitments and actions are delivered and the outcomes are achieved efficiently and effectively. Adaptive management will be triggered on the basis of the findings of the evaluations and will be informed by the monitoring data collected as part of the MER framework.

The approach to adaptive management under the Plan is further described in Chapter 16.

9.6 COMPLIANCE

The Plan will be implemented under several existing mechanisms, particularly the NSW planning system.

As the primary mechanism to implement the Plan is the NSW planning system, most mechanisms that will be used to ensure compliance with the Plan and conditions of approval sit under the planning system.

A compliance strategy will be prepared under the Plan to ensure that the development occurs in accordance with the Plan and conditions of approval. The development of the compliance strategy will be informed by a compliance task force that will be established early during Plan implementation. The compliance strategy will:

- Identify relevant compliance mechanisms
- Set out compliance monitoring and auditing priorities and processes
- Set out a framework to make decisions on appropriate actions for non-compliance
- Set out procedures and protocols for taking compliance action
- Identify roles and responsibilities for compliance monitoring and action

The Plan will provide funding for at least three Council-based surveillance officers to ensure compliance with the Plan.

Part 3 Contents

Part 3 List of Tables

This Part sets out the approach and methods used to prepare the Assessment Report:

- Chapter 10: Provides an overview of the assessment approach
- Chapter 11: Describes the approach and methods for understanding the biodiversity values and other matters that require assessment within the Plan Area
- Chapter 12: Describes the approach to analysing the impacts of the development under the Plan
- Chapter 13: Provides an overview of the data used in the Assessment Report and the limitations with the data

10 Overview

This Chapter sets out:

- Overview of the scope of the assessment
- Summary of the Biodiversity Assessment Method (BAM) that applies to the Biodiversity Certification Assessment Report (BCAR) and the Terms of Reference that applies to the Strategic Assessment Report (SAR)
- Discussion of the key steps in the assessment process
- Overview of the peer review processes for key methods

10.1 SCOPE

The scope of the assessments under the BC Act and EPBC Act are different (see Part 1). This relates to both:

- The development that is being assessed for approval
- The impact assessment requirements under each piece of legislation

The assessment approach was designed to meet the requirements of the assessment processes under both the BC Act and EPBC Act (see Table 10-1), as well as address the various overlaps and differences.

Table 10-1: Impact assessment requirements of the BC Act and the EPBC Act*

Legislation	Impact assessment requirements	Comments
BC Act	Relevant provisions of the legislation and regulations	The Cumberland Plain Conservation Plan (the Plan) is being assessed as a strategic application for biodiversity certification under Part 8 of the BC Act. The relevant regulatory provisions need to be met
	BAM	The BAM specifies the requirements for the BCAR
	Draft guidelines for planning authorities for proposing conservation measures in strategic applications for biodiversity certification (Draft Version 6)(EES, 2019)	The EES Guidelines "*provide guiding principles for demonstrating that the conservation measures proposed for a strategic application for biodiversity certification adequately address impacts on biodiversity values under section 8.7 of the BC Act*". The Guidelines need to be addressed
EPBC Act	Relevant provisions of the legislation and regulations	The Plan is undergoing strategic assessment under Part 10 of the EPBC Act. The relevant regulatory provisions need to be addressed
	Terms of Reference (ToR) for the SAR	The ToR specify the requirements for the SAR
	Relevant statutory documents	The EPBC Act requires that certain statutory documents be considered in the impact assessment process. For example, these include recovery plans, threat abatement plans, and conservation advices
	EPBC Act policies and guidelines	The Australian Government has published a range of EPBC Act policies and guidelines which need to be considered in the impact assessment process

*See Part 1 for detail on the regulatory context of this project

10.2 BIODIVERSITY ASSESSMENT METHOD

The BAM was established under the BC Act to assess impacts on NSW listed threatened species and ecological communities and their habitats. As outlined on the Environment Energy and Science (EES) website:

> "[The BAM] *is a scientific document that provides:*
>
> - *a consistent method for the assessment of biodiversity on a proposed development or major project, or clearing site,*
> - *guidance on how a proponent can avoid and minimise potential biodiversity impacts, and*
> - *the number and class of biodiversity credits that need to be offset to achieve a standard of 'no net loss' of biodiversity."*

The BAM specifies the assessment requirements for the BCAR and was applied within the nominated areas.

The BAM also provides a strong starting point for meeting the EPBC Act ToR. For example, the detailed requirements around data gathering within the nominated areas are also largely appropriate for protected matters.

The BAM is structured around three stages:

- **Stage 1 – Biodiversity assessment**. This stage establishes a consistent approach to identifying and assessing the biodiversity values on land (including the land to be biodiversity certified). It sets out the data gathering requirements for the landscape context, native vegetation, and threatened species
- **Stage 2 – Impact assessment**. This stage provides the method for assessing impacts to biodiversity values. It specifies requirements around:
  - Avoiding and minimising impacts
  - Assessing both direct and indirect impacts
  - Dealing with issues such as prescribed impacts, and serious and irreversible impacts
  - Determining the credits required for meeting the no net loss standard
- **Stage 3 – Improving biodiversity values**. This stage is used to determine the credits that can be created at stewardship sites. This stage does not need to be applied at the time of application for strategic biodiversity certification and has therefore not been applied in this Assessment Report (see Chapter 2)

The outputs of the BAM for this project need to be presented in a BCAR. The components of this Assessment Report that comprise the BCAR are set out in Part 1.

10.3 EPBC ACT TERMS OF REFERENCE

The ToR for the SAR are part of the Strategic Assessment Agreement between the NSW Government and Australian Government. The ToR set out the information requirements that this Assessment Report needs to address for matters protected under the EPBC Act.

Clause 4.2 of the ToR outlines how the Assessment Report should describe the methods used in the assessment:

> *"The Report must describe the method used to understand likely impacts on all protected matters of actions taken under the Plan. The level of the assessment will be proportionate to the level of likely risk to each protected matter. The method must:*
>
> 1. *Be appropriate for assessment at a strategic scale*
> 2. *Rely on the best available information*
> 3. *Discuss uncertainty, including reference to the technical data and information relied upon*
>
> *The Report must identify the data used in the assessment, any limitations it may have, where (or if) the data is available and where it can be accessed, including publicly accessed."*

The ToR specifies the assessment requirements for the SAR and was applied within the Plan Area. The ToR are provided in Supporting Document A.

10.4 PEER REVIEW OF KEY METHODS

Section 4.8 of the ToR for the SAR specifies:

> *"The Report must include justification for key methods used in the assessment, including summaries of independent peer review processes and where the review/s are available to the public."*

The term 'key methods' refers to technical methods for describing the protected matters impacted by the Plan, such as methods used to collect data on protected matters and map the location of protected matters.

The term does not include approaches to understand the likely impacts on protected matters of actions taken under the Plan, such as the approach to assessing direct, indirect and cumulative impacts.

In accordance with section 4.2 of the ToR, the SAR has described these impact assessment approaches in detail and any uncertainties or limitations with them (see Chapter 12 and Chapter 13).

The NSW Department of Planning, Industry, and Environment (the Department) commissioned an independent peer reviewer, Dr Rhidian Harrington, from Niche Environment and Heritage, to review the key methods. The key methods reviewed were:

- The approach to determining the relevant EPBC matters for assessment (see Section 11.1.2)
- The methodology for mapping EPBC listed TECs (see Section 11.4.3)
- The method for identifying important populations of flora and fauna (see Section 11.5.3)
- The approach and criteria for mapping habitat across the Cumberland subregion for approximately 30 threatened species using an expert knowledge-based process (see Section 11.5)
- An evaluation method for determining the viability of the Southern Sydney koala population (see Chapter 30)

The peer review process involved:

- Initial review of key methods by peer-reviewer
- One day workshop with ecological consulting team, technical staff from the Department and peer reviewer to discuss key methods
- Preparation of report that:
  - Sets out the context of the peer review (including expertise of the peer reviewer)
  - Analyses each method against the following questions:
    - Is the general approach to the method appropriate?
    - Are the details of the method appropriate?
    - Are there critical components of the method that need improvement?

The peer review report is provided in Supporting Document B.

The peer review report concluded that in general:

- The datasets, methods for data collection and assumptions associated with the methods are appropriate for a large-scale strategic assessment process such as this project
- The methods used are generally conservative and are unlikely to under-represent the presence or distribution of any TEC or species, and are more likely to over-predict presence and distributions

The report recommended that further details associated with the input data and assumptions be provided in the Assessment Report to provide the regulators and the public more complete understanding of limitations.

The limitations associated with the methods are set out in Chapter 13.

Several other methods were used to prepare the SAR. These methods and a rationale for not undertaking a peer review of them is provided in Table 10-2.

Table 10-2: Rationale for not undertaking peer review of other methods

Method	Rationale
Data collection and surveys for EPBC listed TECs and species	Data collection within the nominated areas was undertaken in accordance with the BAM. The BAM was independently peer reviewed in 2015. The previous formalised biodiversity assessment method – the BioBanking Assessment Method – was also independently reviewed
Species Distribution Modelling for Commonwealth-listed species mapping	The Species Distribution Modelling work was undertaken by a Senior Research Fellow at RMIT University. The modelling process is a well-recognised and peer reviewed method for mapping species habitat at a landscape scale. References to published literature establishing the validity of the method are provided in the Species Distribution Modelling Report (see Supporting Document F) Species experts at EES reviewed several example outputs of the model and provided input into the modelling method
Migratory shorebird mapping	Mapping was undertaken in accordance with EPBC Policy Statement 3.21 (DEWHA, 2009b)
Trend analysis	The trend analysis was undertaken by a Senior Research Fellow at RMIT University. The work involved an expert elicitation process involving eight people considered to be experts on the native vegetation of the Cumberland subregion, including representation from academia. As part of this process, several experts reviewed or provided input into the trend analysis method

11 Approach to understanding biodiversity values

This Chapter describes the approach and methods for understanding the biodiversity values and other matters that require assessment within the Plan Area. It includes information about:

- The approach to identifying NSW and Commonwealth matters needing assessment
- The approach to understanding the landscape context
- The surveying and mapping methods for native vegetation communities
- The mapping methods for threatened ecological communities (TECs)
- The surveying and mapping methods for threatened species and their habitats
- The approach to understanding the other matters protected by the EPBC Act

It should be noted that an initial assessment of the implications of the 2019/2020 NSW bushfires on species impacted by the Plan was also undertaken based on available information. This assessment is set out in Part 1 and Supporting Document G.

11.1 IDENTIFICATION OF MATTERS FOR ASSESSMENT

The BAM and ToR require the Assessment Report to identify the NSW and Commonwealth matters that may occur in the Plan Area and that may be impacted by the development.

Section 6.4 of the BAM provides a process to predict all NSW-listed species that may occur in the nominated areas and consider whether any of these species can be excluded from the assessment based on likelihood of occurrence.

The ToR requires all Commonwealth matters relevant to the Strategic Assessment Area to be identified. Clause 4.2 provides that the level of assessment be proportionate to the level of likely risk of impacts to each matter.

Separate processes were undertaken to identify the NSW and Commonwealth matters needing assessment.

11.1.1 NSW MATTERS NEEDING ASSESSMENT UNDER THE BCAR

PURPOSE

Section 6.4 of the BAM requires several steps be applied to determine the NSW-listed threatened species that require assessment under the BCAR. This process was applied to the nominated areas.

The BAM categorises species into two groups:

- Ecosystem credit species (ECS) – these species can be reasonably predicted to occur at a location based on habitat type and condition
- Species credit species (SCS) – these species cannot be reasonably predicted to occur at a location based on habitat

In some cases, SCS can be both listed as an ECS as well as a SCS, based on species life cycle and breeding requirements.

The process for determining what species require assessment is different for ecosystem and species credit species.

METHOD

NSW-listed species

Relevant NSW-listed species were identified by:

Step 1: Identification of an initial list of species using the BAM credit calculator in accordance with Step 1, Section 6.4 of the BAM. The calculator uses data contained in the NSW Threatened Biodiversity Data Collection and on Plant Community Types (PCTs) in the nominated areas to predict the initial list of species on the basis of the following:

- Distribution of the species includes relevant subregion where the nominated areas are mostly located
- Nominated areas are within any geographic constraints of the distribution of the species within the subregion

- Species associated with any of the PCTs identified as occurring within the nominated areas
- Native vegetation cover within an assessment area including a 1,500 m wide buffer surrounding the boundary of the nominated areas is equal to or greater than the minimum native vegetation cover required for the species
- Patch size of which the vegetation zone is part is equal to or greater than minimum value specified for the species

Step 1 was completed separately for each nominated area.

ECS identified in Step 1 were identified for assessment in the BCAR based on the associated PCTs. SCS identified in Step 1 were considered further under Step 2.

Step 2: A SCS may be excluded from needing further assessment because:

- Ecological information about a species provided in BioNet or published, peer reviewed literature, suggests that the SCS is unlikely to occur, or habitat is unlikely to be suitable (BAM section 6.1.1.2)
- Habitat constraints (defined in Threatened Biodiversity Data Collection) are not present (BAM section 6.4, step 2)
- Habitat is not suitable because it is substantially degraded (BAM section 6.4, step 3)
- An expert report determines that habitat for the species is unlikely to be present (BAM section 6.4, step 3)

Step 2 involved a series of workshops with accredited assessors and ecologists from Biosis and Ecoplanning to consider each SCS identified in Step 1. The workshops involved:

- Consolidating information on habitat types present within the urban capable land for each nominated area based on field surveys and the most up to date native vegetation mapping
- Reviewing each species' habitat preferences, and known distributions based on BioNet and published peer reviewed literature, including habitat constraints identified in the NSW Threatened Biodiversity Data Collection
- Interrogation of records data, including BioNet records
- Application of knowledge and expertise of accredied assessors and ecologists who had surveyed the nominated areas, as well as ecologists with detailed knowledge of the flora and fauna of Cumberland subregion
- Determining whether any species is likely to occur outside the urban capable lands of the nominated areas and would not be impacted by clearing of native vegetation or habitat
- Determining which species should be subject to an expert report

SCS considered likely to have suitable habitat in the nominated areas after Step 2 and requiring assessment under the BCAR are called 'candidate SCS'. Step 4, Section 6.4 of the BAM requires the accredited assessor to determine whether each candidate SCS is present or is likely to use suitable habitat on the basis of:

- Undertaking threatened species surveys
- Assuming the species is present
- Obtaining an expert report

Attachment A provides a justification for each SCS removed from needing further assessment and identifies the relevant section of the BAM under which a SCS was removed.

The removal of SCS from needing further assessment was based primarily on distribution (the natural distribution of the species is not within the assessment area, or a species' distribution is restricted and it would not occur within one or more of the nominated areas) (see Attachment A). This is consistent within section 6.1.1.2 of the BAM, which states that 'an assessor may use additional information about a threatened species, in BioNet (e.g. the profile of a threatened species) or published, peer reviewed literature, when assessing the habitat suitability of a site'.

Several SCS were dismissed based on a lack of suitable habitat within the nominated areas. Where this has occurred, reference is made to published sources. A small number of SCS have been dismissed due to a lack of known records over the past 30 - 50 years within the nominated areas. It can reasonably be expected that the presence of these species would have been recorded across this well surveyed part of NSW if the species was still present.

A total of 84 SCS were predicted to occur within the nominated areas. Of these, 40 SCS were determined to be candidate SCS needing further assessment, and 44 were removed.

The methods used to determine the presence of each candidate SCS are described in section 11.5.

Justification for excluding koala in GPEC and WSA

Koala was excluded as a candidate SCS in Greater Penrith to Eastern Creek Investigation Area (GPEC) and Western Sydney Aerotropolis (WSA) (see Attachment A). This was determined on the basis of:

- Habitat mapping
- Consideration of threatening processes
- Consideration of distribution of koala records

Habitat mapping within GPEC and WSA: While koala was excluded as a candidate species in GPEC and WSA, mapping was undertaken for koala within these nominated areas. This mapping informed the decision to exclude koala as a candidate species from these areas. Three methods of mapping were conducted to determine the availability and importance of koala habitat within GPEC and WSA (see section 11.5.4). The first method, known as a Species Distribution Model (SDM), did not find any areas of potential koala habitat within either GPEC or WSA. The second method, known as corridor mapping, found only scattered areas of supporting koala habitat within GPEC or WSA. The NSW Threatened Biodiversity Data Collection requires the assessment of impacts on koala to be determined on the basis of 'important habitat'. The koala corridor habitat mapping undertaken within all the nominated areas was used to identify important habitat that comprises the species polygons for koala as required by the BAM. No areas of important habitat (defined as primary or secondary corridors – see section 11.5.4) were identified. The third method, known as habitat critical to the survival mapping, did not map any habitat critical in GPEC or WSA.

Consideration of threatening processes: GPEC already contains large areas of existing urban development. Urban environments pose significant threats to koalas, through factors including high road and traffic densities, high densities of predators such as domestic dogs, landscape hazards such as swimming pools and barriers to movement such as fences. Whilst koalas may occasionally occur within areas of vegetation within GPEC, it is considered unlikely that a breeding and persisting population of koalas would be able to permanently reside in habitat within GPEC, as it is likely that the mortality rates of koalas due to the high threat pressures would be greater than the breeding rate. Therefore, it is probable that habitat currently available within GPEC constitutes 'sink' habitat. WSA does not currently have such a high density of urban development, and therefore is less likely to have threat densities which are as significant as those in GPEC. However, the scarcity of native vegetation within the nominated area would require koalas to cross large areas of open habitat whilst traversing between vegetation, which would increase the vulnerability of koalas to threats such as predation by dogs. Overall, it is considered that significant threats would be present within both GPEC and WSA.

Consideration of koala record distribution: The BioNet record database was examined to determine the likelihood that koalas are present within GPEC and WSA. It is noted that there are high human population densities in both areas, particularly within GPEC, and therefore an absence of records would be likely to accurately reflect an absence of koalas (as opposed to an absence of surveys). There are no records of koalas within WSA, and only one koala record within GPEC dated from 1990 in Blackett. A small number of records also occur in semi-rural areas north of GPEC, as follows:

- One record is dated from 1984 in the Londonderry locality
- One record is dated from 2006 and located in a biodiversity offset site near Colebee
- Two records are dated from 2018 and located to the west of Shanes Park

Further koala records are located to the west of the GPEC and WSA, within and in proximity to areas of remnant vegetation associated with the eastern boundary of the Blue Mountains.

Whilst a small number of koala records occur within and in the vicinity of the GPEC and WSA, the scarcity of these records, and the length of time between sightings, suggests that koalas are extremely rare within the locality, and that it is very unlikely that there is a persistent population in the locality. Instead, it is more likely that koala sightings within these localities are of dispersing individuals travelling between areas of more suitable habitat.

Koala habitat mapping, consideration of threatening processes and koala BioNet records all suggest that:

- It is very unlikely that suitable koala habitat is present within either GPEC or WSA
- It is likely that any koalas present within GPEC or WSA are dispersing between areas of more suitable habitat

It is therefore considered that any koalas within the GPEC or WSA would likely constitute individuals which have dispersed from the Blue Mountains koala population, as this is the closest habitat area which is known to support a self-sustaining and expanding population from which koalas are known to disperse.

NSW-listed TECs

Relevant NSW-listed TECs were identified by:

- Identifying the relationship between PCTs and NSW-listed TECs. In accordance with the BAM, this relationship was identified in the NSW BioNet Vegetation Classification System
- Reviewing updated native vegetation maps that identify the PCTs within the nominated areas
- Conformance with NSW listed TEC profile information (structure, floristics, landscape position, soil association etc.)

RESULTS

The results of the process to identify the matters requiring assessment under the BCAR are presented in Section 11.5 and Attachment A. This includes the list of NSW-listed candidate SCS requiring assessment under the BCAR, along with justification for the inclusion or exclusion of species from further assessment.

11.1.2 EPBC ACT MATTERS NEEDING ASSESSMENT UNDER THE SAR

PURPOSE

As required by Section 3.2 of the ToR, the SAR must identify the protected matters that may be impacted directly, indirectly and cumulatively by actions taken under the Plan.

METHOD

This was undertaken by:

- Identifying the full list of protected matters that may potentially be relevant to the Plan and require assessment under the SAR (both within and outside of the Strategic Assessment Area)
- Categorising those matters to identify the subset that have the potential to be impacted and require assessment

A precautionary approach was applied to both steps to ensure that all matters requiring assessment were identified. In accordance with Section 4.8 of the ToR, the approach was supported by peer review of both the method and results.

It is important to note that this process did not relate to how protected matters were assessed. Rather, this step merely identified the matters requiring assessment under the SAR.

Identification of protected matters

The full list of protected matters potentially relevant to the Plan was identified through searches of:

- The Australian Government's online Protected Matters Search Tool
- NSW BioNet
- Atlas of Living Australia
- The Australian Government's Finalised Priority Assessment List (FPAL)

These searches were done using the Strategic Assessment Area boundary plus a 10 km buffer around the boundary. This was considered an appropriate area to identify matters that may be impacted directly, indirectly or cumulatively by the Plan. This work identified the following groups of protected matters as being relevant to the assessment:

- Listed threatened species and ecological communities
- Listed migratory species
- Wetlands of international importance (Ramsar wetlands)
- World and National Heritage
- Commonwealth land

The full list of protected matters was then assigned to one of two categories:

- Category 1: matter needs detailed assessment. These matters are reliant on the Strategic Assessment Area, have some potential to be impacted (directly, indirectly or cumulatively), and are addressed in detail

- Category 2: matter does not need further assessment. These matters are not reliant on the Strategic Assessment Area, are subject to very low risk of impacts (directly, indirectly or cumulatively), and are not addressed further

Commonwealth-listed TECs

Commonwealth-listed TECs present in the Strategic Assessment Area that have some potential to be impacted (directly, indirectly or cumulatively), were identified and assigned to Category 1 based on:

- The Australian Government's Protected Matters Search Tool
- Existing native vegetation mapping for the Cumberland Plain (OEH, 2013b, 2016b)
- Detailed native vegetation mapping undertaken within the nominated areas for this project
- Assignment of a PCT in the BioNet Vegetation Classification (formerly known as Vegetation Information System Classification (VIS-C))
- Conformance with Commonwealth-listed TEC profile information (structure, floristics, landscape position, soil association, patch size etc.)

Commonwealth-listed threatened species

Two steps were applied to categorise threatened species for assessment:

- Application of criteria
- Expert review

Application of criteria

Criteria were applied to initially identify the threatened species that may be impacted by actions under the Plan (see Table 11-1). A species was allocated to Category 1 (meaning it required detailed assessment) if it met any of the criteria. Species that did not meet one or more of the criteria were assigned to Category 2 (no further assessment required).

Two senior ecologists with extensive expertise in species within Western Sydney reviewed the criteria and overall approach to ensure that all matters that may be directly, indirectly or cumulatively impacted by the Plan were identified. The ecologists recommended taking a precautionary approach and simplifying some of the criteria.

Table 11-1: Criteria and process for categorising threatened species

Category 1 criteria*	Rationale for the criteria	Process to apply the criteria
1. The species was identified as a species requiring assessment as part of the BAM process for the nominated areas	The BAM process identifies the NSW-listed species that may be impacted within the nominated areas. The process is based on a range of detailed on ground surveys and analysis Where these species are also listed as a Commonwealth-listed species they should be assigned to Category 1	See Section 11.5 for a description of the relevant part of the BAM process
2. The species was subject to a commitment in the Sydney Growth Centres Strategic Assessment Program Report (DECCW, 2010)	A range of species are subject to commitments associated with the previous Growth Centres strategic assessment. Given the close association in areas that may be affected by the Plan it is appropriate that these species be assigned to Category 1	This criterion was applied through a review of the Growth Centres Program Report to identify relevant species

Category 1 criteria*	Rationale for the criteria	Process to apply the criteria
3. The Strategic Assessment Area contains a known important population	Important populations of threatened species require particular consideration under the EPBC Act (DoE, 2013). Where they are present in the Strategic Assessment Area the species should be assigned to Category 1	Important populations within the Strategic Assessment Area were identified through: • Review of recovery plans, conservation advices, species profiles, EPBC policies, and other published literature • Application of the process for mapping important populations in the Strategic Assessment Area It is important to note that any record of an endangered or critically endangered species is considered to form part of an important population (DoE, 2013)
4. The Strategic Assessment Area contains >5 per cent of all known records in NSW of a species since 1990 on the Atlas of NSW Wildlife	Known records provide an indication of the importance of the Strategic Assessment Area to a species. Using a precautionary approach, greater than 5 per cent of records in NSW was chosen as a threshold for assigning species to Category 1	This criterion was applied using post 1990 species records from the NSW BioNet Atlas database. Records within the Strategic Assessment Area were compared to the total number of records across NSW
5. The Strategic Assessment Area comprises >5 per cent or more of the mapped distribution of the species according to the Department of Agriculture, Water and the Environment's (DAWE) current distribution mapping	DAWE's distribution mapping of habitat showing where a species is 'known to occur', 'likely to occur' and 'may occur' also provides an indication of the importance of the Strategic Assessment Area to a species. Using a precautionary approach, greater than 5 per cent of a species distribution was chosen as a threshold for assigning species to Category 1	This criterion was applied using distribution statistics provided by DAWE about the percentage of each species distribution within the Strategic Assessment Area
6. It is an FPAL species, and available information suggests it occurs in the Strategic Assessment Area	The FPAL includes species nominated for listing as threatened or for up-listing. Any FPAL species likely to occur in the Strategic Assessment Area warrants assessment and should be assigned to Category 1	Where DAWE's distribution and records information for an FPAL species was available, this was used to determine occurrence in the Strategic Assessment Area Where this information was not available, information from the NSW Threatened Biodiversity Data Collection in BioNet or DAWE's listing documentation was used

* A species was allocated to Category 1 if it met <u>any</u> of the criteria

Review of the initial list

The initial list was reviewed by two expert senior ecologists to confirm the categorisation or to move species between categories based on specific expert knowledge. This step was important as it provided the opportunity to consider specific information to ensure that all species that may be impacted were identified.

The findings of this review are incorporated into the results in Chapter 28.

Migratory species

Migratory species were addressed in three groups:

- Migratory shorebirds
- Migratory birds addressed in the *Draft referral guideline for 14 birds listed as migratory species under the EPBC Act* (DoE, 2015)
- Other migratory species

Migratory shorebirds

Thirty-seven migratory shorebirds visit Australia each year. They are addressed as a group in EPBC Act Policy Statement 3.21 (DoE, 2017). Given the overlap in habitat used by many of these species and the similar way they are treated under the EPBC Act, any migratory shorebirds that were known to occur in the Strategic Assessment Area were assigned to Category 1. This was based on post 1990 records within the area from NSW BioNet and Birdlife Australia.

Any species without records were assigned to Category 2.

Other migratory birds

Fourteen migratory bird species are addressed in another EPBC guideline (DoE, 2015). A similar approach to shorebirds was applied. Any species with records in the Strategic Assessment Area was assigned to Category 1.

Any species without records were assigned to Category 2.

Remaining migratory species

For the remaining migratory species, two steps were applied to categorise them:

1. **Application of criteria:** Criteria were applied to initially identify the other migratory species that may be impacted by actions under the Plan (see Table 11-2). A species was allocated to Category 1 if it met any of the criteria. Species that did not meet one or more of the criteria were assigned to Category 2
2. **Expert review:** The list was reviewed by two senior ecologists to confirm the categorisation or to move species between categories based on specific expert knowledge

Table 11-2: Criteria and process for categorising the remaining migratory species

Category 1 criteria*	Rationale for the criteria	Process to apply the criteria
1. **The Strategic Assessment Area supports important habitat or an ecologically significant proportion of a species**	"Important habitat" and "ecologically significant proportion" are key concepts for migratory species (DoE, 2013). Where these are present within the Strategic Assessment Area it is appropriate to assign a species to Category 1	Important habitat and ecologically significant proportion need to be determined on a species-by-species basis. The guidance around these concepts from the EPBC Act significant guidelines (DoE, 2013) were applied Information from recovery plans, conservation advices, species profiles, EPBC policies, and other published literature were used to identify if the Strategic Assessment Area supported important habitat or an ecologically significant proportion of a species
2. **The Strategic Assessment Area contains >5 per cent of all known records in NSW of a species since 1990 on the Atlas of NSW Wildlife**	Known records provide an indication of the importance of the Strategic Assessment Area to a species. Using a precautionary approach, greater than 5 per cent of records in NSW was chosen as a threshold for assigning species to Category 1	This criterion was applied using post-1990 species records from the NSW BioNet Atlas database. Records within the Strategic Assessment Area were compared to the total number of records across NSW

* A species was allocated to Category 1 if it met any of the criteria

<u>Wetlands of international importance (Ramsar)</u>

There are no Ramsar Wetlands within the Plan Area. However, Towra Point Nature Reserve occurs downstream of the Plan Area and was assigned to Category 1.

<u>World and national heritage</u>

Any World or National Heritage places within or within the vicinity of the Plan Area were assigned to Category 1.

<u>Commonwealth land</u>

Any Commonwealth land within the Plan Area was assigned to Category 1.

<u>Finalised Priority Assessment List (FPAL) matters</u>

Any matters on FPAL that were known to occur in the Strategic Assessment Area were put into Category 1.

Results

The results of the process to identify the matters requiring assessment under the SAR are presented in Chapter 28.

11.2 LANDSCAPE CONTEXT

11.2.1 LANDSCAPE CONTEXT WITHIN THE NOMINATED AREAS

Purpose

Section 4 of the BAM requires the BCAR to describe:

- Landscape context, including landscape features such as waterways, wetlands and habitat connectivity
- Site context, including native vegetation cover and patch size

Method

<u>Native vegetation cover</u>

Native vegetation cover was assessed within a 1500 m buffer from the urban capable footprint of each of the nominated area separately, and entered into the BAM Calculator.

This approach was undertaken in accordance with Section 6.4.1.3 of the BAM and to ensure that all ECS and SCS with a native vegetation cover class requirement lower than, or equal to that of each nominated area, were considered. This ensured accurate and area specific information was used, and that no species were excluded based on a higher overall value for native vegetation cover resulting from averaging across all nominated areas.

<u>Rivers and streams</u>

Rivers and streams were identified in accordance with Appendix 3 of the BAM.

<u>Wetlands</u>

Wetlands were identified through aerial photographic interpretation (API), as well as data in the Digital Topographic Database hydro area layer (LPI, 2016) and the Directory of Important Wetlands (DoEE, 2018).

<u>Habitat connectivity</u>

Habitat connectivity was assessed by senior ecologists through API and maps of existing native vegetation. Habitats of similar types (e.g. riparian corridors, dry forests, grasslands) were identified, and connectivity between these areas was then determined and mapped using GIS.

Areas of geological significance and soil hazard features

The likely locations of areas of geological significance, including cliffs, caves and escarpments, were identified on the basis of existing knowledge of senior ecologists, field investigation results, topographic and geological maps, and the following datasets:

- Geological sites of NSW (Cartoscope, 2019)
- Karst Environments of NSW (OEH, 2018d)

Soil hazard features including dryland salinity, acidification, compaction, structural breakdown, sodicity and contamination were identified on the basis of the following datasets:

- NSW soils datasets at 1:100,000 from the EES data portal
- NSW geology datasets at 1:250,000 from the Department data portal
- eSpade (OEH, 2018c)
- NSW (Mitchell) Landscapes (OEH, 2018e)
- Western Sydney Hydrogeological Landscapes (OEH, 2011)

RESULTS

The results of the landscape context analysis within the nominated areas is provided in Chapter 18.

11.2.2 LANDSCAPE CONTEXT WITHIN THE STRATEGIC ASSESSMENT AREA

PURPOSE

Clause 3 of the ToR requires the SAR to describe the nature of the environment within the Strategic Assessment Area, and other areas outside this area that may be impacted by actions taken under the Plan. This includes:

- A description of historical and current land use
- The extent and quality of native vegetation
- The nature of the environment (including ecosystem processes and threatening processes)
- A description of landscape context for key matters (including connectivity, fragmentation, ecological processes)
- A map of areas that are already protected

METHOD

The nature of the environment was described through a review of relevant literature. Key source documents are referenced in Chapter 28 and included:

- The Cumberland Plain Recovery Plan (DECCW, 2011)
- Cumberland subregion BIO Map report (OEH, 2015)
- A range of technical papers on the ecology and ecological processes of the Cumberland subregion
- Relevant government policies and guidelines

RESULTS

The results of the landscape context analysis within the Strategic Assessment Area is provided in Chapter 28.

11.3 NATIVE VEGETATION

11.3.1 OVERALL APPROACH TO NATIVE VEGETATION MAPPING

Native vegetation maps were prepared:

- Within the nominated areas to meet the requirements of the BAM. Detailed mapping of the nominated areas was undertaken based on field surveys and API

- Within the Strategic Assessment Area outside the nominated areas to meet the requirements of the ToR. Mapping of the Strategic Assessment Area was based on existing native vegetation maps (OEH, 2013b, 2016b)

11.3.2 NATIVE VEGETATION MAPPING WITHIN THE NOMINATED AREAS

PURPOSE

Section 5 of the BAM requires the BCAR to identify and map for the nominated areas:

- Extent of native vegetation
- PCTs and TECs
- Vegetation integrity

METHOD

The extent of native vegetation and PCT allocation, as well as the determination of vegetation integrity scores within the nominated areas, was assessed in accordance with Section 5 and Appendix 6 of the BAM using:

- API
- Interrogation of LiDAR data
- Existing desktop mapping
- Previous surveys and studies
- Rapid assessment ground-truthing
- Field surveys

Given the scale of the assessment area, the native vegetation mapping method was developed in consultation with EES to ensure consistency with BAM requirements. Use of existing vegetation mapping as a basis to determine the type and extent of native vegetation in the assessment area is consistent with section 5.1.1.2 of the BAM.

<u>Native vegetation community extent</u>

Native vegetation community extent within the nominated areas was determined using API, existing vegetation mapping (OEH, 2013b, 2016b) and GIS analysis. All native vegetation, including native ground cover and the canopy area of trees was mapped.

<u>Identification of Plant Community Types</u>

PCTs present within the nominated areas were determined using the BioNet PCT identification tool and the Tozer-types PCT identification tool for vegetation communities of the Cumberland subregion.

All data collected in the field was analysed to provide the 'best fit' PCT for each community.

Draft PCT map based on desktop analysis

A draft PCT map for each nominated area was prepared based on desktop analysis. This involved:

Step 1: Collating relevant datasets and GIS layers, including:

- Recent Nearmap imagery at 15 cm resolution
- NSW landuse polygons (OEH, 2013a)
- NSW soils datasets at 1:100,000 from the NSW Government data portal
- NSW geology datasets at 1:250,000 from the NSW Government data portal

Step 2: Processing multispectral aerial imagery into Normalised Difference Vegetation Index (NDVI) imagery

Step 3: Amalgamating previous native vegetation mapping across the nominated areas

Step 4: Combining two existing EES maps of native vegetation within the Cumberland subregion (OEH, 2013b, 2016b) into a single layer and clipping the layer to the nominated area boundaries

Step 5: Creating a Canopy Height Model (CHM) using 1 m LiDAR data

Step 6: Processing the CHM into amalgamated canopy polygons for vegetation over 1 m in height

Step 7: Compiling the data into a single GIS map for the nominated areas with 500 m by 500 m grid squares

Interpretation of Nearmap imagery, desktop analysis and refinement of existing native vegetation mapping (OEH, 2013b, 2016b) using the BioNet Vegetation Classification database (OEH, 2018a) and the ArcGIS mapping application was undertaken by botanists experienced in the survey and identification of the PCTs of the subregion. The botanists moved cell by cell through the grid within each nominated area. All vegetation polygons shown within the existing native vegetation mapping and any unmapped vegetation was assessed and assigned a likely PCT.

A condition type for each vegetation polygon was assigned through analysis of canopy structure using LiDAR, the CHM, and API of the Nearmap imagery. In most instances, subject to land access restrictions, this was verified in the field by collection of data in accordance with the BAM.

The condition states used for each vegetation polygon were:

- **Intact:** This condition state was assigned to areas of wooded vegetation community, including regrowth, that displays a range of structural layers and habitat features (e.g. tree hollows and large trees, fallen timber, leaf litter) with a largely unmodified canopy density and a range of age classes and species present. This condition state was assigned during the desktop mapping to areas where the Nearmap imagery indicated significant patches of continuous canopy and the CHM indicated vegetation in both the upper and middle storeys
- **Thinned:** This condition state was assigned to native vegetation in various states of modification, including:
  - Wooded vegetation with a partly-cleared canopy and a more open structure compared to the intact PCT
  - Wooded vegetation that has been under scrubbed. This condition state was assigned during desktop mapping to areas where the Nearmap imagery indicated patches of notably reduced canopy density, which was typically where the CHM indicated canopy and visible ground only, with no discernible shrub layer or structural complexity
- **Scattered trees:** This condition state includes a single tree or small group of trees surrounded by native or exotic pasture or areas of cultivation. Other structural components of the vegetation have typically been removed. This condition state was assigned during the desktop mapping to areas where the Nearmap imagery and LiDAR canopy polygons indicated one or a few likely native trees surrounded by cleared land
- **Grasslands:** Grasslands included two separate state zones – exotic grassland and native grasslands. Areas of potential derived native grassland (DNG) were identified from the Nearmap imagery and later verified or reclassified in the field. Grasslands were considered to be DNG where they had a vegetation integrity score of greater than or equal to 15 (based on data collected in the field). Where grasslands were dominated by exotic species and the vegetation integrity score was less than 15, these were considered to be 'non-offsettable grasslands' (NOG)
- **Urban native/exotic:** This condition type was assigned to areas of vegetation within urban areas that consisted of street trees, urban parks and other patches of planted vegetation that could provide habitat for native species. This condition type was also used to map areas of exotic vegetation

Final draft PCT maps

Draft PCT maps were made available online to the ecological consultants in the field to allow an ongoing process of field verification and refinement. Ecological consultants undertook rapid assessment ground-truthing and validation or amendment of the PCTs and/or condition states assigned during the desktop analysis. Amendments were usually recorded in the field using Collector for ArcGIS and later cross checked with field data.

Final draft maps were used to determine the number of plot-based survey sites required to be surveyed to meet BAM requirements. As plots were surveyed, the number of plots required for each PCT and condition state (in section 5.3.4 of the BAM) was reviewed and the vegetation mapping was updated to develop a final PCT map for each nominated area.

Floristic plot surveys

A stratified field survey was designed to verify and identify PCTs within the nominated areas, including:

- PCT and condition state
- Environmental variation

- Gaps in existing mapping and site data

A total of 258 plots were surveyed across the nominated areas (see Table 11-4). Of these plots, 123 were located within urban capable lands or transport corridors within the nominated areas, and 12 plots were located either in PCTs not impacted by the final urban capable lands or within Urban Native / Exotic vegetation. Plot surveys were undertaken in accordance with the requirements of the BAM by BAM accredited assessors and ecological consultants. Plot surveys were undertaken during the period February 2018 to March 2019.

Plot data was collected from a 20 m x 20 m plot to capture:

- Species presence (by scientific name and any relevant common name)
- Stratum and layer in which each species occurs
- Growth form of each species (as per the BAM)
- Percent foliage cover
- Abundance count (as per the BAM)

The PCT at each plot location was assigned in the field and later verified using assessment of a number of attributes including soil type, landscape position, diagnostic species and community structure. Floristic data collected from the plot surveys was analysed to identify PCT to the best match using the BioNet PCT identification tool.

The PCT results obtained from the identification tool were then checked by a senior ecologist for any discrepancies and a final PCT was allocated to the plot and to the broader vegetation community polygon.

The vegetation maps were continually updated throughout this process.

Plot data collected during previous surveys in accordance with the previous BioBanking Assessment Method (BBAM) was also used to supplement plot data collected in accordance with the BAM. Additional data was collected to supplement the BBAM data in order to meet BAM requirements, including:

- Tree stem count
- 1 x 1 metre plots (litter, bare ground, cryptogram and rock cover)
- High threat weed cover
- Updated growth forms

Vegetation integrity assessment

Vegetation zones

Areas of each PCT in different broad condition states were stratified into separate vegetation zones. Derived grasslands were assessed against the benchmark data for the original, or likely original PCT, and included as a separate vegetation zone. Non-offsettable Grasslands were also included as a separately vegetation zone. A map of vegetation zones was prepared by GIS consultants using the final PCT map.

To ensure consistency of data across the assessment area and to prevent over-complicating the assessment approach and data collection requirements, vegetation zones were not broken down by nominated area. For example, vegetation zone 849 (thinned) occurs across all four nominated areas, and all data collected from within that zone has been pooled to determine the vegetation integrity score, independent of where each plot was collected.

This approach ensured that an accurate and consistent landscape scale vegetation integrity assessment for each vegetation zone was undertaken, which is considered the most suitable approach for an assessment of this scale.

Patch size

The patch size of each vegetation zone was assigned using GIS on the basis of the final PCT map as follows:

- Vegetation zones were assigned to the same patch where they were located within 100 m of each other for intact native woody vegetation and within 30 m of each other for intact native non-woody vegetation
- Any intact native vegetation that adjoined vegetation zones beyond the nominated areas was included
- Each patch was digitised, and separate polygons were mapped where multiple patches existed

- The area of each patch in hectares was calculated

Site condition

For each vegetation zone identified within the urban capable land or transport corridors, a quantitative measure of composition, structure and function was determined through plot and transect surveys in accordance with the BAM.

Table 11-3 shows the attribute data collected.

Table 11-3: Site condition attributes

Growth form groups to assess composition and structure	Attributes to assess function
Tree	Number of large trees
Shrub	Tree regeneration
Grass and grass like	Tree stem size class
Forb	Total length of fallen logs
Fern	Litter cover
Other	High threat exotic vegetation cover
	Hollow-bearing trees

Vegetation integrity plot surveys

For this Assessment Report, the plots used for floristic survey were also used to assess vegetation integrity, consistent with the BAM. Plots and transects were established to provide a representative assessment of the vegetation integrity of the vegetation zone. Plots were undertaken on properties where access was available, which resulted in a number of plots being collected in patches of vegetation outside the urban capable lands or transport corridors of the nominated areas. All plots were collected within vegetation contiguous with urban capable lands or transport corridors within nominated areas, and within vegetation mapped specifically for this assessment.

Plots were randomly located within each vegetation patch using the following method:

- PCT vegetation polygons identified based on the desktop native vegetation mapping were verified in the field to confirm or revise PCT and/or extent
- Locations of BAM plots were determined with the aim of capturing the representative condition of the PCT within the zone, avoiding bias wherever possible
- Ecotones, vehicle tracks and their edges, or other disturbed areas that are readily distinguishable from the broad condition state of the vegetation zone were avoided
- In large patches, the orientation of transects were randomly assigned by throwing an object flagged with tape into the patch of vegetation – the direction that the tape pointed following landing was assigned the plot orientation
- In smaller patches of vegetation, particularly narrow, linear strips, the location of plots was determined based on capturing a representative sample of the patch, avoiding edge areas where possible

The floristic survey plots were 10 m either side of the first 20 m of the transect (nested within the larger 0.1 ha quadrat).

The following data were collected from the plots and transects:

- 20 m x 20 m plot: floristic data (composition and structure) attributes listed in Table 11-3
- 20 m x 50 m plot: function attributes listed in Table 11-3 (except litter cover)
- Five 1 m x 1m sub-plots: average litter cover

Table 11-4 shows the number of plots/transects required to be surveyed to meet BAM requirements for each vegetation zone, and the number of plots and/transects completed for this Assessment Report.

Table 11-4: Number of plots surveyed for each PCT and vegetation zone within the nominated areas

PCT	State	Total impact area (ha)	Minimum plots required	Total plots completed
724	Intact	8.0	3	4
	Scattered Trees	0.2	1	1
	Thinned	44.0	4	4
725	Intact	15.6	3	3
	Scattered Trees	3.0	2	2
	Thinned	18.3	3	7
781	Thinned	2.1	2	4
830	Thinned	0.1	1	2
835	Intact	12.2	3	3
	Non-offsettable Grassland	941.6	7	9
	Scattered Trees	17.8	3	6
	Thinned	135.1	6	7
849	DNG	239.2	6	16
	Intact	29.7	4	9
	Non-offsettable Grassland	5135.1	8	16
	Scattered Trees	125.3	6	12
	Thinned	335.6	7	18
850	DNG	188.5	6	6
	Intact	8.1	3	9
	Non-offsettable Grassland	682.8	7	9
	Scattered Trees	22.2	4	4
	Thinned	66.1	5	6
1395	DNG	237.3	6	15
	Intact	44.9	4	16
	Non-offsettable Grassland	778.4	7	9
	Scattered Trees	50.5	4	5
	Thinned	155.0	6	30
1800	Intact	0.2	1	4
	Scattered Trees	0.4	1	2
	Thinned	18.6	3	8
		Total	**126**	**246**

RESULTS

The native vegetation maps of the nominated areas, including plot locations relative to vegetation zones, are provided in Chapter 19.

11.3.3 NATIVE VEGETATION MAPPING ACROSS THE BROADER STRATEGIC ASSESSMENT AREA

Purpose

Clause 3 of the ToR requires the SAR to describe the nature of the environment within the Strategic Assessment Area. This includes the extent and quality of native vegetation.

Method

The approach to identify and map native vegetation across the broader Strategic Assessment Area involved

Step 1: Collating the most recent and highest resolution existing native vegetation mapping data relevant to the Cumberland subregion. This data included:

- Native Vegetation of the Sydney Metropolitan Area Version 3.0 (OEH, 2016b)
- Remnant Vegetation of the Western Cumberland subregion, 2013 Update (OEH, 2013b)
- Native Vegetation of Southeast NSW (Tozer, Turner et al., 2010)
- Biometric Vegetation Compilation for the South East Local Land Services Region (Eco Logical Australia, 2015)

Step 2: Merging the data into a single native vegetation data layer for the Cumberland subregion using GIS and clipping the data to the Cumberland subregion boundary

Step 3: Incorporating the updated the native vegetation maps for the nominated areas into the single native vegetation data layer for the parts of the Cumberland subregion within the nominated areas

Step 4: Reviewing vegetation condition or disturbance data held within the attributes the existing mapping data (Step 1) and updating this data to align with the condition types used for the nominated areas (see section 11.3.2)

Step 5: Where condition data was unavailable in the existing mapping data, undertaking a desktop assessment of the vegetation polygons and determining condition based on patch size, connectivity and edge impacts. This was only required for the Tozer et al (2010) and Eco Logical Australia (2015) data layers

Results

The native vegetation maps of the nominated areas are provided in Chapter 19.

11.4 THREATENED ECOLOGICAL COMMUNITIES

11.4.1 OVERALL APPROACH TO TEC MAPPING

To meet the requirements of the BAM and the ToR, TEC maps have been prepared for all:

- NSW-listed TECs (see Section 11.1.1) within the nominated areas
- Commonwealth-listed Category 1 TECs (see Section 11.1.2) within the Strategic Assessment Area

TECs were mapped based on associations between PCTs and TECs and rule-sets applied to these associations to refine the maps based on TEC definitions. Separate rule-sets were applied to NSW-listed TECs and Commonwealth-listed Category 1 TECs because of the typically different definitions of each TEC under the BC Act and EPBC Act.

Table 11-5 summarises the mapping approaches within and outside the nominated areas for NSW-listed TECs and Commonwealth-listed Category 1 TECs.

Table 11-5: Summary of mapping approaches for NSW- and Commonwealth-listed TECs

TECs	Mapping area	Mapping method
NSW-listed TECs	Nominated areas	Rule set specific to NSW-listed TECs applied to updated native vegetation maps of the nominated areas (see Section 11.3)

TECs	Mapping area	Mapping method
Commonwealth-listed Category 1 TECs	Strategic Assessment Area	Rule set specific to Commonwealth-listed TECs applied to: • Within the nominated areas – updated native vegetation maps of the nominated areas (see Section 11.3) • Outside the nominated areas – existing native vegetation maps of the Cumberland subregion (see Section 11.3)

11.4.2 NSW-LISTED TECS

PURPOSE

Section 5 of the BAM requires the BCAR to:

- Identify any TECs that are associated with PCTs, or the most likely PCT
- Map the extent of TECs

METHOD

The method to identify and map NSW-listed TECs within the nominated areas was:

Step 1: The updated native vegetation map (see Section 11.3) was used to identify areas of potential TECs on the basis of associations between PCTs and TECs and the rule set in Table 11-6.

Step 2: A draft map showing candidate TECs was created by GIS consultants on the basis of Step 1.

Step 3: Plots were surveyed in the field within and outside potential TEC areas. The plot data were cross checked by ecologists with the definition of TECs using the BioNet PCT identification tool and against final determinations, to confirm that the specific criteria as shown in Table 11-6 were met for the TEC at that location. Where no field survey of a potential TEC was possible, the TEC was assumed to be present at that location.

Step 4: Draft TEC maps for the nominated areas were developed and a report on the method and field verification was prepared for consultation and review by EES.

Step 5: The method and rule set were amended based on comments from EES. Final TEC maps for the nominated areas were prepared based on the updated method and rule-set and final native vegetation maps. Table 11-6 shows the rule set developed for mapping NSW TECs.

GRASSLAND TECS

Where derived native grasslands form part of a TEC listing all such vegetation zones were mapped as the relevant TECs. Where grasslands were assessed as potentially supporting a native component, but were not determined as derived native grasslands, they were not considered to form part of the relevant TEC. These vegetation zones were deemed 'non-offsettable grasslands' and floristic plot data was collected in accordance with the BAM to determine the associated vegetation integrity score. In each case, the vegetation integrity score was found to be less than 15, which is lower than the minimum score required to offset a TEC in accordance with BAM section 10.3. Non-offsettable grasslands with a vegetation integrity score of less than 15 were not considered to form part of a TEC as the vegetation is considered so degraded it no longer meets the minimum requirements for the TEC or requires any offsetting.

Table 11-6: Rule set for mapping NSW listed TECs within the nominated areas

PCT	NSW TEC	Condition state	Specific criteria – field verification
724 Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion	*Shale Gravel Transition Forest in the Sydney Basin Bioregion*	All	Species composition, elevation, soils and landscape position met based on listing advice
725 Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion	*Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion*	All	
781 Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion	*Freshwater wetlands on coastal floodplains of the NSW North Coast, Sydney Basin and South East Corner bioregions*	All	
830 Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	*Moist Shale Woodland in the Sydney Basin Bioregion*	All	
835 Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	*River-flat Eucalypt Forest in the Sydney Basin Bioregion*	All except non-offsettable grasslands	
849 Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	*Cumberland Plain Woodland in the Sydney Basin Bioregion*	All except non-offsettable grasslands	
850 Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	*Cumberland Plain Woodland in the Sydney Basin Bioregion*	All except non-offsettable grasslands	
877 Grey Myrtle dry rainforest of the Sydney Basin Bioregion and South East Corner Bioregion	*Western Sydney Dry Rainforest in the Sydney Basin Bioregion*	All	
883 Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion	*Castlereagh Scribbly Gum Woodland in the Sydney Basin Bioregion*	All	
1395 Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion	*Shale Sandstone Transition Forest in the Sydney Basin Bioregion*	All except non-offsettable grasslands	

PCT	NSW TEC	Condition state	Specific criteria – field verification
1800 Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley	*Swamp Oak Floodplain Forest of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions*	All	

11.4.3 COMMONWEALTH-LISTED TECS

PURPOSE

Section 3.1 and 3.2 of the Terms of Reference requires the SAR to:

- Describe the nature of the environment within the Strategic Assessment Area, and other areas outside the Strategic Assessment Area that may be impacted by actions taken under the Plan. This must include the extent and quality of native vegetation, including mapping of Commonwealth-listed TECs
- Identify and describe each protected matter that may be impacted directly, indirectly and cumulatively by actions taken under the Plan, including:
  - Key sites
  - Condition, including seasonal and annual variability, and likelihood to alter over time

IDENTIFYING POTENTIALLY RELEVANT COMMONWEALTH TECS

Commonwealth TECs potentially present in the Strategic Assessment Area (see Table 11-7) were identified based on:

- The Australian Government's Protected Matters Search Tool
- Existing native vegetation mapping for the Cumberland Plain (OEH, 2013b, 2016b)
- Detailed native vegetation mapping undertaken within the nominated areas for this project

Table 11-7: EPBC Act TECs potentially relevant to the Plan

Commonwealth TEC	Commonwealth status
Blue Gum High Forest of the Sydney Basin Bioregion	CE
Castlereagh Scribbly Gum and Agnes Banks Woodlands of the Sydney Basin Bioregion	E
Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland ecological community	E
Cooks River/Castlereagh Ironbark Forest of the Sydney Basin Bioregion	CE
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest	CE
Coastal floodplain eucalypt forest of eastern Australia*	FPAL
Elderslie Banksia Scrub Forest in the Sydney Basin Bioregion	CE
Shale Sandstone Transition Forest of the Sydney Basin Bioregion	CE
Turpentine-Ironbark Forest of the Sydney Basin Bioregion	CE
Western Sydney Dry Rainforest and Moist Woodland on Shale	CE

* Currently being considered for listing under the EPBC Act

The general relationship between these TECs and PCTs is set out in Table 11-8.

Table 11-8: General relationship between Commonwealth TECs and PCTs

EPBC TECs	Associated PCTs	General relationship
Blue Gum High Forest in the Sydney Basin Bioregion	1237 Sydney Blue Gum – Blackbutt – Smooth-barked Apple moist shrubby open forest on shale ridges of the Hornsby Plateau, Sydney Basin Bioregion	PCT equivalent to (wholly subset of) Commonwealth TEC (VIS database)
Castlereagh Scribbly Gum and Agnes Banks Woodlands of the Sydney Basin Bioregion	883 Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion	PCT is equivalent to (partial subset of) Commonwealth TEC (VIS database)

EPBC TECs	Associated PCTs	General relationship
	958 Narrow-leaved Apple – Hard-leaved Scribbly Gum heathy woodland on sand at Agnes Banks, Sydney Basin Bioregion	PCT equivalent to (wholly subset of) Commonwealth TEC (VIS database)
Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland	1800 Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley	PCT is equivalent to Commonwealth TEC (VIS database; OEH 2016)
Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion	725 Broad-leaved Ironbark – Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion	PCT equivalent to (wholly subset of) Commonwealth TEC (VIS database)
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest	724 Broad-leaved Ironbark – Grey Box – Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion	PCT is equivalent to (wholly subset of) Commonwealth TEC (VIS database)
	849 Grey Box – Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	PCT is equivalent to (wholly subset of) Commonwealth TEC (VIS database)
	850 Grey Box – Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	PCT is equivalent to (partial subset of) Commonwealth TEC (VIS database)
*Coastal floodplain eucalypt forest of eastern Australia**	835 Forest Red Gum – Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	PCT is assumed to be equivalent to potential listing of Commonwealth TEC (FPAL)
Elderslie Banksia Scrub Forest in the Sydney Basin Bioregion	774 Coast Banksia scrub on sand in the Elderslie area, Sydney Basin Bioregion	PCT is equivalent to (wholly subset of) Commonwealth TEC (VIS database)
Shale Sandstone Transition Forest in the Sydney Basin Bioregion	1395 Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion	PCT is equivalent to (wholly subset of) Commonwealth TEC (VIS database)
	1281 Turpentine - Grey Ironbark open forest on shale in the lower Blue Mountains, Sydney Basin Bioregion	PCT is equivalent to (wholly subset of) Commonwealth TEC (VIS database)
Turpentine–Ironbark Forest of the Sydney Basin Bioregion	1281 Turpentine - Grey Ironbark open forest on shale in the lower Blue Mountains, Sydney Basin Bioregion	PCT is partial subset of Commonwealth TEC (VIS database)
	1284 Turpentine - Smooth-barked Apple moist shrubby forest of the lower Blue Mountains, Sydney Basin Bioregion	PCT partially contains TEC (VIS database)
Western Sydney Dry Rainforest and Moist Woodland on Shale	830 Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	PCT is largely equivalent to Commonwealth TEC (VIS database; OEH 2016)

EPBC TECs	Associated PCTs	General relationship
	877 Grey Myrtle dry rainforest of the Sydney Basin Bioregion and South East Corner Bioregion	PCT is a partial subset/component of Commonwealth TEC (VIS database; OEH 2016)

* Currently being considered for listing under the EPBC Act

COMMONWEALTH TEC MAPPING METHOD

Within the nominated areas

The approach to identify and map Commonwealth-listed TECs within the nominated areas was broadly similar to the approach used to map NSW-listed TECs, but involved a number of additional steps which reflected the listing definitions of the TECs. The approach involved:

Step 1: The updated native vegetation map (see Section 11.3) was used to identify areas of potential TECs on the basis of associations between PCTs and TECs (see Table 11-8).

Step 2: Rapid assessment ground truthing was undertaken to contribute to the reliability of the desktop process. GIS consultants used this data to assist with assigning condition classes to the PCTs within the nominated areas.

Step 3: PCTs were correlated with potential TEC types. Once the vegetation maps were updated, the PCTs were selected for further assessment against the EPBC TEC criteria.

Step 4: To account for potential occurrence of DNG around treed patches of PCTs, polygons were buffered by 30 m and overlapping buffers were merged into single polygons.

Step 5: A patch size was attributed to each polygon and distribution criteria for each potential TEC were applied to the polygons. Table 11-9 shows the distribution criteria and patch size criteria for each TEC with potential to occur within the nominated areas. Where a polygon did not meet the criteria, it was not considered further as an area of TEC.

Step 6: Projected Foliage Cover (PFC) as assessed (where relevant to the TEC threshold criteria (see Table 11-9)) and polygons not meeting the criteria were removed. This was done by:

- Reclassifying the canopy height model raster (derived from 1 metre LiDAR point cloud) to select vegetation pixels over 15 m tall to represent canopy trees
- Calculating the number of 1 m x 1 m tree pixels in each contiguous patch of vegetation
- Calculating the per cent canopy coverage by dividing the area covered by tree pixels by the total area of the polygons and multiplying by 100
- Calculating PFC by multiplying the per cent canopy coverage by 0.5
- Removing polygons that fell below the criteria for the TEC

Step 7: Where a TEC included elevation criteria, this was applied and polygons not meeting the criteria were removed. This was done by calculating the maximum elevation for each vegetation polygon (derived from 1 m LiDAR point cloud) and removing areas that fell outside the elevation threshold criteria.

Step 8: Candidate TEC polygons were mapped. If a vegetation polygon satisfied the conditions in Steps 3-7, it was mapped as a 'candidate' TEC polygon, and Step 9 or Step 10 were undertaken to further classify the PCT.

Step 9: Where plot data was available in a candidate TEC polygon, condition class criteria were applied to determine if the polygon met the definition of the TEC. The following steps were undertaken in this step:

- BAM plot data points were joined to TEC candidate polygons
- Condition class criteria for respective TECs were applied
- For polygons achieving all criteria, they were assigned to the respective TEC as 'known'
- For all other candidate polygons that did not meet the condition class criteria, they were removed from being considered a TEC

Step 10: Where plot data was not available in a candidate TEC polygon, they were categorised into 'high', 'moderate' or 'low' potential EPBC TEC based on the following parameters:

- High potential TEC – Intact veg with a patch size > 10 ha
- Moderate potential TEC – All veg conditions with a patch size > 1 ha
- Low potential TEC – All veg conditions with a patch size between 0.5-1 ha

Table 11-9 shows the rule set developed for identifying Commonwealth TECs.

<u>Outside the nominated areas</u>

The approach for TEC mapping outside the nominated areas within the Strategic Assessment Area used additional mapping sources and did not apply detailed criteria to the mapping models.

The approach involved:

Step 1: Potential areas of the TEC were identified from existing native vegetation maps. This involved:

- Combining the Cumberland Plain West vegetation mapping with SMCMA vegetation mapping into a single layer and clipping it to the Cumberland subregion
- Correlating PCTs with potential TEC types

Step 2: Distribution and patch size class criteria were applied. A patch size was attributed to each potential TEC polygon and polygons were filtered for distribution criteria. Where a polygon did not meet the criteria, it was not considered further as an area of TEC

Step 3: Condition class criteria were applied. This involved selecting potential TEC polygons for further consideration by sorting for the following condition classes in the vegetation mapping (OEH, 2013b, 2016b): A and B, and Low and Moderate condition classes respectively. These condition classes are the only ones considered likely to meet EPBC condition class criteria. This step was undertaken by GIS consultants

Step 4: Candidate TEC polygons were mapped. If a vegetation polygon satisfied the conditions in Step 3, it was mapped as a candidate TEC polygon. The candidates were based on the following parameters:

- High potential TEC – Intact veg with a patch size > 10 ha
- Moderate potential TEC – All veg conditions with a patch size > 1 ha
- Low potential TEC – All veg conditions with a patch size between 0.5-1 ha
- Not TEC

<u>Justification of method</u>

The mapping of Commonwealth-listed TECs is particularly challenging at the scale of the Strategic Assessment Area. It poses greater challenges to the mapping of NSW-listed TECs as Commonwealth-listed TECs are subject to additional key diagnostic characteristics and condition thresholds identified in conservation or listing advices that determine whether a patch of vegetation comprises the TEC. These criteria aim to focus protection on the most valuable patches, and generally exclude highly degraded patches of less value (DEWHA, 2009a). The method for mapping Commonwealth-listed TECs aimed to ensure these criteria were considered to the greatest extent possible with the data available.

Several criteria in the conservation or listing advices can be assessed through desktop methods using data such as high definition aerial imagery and LiDAR, as well as GIS tools. However, this process is limited by the accuracy of the input data, including the underlying vegetation mapping. The limitations of the vegetation mapping that underpins the Commonwealth-listed TEC mapping within the nominated areas is summarised in Chapter 13.

Within the nominated areas the vegetation mapping is considered to be reasonably accurate, as mapping was undertaken based on detailed desktop analysis and on-ground validation (see section 11.3).

Outside the nominated areas, the mapping is based on vegetation modelling and has not undergone the same degree of validation. In these areas, the process to determine candidate TEC polygons was subject to several assumptions and limitations relating to the accuracy of the vegetation mapping, the age of the LiDAR data, and the angle and aspect of the aerial imagery used. These limitations were addressed where possible by testing the models that generated the TEC mapping based on desktop validation and making iterative updates to the models.

Other criteria in the conservation or listing advices relating to the condition or floristic composition and structure of the patch, can only be accurately determined from on-ground surveys. Where surveys were undertaken, this data was used to provide an accurate determination about whether a patch comprised a TEC. However, due to the large size of the Strategic Assessment Area and limited land access, many candidate TEC patches could not be validated on-ground. To address this limitation, assumptions about the condition of a patch were made at a desktop level based on the size of the patch, its likely resilience to degradation, and its likelihood of being edge effected.

To address the lack of certainty around patches of candidate TEC that could not be validated through on-ground surveys, all non-validated candidate TEC patches were assigned to a category reflecting the potential of the patch to comprise the TEC. This was based on the assumption that larger and better condition patches of vegetation that have satisfied the criteria for Steps 3 to 7 are more likely to meet the listing criteria for the TEC. This step was undertaken to provide transparency around the level of certainty in the TEC mapping and to provide the highest level of assurance possible around the potential impacts of the project on Commonwealth-listed TECs.

It is important to note that the peer review (see section 10.4) concluded that the Commonwealth-listed TEC mapping method is generally conservative and likely to over-predict the distribution of TECs in the Strategic Assessment Area.

RESULTS

Nine of the ten potentially relevant TECs were determined to be present in the Strategic Assessment Area. *Blue Gum High Forest in the Sydney Basin Bioregion* was found not to be present.

The results of the mapping for Commonwealth-listed TECs is provided in Chapter 31.

Table 11-9: Rule set for mapping Commonwealth-listed TECs within the nominated areas

PCT no.	Commonwealth TEC	Distribution/ size class criteria	Specific criteria
883 958	*Castlereagh Scribbly Gum and Agnes Banks Woodlands of the Sydney Basin Bioregion*	Patch size ≥0.5 ha AND greater than 30 per cent (and less than 50 per cent) of the perennial understorey vegetation cover is made up of native species (field verification) AND the patch is contiguous with a native vegetation remnant >1 ha in area AND Growing on tertiary sands and gravels of the Hawkesbury-Nepean river system	Greater than (or equal to) 50 per cent of the perennial understorey vegetation cover is made up of native species A low woodland, with canopy species reaching an average 15 m in height, but with some trees growing to around 20 m
		Patch size ≥ 0.5 ha AND Greater than (or equal to) 50 per cent of the perennial understorey vegetation cover is made up of native species (field verification) AND Patch is contiguous with a native vegetation remnant >1 ha in area AND Elevations below 80 m AND Growing on tertiary sands and gravels of the Hawkesbury-Nepean river system AND greater than 30 per cent (and less than 50 per cent) of the perennial understorey vegetation cover is made up of native species	A low woodland, with canopy species reaching an average 15 m in height, but with some trees growing to around 20 m
1800	*Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland ecological community*	Patch size ≥ 5 ha OR Patch size at least 2 ha and < 5 ha OR Patch is at least 0.5 ha and < 2 ha and is connected to a larger area of native vegetation of at least 5 ha AND Non-native species comprise less than 20 per cent of total understorey vegetation cover	Non-native species comprise less than 50 per cent of total understorey vegetation cover
		Patch size ≥ 5 ha OR Patch size at least 2 ha and < 5 ha OR Patch is at least 0.5 ha and < 2 ha and is connected to a larger area of native vegetation of at least 5 ha	Non-native species comprise less than 50 per cent of total understorey vegetation cover AND transformer species* comprise less than 30 per cent of total understorey vegetation cover

PCT no.	Commonwealth TEC	Distribution/ size class criteria	Specific criteria
		AND Non-native species comprise less than 50 per cent of total understorey vegetation cover	
725	*Cooks River / Castlereagh Ironbark Forest in the Sydney Basin Bioregion*	Patch size greater than or equal to 0.5 ha (Patch size > 0.1 ha in areas east of Riverstone 150◎ 51′ 38″E) AND Greater than or equal to 30 per cent of the perennial understorey vegetation cover is made up of native species (field verification) AND Below 100 m elevation AND Rainfall 800-1000 mm pa AND Growing on Clay rich soils derived from tertiary alluvium and on Wianamatta derived shale soils found next to tertiary alluvium AND the patch is contiguous with a native vegetation remnant > 1ha OR the patch has at least one tree with hollows or at least one large locally indigenous tree (>80 cm diameter at breast height) (field verification)	Greater than or equal to 50 per cent of the perennial understorey vegetation cover is made up of native species
		Patch size ≥ 0.5 ha (Patch size > 0.1 ha in areas east of Riverstone 150 51′ 38″E) AND Greater than or equal to 50 per cent of the perennial understorey vegetation cover is made up of native species (field verification) AND Below 100 m elevation AND Rainfall 800-1000 mm pa AND Growing on clay rich soils derived from tertiary alluvium and on Wianamatta derived shale soils found next to tertiary alluvium	Consistent canopy, mid and ground strata layers in accordance with the listing advice species composition Greater than or equal to 30 per cent of the perennial understorey vegetation cover is made up of native species Where patch is not contiguous with a native vegetation remnant >1 ha, patch must have one tree with hollows or at least one large locally indigenous tree (>80 cm diameter at breast height)
724 849 850	*Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest*	Patch size ≥ 0.5 ha AND > 50 per cent perennial understorey vegetation made up of natives (field verification) OR patch size ≥ 5 ha AND >30 per cent perennial understorey made up of natives (field verification) AND Below 350 m elevation	Canopy cover greater than 10 per cent For patches greater than 0.5 ha native understorey cover is greater than 50 per cent OR for patches greater than 5 ha, native understorey cover is greater than 30 per cent

PCT no.	Commonwealth TEC	Distribution/ size class criteria	Specific criteria
		AND Growing on clay soils derived from Wianamatta	
		Patch size ≥ 0.5 ha AND > 30 per cent native understorey (field verification) AND is contiguous with a native vegetation remnant ≥ 5 ha OR patch size ≥ 0.5 ha AND > 30 per cent perennial understorey vegetation made up of natives AND the patch has at least one tree with hollows per ha or at least one large tree (≥ 80 centimetre diameter at breast height) per ha (field verification). AND Below 350 m elevation AND Growing on clay soils derived from Wianamatta	Native understorey cover is greater than 30 per cent AND/OR at least one tree with at least one tree with hollow per ha or at least one large tree (≥80 centimetre diameter at breast height) per ha Consistent canopy, and either mid and/or ground strata layers in accordance with the listing advice species composition
1395 1281	*Shale Sandstone Transition Forest in the Sydney Basin Bioregion*	Patch size ≥ 0.5 ha AND > 50 per cent of the perennial understorey vegetation cover is made up of native species (field verification) OR patch size ≥ 2 ha AND > 50 per cent of the perennial understorey vegetation cover is made up of native species (field verification) AND Rainfall 800-1100 mm pa AND Growing on Shale or sandstone soil substrates	Consistent canopy, mid and ground strata layers in accordance with the listing advice species composition Where patch size is 0.5–2 ha, native understorey cover is greater than 70 per cent OR where patch size is greater than 2 ha, native understorey cover is greater than 50 per cent
		Patch size ≥ 0.5 ha AND > 30 per cent perennial understorey vegetation made up of natives AND the patch has at least one tree with hollows per ha or at least one large tree (≥ 80 centimetre diameter at breast height) per ha OR the patch is contiguous with a native vegetation remnant ≥ 1 ha (field verification) OR patch size ≥ 0.5 ha and > 50 per cent perennial understorey vegetation made up of natives (field verification) AND Rainfall 800-1100 mm pa AND Growing on Shale or sandstone soil substrates	Where patch size is greater than 0.5 ha, native understorey cover is greater than 50 per cent OR where patch size is greater than 0.5 ha, native understorey cover is greater than 30 per cent and patch is not contiguous with another remnant greater than 1ha, at least one tree with hollows per ha or at least one large tree (≥ 80 cm diameter at breast height) per ha

PCT no.	Commonwealth TEC	Distribution/ size class criteria	Specific criteria
		Some areas of regrowth intact woodland	
830 877	*Western Sydney Dry Rainforest and Moist Woodland on Shale*	Patch size ≥ 0.1 ha AND at least 20 native species present in sample 0.04 ha plot AND non-native perennial plants no more than 50 per cent of total vegetation cover (field verification) AND Below 300 m elevation AND Growing on clay soils derived from Wianamatta	At least 20 native species present in sample 0.04 ha plot AND non-native perennial plants no more than 50 per cent of total vegetation cover

Table 11-10: Rule set for mapping Commonwealth-listed TECs outside the nominated areas

PCT no.	Commonwealth TEC	Condition Class	Distribution criteria – GIS	Specific criteria – assumed
1237	*Blue Gum High Forest in the Sydney Basin Bioregion*	A or B	Patch size > 1 ha	Canopy cover greater than 10 per cent
		Low and moderate	Patch size > 1 ha AND occurs in areas of native vegetation in excess of 5 ha	Canopy cover less than 10 per cent Diagnostic species present
883 958	*Castlereagh Scribbly Gum and Agnes Banks Woodlands of the Sydney Basin Bioregion*	A or B	Patch size ≥ 0.5 ha AND Patch is contiguous with a native vegetation remnant > 1 ha in area	Diagnostic species present Greater than (or equal to) 50 per cent of the perennial understorey vegetation cover is made up of native species
		Low and moderate	Patch size ≥ 0.5 ha AND the patch is contiguous with a native vegetation remnant > 1 ha in area	Greater than 30 per cent (and less than 50 per cent) of the perennial understorey vegetation cover is made up of native species Diagnostic species present
1800	*Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland ecological community*	A or B Low and moderate	Patch size ≥ 5 ha OR Patch size at least 2 ha and < 5 ha OR Patch is at least 0.5 ha and < 2 ha and is connected to a larger area of native vegetation of at least 5 ha	Non-native species comprise less than 50 per cent of total understorey vegetation cover AND transformer species* comprise less than 30 per cent of total understorey vegetation cover
725	*Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion*	A or B	Patch size ≥ 0.5 ha (Patch size > 0.1 ha in areas east of Riverstone (150° 51′ 38″E))	Greater than or equal to 50 per cent of the perennial understorey vegetation cover is made up of native species Diagnostic species present
		Low and moderate	Patch size greater than or equal to 0.5 ha (Patch size > 0.1 ha in areas east of Riverstone (150° 51′ 38″E)) AND the patch is contiguous with a native vegetation remnant > 1ha OR the patch has at least one tree with hollows or at least one large locally indigenous tree (> 80 cm diameter at breast height) (field verification)	Diagnostic species present Greater than or equal to 30 per cent of the perennial understorey vegetation cover is made up of native species Where patch is not contiguous with a native vegetation remnant greater than 1 ha, patch must have one tree with hollows or at least one large locally indigenous tree (>80 cm diameter at breast height)

PCT no.	Commonwealth TEC	Condition Class	Distribution criteria – GIS	Specific criteria – assumed
724 849 850	*Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest*	A or B Low and moderate	Patch size ≥ 0.5 ha AND > 50 per cent perennial understorey vegetation made up of natives (field verification) OR patch size ≥ 5 ha AND > 30 per cent perennial understorey made up of natives (field verification)	For patches greater than 0.5 ha native understorey cover is greater than 50 per cent OR for patches greater than 5 ha, native understorey cover is greater than 30 per cent Diagnostic species present
			Patch size ≥ 0.5 ha AND > 30 per cent native understorey (field verification) AND is contiguous with a native vegetation remnant ≥ 5 ha OR patch size ≥ 0.5 ha AND > 30 per cent perennial understorey vegetation made up of natives AND the patch has at least one tree with hollows per ha or at least one large tree (≥ 80 cm diameter at breast height) per ha (field verification)	Native understorey cover is greater than 30 per cent AND / OR at least one tree with hollow per ha or at least one large tree (≥ 80 cm diameter at breast height) per ha Diagnostic species present
1395 1281	*Shale Sandstone Transition Forest in the Sydney Basin Bioregion*	A or B Low and moderate	Patch size ≥ 0.5 ha AND > 70 per cent of the perennial understorey vegetation cover is made up of native species (field verification) OR patch size ≥ 2 ha AND > 50 per cent of the perennial understorey vegetation cover is made up of native species (field verification)	Consistent canopy, mid and ground strata layers in accordance with the listing advice species composition Where patch size is 0.5 – 2 ha, native understorey cover is greater than 70 per cent OR where patch size is greater than 2 ha, native understorey cover is greater than 50 per cent Tree density and diversity present, including mature trees Regrowth is acceptable for intact vegetation assuming the justification criteria are met
			Patch size ≥ 0.5 ha AND > 30 per cent perennial understorey vegetation made up of natives AND the patch has at least one tree with hollows per ha or at least one large tree (≥80 centimetre diameter at breast height) per ha OR the patch is contiguous with a native vegetation remnant ≥1 ha (field verification) OR patch size ≥ 0.5 ha and > 50 per cent perennial understorey	Diagnostic species present Where patch size is greater than 0.5 ha native understorey cover is greater than 50 per cent OR where patch size is greater than 0.5 ha, native understorey cover is greater than 30 per cent and patch is not contiguous with another remnant greater than 1ha, at least one tree with hollows per ha or at least one large tree (≥80 centimetre diameter at breast height) per ha

PCT no.	Commonwealth TEC	Condition Class	Distribution criteria – GIS	Specific criteria – assumed
			vegetation made up of natives (field verification)	
1281 1284	*Turpentine–Ironbark Forest of the Sydney Basin Bioregion*	A or B Low and moderate	Patch > 1 ha AND tree canopy cover > 10 per cent (field verification)	Tree canopy cover > 10 per cent Consistent canopy, mid and ground strata layers in accordance with the listing advice species composition Diagnostic species present
			Patch > 1 ha AND tree canopy cover < 10 per cent (field verification) AND part of a remnant of native vegetation > 5 ha	Tree canopy cover less than 10 per cent Diagnostic species present
830 877	*Western Sydney Dry Rainforest and Moist Woodland on Shale*	A or B Low and moderate	Patch size ≥ 0.1 ha	At least 20 native species present in sample 0.04 ha plot AND non-native perennial plants no more than 50 per cent of total vegetation cover Extent accuracy of updated native vegetation map Diagnostic species present

*Transformer species (e.g. *Chrysanthemoides monilifera, Asparagus* spp, *Pennisetum* spp, *Ipomoea* spp. etc.) are non-native plant species with the potential to permanently change the character, condition, form or nature of patches of the ecological community.

11.5 THREATENED SPECIES

11.5.1 OVERALL APPROACH TO SPECIES MAPPING

To meet the requirements of the BAM and the ToR, species habitat maps have been prepared for all:

- NSW-listed candidate SCS within the nominated areas
- Commonwealth-listed Category 1 species within the Strategic Assessment Area

The BAM does not require mapping of NSW-listed ECS, as these species are associated with specific PCTs and their presence in these PCTs is assumed for the purposes of the BAM.

Different mapping methods were applied within the nominated areas and outside the nominated areas within the Strategic Assessment Area, as well as to NSW-listed candidate SCS and Commonwealth-listed Category 1 species because of the different requirements of the BAM and ToR.

In general:

- Within the nominated areas – detailed species habitat mapping was undertaken based on field surveys (where landholders granted access to land) in accordance with the BAM, or an expert report was generated to complement the survey work to ensure compliance with BAM
- Outside the nominated areas – broader species habitat mapping was undertaken based on the best available existing information on species (including species records) in accordance with the ToR

In some cases, a habitat map was prepared for a Commonwealth-listed Category 1 species within the nominated areas in accordance with the BAM because the Commonwealth species is also a NSW-listed species. In these cases, that nominated areas species map was integrated into the species map of the Strategic Assessment Area and formed the basis of the assessment of impacts on that species within the nominated areas.

Table 11-11 summarises the mapping methods within and outside the nominated areas for NSW-listed candidate SCS and Commonwealth-listed Category 1 species.

Table 11-11: Summary of mapping approaches for NSW and Commonwealth-listed species

Species	Mapping area	Mapping method
NSW-listed candidate SCS	Nominated areas	Species polygon mapping, either based on: • Expert reports (section 6.5.2 of BAM), or • Assumed presence using a knowledge-based method (section 6.4.1.30 of BAM)
Commonwealth-listed Category 1 species	Strategic Assessment Area	• Species Distribution Modelling, where species records are adequate, or • Assumed presence using a knowledge-based method as for NSW-listed candidate SCS, where species records are not adequate
		For Commonwealth-listed species that have habitat maps prepared within the nominated areas (because they are also NSW-listed candidate SCS), the maps incorporate the nominated area mapping (e.g. including any expert report polygons)

11.5.2 NSW-LISTED SPECIES

Purpose

Section 6 of the BAM requires the BCAR to map 'species polygons' (area of occupied habitat with buffer, or suitable habitat, or likely suitable habitat) for each NSW-listed candidate SCS within the nominated areas, where either:

- A survey or expert report confirms a SCS is present or likely to use suitable habitat, or
- A SCS is assumed to be present

A species polygon must be used to identify:

- The location of suitable habitat for each species
- The area of suitable habitat, or number of individuals within suitable habitat, for each species
- The condition of the suitable habitat (for species assessed on the basis of area of suitable habitat)

METHOD

Consistent with the BAM, NSW-listed candidate SCS were mapped using either:

- Expert reports (section 6.5.2 of BAM), or
- Assumed presence using a knowledge-based method (section 6.4.1.30 of BAM)

It is important to note that both methods resulted in maps of potential habitat for each species within the nominated areas. Potential habitat represents areas where a species may occur, but it not necessarily known to occur. These habitat maps are conservative and are very likely to greatly overestimate the area of actual habitat for these species.

Table 11-12 summarises the mapping method used for each NSW-listed candidate SCS.

Table 11-12: Summary of mapping method used for NSW-listed candidate SCS

Species	Expert report	KBM
Acacia bynoeana	Yes	
Acacia pubescens	Yes	
Allocasuarina glareicola		Yes
Callocephalon fimbriatum		Yes
Calyptorhynchus lathami		Yes
Cercartetus nanus		Yes
Chalinolobus dwyeri		Yes
Dillwynia tenuifolia	Yes	
Epacris purpurascens var. *purpurascens*		Yes
Eucalyptus benthamii		Yes
Grevillea juniperina subsp. *juniperina*	Yes	
Grevillea parviflora subsp. *parviflora*		Yes
Haliaeetus leucogaster		Yes
Heleioporus australiacus		Yes
Hibbertia fumana	Yes	
Hibbertia puberula	Yes	
Hieraaetus morphnoides	Yes	Yes
Litoria aurea	Yes	
Lophoictinia isura	Yes	Yes
Marsdenia viridiflora subsp. *viridiflora* - endangered population		Yes
Maundia triglochinoides		Yes
Melaleuca deanei	Yes	
Meridolum corneovirens	Yes	
Micromyrtus minutiflora		Yes

Species	Expert report	KBM
Myotis macropus		Yes
Ninox connivens		Yes
Ninox strenua		Yes
Persicaria elatior		Yes
Persoonia bargoensis		Yes
Persoonia nutans	Yes	
Petaurus norfolcensis		Yes
Phascolarctos cinereus		Yes
Pimelea curviflora var. *curviflora*		Yes
Pimelea spicata	Yes	
Pomaderris brunnea		Yes
Pseudophryne australis		Yes
Pterostylis saxicola	Yes	
Pultenaea parviflora		Yes
Pultenaea pedunculata		Yes
Tyto novaehollandiae		Yes

Expert reports

This method was used to define species polygons for species where expert reports were prepared. The expert reports were prepared in accordance with Section 6.5.2 of the BAM and are provided in Supporting Document C.

Expert reports were prepared for species that:

- Could not be sufficiently surveyed for due to either access restrictions, seasonality or their cryptic nature
- Had highly specific habitat requirements and restrictions for which expert advice was required

Table 11-12 shows the NSW-listed candidate SCS for which expert reports were prepared.

The methods and assumptions used to map species habitat for each species, and the credentials of the expert who prepared the report, is provided in each expert report. The experts conducted field surveys where access was granted.

Habitat polygons in expert reports were further refined by undertaking seasonal surveys within potential habitat and excluding areas from the habitat polygons where either the specific habitat components required by the species were found not to be present (in accordance with BAM section 6.4), or the species were not detected (in accordance with BAM section 6.5). Where adequate surveys were undertaken within potential habitat and the species was not found to be present, the areas surveyed were removed from the habitat map for that species.

For flora species, this was done by classifying habitat into high, moderate or low quality for each species based on native vegetation condition, and applying the following buffers to GPS survey tracks depending on the classification:

- Trees:
  - High (Intact): 40 m either side of the transect line
  - Moderate or Low (Thinned, Scattered Trees, DNG): 40 m either side of the transect line
- Shrubs, herbs, forbs, grasses, other:
  - High (Intact): 20 m either side of the transect line
  - Moderate or Low (Thinned, Scattered Trees, DNG): 40 m either side of the transect line

It is acknowledged that these buffers were generally greater than those prescribed for transect separation distances in the *NSW Guide to Surveying Threatened Plants* (OEH 2016). Increased transect separation widths were undertaken to ensure a greater coverage of potential habitat during surveys. Transect separation distances were generally doubled from the recommended separation detailed in the guidelines. This is considered appropriate given the very large size of the study area. Based on experience in the field for this project and nature of the habitats being surveyed, it is considered likely that any larger populations of threatened plants would be (and were) recorded in undertaking surveys in this manner.

For fauna species, habitat assessment polygons and habitat confirmation polygons were used to refine the habitat polygons based on the ground-truthed habitat data collected (these were captured in the field using handheld tablet devices running Collector for ArcGIS software). Where field data confirmed a specific habitat component was missing from a patch of vegetation (i.e. leaf litter and woody debris), the habitat polygons for the species dependant on those components (i.e. Cumberland Plain Land Snail) was refined.

Assumed presence using a knowledge-based method

Assumed presence using a knowledge-based method was used to define species polygons for species where expert reports were not prepared. For some species, habitat polygons were mapped by assuming presence over all vegetation zones that the species is predicted to occur within (following steps 1-4, BAM section 6.4), in accordance with BAM section 6.4.1.30 (note that no vegetation zones were excluded on the basis of an assessment of habitat constraints under BAM section 6.4.1.10). For other species, vegetation zones were refined based on additional information about the species in BioNet or other published literature (e.g. known habitat or geographic constraints). This is consistent with section 6.1.1.2 of the BAM, which states that 'an assessor may use additional information about a threatened species, in BioNet (e.g. the profile of a threatened species) or published, peer reviewed literature, when assessing the habitat suitability of a site'. The rule sets applied to refine the vegetation zones for these species is provided in Attachment B.

The key steps in the method were:

Step 1: Collate information on records and potential habitat into species profiles for each species. The following information and datasets were used to collate species profiles:

- DAWE Protected Matters Search Tool and Species Profile and Threats Database
- EES BioNet Atlas and Threatened Biodiversity Data Collection
- PlantNET
- BirdLife Australia, the New Atlas of Australian Birds 1998-2015
- BioNet Vegetation Classification database (OEH, 2018a)
- Remnant Vegetation of the Western Cumberland Subregion 2013 Update VIS_ID 4207 (OEH, 2013b)
- Native Vegetation of the Sydney Metropolitan Area VIS_ID 4489 (OEH, 2016b)
- Catchment Boundaries of New South Wales dataset
- NSW (Mitchell) Landscapes Version 3.0
- State Environmental Planning Policy (SEPP) Coastal Management
- NSW Soil and Land Information System (SALIS)
- Soil Landscapes of the Sydney, Penrith and Wollongong-Port Hacking 1:100 000 map sheets (Chapman & Murphy, 1989; Hazelton & Tille, 1990; Bannerman & Hazelton, 1990)
- Handbook of Australian, New Zealand and Antarctic Birds (Higgins, 1999)
- Conserving Koalas in Wollondilly and Campbelltown LGAs (OEH, 2018b)
- Terrestrial Vertebrate Fauna of the Greater Southern Sydney Region Volume 2 (DECC, 2007)
- Cumberland Plain Recovery Plan (DECCW, 2011)
- Threatened ecological community determinations, conservation advices and listings
- BirdLife Australia shorebird data
- Topographic information

Step 2: Map areas of potential habitat. Potential habitat was initially mapped for each species on the basis of habitat associations with PCTs using the relevant PCT and condition class for the species identified in BioNet and the updated native vegetation maps. These maps were then refined for each species using the information within species profiles collated in step 1, including data on species records. The rule-sets built from the species profiles that were used to map potential habitat for each species are provided in Attachment B.

Step 3: Undertake targeted field surveys. Surveys were undertaken within urban capable lands or transport corridors on land where access was provided by landholders. Details of species surveys and survey effort is provided below.

Step 4: Integrate results from targeted surveys. The results of species surveys were used to refine the potential habitat maps for each species. Where adequate surveys were undertaken within potential habitat in Step 3, and the species was not found to be present, the areas surveyed were removed from the habitat map for that species. This was done by classifying habitat into high, moderate or low quality for each species based on native vegetation condition, and applying the following buffers depending on the classification:

- Trees:
  - High (Intact): 40 m either side of the transect line
  - Moderate or Low (Thinned, Scattered Trees, DNG): 40 m either side of the transect line
- Shrubs, herbs, forbs, grasses, other:
  - High (Intact): 20 m either side of the transect line
  - Moderate or Low (Thinned, Scattered Trees, DNG): 40 m either side of the transect line

Step 5: Define species polygons by assuming presence in potential habitat. Species polygons were created for each species based on the:

- Area of potential habitat, including species records (Step 1 and Step 2)
- Results of targeted surveys (Step 4)

Targeted surveys

The BAM requires surveys to be undertaken for candidate SCS in accordance with EES survey guidelines, including the *'Species credit' threatened bats and their habitats NSW survey guide for the Biodiversity Assessment Method* (OEH, 2018f), *Threatened species survey guidelines for Amphibians* (DECC, 2009) and *NSW Guide to surveying threatened plants* (OEH, 2016a). Where no survey guidelines exist, surveys must be undertaken using best practice methods.

Targeted surveys were focused within areas of potential habitat for species within the urban capable lands and transport corridors of the nominated areas. A total of approximately 2,190 hectares of combined threatened species habitat was surveyed. The candidate SCS recorded during the surveys are identified in Part 5.

Surveys were undertaken on all land where access was granted by landholders, in accordance with relevant EES survey guidelines where possible. Not all surveys were able to be undertaken in accordance with survey guidelines due to lack of access to land or seasonal constraints. In accordance with the BAM, this was addressed by:

- Preparing expert reports
- Assuming species presence within areas of potential habitat

Initial surveys – 2017 to 2018

Initial surveys for flora and fauna were undertaken across all nominated areas between November 2017 and November 2018, by Biosis and Ecoplanning ecologists. Each survey team comprised of a minimum of two people, including one Accredited BAM Assessor.

The knowledge-based method and expert report species polygons were reviewed following initial field surveys and further refined by excluding areas of habitat where the species, or suitable habitat, was not recorded. Habitat polygons that were not surveyed (or survey data was deficient), were retained for each species credit species, and presence was assumed for the purpose of impact calculations in accordance with the BAM.

Winter and spring surveys – 2019

Following analysis by the ecological consulting team, it was decided that further surveys were required. These surveys were undertaken to ground-truth the KBM and expert report habitat maps with the purpose of confirming the presence or absence of species habitat in locations where access had been limited in the past.

Habitat maps were then updated based on the results of the surveys.

Pre-survey workshops were held between the ecological consulting team and the Department in June 2019 to determine an approach to the survey work, prioritise species for survey, determine which species could be surveyed for immediately, and the locations where targeted surveys should be undertaken.

The approach to gaining land access included targeted letter correspondence, phone calls (where available) and door knocking. It was determined that two additional survey periods would be undertaken, a winter 2019 survey and a spring 2019 survey in order to cover the defined survey periods of the included targeted species under the BAM. These surveys included targeted flora searches as well as targeted fauna habitat assessments.

The survey locations of the winter and spring surveys were determined and prioritised based on a combination of:

- Land access availability
- Total area of target species potential habitat mapped on a property
- Total number of species with potential habitat mapped on a property
- Distribution of properties across the nominated areas, to gain a broader coverage

Broad priority locations were determined based on the above criteria, and the Department contacted landowners to arrange access for targeted surveys. Once permission was obtained, each survey day was planned to ensure maximum coverage of the Plan Area by grouping sites supported by multiple survey teams across the nominated areas. In addition to the Department contacting landowners to arrange access, Biosis also undertook a number of doorknocking surveys in an attempt to gain access to additional private properties located within the Plan Area.

The winter 2019 targeted surveys were undertaken between 29 June and 02 August 2019 by both Biosis and Ecoplanning ecologists. The spring 2019 targeted surveys were undertaken between 17 October and 17 December 2019 by Biosis ecologists. Each survey team comprised of a minimum of two people, including one Accredited BAM Assessor.

Fauna surveys

Survey effort for the initial targeted fauna surveys undertaken within the nominated areas is summarised in Table 11-13. Survey effort for the targeted fauna habitat assessments undertaken during the winter 2019 and spring 2019 surveys is included in Table 11-14 (winter 2019), and Table 11-15 (spring 2019).

The weather conditions during the initial targeted fauna survey period are summarised in Table 11-16.

Map 8 shows the locations of targeted fauna surveys within the nominated areas.

Flora surveys

Targeted flora survey effort is summarised in Table 11-17 (initial targeted flora survey effort), Table 11-18 (winter 2019 targeted flora survey effort) and Table 11-19 (spring 2019 targeted flora survey effort). Flora surveys were undertaken within each PCT and vegetation zone and extended up to 50 m into habitat adjacent to the edge of urban capable lands or transport corridors. Flora species included in winter and spring targeted surveys are detailed in Table 11-20.

Map 8 shows the locations of the targeted flora surveys within the nominated areas.

Table 11-17: Initial targeted flora survey effort

Nominated area	Date	Method	Combined area (ha) of habitat surveyed	Surveyor
Wilton	34 days, Nov 2017 - Sept 2018	Targeted meanders/transects in suitable habitat	445.76	Ecoplanning and Biosis

Scientific name	Common name	Initial surveys*	Winter 2019 survey	Spring 2019 survey	Nominated area
Pultenaea pedunculata	Matted Bush-pea		No	Yes	Wilton GMAC GPEC WSA

*The initial survey period occurred from November 2017 to November 2018 with targeted species surveys within this period occurring according to applicable species survey timeframes.

RESULTS

The habitat maps of each NSW-listed candidate SCS are provided in Chapter 21.

As for the expert report habitat polygons, polygons based on KBMs were further refined by undertaking seasonal surveys within potential habitat and excluding areas from the polygons where either the specific habitat components required by the species were found not to be present (in accordance with BAM section 6.4), or the species were not detected (in accordance with BAM section 6.5). Where adequate surveys were undertaken within potential habitat and the species was not found to be present, the areas surveyed were removed from the habitat map for that species. The process used to refine the KBM habitat polygons is outlined above under 'expert reports'.

11.5.3 COMMONWEALTH-LISTED SPECIES

PURPOSE

Section 3.2 of the ToR requires the SAR to describe for the Strategic Assessment Area the protected matters that may be impacted directly, indirectly and cumulatively by actions taken under the Plan. This includes:

- Identification of key sites and habitats
- Identification of important populations

METHOD

Habitat for Commonwealth-listed Category 1 species was mapped within the Strategic Assessment Area using either:

- Species Distribution Modelling where species data is adequate, or
- Assumed presence using a knowledge-based method

In some cases, a map has been prepared for a Commonwealth-listed Category 1 species within the nominated areas in accordance with the BAM because the Commonwealth species is also a NSW-listed candidate SCS. In these cases, that nominated areas species map was integrated into the Strategic Assessment Area species map and formed the basis of the assessment of impacts on that species within the nominated areas.

Table 11-21 summarises the mapping method used for each Commonwealth-listed Category 1 species, and shows where any nominated area mapping has been integrated into the Strategic Assessment Area map for a Commonwealth species.

Table 11-21: Summary of mapping method used for Commonwealth-listed Category 1 species

Scientific Name	Nominated areas		Strategic Assessment Area

Pterostylis saxicola	Yes			Yes
Pultenaea parviflora		Yes	Yes	
Rostratula australis				Yes

Species Distribution Modelling

SDM was undertaken for Commonwealth-listed Category 1 species within the Strategic Assessment Area where adequate species records were available to develop a model. SDMs were developed for 19 Commonwealth-listed Category 1 species (6 fauna species and 13 flora species).

SDMs are statistical models used to estimate the relationship between species records at sites and the environmental and/or spatial characteristics of those sites. Once this relationship has been estimated, the SDM can be used to predict other locations in the landscape where the species is likely to occur.

SDMs were developed using the software package 'Maxent'. Data required for the modelling included:

- Species records obtained from BioNet. During a review of the records, various errors were identified. Ecologists were engaged to review the records and amend or exclude those with errors.
- Twenty-one environmental predictors that were used to establish the relationships between species records at sites and the environmental and/or spatial characteristics of those sites. These included:
    - Native vegetation community (PCTs)
    - Soil type
    - Mean annual temperature
    - Mean annual radiation
    - Number of days per year with minimum temperature less than 2 degrees
    - Latitude
    - Distance to streams
    - Topographic position

An approach was developed to account for the different levels of bias likely to be present in the species records. This resulted in the development of three maps for each species with different assumptions regarding bias in the records, depicting the likelihood of occurrence for each species. These three maps were then combined to produce a single SDM for each species with three classes of occurrence for each species:

- Unlikely to occur – none of the three models predicted the species to occur
- Potential to occur – at least one of the three models predicted the species to occur
- Likely to occur – all three of the models predicted the species to occur

Details of the SDM method and the results of the mapping is provided in Supporting Document F.

Assumed presence using a knowledge-based method

Where adequate species records were not available, Commonwealth-listed Category 1 species within the Cumberland subregion were mapped on the basis of assumed presence using a knowledge-based method. This method is the same method applied to NSW-listed candidate SCS within the nominated areas (see Section 11.5.2). The species profiles for each species, including habitat associations with PCTs, are provided in Attachment B.

Important populations

The term 'important populations' refers to a concept applied under the EPBC Act to inform the assessment of impacts of actions, such as urban development, on matters of national environmental significance. Important populations are defined in the Commonwealth's Significant Impact Guidelines (Policy Statement 1.1) (DoE, 2013) as:

> *Any population of a vulnerable species which meets the definition of an important population in the Commonwealth's Significant Impact Guidelines (Policy Statement 1.1) as follows:*
>
> *'A population that is necessary for a species' long-term survival and recovery. This may include populations identified as such in recovery plans, and/or that are:*
>
> - *key source populations either for breeding or dispersal*
> - *populations that are necessary for maintaining genetic diversity, and/or*
> - *populations that are near the limit of the species range'*

For the purposes of the SAR, important populations are also defined as including any population of an endangered or critically endangered species. Under the EPBC Act, all populations of an endangered or critically endangered species are considered to be important for the survival and recovery of the species.

The following steps were undertaken to identify and map important populations for critically endangered, endangered and vulnerable Commonwealth-listed Category 1 matters:

Step 1: Development criteria for defining important populations for vulnerable Commonwealth-listed Category 1 matters. The criteria and rationale for each criterion is provided in Table 11-22.

Step 2: For each species, BioNet records were analysed to define biological populations of the species. This analysis was undertaken by senior ecologists with knowledge and expertise in the ecology of each species. Where gene flow between two records is considered likely, the records were assigned to the one population. The ecologists took the following factors into account in determining whether gene flow is likely between records:

- Distance between individual flora records
- The presence of features or barriers that might limit demographic or genetic exchange
- Pollinator type and seed dispersal mechanism (where known)
- The continuity of patches of vegetation

Attachment C sets out the assumptions made in defining biological populations for each species.

Step 3: For critically endangered and endangered Category 1 matters:

- Describe and map each population (including identifying population sizes)

Step 4: For vulnerable Category 1 species:

- Collate the required data on each species as per the data sources in Table 11-22
- Apply the criteria in Table 11-22 to each species, using GIS analysis where necessary
- Describe and map each population (including identifying population sizes)

RESULTS

The habitat and important population maps for each Commonwealth-listed Category 1 species are provided in Chapters 29 and 30.

Table 11-22: Criteria for identifying and mapping important populations of vulnerable Commonwealth-listed Category 1 species

	Criteria	Rationale	Data sources
1	Any population of a species identified as a Serious and Irreversible Impacts (SAII) entity under the NSW BC Act	SAII entities have been identified under the NSW BC Act and meet one or more of the following principles: • Species in rapid rate of decline • Very small population size • Very limited geographic distribution • Unlikely to respond to management and therefore irreplaceable Populations of SAII entities therefore make a significant contribution to the conservation of the species	• Threatened Biodiversity Data Collection
2	A population identified or inferred in a Commonwealth conservation advice, recovery plan, final determination, or other relevant policy document as being important	Consistent with the EPBC Act Policy Statement 1.1 (DoE, 2013)	• Recovery plans • Conservation advices • Final determinations
3	A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program	Species targeted by the Saving our Species program have been prioritised for conservation effort under a program that aims to maximise the chance of securing the greatest number of species in the wild. Therefore populations targeted under the NSW Saving our Species program could comply with the following EPBC important population criteria: • Key source populations either for breeding or dispersal • Populations that are necessary for maintaining genetic diversity, and/or • Populations that are near the limit of the species' range	• Saving our Species program conservation projects database
4	A population associated with a commitment made under the Sydney growth centres conservation program	These populations have been previously identified for conservation, have had significant resources attributed to their conservation and are subject to existing commitments under the Sydney growth centres conservation program and should therefore be considered important	• Sydney Growth Centres Strategic Assessment: Program Report (DECCW & DOP, 2010) • NSW *Threatened Species Conservation Act 1995* Order to confer biodiversity certification on the State Environmental Planning Policy (Sydney Region Growth Centres) 2006

	Criteria	Rationale	Data sources
5	Any population of a species that contains more than 20 per cent of the total population (total number of mature individuals in the species) or 20 per cent of the Area of Occupancy (AOO)* of that species	Significant contribution to the conservation of the species. Loss of any population that contains 20 per cent or more of the total population or AOO is justification for change in status from Vulnerable to Endangered under IUCN and EPBC Act criteria (IUCN, 2012)	• BioNet, site specific surveys
6	Any population of a species where the species has less than 10 known subpopulations	These are species that have very few populations. All known populations therefore make a significant contribution to the conservation of the species. Loss of any population of such a species would be significant	• BioNet, site specific surveys
7	Any population of a species that is a large population in the context of the ecology of that species, in the opinion of senior ecologists	Large populations are important from a genetic perspective. They typically will have sufficient genetic diversity, increased evolutionary potential, reduced inbreeding effects and increased probability of long-term viability and persistence	• BioNet, site specific surveys
8	Any population of a species within a conservation reserve (regardless of the number of plants or size, etc)	These populations are important because they are more likely to be effectively managed and have a greater chance of persistence due to their occurrence in a conservation reserve, and therefore make a significant contribution to the conservation and recovery of the species. Conservation reserve refers to those that meet IUCN protected area categories I-IV	• BioNet, site specific surveys • National parks estate data • BioBank and stewardship site data
9	Any population of a species that is important for maintaining the Extent of Occurrence (EOO)^ of that species	Maintaining the full range of a species has a greater chance of retaining the variation within the species (a primary aim of biodiversity conservation). Populations at the extent of occurrence or that are outliers to the more general distribution are likely to contain genetic difference or capacity to persist in different environmental conditions that will provide the species ability to cope and respond to changes in the environment, such as climate change	• BioNet, site specific survey • Commonwealth database profiles/distribution mapping

*AOO is defined as the area within a species 'extent of occurrence' which is occupied by a taxon, excluding cases of vagrancy. The measure reflects the fact that a taxon will not usually occur throughout the area of its extent of occurrence, which may contain unsuitable or unoccupied habitats

^EOO is defined as the area contained within the shortest continuous imaginary boundary which can be drawn to encompass all the known, inferred or projected sites of present occurrence of a species, excluding cases of vagrancy

11.5.4 KOALA

Specific habitat mapping was undertaken for the koala. Three forms of habitat mapping were undertaken. They include:

- An SDM for the species across the Cumberland subregion
- Corridor habitat mapping to identify the species polygons for koala as required by the BAM
- Mapping of habitat critical to the survival of the species

In addition, a connectivity analysis was undertaken for part of the Southern Sydney population.

SPECIES DISTRIBUTION MODEL FOR THE CUMBERLAND SUBREGION

RMIT University was engaged to prepare SDMs for a total of nineteen EPBC listed species found within the Cumberland subregion (see Supporting Document F). As part of this assessment, an SDM was prepared for koalas.

The SDM for koalas was prepared through the following process (Gordon & Koshkina, 2018):

1. Species records for koalas within the Cumberland subregion were sourced from BioNet and examined. The following records were removed:
    - Erroneous/inaccurate records
    - Records which were *not* associated with native vegetation were also removed, as records outside of native vegetation were taken to represent dispersing male koalas outside of regular habitat areas following the breeding season, or of records of areas that previously supported vegetation that is no longer there
2. A range of environmental parameters associated with koala records were tested for their capacity to predict koala occurrence across the subregion. The parameters which were selected for use in the SDM were those which:
    - Performed well in predicting koala occurrence
    - Did not increase the risk of introducing bias into the model
3. The selected environmental parameters, in addition to koala records, were used as inputs to generate three different SDMs. Each SDM adopted a different modelling methodology which accounted for different types of bias which were likely to be present within the input data
4. The outputs of each SDM were correlated, and a final SDM map was produced with the following categories:
    - 'Unlikely to occur' – Locations where none of the SDM models showed the species occurring
    - 'Potential to occur' – Locations where at least one of the SDM models showed the species occurring. These areas are the most appropriate for assessing potential impacts on the target species
    - 'Likely to occur' – Locations where all three of the SDM models showed the species occurring. These areas are the most appropriate for targeting conservation actions such as offsetting

The results of the SDM mapping are provided in Part 6. Results show the presence of higher quality ('likely to occur') koala habitat in the south of the Cumberland Plain, with small areas of lower quality habitat ('potential to occur') occurring elsewhere in the subregion (predominantly to the north-west and west). Overall, results indicate that there is likely to be very little koala habitat available within the Cumberland subregion.

Despite there being few koala records within the Cumberland subregion, it is recognised that there is an abundance of koala records in close proximity to the boundaries of the Cumberland subregion. For instance, Gordon & Koshkina (2018) recognise that there are over 2,700 records of koalas within a 10 km buffer distance of the subregion boundary.

It is important to recognise that the SDM mapping only shows areas where koalas are likely to be present based on environmental predictors. It does not take into account other key considerations, such as connectivity, habitat quality, minimum habitat patch sizes for population viability or presence of threats. The mapping is therefore indicative, showing the extent and distribution of potential habitat available within the subregion; it does not necessarily indicate which areas of habitat are the most important locations to conserve a species (Gordon & Koshkina, 2018).

CORRIDOR HABITAT MAPPING

Corridor habitat mapping was undertaken using slightly different approaches for:

- Wilton Growth Area (Wilton) and Greater Macarthur Growth Area (GMAC)
- GPEC and WSA

Important habitat

The NSW Threatened Biodiversity Data Collection requires the assessment of impacts on koala to be determined on the basis of 'important habitat'. The koala corridor habitat mapping undertaken within all the nominated areas was used to identify important habitat that comprises the species polygons for koala as required by the BAM.

Koala corridor habitat was mapped using an approach that was consistent with the mapping undertaken by EES (OEH, 2018b) as part of the *Conserving Koalas in the Wollondilly and Campbelltown Local Government Areas* project.

As described in more detail below, the following four types of habitat were mapped:

- Primary corridors: Defined as connected areas of principal habitat (and associated supporting habitat) that provide for ecological function of a population. EES (OEH, 2018b) characterise primary corridors as, "the most important koala habitat in which the bulk of koalas in the area live and breed. The breaking or weakening of primary corridors would have serious ramifications on the long-term viability of koalas in the area, and thereby, the regional koala population"
- Secondary corridors: Defined as corridor areas that become narrow to less than 50 metres wide, or that are not connected at both ends. EES (OEH, 2018b) suggest that, "the retention of secondary corridors is not critical to the long-term viability of the regional koala population; however, enhancement of these corridors would support primary corridors and [principal] koala habitat"
- Tertiary corridors: Defined as smaller corridor areas that are not connected at the landscape level. EES (OEH, 2018b) suggest that, "…[tertiary corridors] are the least valuable connectivity asset to retain for koalas and the regional koala population"
- Supporting habitat: Defined by EES (OEH, 2018b) as "Scattered trees peripheral to and outside of identified koala movement corridors"

Consistent with the categorisation of koala habitat and the focus on protecting key linkages for koala in the landscape (OEH, 2018b), 'important habitat' was defined as primary and secondary corridors. This was considered appropriate as it identifies the areas that are critical to the long-term viability of koalas (primary corridors) as well as the areas (if enhanced) that would support the population (secondary corridors).

Mapping method for Wilton and GMAC

The mapping method for Wilton and GMAC is driven by the "long-established relationship between the presence of koalas and vegetation that grow on higher fertility soils such as shale or shale-transition soils" (OEH, 2018b).

There are five steps in the mapping method:

1. Map koala habitat
2. Identify principal and supporting habitat
3. Identify movement corridors
4. Categorise corridors into primary, secondary and tertiary
5. Define important habitat

Spatial scope of the mapping

The spatial scope of the mapping for Wilton and GMAC was identified as:

- The two nominated areas
- Connected habitat between them
- Habitat to the east to the edge of the Strategic Assessment Area
- West to Bargo

Step 1: Map koala habitat

Using PCTs (see Table 11-23), koala habitat was mapped into three categories (Table 1):

- High quality habitat (HQH) = all shale and shale-enriched vegetation types with a dominant eucalypt canopy

- Moderate quality habitat (MQH) = Eucalypt-dominated riparian sandstone communities, rainforest communities on shale with some eucalypts present, and regenerating *Acacia* scrubs on shale. **NB:** based on the vegetation within Wilton and GMAC and the surrounding land in the Plan Area there are no PCTs that meet this definition of moderate quality
- Low quality habitat (LQH) = Low-fertility sandstone vegetation communities including heaths, heathy woodlands, swamps, and rocky woodlands

Table 11-23: PCTs and koala habitat in Wilton and GMAC

PCT	HQH	MQH	LQH
724 - Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion	Y		
725 - Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion	Y		
830 - Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Y		
835 - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	Y		
849 - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	Y		
850 - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Y		
1081 - Grey Gum woodland on the edges of the Cumberland Plain, Sydney Basin Bioregion.	Y		
1181 - Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion	Y		
1395 - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion.	Y		
1292 - Water Gum - Coachwood riparian scrub along sandstone streams, Sydney Basin Bioregion			Y
883 - Hard- leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion			Y
1800 - Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley			Y

Step 2: Identify principal and supporting koala habitat

Principal habitat is defined as HQH patches greater than 100 ha that contain Koala records.

The remainder of habitat is defined as “supporting”.

Step 3: Identify movement corridors

Movement corridors include:

- All principal habitat except for those patches of principal habitat that are separated by more than 1 km
- Smaller patches of HQH within 100 m of patches of principal habitat in corridors
- Patches of MQH or LQH that connect patches of principal habitat within corridors or are entirely within principal habitat in corridors
- Scattered trees where they are completely or largely contained within corridors

Movement corridors exclude:

- Patches of principal habitat that are separated by more than 1 km
- Patches of MQH or LQH peripheral to corridors
- Scattered trees peripheral to corridors

Step 4: Categorise corridors into primary, secondary and tertiary

Primary corridors are identified as:

- Movement corridors that include patches of principal habitat which are contiguous (gaps between trees <100 m) and together contain greater than 380 ha

Secondary corridors are identified as:

- Movement corridors that include patches of principal habitat separated by more than 100 m from scattered trees or other principal habitat
- Are narrow or have pinch points of less than 50 m wide
- Together contain between 100 ha and 380 ha of principal habitat
- Otherwise, if containing greater than 380 ha of habitat or are not narrow, secondary corridors are those that do not connect to primary corridors on both ends

Tertiary corridors are identified as:

- Patches of principal habitat not linked to primary corridors
- Together contain between 30 ha and 100 ha of principal habitat
- Do not connect to other corridors on both ends
- Otherwise, if containing greater than 100 ha of habitat, tertiary corridors are those that lead away from other corridors

Step 5: Define important habitat

As described above, important habitat comprises the species polygons for koala as required under the BAM and is defined for this assessment as comprising primary and secondary corridors.

Mapping method for GPEC and WSA

The koala habitat mapping method for GPEC and WSA is based on the same concepts used for Wilton and GMAC. However, the same quantitative thresholds used for Wilton and GMAC are not transferrable to other areas. For this reason, habitat quality, and area thresholds for Koala habitat and corridors are not defined, nor any buffer areas.

This method of mapping is only indicative in identifying areas that could potentially be utilised by koalas.

There are four steps:

1. Map koala habitat
2. Identify principal and supporting habitat
3. Identify potential movement corridors
4. Categorise potential corridors into primary, secondary and tertiary
5. Define important habitat

Spatial scope of the mapping

The spatial scope of the mapping for this method included the GPEC and WSA boundaries.

Step 1: Map koala habitat

Koala habitat is identified as PCTs (excluding derived grasslands and urban native condition classes) that contain preferred koala feed trees (see Table 11-24) (DECC 2008; Environment Protection Authority 2016).

Table 11-24: PCTs - Potential koala habitat GPEC, WSA and buffer area

PCT No.	PCT Name	Type of feed tree (DECC 2008)
724	Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion	Primary
725	Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion	Primary
830	Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Primary
835	Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	Primary
849	Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	Primary
850	Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Primary
883	Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion	Primary
941	Mountain Blue Gum - Thin-leaved Stringybark open forest on river flat alluvium in the Sydney Basin Bioregion	Supplementary
1067	Parramatta Red Gum woodland on moist alluvium of the Cumberland Plain, Sydney Basin Bioregion	Primary
1081	Red Bloodwood - Grey Gum woodland on the edges of the Cumberland Plain, Sydney Basin Bioregion	Secondary
1083	Red Bloodwood - scribbly gum heathy woodland on sandstone plateaux of the Sydney Basin Bioregion	Supplementary
1181	Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion	Secondary
1281	Turpentine - Grey Ironbark open forest on shale in the lower Blue Mountains, Sydney Basin Bioregion	Secondary
1319	White Stringybark - Grey Gum grassy forest on shale caps of the Woronora Plateau, Sydney Basin Bioregion	Secondary
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion	Secondary
1787	Red Bloodwood - Scribbly Gum - Stringybark open forest on sandstone ridges along the western side of the Woronora and Hornsby plateaus	Secondary
1789	Smooth-barked Apple - Blackbutt - Red Bloodwood open forest in enriched sandstone gullies of the western Woronora plateau	Secondary
1790	Red Bloodwood - Grey Gum - Stringybark open forest on enriched sandstone ridges of the western Woronora plateau and lower Blue Mountains	Secondary
1800	Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley	Primary
1841	Smooth-barked Apple - Turpentine - Blackbutt tall open forest on enriched sandstone slopes and gullies of the Sydney region	Primary

Step 2: Identify principal and supporting koala habitat

Principal habitat is defined as potential habitat (above) that contains Koala records.

The remainder of habitat is defined as "supporting". PCTs representative of supporting habitat are not listed in this document.

Step 3: Identify potential movement corridors

Potential movement corridors include all identified koala habitat, except for those patches that are separated by more than 1 km.

Step 4: Categorise corridors into primary, secondary and tertiary

Primary corridors are identified as:

- Patches of principal habitat which are contiguous (gaps between trees <100 m).

Secondary corridors are identified as:

- Patches of principal habitat separated by more than 100 m from other habitat.
- Are narrow or have pinch points of less than 50 m wide.
- Patches of principal habitat that do not connect to primary corridors on both ends.

Tertiary corridors are identified as:

- Patches of principal habitat not linked to primary corridors.
- Do not connect to other corridors on both ends.

Step 5: Define important habitat

As described above, important habitat comprises the species polygons for koala as required under the BAM and is defined for this assessment as comprising primary and secondary corridors.

HABITAT CONNECTIVITY MAPPING – GAPCLOSR

Mapping of habitat connectivity was undertaken using a GIS-based spatial analytical framework known as the Generalised Approach to Planning Connectivity at Local and Regional Scales (GAPCLoSR) (Biolink, 2018). The text below provides a high level summary of that work, and the full report should be read to understand the project.

GAPCLoSR enables examination of issues associated with landscape connectivity and fragmentation. However, it is noted that the model only considers the length and arrangement of dispersal pathways; it does not consider other important factors which impact corridor usage (such as corridor width). The model is therefore useful as a support tool which enables more detailed analysis.

GAPCLoSR takes into account two key factors:

- The ecological needs and movement characteristics of the target species (e.g. the key characteristics of preferred habitat, the distribution and extent of preferred habitat, the greatest distance of open ground which can be crossed by the target species and the total distance which can be moved across the landscape by the species)
- The extent to which the existing landscape enables, influences and/or impedes movement of the target species

The program was used to investigate three different scenarios:

- **Baseline (*status quo*):** This constituted an analysis of the distribution of current habitat patches and connectivity through the Plan Area
- **Scenario 1:** This constituted analysis in which clearing occurred within the urban capable footprint, and where Appin Road was upgraded to a multi-lane dual carriageway with wildlife fencing on the eastern side of the road
- **Scenario 2:** This constituted analysis in which clearing occurred within the urban capable footprint, and where Appin Road was upgraded to a multi-lane dual carriageway with wildlife fencing on the eastern side of the road, with a wildlife crossing in place at the Ousedale-Mallaty corridor

Methodology

The basic model process involves inputting of key landscape features, determining the capacity for koala movement across each landscape feature, and then analysing the spatial distribution of the overall landscape to determine the degree of connectivity and fragmentation across the Plan Area.

Mapping landscape features

Key landscape features within the model included:

- Transport infrastructure (e.g. roads and railway lines)
- Hydrology (drainage lines, canals, etc.)
- Vegetation cover (including Preferred Koala Habitat)
- Mining and quarrying
- Agricultural areas (grazing and horticulture)
- Urban, commercial and industrial areas

Preferred Koala Habitat (PKH) was determined through the following process:

1. Vegetation mapping data was sourced from EES and from publicly available NSW Government databases
2. Vegetation maps were analysed, and the following areas were removed from analysis as being non-suitable for koala habitat:
    - Cleared areas
    - Highly-disturbed areas
    - Areas of scattered trees
    - Areas where satellite imagery did not match the vegetation type
3. Remaining vegetation layers are all considered to be Preferred Koala Habitat (PKH)
4. Areas of PKH were then classified into different sub-categories based on the availability of Preferred Koala Food Trees[1] (PKFTs). The following classes were made:
    - Primary Koala Habitat – where primary PKFTs comprise the dominant or co-dominant overstorey species
    - Secondary Koala Habitat (Class A) – where primary PKFTs are a sub-dominant component of the overstorey species
    - Secondary Koala Habitat (Class B) – primary PKFTs are absent, but the vegetation type is dominated by one or more 'secondary' PKFT
    - Secondary Koala Habitat (Class C) – primary PKFTs are absent, but one or more 'secondary' PKFTs are present as a sub-dominant component of the overstorey species
    - Other – does not contain PKFT
5. Each vegetation class was then assigned a different movement cost as follows:
    - Where PKH (of any class) is within a 'habitat patch' (i.e. area of habitat >10ha, an area defined by the authors), there are no movement costs
    - When PKH is present as a corridor, Primary Koala Habitat has no movement cost, and Secondary Class Habitat has an increasing scale of movement cost (with the least movement cost for Class A, and the highest movement cost for Class C)

Allocating resistance values to landscape features

Each landscape feature was then assigned a Percentage Resistance Value (PRV). This value refers to the effort or cost it takes for a koala to cross a particular land-use type or class.

[1] These include the following: *E. moluccana, E. longifolia, E. punctata, E. viminalis, E. tereticornis*

The resistance of the Plan Area to koala movement was then calculated as follows:

1. A rasterised surface was produced from land use layers of the Plan Area
2. Each pixel was then assigned a dispersal cost for koalas to cross at each point. Dispersal costs were calculated through considering each of the land use layers present for each pixel
3. In instances where multiple land use layers intersected at a particular point, it was important to define which data layer took precedence over the other. The following outlines the precedence in terms of their cost value:
    a) Connectivity structures spanning roads, train lines and aqueducts
    b) Train lines and aqueducts
    c) Roads
    d) Hydrology
    e) Vegetation cover (including PKH and non-PKH)
    f) Urban / commercial / industrial / agricultural land uses
4. A Gap Crossing Layer of 220 m was applied as a buffer around all vegetation, which was taken to be the maximum distance that a koala would travel across an open area (based on Euclidian distance of all koala records within the region from the nearest patch of mapped vegetation)

Mapping habitat connectivity

The locations and importance of connectivity corridors through the Plan Area were then modelled as follows:

a) The PRV of each pixel was examined
b) The cumulative PRV cost of any potential pathway between habitat patches was calculated
c) If the cumulative PRV cost of any potential pathway between habitat patches exceeded a threshold value, then a pathway would not be formed

It is noted that this method for identifying connectivity corridors does not rely on the Euclidian distance between habitat patches, but instead considers how hostile the landscape is to movement.

HABITAT CRITICAL TO THE SURVIVAL OF THE SPECIES MAPPING

In order to address the requirements of the EPBC Act referral guidelines for the vulnerable Koala (DoE, 2014) a map was prepared to identify habitat critical to the survival of the Koala. This mapping was prepared by adapting the method proposed in Koala Habitat Assessment Tool (KHAT) (Table 4, (DoE, 2014)) for use with the data available within the nominated areas and broader Strategic Assessment Area.

The KHAT scores five attributes related to the quality and extent of Koala habitat, with each attribute scored out of 2. A total score of 10 is possible, and habitat a score of five or greater is habitat critical to the survival of the Koala. The five attributes considered in the KHAT are:

- Koala occurrence
- Vegetation composition
- Habitat connectivity
- Key existing threats
- Recovery value

A number of data sets were compiled for use in the mapping of habitat critical to the survival of the Koala within the Strategic Assessment Area. A method was then prepared based on the KHAT for use in the Strategic Assessment Area.

As a first step the habitat units to be assessed were defined by combining a compilation vegetation data set (Biosis 2019) with the mapping of Koala corridors for this project. These units were then interrogated against a number of different data sets (Step 2 – Step 6) to identify habitat critical to the survival of the Koala. Data sets used to define habitat critical to the survival of the Koala include Koala sighting records (OEH, 2019), Koala corridor mapping, an assessment of connectivity and key existing threats (road kill records (OEH, 2019) and adjacency to urban areas).

The method applied is described in Table 11-25.

Table 11-25: Method used to map habitat critical to the survival of the Koala within the Strategic Assessment Area

Step	KHAT attribute	Approach	Score allocated	Data used
Step 1	N/A	Habitat units were defined by combining a compilation vegetation data set (Biosis 2019) with the mapping of Koala corridors. Koala corridors were assigned to individual habitat units by Plant Community Type (PCT) and broad vegetation condition (intact, scattered etc.) All internal linework between habitat units was dissolved where PCT, condition and corridor rank were identical. In the case of a Koala corridor not being allocated a PCT or condition state due to the land not being identified as native vegetation: Polygons smaller than 0.5 ha were removed from the habitat units layer Polygons >0.5 ha were allocated a PCT of 9999 and a condition of Unknown The habitat units were used as the based layer for the assessment	N/A	Biosis 2019 - Compilation vegetation data set (100 km buffer from Cumberland subregion). Layer includes Biosis nominated area vegetation mapping, and where this isn't available a compilation of the best available data sets, including: Remnant Vegetation of the western Cumberland subregion, 2013 Update. VIS_ID 4207 The Native Vegetation of the Sydney Metropolitan Area - Version 3.1 (OEH, 2016b) VIS_ID 4489 South East Local Land Services Biometric vegetation map, 2014. VIS_ID 4211 Southeast NSW Native Vegetation Classification and Mapping - SCIVI. VIS_ID 2230 Koala corridor mapping
Step 2	Koala occurrence	Koala occurrence was scored based on Koala records recorded within, and adjacent to, the Strategic Assessment Area over a five year period (2014 – 2019). Distance buffers were applied to allocate appropriate scores	2 - Within 1 km of a record 1 - Within 1-2 km from a record 0 - Beyond 2 km from a record	Koala BioNet species records (OEH, 2019)
Step 3	Vegetation composition	Each habitat unit was allocated a vegetation composition score. The Koala corridors mapped for the Strategic Assessment Area were used as a surrogate for this score	2 - Primary and secondary corridors 1 - Tertiary corridors 0 - Supporting habitat	Koala corridor mapping

Step	KHAT attribute	Approach	Score allocated	Data used
Step 4	Habitat connectivity	A score for habitat connectivity was calculated for each habitat unit. This was done by, first, calculating the patch size of each habitat unit. Habitat units were considered to be part of the same patch where adjacent or within 100 m of another patch. Patches were then separated where intersected by a major road or rail line as these features are likely to create barriers to the movement of corridors. The roads identified for this analysis include those classified as Arterial, Motorway or Primary Road	2 - >500 ha of contiguous habitat 1 - 300-500 ha of contiguous habitat 0 - <300ha of contiguous habitat	NSW Spatial Data Services (Six Clip and Ship) (2019) – Railway and Road Segment (where road = Arterial, Motorway or Primary Road)
Step 5	Key existing threats	Key existing threats were assessed, with the lower score taken for each habitat unit. Threat from road kill was determined by calculating the distance from each road kill record to each habitat unit. The threat from existing urban development was determined by calculating the distance from existing urban areas to each habitat unit	The lowest of: Threat from road kill (road kill records from 2014 - 2018). 2 - >2 km from road kill record 1 - 1-2 km from road kill record 0 - 0-1 km from road kill record Threat from urban land use (adjacency to urban land): 2 - >2 km from existing urban area 1 - 1-2 km from existing urban area 0 - 0-1 km from existing urban area	Koala BioNet species records (observation type = roadkill) (OEH, 2019) NSW Spatial Data Services (SiX Clip and Ship) (2019) – General cultural area (where area = Builtup)
Step 6	Recovery value	Each habitat unit was allocated a score based on whether the habitat is likely to be important for achieving the interim recovery objectives for the species. The Koala corridors mapped for the Strategic Assessment Area were used as a surrogate for this score	2 - Primary and secondary corridors 1 - Tertiary corridors 0 - Supporting habitat	Koala corridor mapping

11.6 OTHER MATTERS OF NATIONAL ENVIRONMENTAL SIGNIFICANCE

The assessment considered all protected matters that may be impacted directly, indirectly and cumulatively by actions taken under the Plan and identified the following groups of protected matters as being relevant to the assessment in addition to listed threatened species and ecological communities:

- Commonwealth land
- Migratory species
- Wetlands of international importance (Ramsar wetlands)
- World and National Heritage

11.6.1 COMMONWEALTH LAND

PURPOSE

The Commonwealth land assessment considered the whole of the environment that might be affected over the life of the Plan. As required by Section 4.3 of the ToR, the assessment was undertaken to "describe and assess separately the likely impacts (if any) of actions taken under the Plan on the environment on Commonwealth land (as defined in section 528 of the EPBC Act)".

METHOD

All known areas of Commonwealth land within the Strategic Assessment Area were assessed. The location of these areas was identified with the help of DAWE and relevant NSW Government agencies. Consideration was also given to areas of Commonwealth land outside of the Strategic Assessment Area that may be affected indirectly by the classes of action.

Desktop information was used to understand the environment on Commonwealth land. Environmental values are presented in relation to soils, waterways and topography, vegetation, fauna, rare or sensitive values, heritage and information on the biodiversity landscape context of the site.

The assessment has been framed around the Commonwealth's 'Significant Impact Guidelines 1.2 – Actions on, or impacting upon, Commonwealth land and Actions by Commonwealth Agencies'.

RESULTS

A profile of the environment on each of the Commonwealth land sites is provided in Chapter 35.

11.6.2 MIGRATORY SPECIES

PURPOSE

Section 3.2 of the ToR requires the SAR to describe for the Strategic Assessment Area the protected matters that may be impacted directly, indirectly and cumulatively by actions taken under the Plan. This includes:

- Identification of key sites and habitats
- Identification of important populations

METHOD

The migratory species relevant to the assessment include:

- Nine species addressed in the *Referral guideline for 14 migratory birds listed under the EPBC Act* (migratory bird referral guidelines), released in September 2015 (DoE, 2015)
- 21 species addressed in the *Industry guidelines for avoiding, assessing and mitigating impacts on EPBC Act listed migratory shorebird species* (migratory shorebird referral guidelines), released in 2017 (DoEE, 2017)

The approach to understanding the values within the Strategic Assessment Area for each of these migratory species was framed around the key elements of these guidelines.

Migratory bird species

For the nine migratory bird species, the assessment drew on the concepts of important habitat and ecologically significant proportions of a population. Important habitat for each species was identified based on the PCTs that correspond to the important habitat descriptions set out in the passerine bird referral guidelines.

Ecologically significant proportions of a population of each of the species was determined using observation records from Birdlife Australia, the Atlas of Living Australia, and BioNet Atlas. The analysis used a conservative estimate of individuals based on the total recorded sightings of each species per year across the Cumberland subregion.

Migratory shorebird species

Habitat mapping was undertaken broadly in accordance with the approach outlined in the EPBC guidelines (DoEE, 2017). However, the method applied was more precautionary than required under the EPBC guidelines to ensure that no important habitat sites were missed.

The process involved the following steps:

Step 1: Analysis of records across the Cumberland subregion

Records were compiled and examined across the whole of the Cumberland subregion. The initial step considered the subregion as a single habitat unit to determine which species exceeded the thresholds for important habitat across the whole area (i.e. which species occur in numbers greater than the threshold when records in the subregion are summed).

Step 2: Identification of important migratory shorebird habitat sites

The spatial distribution of records was then assessed to identify the individual wetland and waterbody (or wetland mosaic) where the thresholds were exceeded at a site level. Each wetland that was identified as important for migratory shorebirds had its boundary marked and a 250 m buffer applied. This buffer distance is consistent with the guidelines which suggest buffer distances ranging from 165 to 255 m to mitigate against disturbance (DoEE, 2017).

For ephemeral wetlands the threshold was considered across every year where records were held.

For permanent wetlands, the guidelines suggest considering the last five years. The approach taken for this assessment was to look at records for the last 20 years (since 2000) for sites that were thought to be permanent. This acknowledges the uncertainty in determining if habitat sites are permanent or ephemeral across the Strategic Assessment Area.

Step 3: Identification of potential migratory shorebird habitat

The remaining potential migratory shorebird habitat in the subregion was determined based on the presence of suitable wetlands throughout the landscape that exceed 1.5 ha in area. This 1.5 ha threshold was used as a proxy for the minimum disturbance distance for shorebirds of 150 m.

Wetland mapping layers were interrogated from the Directory of Important Wetlands (DoEE, 2018) and the LPI topographical data Hydro_Area layer (LPI, 2016) to identify areas of potential habitat.

RESULTS

The results of the migratory bird and migratory shorebird habitat assessment is provided in Chapter 32.

11.6.3 WETLANDS OF INTERNATIONAL IMPORTANCE (RAMSAR WETLANDS)

PURPOSE

Section 3.2 of the ToR requires the SAR to describe for the Strategic Assessment Area the protected matters that may be impacted directly, indirectly and cumulatively by actions taken under the Plan. This includes:

- Identification of key sites and habitats
- Condition of protected matters, including where relevant, seasonal and annual variability, and their likelihood to alter over time
- Key threatening processes

METHOD

Towra Point Nature Reserve Wetland is the only Ramsar wetland relevant to the assessment. It is located outside of the Strategic Assessment Area. Available desktop information was used to understand the environmental values at Towra Point Nature Reserve. The assessment focused on the ecological character of the wetland, which is a key concept under the Ramsar Convention and the main element for the consideration of significant impacts under the EPBC Act.

RESULTS

The description of the environmental values at Towra Point Nature Reserve is provided in Chapter 33.

11.6.4 WORLD AND NATIONAL HERITAGE

PURPOSE

Section 3.2 of the ToR requires the SAR to describe for the Strategic Assessment Area the protected matters that may be impacted directly, indirectly and cumulatively by actions taken under the Plan.

METHOD

A description of the World and National Heritage properties relevant to the assessment was developed based on available desktop information. For World Heritage, the assessment focused on the Outstanding Universal Value of the property, including an understanding of the attributes that meet the relevant listing criteria, how the property meets the conditions of integrity and the way in which the property is protected and managed.

For National Heritage, a description of each site focused on the heritage values that meet the criteria for listing.

RESULTS

A description of the World and National Heritage properties relevant to the assessment is provided in Chapter 34.

12 Approach to the impact assessment

The approach to analysing and assessing the impacts of the development under the Plan is set out in detail in each of the relevant Chapters of the Assessment Report, as follows:

- Avoiding and minimising impacts – see Chapter 14
- Addressing serious and irreversible impacts – see Chapter 25
- Assessing:
  - Direct impacts:
    - see Chapter 23 for the approach to NSW-listed matters
    - see Chapters 27-35 for the approach to Commonwealth-listed matters
  - Indirect impacts – see Chapter 15 for the approach to NSW and Commonwealth-listed matters
  - Prescribed impacts – see Chapter 24
  - Cumulative impacts – see Chapter 38
- Evaluation of the overall acceptability of the Plan – see Chapter 41

13 Data and limitations

This Chapter:

- Summarises the key types of information used in the Assessment Report
- Describes the key data sets on biodiversity values and how they were used
- Identifies the key limitations associated with:
  - Field surveys
  - Vegetation and species mapping
  - BAM credit calculations

The data and limitations associated with the preparation of specific reports that informed this Assessment Report, such as expert reports and the trend analysis, are described in these documents (see Supporting Documents C and D).

As described in Chapter 10, the technical methods for describing the EPBC protected matters impacted by the Plan were independently peer-reviewed to meet a requirement of the ToR. The peer review report concluded that in general:

- The data sets, methods for data collection and assumptions associated with the methods are appropriate for a large-scale strategic assessment process such as this project
- The methods used are generally conservative and are unlikely to under-represent the presence or distribution of any TEC or species (and are more likely to over-predict presence and distributions)

The report recommended that further details associated with the input data and assumptions be provided in the Assessment Report to provide regulators and the public more complete understanding of limitations, including:

- Categorisation of EPBC species – further explain limitations associated with information sources used in the categorisation process, including whether they incorporate up to date information and their relevant scale
- TEC mapping method – provide further details associated with the input data, including details of the extent and dates of field validation undertaken for the source mapping
- SDM mapping method – provide further details associated with the assumptions of the model to provide a more complete understanding of the factors affecting the outcomes of the model
- KBM mapping method – the exclusion of habitat based on patch size needs to be explained and justified
- Important populations – for the species that have been determined not to have important populations within the subregion and have had records excluded based on the lifespan of the species, discuss implications of this approach

These limitations are discussed in Section 13.3.

13.1 TYPES OF INFORMATION SOURCES

A wide variety of information sources and processes were used to prepare the Assessment Report, including:

- Data sets on biodiversity values
- Surveys and field verification
- Scientific literature
- Government strategies, plans, policies and guidelines
- Use of expert reports under the BAM
- Existing knowledge of ecological consultants
- Expert workshops , including technical representatives from EES
- Expert elicitation for the trend analysis (see Supporting Document D)

The information used in this Assessment Report is consistent with the requirements of the BAM and the ToR.

The data sets used across the nominated areas and broader Strategic Assessment Area represent the best available information on biodiversity and other values, and were drawn from a wide variety of sources. Where land access was granted, field surveys and verification were undertaken to improve the data.

13.2 KEY DATA SETS

A large number of data sets were collated and generated for use in the Assessment Report. These are summarised in Table 13-1. The data sets cover a range of themes, including:

- Vegetation mapping
- Mapping of species distribution and habitat
- Mapping of protected lands and other conservation planning information
- Soil, geology and landscape mapping
- Mapping of topographic features such as water bodies and drainage lines

Table 13-1: Sources of data used in the Assessment Report

Data set theme	Data set name	Custodian	Date	Details	Use on project
Drainage and water bodies	Directory of Important Wetlands	DAWE	2018	Data set containing boundaries for wetlands listed on the Directory of Important Wetlands	Used in determining the landscape context components of the BAM plus mapping for water dependant species
	NSW Digital Topgraphic Database - Hydro Areas Dataset	LPI	2019	Data set containing boundaries of hydrography feature types - water body areas and water courses	Used to inform the assessment of prescribed impacts for hydrology and water bodies
Land use	NSW land use polygons	EES	2013	NSW land use information including food production, forestry, nature conservation, infrastructure and urban development	Layer used in preparing native vegetation mapping for the nominated areas
Protected lands and conservation planning	Biobank sites	EES	2019	Data layer containing boundaries of Biobank sites	Layer used in determining the amount of protected land within the Plan Area
	Conservation agreements	EES	2018	Data layer containing boundaries of conservation agreements	Layer used in determining the amount of protected land within the Plan Area
	Cumberland subregion BIO Map	EES	2015	A map of core areas and corridors identified in western Sydney	Used to calculate impacts to, and protection of, important landscape features and as a surrogate for connectivity
	Metro Region biodiversity offsets	EES	2018	Data layer containing boundaries of known biodiversity offsets protected under relevant covenants governed by the relevant local Council, in the Sydney Metropolitan Region	Layer used in determining the amount of protected land within the Plan Area
	NCT Agreements	EES	2018	Data layer containing boundaries of Nature Conservation Trust Agreements	Layer used in determining the amount of protected land within the Plan Area
	NSW National Parks Estate	EES	2020	Data layer containing boundaries of National Parks, Nature Reserves and other NPWS estate	Layer used in determining the amount of protected land within the Plan Area
	Perpetual Lease Covenant	EES	2018	Data layer containing boundaries of Perpetual Lease Covenants	Layer used in determining the amount of protected land within the Plan Area

Data set theme	Data set name	Custodian	Date	Details	Use on project
	Registered Property Agreements	EES	2018	Data layer containing boundaries of Registered Property Agreements	Layer used in determining the amount of protected land within the Plan Area
Soils, geology and landscapes	NSW (Mitchell) Landscapes Version 3.1	EES	2002	Mapping of landscapes in NSW defined by landform, topography, geology, soil, climate and vegetation	Soil landscape assessment as part of the BAM assessment
	LiDAR data	New South Wales Spatial Services	2018	Layer containing LiDAR point cloud for nominated areas. LiDAR data used of varying currency, and is generally captured in 2011 across the nominated areas	Preparation of a Canopy Height Model (CHM) to assist vegetation mapping preparation within the nominated areas and identification of topographic features such as cliff lines etc.
	NSW Soil Landscapes	EES	2017	Mapping provides an inventory of soil and landscape properties and identifies major soil and landscape qualities and constraints	Soil hazard assessment as part of the BAM assessment, informed vegetation mapping
	Topographic data (Digital Topographic Database)	New South Wales Spatial Services	2019	A range of data sets which display topographic features, such as contours, drainage features and water bodies	Used for a number of project tasks including species habitat and distribution mapping, shorebird mapping and vegetation mapping
	Western Sydney Hydrogeological Landscapes	EES	2011	Spatial layer defining the areas of similar salt stores and pathways for salt mobilisation	Soil landscape assessment as part of the BAM assessment
Species sightings and habitat	BioNet (Wildlife Atlas) records of species sightings in western Sydney and surrounds – download of records provided by the Department	EES	2019	Fauna and flora sightings records stored in the NSW BioNet database	Used for a number of project tasks including important habitat mapping, one input for species distribution models, an input into determining whether a species requires needs consideration under the EPBC Act and an input into determining whether a species is a candidate species for the BAM assessment
	Conserving Koalas in Wollondilly and Campbelltown LGAs	EES	2019	Koala habitat and corridor mapping of the Appin, Wilton and Picton areas of Sydney	Data layer used to inform updated koala corridor mapping within the nominated areas. Layer accepted without modification outside nominated areas

Data set theme	Data set name	Custodian	Date	Details	Use on project
	New Atlas of Australian Birds	BirdLife Australia	1998-2015	Bird sightings database administered by BirdLife Australia	Used in the preparation of species maps for bird species
Vegetation mapping	Remnant Vegetation of the western Cumberland subregion, 2013 Update. VIS_ID 4207	EES	2013	Vegetation data layer covering western Sydney. Update of the Remnant Vegetation Mapping of the Cumberland Plain (OEH, 2013b). Contains details on Plant Community Type (PCT), map unit and dated condition information	Used as part of a compilation vegetation data set outside the nominated areas. One of the inputs for species mapping outside the nominated areas
	South East Local Land Services Biometric vegetation map, 2014. VIS_ID 4211	EES	2015	A seamless standardised vegetation map, from a combination of existing available data, which covers the full extent of the South East Local Land Services (SE LLS) region. Compiled from best available data sets in the region. Contains information on PCTs and map units	Used as part of a compilation vegetation data set outside the nominated areas. One of the inputs for species mapping outside the nominated areas
	Southeast NSW Native Vegetation Classification and Mapping - SCIVI. VIS_ID 2230	EES	2010	Classification, descriptions and mapping of native vegetation types of southeast NSW (including the South Coast and parts of the eastern tablelands)	Used as part of a compilation vegetation data set outside the nominated areas. One of the inputs for species mapping outside the nominated areas
	The Native Vegetation of the Sydney Metropolitan Area - Version 3.1 VIS_ID 4489	EES	2016	Vegetation data layer covering the Sydney metropolitan area. Extends west to cover all of Georges and Parramatta River catchments. Contains details on PCT, map unit, TEC, and disturbance	Used as part of a compilation vegetation data set outside the nominated areas. One of the inputs for species mapping outside the nominated areas

13.3 LIMITATIONS

There are a number of limitations associated with the collection and use of data in this Assessment Report.

The limitations can be categorised into three main themes:

- Field survey limitations (i.e. land access, project scale, data and drought)
- Vegetation and species mapping limitations
- BAM credit calculation limitations

13.3.1 FIELD SURVEYS

Table 13-2 identifies limitations with field surveys and provides comment on the implications of these limitations or any precautionary measures that were taken to address these.

Table 13-2: Limitations of field surveys

Limitation	Comment
BAM native vegetation plots and threatened species surveys were only undertaken within the nominated areas, and were not undertaken within the transport corridors outside the nominated areas	While the best available data was used to assess impacts of the transport corridors outside the nominated areas, the assessment may be less accurate as it is based on existing data that has not been recently confirmed
Within the nominated areas, BAM native vegetation plots and threatened species surveys were restricted to sites where access was granted by landholders. While the number and distribution of BAM plots met BAM requirements, limited land access meant surveys were not possible across the entire urban capable land	The Department undertook an extensive program to seek approval from landholders for land access, involving: • Letter mailouts to landholders in the nominated areas • Follow-up emails or phone calls to public landholders and businesses such as developers where phone numbers were publicly available • Door knocking (Biosis) in high priority areas for surveys where no responses were received
Targeted species surveys were not always undertaken in accordance with EES survey guidelines due to the very large scale of the Plan Area	Species were assumed to be present across all areas mapped as potential habitat in accordance with the BAM, except where targeted species surveys confirmed the species was unlikely to be present
For some BAM plots, some BAM data components were based on existing BBAM plot data	In these cases, sites were re-visited and the additional BAM data components were captured to ensure the plot data was consistent with BAM
The survey period was exceptionally dry. Significant rainfall deficiencies occurred across eastern Australia and the eighth-lowest January to November rainfall since 1900 was recorded for NSW for 2018 Rainfall was in the lowest 10 per cent of all years for Western Sydney. NSW had its warmest January–November period on record for 2018, compounding the impact of low rainfall (BOM, 2019)	These conditions are likely to have affected the results of the field surveys – likely reducing vegetation integrity scores and the ability to detect some flora species

13.3.2 MAPPING AND OTHER METHODS

Table 13-3 identifies limitations with vegetation and species mapping and provides comment on the implications of these limitations or any precautionary measures that were taken to address these.

Table 13-3: Limitations of mapping and other methods

Limitation	Comment
The criteria used to categorise EPBC matters needing assessment was applied based largely on existing data	There may be limitations associated with the quality and accuracy of the existing data, such as DAWE's species distribution maps. However, the best available information was used in applying the criteria The criteria used to categorise EPBC matters is generally objective and does not involve subjective judgement. Where applying the criteria involved judgement (criteria 3), expert ecologists from Biosis were used
Mapping - general Native vegetation, TEC and species mapping was undertaken based largely on existing data	The final outputs from the mapping and modelling will be limited by the input data. Poor quality (i.e. inaccurate species data, soil mapping or vegetation mapping) or missing data may result in the identification of conservation priorities or potential development impacts that do not align with the on-ground environment
On-ground validation of native vegetation, TEC and species mapping was only undertaken within the nominated areas where land access was granted. No validation of mapping was undertaken within the transport corridors outside the nominated areas	While the best available data was used to assess impacts of the transport corridors outside the nominated areas, the assessment may be less accurate as it is based on existing data that has not been recently confirmed
Assumptions were made about PCT types and condition for areas not surveyed. The type of PCT was assumed to be correct where native vegetation extent aligns with PCTs as mapped by EES (2013, 2016) and soil/landscape mapping aligned with the PCT description	Over the fence verification was undertaken where possible (where sufficient visibility was available) within all nominated areas to validate PCTs and condition, where access was not available
The vegetation mapping within the 1500 m buffer for the assessment under the BAM was undertaken using existing vegetation mapping only and therefore the native vegetation extent for derived grasslands is likely to be under-represented	
TEC mapping TEC mapping is based on the native vegetation mapping and is subject to the same limitations (discussed above) Due to data limitations, some assumptions were made to establish the rule-sets used to map Commonwealth and NSW-listed TECs	Details of the rule-sets used to map EPBC TECs and the field validation undertaken for the TEC mapping within the nominated areas are provided in Chapter 11 The peer review concluded that the TEC mapping method used is generally conservative and is more likely to over-predict distribution of TECs
Species mapping Some candidate SCS were considered to be too cryptic for detection or difficult to map and model	These species were assigned to recognised experts for assessment (BAM expert reports)

Limitation	Comment
Species mapping - KBM Only potential habitat for species was able to be mapped due to the very large scale of the Plan Area. The species maps are therefore likely to be precautionary and greatly overpredict actual habitat Due to data limitations, some assumptions were made to establish the rule-sets used to map species habitat For species with known patch size thresholds identified in scientific literature, the rule-set included exclusion of small patches of native vegetation from the species map to provide a more accurate prediction of potential habitat	The rule-sets used to map species were based on the best available information sourced from SPRAT and BioNet profiles, NSW Threatened Biodiversity Data Collection, conservation advices, recovery plans and scientific literature. Where judgement was needed to make a decision, expert ecologists from Biosis were used Details of the rule-sets used to map species and the field validation undertaken for the KBM mapping within the nominated areas are provided in Chapter 11 The peer review concluded that KBM species mapping method used is generally conservative and is more likely to overpredict species habitat
Species mapping - SDM modelling All data used for species distribution models was based on presence-only data, meaning it is data without any 'absence' records of species (i.e. where observers have not noted the absence of a species at surveyed sites)	Undertaking SDM modelling with presence-only data results in relative measures of habitat suitability. A location with a predicted high habitat suitability score is only high relative to other locations in the Plan Area, and not necessarily high-quality habitat in absolute terms
The study area for the SDM modelling was limited to a 10 km buffer around the Cumberland subregion. For some species, this comprises only a small part of their range, which may reduce the accuracy of the modelling	
SDM modelling does not account for factors such as historical accidents and competition with other species that may significantly drive species distributions	
SDM modelling may overpredict actual habitat in highly-modified landscapes such as the Cumberland subregion due to the standard assumptions regarding a species occupying its niche not applying in such landscapes	
There may be large amounts of bias in the species records	Species data used in the SDM modelling was cleaned (likely inaccurate records removed) and multiple bias layers were used in the modelling to address this bias
For some of the species, there may be false associations between records and PCTs due to spatial errors in the point locations and and/or the PCT maps	
Important populations The criteria used to identify important populations was applied based largely on existing data Due to data limitations, some assumptions were made in applying the criteria to identify important populations. For some species, this included excluding records that were older than the lifespan of the species in some cases	There may be limitations associated with the quality and accuracy of the existing data, such as information on species' Area of Occurrence. However, the best available information was used in applying the criteria Information was sourced from SPRAT/BioNet profiles, Threatened Biodiversity Data Collection, conservation advices, recovery plans and scientific literature Where applying the criteria involved judgement (particularly criteria 7 and 9), expert ecologists from Biosis were used to inform decisions Excluding old records based on the lifespan of the species was undertaken for five fauna species. This was only done where few records existed and there were no recent records in the Cumberland subregion

Limitation	Comment
Shorebird mapping Where count data has not been provided with a BioNet or Birds Australia record, each point has been assumed to represent one individual within the shorebird mapping	

13.3.3 BAM CREDIT CALCULATIONS

Table 13-4 identifies limitations with the BAM credit calculations and provides comment on the implications of these limitations or any precautionary measures that were taken to address these.

Table 13-4: Limitations of BAM credit calculations

Limitation	Comment
Some plot data collected in vegetation mapped as NOG has returned a Vegetation Integrity (VI) of >15 (the cut-off score for the requirement to offset endangered or critically endangered TECs)	This has occurred across a low proportion of the plots and is largely explained through either a high cover of a single native grass species in the ground layer (most often Common Couch *Cynodon dactylon*) or a high cover of "litter" as defined under the BAM (most often a result of dead and/or detached grass on the ground as a result of the unusually dry survey seasons). Furthermore, the majority of the BAM plot data shows the areas sampled to be of very low ecological condition
Where impacts to species credit species were less than 0.005 ha (i.e. 0.00 when rounded to 2 decimal places), the impact was completely discounted and not entered into the BAM calculator	Such impacts typically relate to 'slivers' of slight mismatch between various spatial layers used to prepare the impact assessments
Impacts to candidate SCS were generally either allocated to a vegetation zone or NOG polygon for entry into the credit calculator. Where the habitat for the threatened species fell outside of these areas the impact was not entered into the BAM calculator and was identified as a prescribed impact

Part 3 Attachment List of Tables

A. Justification for removal of SCS

Table A-1: Justification for removal of species credit species from requiring further assessment

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
Acacia bynoeana	Bynoe's Wattle	✓	✓	✓	✓	Yes	*Acacia bynoeana* is a shrub that occurs in central eastern NSW, from the Hunter District (Morisset) south to the Southern Highlands and west to the Blue Mountains. Habitat comprises heath or dry sclerophyll forest on sandy soils. It prefers open, sometimes slightly disturbed sites. Records occur in about 30 locations within the distribution of the species (OEH, 2019f). The closest records to the nominated areas occur immediately to the North East of Glenfield on sandy soils, outside the nominated areas The species was retained as a candidate species in all nominated areas because suitable habitat has the potential to occur in urban capable lands. An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands.	N/A	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
Acacia gordonii	Gordon's wattle	R	X	X	X	No	*Acacia gordonii* is a shrub that is restricted to the north-west of Sydney. It has a disjunct distribution in the lower Blue Mountains and the Maroota/Glenorie area. Habitat comprises dry sclerophyll forest and heathlands amongst or within rock platforms on sandstone outcrops. Records occur in only a few locations in the lower Blue Mountains and Maroota/Glenorie area(OEH, 2019a). The species was removed as a candidate species in Wilton because urban capable land is outside the geographic extent of the species.	Section 6.1.1.2 (outside geographic extent, lack of BioNet records)	No	No	N/A
Acacia prominens - endangered population	Gosford Wattle	R	X	R	R	No	*Acacia prominens* is a tree. The endangered population occurs outside the nominated areas in the Kogarah – Hurstville local government areas. This occurrence is disjunct from other occurrences of the population of the species and at the southern limit of the species range (NSW Scientific Committee, 1998a). The population was removed as a candidate species in Wilton, WSA, and GPEC due to the listed extent occurring outside urban capable land.	N/A	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
Acacia pubescens	Downy Wattle	✓	✓	✓	✓	Yes	*Acacia pubescens* is a shrub that occurs around the Bankstown-Fairfield-Rookwood area and the Pitt Town area, with outliers occurring at Barden Ridge, Oakdale and Mountain Lagoon. Habitat comprises gravely soils, often with ironstone, within open woodland and forest in a variety of vegetation communities, including Cooks River/Castlereagh Ironbark Forest, Shale/Gravel Transition Forest and Cumberland Plain Woodland (OEH, 2019i). There are recent records of this species outside the nominated areas, and the species has the potential to occur within WSA. The other nominated areas contain mostly old records (from 1910 and 1960) with low spatial accuracy in areas that are now highly urbanised. This species is easily recognisable so is unlikely to be missed during surveys. The species was retained as a candidate species in all nominated areas due to suitable habitat that has the potential to occur in urban capable lands. An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands.	N/A	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
Allocasuarina glareicola		X	X	R	✓	Yes	*Allocasuarina glareicola* is a shrub largely found in the vicinity of Castlereagh and Londonderry within an area of 27 km2 (Fairley, 2004). An outlier population occurs on Commonwealth land at the Holsworthy Military Area, south-west of Sydney (French, Pellow et al., 2001). Habitat comprises open Castlereagh woodland, growing on tertiary alluvial gravels, with yellow clayey subsoil and lateritic soil (DEWHA, 2008a). Preferred soils for the species are found in GPEC around the Penrith Lakes area. The species was retained as a candidate species in GPEC because suitable habitat has the potential to occur in urban capable land. The species was removed in WSA because of a lack of records and suitable habitat within urban capable land.	Section 6.1.1.2 (lack of BioNet records)	Yes	No	N/A
*Anthochaera Phrygia**	Regent honeyeater	R	R	R	R	No	*Anthochaera Phrygia* is a medium sized bird mainly confined to its two main breeding areas in NSW – at Capertee Valley and the Bundarra-Barraba region –and surrounding fragmented woodlands. Minor and sporadic breeding occurs in other areas such as Warrumbungle National Park, Pilliga forests, Mudgee-Wollar region, and the Hunter and Clarence Valleys (NSW Scientific Committee, 2010). Habitat comprises dry open forest and woodland, particularly Box-Ironbark woodland,	EES confirmed no important habitat mapped	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
							and riparian forests of River Sheoak. No breeding habitat for the species occurs in the Cumberland subregion. The species was removed as a candidate species from all nominated areas because EES confirmed mapped important habitat for the species does not occur within urban capable lands.				
Burhinus grallarius	Bush Stone-curlew	R	R	R	R	No	*Burhinus grallarius* is a large bird that occurs throughout much of Australia, although in the south-east it is rare or extinct throughout its former range. Habitat comprises open woodlands with few shrubs, and short, sparse grasses of less than 15 cm, with scattered fallen timber, leaf litter and bare ground present (NSW DEC, 2006). Habitat is associated with broad ground and understorey structural features and is not necessarily associated with any particular vegetation communities. Removal of fallen timber affects the suitability of habitat as this comprises foraging habitat and the species relies on it for camouflage when roosting (NSW DEC, 2006). Records occur across the Cumberland subregion, but there are few recent records and no records within WSA or Wilton. Records only occur within GPEC and GMAC, a total of four within GPEC, and five within GMAC. GPEC records are prior to 1996 from within the	Section 6.1.1.2 (lack of BioNet records, lack of suitable habitat)	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
							RAAF base at Orchard Hills. As no new BioNet records of the species exist in that location for over the last 23 years, more than a generation's length for this species, the birds are considered no longer to be present, based on lack of sightings/records. The remaining records from GPEC are specimen records form the Australian Museum, dated as 1884 and 1895. GMAC records are prior to 1981, with a very low level of accuracy (10,000m), with limited location descriptions. Records from 1981 are noted as 'Appin', with the remainder being specimen records form the Australian Museum, dated as 1860/1861. A single record occurs from within the Cumberland subregion since 1996, noted as being from 2012 in Greystanes and associated with WIRES. No more information is provided in BioNet. Due to the isolated nature of this record, both temporally and spatially, it is considered a vagrant record, and not evidence of the species persistence in the subregion. The species was removed as a candidate species in all nominated areas because suitable micro-habitats have undergone a long history of degradation and are now considered scarce in urban capable land, and the substantial lack of recent records within				

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
							the subregion. Considerable survey effort has been undertaken for the species across the Cumberland subregion since 1996 and if present, it is considered likely that the species would have been positively recorded in that time.				
Caladenia tessellata	Thick Lip Spider Orchid	R	R	R	R	No	*Caladenia tessellata* is an orchid that is known within NSW from two disjunct areas; one population near Braidwood on the Southern Tablelands and three populations in the Wyong area on the Central Coast (NSW Scientific Committee, 2002a). Habitat comprises grassy sclerophyll woodland in clay loam or quartz-rich sandier soil (OEH, 2019af). The total population size is estimated to be less than 50 individuals. Old records occur in the Penshurst (recorded 1901) and Como (recorded 1930) areas. The species was removed as a candidate species in all nominated areas because of a lack of records and suitable habitat within urban capable lands.	Section 6.1.1.2 (lack of BioNet records, lack of suitable habitat)	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
*Calidris ferruginea**	Curlew sandpiper	X	X	R	X	No	*Calidris ferruginea* is a small bird that breeds in Siberia and migrates to Australia (as well as Africa and Asia) for the non-breeding period (NSW Scientific Committee, 2011). In NSW, the species occurs along the coast, particularly in the Hunter Estuary, and sometimes in freshwater wetlands in the Murray-Darling Basin. Foraging habitat in NSW mainly comprises intertidal mudflats. The species was removed as a candidate species in WSA because of a lack of suitable habitat within urban capable land.	Section 6.1.1.2 (lack of suitable habitat)	No	No	N/A
Callistemon linearifolius	Netted Bottle Brush	R	R	R	R	No	*Callistemon linearifolius* is a shrub that occurs from the Georges River to Hawkesbury River in the Sydney area, and north to the Nelson Bay area of NSW. Habitat comprises dry sclerophyll forest. For the Sydney area, recent records are limited to the Hornsby Plateau area near the Hawkesbury River. There are currently only five or six known populations of the species remaining in the Sydney area, of the 22 populations recorded in the past. Three of these are reserved in Ku-ring-gai Chase National Park, Lion Island Nature Reserve, and Spectacle Island Nature Reserve. Further north it has been recorded from Yengo National Park (NSW Scientific Committee, 1999a). The species was removed as a candidate species in	Section 6.1.1.2 (outside geographic extent, lack of BioNet records)	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
							all nominated areas because urban capable lands are outside the geographic extent of the species.				
*Callocephalon fimbriatum**	Gang-gang cockatoo	✓	✓	R	✓	Yes	*Callocephalon fimbriatum* is a bird restricted to the south-eastern coast and highlands, from the lower Hunter and northern Blue Mountains to the Southwestern Slopes, south to and contiguous with the Victorian population (e.g. (Barrett, 2003)). Habitat comprises eucalypt open forests and woodlands with an acacia understorey (NSW Scientific Committee, 2008a). Breeding habitat includes remnant tall moist forest and riparian corridors along major streams (3rd and higher order). Nests are located in hollows that are 10 cm in diameter or larger and at least 9 m above the ground in eucalypts (OEH, 2019l). The species has been recorded within the vicinity of the nominated areas nesting in tall eucalypts within sandstone gullies (e.g. The Oaks area). The species was retained as a candidate species in Wilton, GMAC and GPEC because records occur in the vicinity of urban capable lands. The species was removed in WSA because of a lack of records within the nominated area and a lack of suitable breeding habitat within urban capable lands. Targeted surveys during breeding season and habitat assessment surveys have been undertaken	Section 6.1.1.2 (lack of BioNet records, lack of suitable habitat)	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
							across the nominated areas for this species. The species was not recorded, however potential breeding habitat was found to be present.				
*Calyptorhynchus lathami**	Glossy black cockatoo	✓	✓	R	✓	Yes	*Calyptorhynchus lathami* is a bird that occurs mainly in the eastern part of NSW from the coast to the tablelands, with populations on the western slopes and plains tenuously connected to those on the tablelands. Habitat comprises eucalypt open forest and woodland with hollow-bearing trees and a midstorey of sheoaks. It nests in tree hollows, and forages exclusively in sheoak species (NSW Scientific Committee, 2008b). Favoured habitat occurs on richer soils and within gentle terrain, and where *Allocasuarina* species are present. Records occur in the vicinity of the nominated areas, mainly where there is better tree cover and *Allocasuarina* species. Hollow-bearing trees within these areas are potential breeding habitat. The species was retained as a candidate species in Wilton, GMAC and GPEC because records occur in the vicinity of urban capable lands. The species was removed in WSA because of a lack of records within the nominated area and a lack of suitable breeding habitat within urban capable lands. Targeted surveys during breeding season and habitat assessment surveys have been undertaken	Section 6.1.1.2 (lack of BioNet records, lack of suitable habitat)	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
							across the nominated areas for this species. The species was not recorded, however potential breeding habitat was found to be present.				
Cercartetus nanus	Eastern Pygmy-possum	✓	✓	✓	✓	Yes	*Cercartetus nanus* is a small marsupial that in NSW occurs from the coast inland as far as the Pilliga, Dubbo, Parkes and Wagga Wagga on the western slopes. The species occurs within a broad range of habitats from rainforest through to sclerophyll forest (including Box-Ironbark) and woodland to heath (OEH, 2019k), generally in more intact forms of vegetation. Records occur to the south-east of Wilton and are all in intact vegetation on a different substrate generally to that of urban capable lands (sandstone rather than shale). Most records within the Cumberland subregion are either inaccurately located or are located in the Bargo River and not within urban capable lands. The record near Campbelltown is located to the north east and is outside the Cumberland subregion. The species was retained as a candidate species in all nominated areas because suitable habitat has the potential to occur in urban capable lands. An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands.	N/A	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
							Targeted habitat assessment surveys have been undertaken across the Growth Ares for this species and potential habitat was found to be present.				
Chalinolobus dwyeri	Large-eared Pied Bat	✓	✓	R	✓	Yes	*Chalinolobus dwyeri* is a small to medium sized bat that is found from Rockhampton in Queensland south to Bungonia in the NSW Southern Highlands. Habitat comprises areas with extensive cliffs and caves (OEH, 2019s). Potential habitat for the species within the nominated areas is likely to occur only in areas outside urban capable lands. The species was retained as a candidate species in Wilton, GMAC and GPEC because foraging habitat within 2 km of sandstone cliffs and caves (potential roosting/breeding habitat) occurs within the nominated areas. The species was removed as a candidate in WSA as no potential roosting / breeding habitat occurs within 2 km of the nominated areas.	N/A	Yes	No	N/A
Cynanchum elegans	White-flowered Wax Plant	R	R	R	R	No	*Cynanchum elegans* is a climbing vine that is restricted to eastern NSW and is found from Brunswick Heads in the north to Gerroa in the South. Habitat usually occurs on the edge of dry rainforest vegetation (OEH, 2019ah). Within the nominated areas, the species is most likely to occur along streamlines and steeper shale lands. No	Section 6.1.1.2 (lack of records, lack of suitable habitat)	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
							records of the species occur in the nominated areas. The species was removed as a candidate species in all nominated areas because of a lack of records and suitable habitat within urban capable lands. The urban capable lands are generally avoiding streamlines and steeper shale lands containing native vegetation where this species is most likely to occur. No dry rainforest vegetation occurs within urban capable land.				
Darwinia biflora		R	X	X	X	No	*Darwinia biflora* is an erect spreading shrub that is restricted to NSW and found in Ku-ring-gai, Hornsby, Baulkham Hills and Ryde Local Government Areas (OEH, 2017d). This species occurs on the edges of weathered shale-capped ridges and the transition area with Hawkesbury Sandstone. Most sites occur on the Lucas Heights Soil Landscape and the transition with Gymea or the Hawkesbury Soil Landscapes (NPWS, 2003). These habitat characteristics tend to occur in the lower-slope areas where the Shale Sandstone Transition Forest intersects with the sandstone enriched gully forests (PCT 1081, PCT 1181). The species may also occur in coastal upland swamp communities, but these do not occur within the nominated areas. The species has been removed as a candidate	Section 6.1.1.2 (outside geographic extent, lack of BioNet records)	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
							species in Wilton because urban capable land is outside the geographic extent of the species.				
Darwinia peduncularis		R	X	X	X	No	*Darwinia peduncularis* is a broad spreading shrub that has been recorded from Brooklyn, Berowra, Galston Gorge, Hornsby, Bargo River, Glen Davis, Mount Boonbourwa and Kings Tableland in NSW. The species occurs as local disjunct populations in coastal NSW with isolated populations in the Blue Mountains. Populations also occur within the Marramarra National Park, Wollemi National Park, Blue Mountains National Park and Berowra Valley Regional Park (NSW Scientific Committee, 1999a). Habitat comprises sandstone soils on either ridge crests or upper slopes and dry sclerophyll forest on sandstone hillsides and ridges. Potential habitat for the species within the nominated areas is likely to occur only in areas outside urban capable lands. The species has been removed as a candidate species in Wilton because of a lack of suitable habitat in urban capable land.	Section 6.1.1.2 (lack of suitable habitat)	No	No	N/A
Deyeuxia appressa		R	X	R	X	No	*Deyeuxia appressa* an erect perennial grass that is a highly restricted in NSW. Habitat comprises wet ground in the Hornsby area (Royal Botanic Gardens & Domain Trust, 2019). The species is primarily found east of the Plan Area with records	Section 6.1.1.2 (outside geographic extent,	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
							from Salt Pan Creek and Killara, and questionable records from Kellyville. The species is considered to be extinct in the wild as the areas confirmed to be formerly occupied are now well developed and the species has not been otherwise reliably recorded since 1942. The species favours wetter areas that will be excluded from urban capable land as major streams will be avoided. It is not known from the Wianamatta (South Creek) area in GPEC that may be potentially impacted by transport corridors. The species has been removed as a candidate species in WSA and Wilton because urban capable lands are outside the geographic extent of the species and a there is a lack of suitable habitat within urban capable lands.	lack of BioNet records)			
Dillwynia tenuifolia		R	R	✓	✓	Yes	*Dillwynia tenuifolia* is a low spreading shrub that primarily occurs in the Cumberland Plain from Windsor and Penrith in the north to Dean Park and near Colebee in the east. Habitat comprises scrubby and dry heath areas that occur in Castlereagh Ironbark Forest and Shale Gravel Transition Forest. It can also be found in the transition areas between these communities and Castlereagh Scribbly Gum Woodland. Outside of its primary distribution, the species has been recorded from Voyager Point and Kemps Creek, Luddenham, and South Maroota	Section 6.1.1.2 (lack of BioNet records, lack of suitable habitat)	Yes	Yes	WSA, GPEC

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record

							(OEH, 2017c). The species is likely to occur in all areas of PCT 724 and most areas of PCT 725. The species was retained as a candidate species in WSA and GPEC because suitable habitat is likely to occur in urban capable lands. The species was removed in GMAC and Wilton because of a lack of records within the nominated areas and a lack of suitable micro-habitat in urban capable lands. An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands.				
Dillwynia tenuifolia - endangered population	Dillwynia tenuifolia	X	X	R	X	No	*Dillwynia tenuifolia* is a low spreading shrub. The endangered population occurs at Kemps Creek south of WSA (the population occurs within the existing South West Sydney Growth Area) (NSW Scientific Committee, 1997). The population was removed as a candidate species in WSA because it does not occur within urban capable land.	Section 6.1.1.2 (outside geographic extent)	No	Yes	WSA
Epacris purpurascens var. *purpurascens*		✓	✓	R	R	Yes	*Epacris purpurascens* var. *purpurascens* is a shrub that is found in NSW from Gosford in the north, Narrabeen in the east, Silverdale in the west, and Avon Dam in the south (OEH, 2017e). Habitat comprises areas in the vicinity of creeks and swamps on sandstone in dry sclerophyll forest and scrub (Royal Botanic Gardens & Domain Trust,	Section 6.1.1.2 (lack of BioNet records, lack of suitable	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
							2019). Surveys have been undertaken for this species within urban capable lands. The species was not recorded during surveys. Though common in the Bingara Gorge and St Marys Towers areas, the species appears to be absent from other areas. This includes adjacent properties that were assessed. The species was retained as a candidate species in Wilton and GMAC because suitable habitat is likely to occur in urban capable lands. The species was removed in WSA and GPEC because of a lack of records and no suitable micro-habitat within urban capable lands.	habitat)			
Eucalyptus benthamii	Camden White Gum	✓	✓	R	R	Yes	*Eucalyptus benthamii* is a tree that is restricted to the alluvial flats of the Nepean River and its tributaries (DoE, 2014; OEH, 2017b). Habitat comprises wet forest on sandy alluvial soils along valley floors (Royal Botanic Gardens & Domain Trust, 2019). The distribution of the species includes Wilton and GMAC and south of GPEC and WSA, including west of WSA in the Bents Basin/Wallacia area. The species was retained as a candidate species in Wilton and GMAC because suitable habitat may occur in urban capable lands, although habitat is most likely to occur only in areas outside urban capable lands. The species was removed in WSA	Section 6.1.1.2 (lack of BioNet records)	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
							and GPEC because of a lack of records within urban capable lands.				
Eucalyptus sp. Cattai		R	X	X	X	No	*Eucalyptus sp. Cattai* is a small tree that occurs between Colo Heights and Castle Hill. It is generally found outside the subregion and considered restricted to the Cattai - Glenhaven region. Historic records occur near the Royal Botanic Gardens, Sydney (NSW Scientific Committee, 1998b). Habitat comprises scrub, heath, and low woodland on sandy soils generally in flat areas and on ridge tops (OEH, 2018e). This species was removed as a candidate species in Wilton as urban capable land occurs outside the geographic extent of the species.	Section 6.1.1.2 (outside geographic extent, lack of BioNet records)	No	No	N/A
Grammitis stenophylla	Narrow-leaf Finger Fern	R	X	X	X	No	*Grammitis stenophylla* is a small fern that occurs in eastern Queensland and NSW as far west as Narrabri. Habitat comprises moist places in rainforest and moist eucalypt forests near streams on rocks or in trees (OEH, 2018k). A single record occurs in the Cumberland subregion at Parramatta. The location of the record is close to the subregion boundary (but occurs in much wetter habitats than occur in the nominated areas). This record is old, and its location is unreliable (Royal Botanic Gardens & Domain Trust, 2019). This species was removed as a candidate species in	Section 6.1.1.2 (outside geographic extent, lack of BioNet records)	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record

		Wilton	GMAC	WSA	GPEC						
*cristatus**	Osprey						Victoria and Tasmania, especially on rocky shorelines, islands and reefs. The species is uncommon to rare or absent from closely settled parts of south-eastern Australia (OEH, 2018d). Habitat comprises coastal areas, particularly large coastal river mouths, lakes and lagoons (OEH, 2018d). The species nests in tall trees in coastal woodland to forest habitat (NSW Scientific Committee, 2009). The breeding population of this species in NSW spans from the Queensland border to Ulladulla in south-eastern NSW (NSW Scientific Committee, 2009). Vagrants have been recorded as far south as Victoria (NSW Scientific Committee, 2009). There are four records in the Cumberland subregion. Three occur in Milperra in 2014 (two have the same coordinates), while the last record is from North Ryde. The species was removed as a candidate species in GMAC, WSA and GPEC because of a lack of suitable breeding habitat within urban capable lands.	(outside geographic extent, lack of BioNet records, lack of suitable habitat)			
Persicaria elatior	Tall Knotweed	X	✓	✓	✓	Yes	*Persicaria elatior* is a herb found in south-eastern and northern NSW and Queensland (OEH, 2018n). It is known from the Cumberland subregion. Habitat comprises damp places, particularly beside streams and lakes. The species is occasionally found in swamp forest or associated with	N/A	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
							disturbance (OEH, 2018n). There are a few records within and nearby the Plan Area. The 1949 record from 'Picton Lakes' refers to Thirlmere Lakes (at that time being called Picton Lakes), and more recent (2010) records occur there. There is an unverified record from 2018. The species has been retained as a candidate in GMAC, WSA and GPEC because it may be subject to prescribed impacts (hydrology) and the transport corridors may have a direct impact on the species in WSA and GPEC. Targeted surveys have not been undertaken for this species within urban capable lands. However, habitat assessments have been completed.				
Persoonia bargoensis	Bargo Geebung	✓	✓	R	R	Yes	*Persoonia bargoensis* is a shrub that is restricted to a small area south-west of Sydney bounded by Picton, Douglas Park, Yanderra and Cataract River (NSW Scientific Committee, 2000). Habitat comprises woodland or dry sclerophyll forest on sandstone and shale soils (OEH, 2017a). The species can be found adjacent to disturbed areas such as roadsides (OEH, 2017a). Many of the records in Wilton and GMAC have very low reliability and are not recent records. The species was retained as a candidate species in Wilton and GMAC because records occur within	Section 6.1.1.2 (lack of suitable habitat)	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
							urban capable lands and suitable habitat has the potential to occur. The species was removed in WSA and GPEC because of a lack of suitable habitat within urban capable lands and no records occur north of Wilton.				
Persoonia glaucescens	Mittagong Geebung	R	X	X	X	No	*Persoonia glaucescens* is a shrub that is found in the Southern Highlands area, roughly between Picton and Berrima (NSW Scientific Committee, 2002b). Recent surveys have indicted this distribution has contracted (OEH, 2018j). Habitat includes woodland to dry sclerophyll forest, mostly on ridge tops, plateaux and upper slopes (OEH, 2018j). Records occur to the south of the Plan Area, with the northernmost records at Tahmoor. Surveys have been undertaken for this species within urban capable lands. The species was not recorded during surveys. The species was removed as a candidate species in Wilton as urban capable land is outside the geographic extent of the species.	Section 6.1.1.2 (outside geographic extent, lack of BioNet records)	No	No	N/A
Persoonia hirsuta	Hairy Geebung	R	R	R	R	No	*Persoonia hirsuta* is a shrub that has a scattered distribution around Sydney, and is found in the area bounded by Bargo to the south, Singleton to the north and the Blue Mountains to the west (OEH, 2017g). Habitat comprises sandstone and sandstone-derived soils in dry sclerophyll open	Section 6.1.1.2 (outside geographic extent, lack of	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
							forest, woodland and heath (OEH, 2017g). There are no records of the species within the Plan Area. The sole record within the Plan Area is a specimen that is misplaced and should correctly be located in 'Long Point, Macquarie Fields', approx. 3 km south-east of the mapped location. The species was removed as a candidate species in all nominated areas as urban capable land is outside the geographic extent of the species.	BioNet records)			
Persoonia mollis subsp. *maxima*	Soft Geebung	R	X	X	X	No	*Persoonia mollis* subsp. *maxima* is a tall shrub with a restricted distribution, and is known from the Hornsby Heights - Mt Colah area north of Sydney (OEH, 2017i). Habitat comprises sheltered, deep Hawkesbury sandstone gullies and upper steep hillsides (OEH, 2017i). These habitats often support relatively moist, tall forest vegetation communities, often with warm temperate rainforest influences (OEH, 2017i). There 11 records within the Cumberland subregion. All records occur outside the nominated areas. The most recent record is 2005. The species was removed as a candidate species in Wilton as urban capable land is outside the geographic extent of the species.	Section 6.1.1.2 (outside geographic extent, lack of BioNet records)	No	No	N/A
Persoonia nutans	Nodding Geebung	R	R	✓	✓	Yes	*Persoonia nutans* is a shrub that is found on the Cumberland Plain, between Richmond in the north	Section 6.4.1.17	Yes	Yes	GPEC

							coastal areas, and box, box-ironbark and river red gum woodlands further inland (OEH, 2017n). The species prefers mature or old growth woodland and requires abundant tree hollows for refuge and nesting sites (OEH, 2017n). Records occur within Wilton in areas outside urban capable lands. The species was retained as a candidate species in Wilton, GMAC and GPEC because suitable habitat has the potential to occur in urban capable lands. The species was removed in WSA because of a lack of suitable habitat and recent records (<100 years old) within urban capable land Habitat assessment surveys have been undertaken across the Growth Ares for this species. Potential habitat was found to be present.	records, lack of suitable habitat)			
*Phascolarctos cinereus**	Koala	✓	✓	R	R	Yes	*Phascolarctos cinereus* is an arboreal marsupial that has a fragmented distribution throughout eastern Australia. In NSW, it mainly occurs on the central and north coasts with some populations in the west of the Great Dividing Range. Habitat comprises eucalypt woodlands and forests (OEH, 2018h). Koalas feed on over 70 species of Eucalyptus and over 30 non-Eucalyptus species (OEH, 2018h). There are a significant number of recent Koala records present within and adjacent to Wilton and GMAC. Breeding habitat occurs through the	Section 6.1.1.2 (lack of BioNet records, lack of suitable habitat)	Yes	Yes	GMAC, Wilton

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment: Wilton	GMAC	WSA	GPEC	Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
							eastern portion of GMAC and around Wilton (OEH, 2018c). Records further indicate the presence of Koalas within the Blue Mountains, particularly in the district of Kurrajong, with very few records occurring east of these areas within the urban matrix. Three forms of Koala habitat mapping were undertaken across the Plan Area, including within all the nominated areas (see Part 3). They include: • A species distribution model (SDM) for the species across the Cumberland subregion • Corridor habitat mapping • Mapping of habitat critical to the survival of the species The BAM requires the assessment of impacts on Koala to be determined on the basis of 'important habitat'. The Koala corridor habitat mapping undertaken within the nominated areas was used to identify important habitat that comprises the species polygons for Koala as required by the BAM. The corridor habitat mapping is built on the work of EES in mapping habitat around Wilton and GMAC (OEH, 2018h). The species was retained as a candidate species in Wilton and GMAC as the corridor mapping found 'important habitat' to be present in the form of				

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record

							primary and secondary corridors, as well as multiple recent records. The species was removed in WSA and GPEC because of a lack of important habitat within these nominated areas (as defined as primary and second habitat corridors). Part 3, section 11.1.1, provides a more detailed justification for the exclusion of Koala as a candidate species from GPEC and WSA, and Part 3, section 11.5.4 provides further detail on the corridor mapping method.				
Pilularia novae-hollandiae	Austral Pillwort	X	R	R	R	No	*Pilularia novae-hollandiae* is a semi-aquatic fern that has a scattered distribution in NSW. Habitat comprises shallow swamps and waterways, often amongst grasses and sedges (OEH, 2018a). The species is probably ephemeral, growing in moist soils following rain events, and is often recorded in drying mud (OEH, 2018a). Despite the high occurrence and coverage of botanical surveys across the Cumberland subregion the species has not been recorded since a single record from 1966 in Doonside. It is expected that more recent records would exist if the species natural range included the Cumberland subregion. Potential habitat for the species (high order Strahler streams) within the nominated areas is likely to only occur in areas outside urban capable	N/A	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
							lands, with all mapped creek lines above Strahler order one, being excluded from the footprint. The species has been removed as a candidate in all nominated areas.				
Pimelea curviflora var. *curviflora*		R	R	R	✓	Yes	*Pimelea curviflora* var. *curviflora* is a shrub found in the coastal area of Sydney and the Illawarra regions (OEH, 2019ac).The species is known from approximately 20 locations in the Baulkham Hills, Blacktown, Hornsby, Parramatta and Warringah Local Government Areas (NSW NPWS, 1999) and the Shellharbour area. The species was formerly recorded around the Parramatta River and Port Jackson areas. Habitat comprises shale, sandstone, and lateritic soils, on ridgetops and upper slopes in woodlands (OEH, 2017j). Records (dated 2000) occur in only two locations in the vicinity of the nominated areas. Despite extensive surveys at Bingara Gorge in suitable habitat, the species was not recorded, suggesting that the two records in the vicinity of the nominated areas may be misapplications for *P. curviflora* var. *sericea* which is recorded in that area. The species was retained as a candidate species in GPEC because records or suitable habitat potentially occur in the vicinity of urban capable lands. The species was removed in Wilton, GMAC	Section 6.1.1.2 (outside geographic extent, lack of BioNet records)	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record

	Greenhood						north and Picton in the south. Habitat comprises sandstone outcrop areas in shale-sandstone transition forest, although it is occasionally found on clay-rich sites (OEH, 2018m). There are a number of records in the vicinity of the nominated areas. Some of these are thought to have low reliability in terms of their location. The species was retained as a candidate species in all nominated areas because suitable habitat has the potential to occur in urban capable lands. An expert report has been prepared to confirm whether suitable habitat exists for this species within urban capable lands.				
Pultenaea parviflora		X	X	✓	✓	Yes	*Pultenaea parviflora* is a small shrub that is endemic to the Cumberland Subregion. The species primarily occurs in areas of Shale Gravel Transition Forest and Cooks River/ Castlereagh Ironbark Forest, with some potential in Castlereagh Scribbly Gum Woodland and Castlereagh Swamp Forest (OEH, 2019a). The species was retained as a candidate species in WSA and GPEC because records occur in the vicinity of the nominated areas and suitable habitat has the potential to occur in urban capable lands.	N/A	Yes	Yes	WSA, GPEC
Pultenaea	Matted	✓	✓	✓	✓	Yes	*Pultenaea pedunculata* is a shrub that occurs in NSW, Victoria, and Tasmania. In NSW it occurs in three	N/A	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
pedunculata	Bush-pea						locations including the Cumberland Subregion. The species occurs in a range of habitats and in the Cumberland Subregion it favours clay or sandy-clay soils that have a lateritic influence with ironstone gravel (nodules) present (OEH, 2018i). The species has been recorded in several places in the vicinity of the nominated areas. The species was retained as a candidate species in all nominated areas because records occur in the vicinity of the nominated areas and suitable habitat has the potential to occur in urban capable lands.				
Tetratheca glandulosa		R	R	X	R	No	*Tetratheca glandulosa* is a small shrub that is restricted to the following Local Government Areas (LGAs): Baulkham Hills, Gosford, Hawkesbury, Hornsby, Ku-ring-gai, Pittwater, Ryde, Warringah, and Wyong (the nominated areas do not occur in these LGAs). The species has a strong association with shale-sandstone soils (OEH, 2017o). The nearest substantiated records to the nominated areas are to the west of Thirlmere lakes where they occur on sandstone communities outside urban capable lands. The species was removed as a candidate species in Wilton, GMAC and GPEC because urban capable lands are outside the geographic range of the species and no records of the species occur within	Section 6.1.1.2 (outside geographic extent, lack of BioNet records)	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
							the vicinity.				
Thesium australe	Austral Toadflax	R	R	R	R	No	*Thesium australe* is a small herb that is found in small populations along the coast of NSW. The species occurs in grasslands on the coast, and grassland or grassy woodland further inland (OEH, 2018a). The species is distinctive in survey (sprawling yellow-grey-green herb) and has only a single old record (1803) from the Cumberland subregion (which is also the type collection). It is currently considered to be extinct in the subregion (OEH, 2018a). The species was removed as a candidate species in all nominated areas because urban capable lands are outside the geographic range of the species and no reliable records of the species occur within the vicinity.	Section 6.1.1.2 (lack of BioNet records)	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
Tyto novaehollandiae (breeding)	Masked Owl	✓	✓	R	✓	Yes	*Tyto novaehollandiae* is a medium-sized owl which occurs over 90 per cent of NSW and is most abundant on the coast. Roosting and breeding habitat for the species comprises moist eucalypt forested gullies, and it uses large tree hollows or caves for nesting (OEH, 2019x). The large-scale breeding habitat and the fairly specific requirements of large hollowed trees (and especially hollowed stag trees) are scarce on the Cumberland subregion. The species was removed as a candidate species in WSA because of a lack of suitable habitat within urban capable land. The species was retained as a candidate species in Wilton, GMAC and GPEC because known sites occur within the vicinity of the nominated areas. Habitat assessment surveys have been undertaken across the Growth Ares for this species. Potential breeding habitat was found to be present.	Section 6.1.1.2 (lack of BioNet records, lack of suitable habitat)	Yes	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
Wahlenbergia multicaulis - endangered population	Tadgell's Bluebell	R	R	R	R	No	*Wahlenbergia multicaulis* is a perennial herb that is found in 13 known sites in northern Sydney and Western Sydney (Rookwood, Chullora, Bass Hill, Bankstown, Georges Hall, Campsie, South Granville and Greenacre) (OEH, 2019ae). In Western Sydney, habitat is associated with the Villawood Soil Series, which is a poorly drained, yellow podsolic extensively permeated with fine, concretionary ironstone (laterite). The species was removed as a candidate species in all nominated areas because the population does not occur within urban capable lands.	Section 6.1.1.2 (outside geographic extent)	No	No	N/A
Zannichellia palustris	Horned Pondweed	X	X	R	X	No	*Zannichellia palustris* is a submerged aquatic plant. In NSW it is only known from the lower Hunter region and Sydney Olympic Park. It occurs in fresh or slightly saline stationary or slowly flowing water (OEH, 2017d). The species was removed as a candidate species in WSA because urban capable land is outside the geographic extent of the species.	Section 6.1.1.2 (outside geographic extent, lack of BioNet records)	No	No	N/A

Scientific name	Common name	Predicted location ✓ = predicted to occur X = not predicted to occur R = predicted to occur but removed from needing further assessment				Candidate species	Justification for removal of species from further assessment	Basis for removal under BAM	Targeted for survey for this project (y/n)	Recorded during survey (y/n)	Location of record
		Wilton	GMAC	WSA	GPEC						
Zieria involucrata		R	X	X	X	No	*Zieria involucrata* is a small shrub that occurs to the north and west of Sydney in the Baulkham Hills, Hawkesbury, Hornsby and Blue Mountains Local Government Areas. The species is associated with Hawkesbury sandstone, as well as Narrabeen Group sandstone and Quaternary alluvium (OEH, 2017e). The Cumberland subregion occurs within the predicted distribution of the species (OEH, 2017e), and there is one old record from Kurrajong in 1959. The species was removed as a candidate species in Wilton because urban capable land is outside the geographic extent of the species.	Section 6.1.1.2 (outside geographic extent, lack of BioNet records)	No	No	N/A

* These species are SCS in relation to breeding habitat or mapped "important habitat" only

B. Knowledge-based Method parameters

Two tables are provided to describe the KBM parameters:

- Table B-1 – KBM parameters for species within the nominated areas
- Table B-2 – KBM parameters for species outside the nominated areas within the Cumberland subregion

Table B-1: Nominated area threatened species KBM parameters

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	LiDAR – EM / CHM
Allocasuarina glareicola	-	Intact, Thinned	BioNet PCT associations	-	-	SOILS: (Blacktown, Agnes Banks, Berkshire Park, Gymea) Justification: Existing records occur within these soils	-	-	-
Callocephalon fimbriatum	Gang-gang Cockatoo	Intact	BioNet PCT associations	> 25 ha Justification: Medium BAM patch size. Favours old growth forest and woodland attributes for nesting and roosting (OEH, 2019c)	-	-	-	-	Tree height >20 m (CHM) Justification: Breeding habitat information (Higgins, 1999)

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	LiDAR – EM / CHM
Calyptorhynchus lathami	Glossy Black-Cockatoo	Intact	BioNet PCT associations	> 25 ha Justification: Medium BAM patch size. Breed in hollows, often near water, usually within tall mature sclerophyll forest with dense shrubby understorey, often in secluded valleys (Higgins, 1999)	-	-	-	-	Tree height >15 m (CHM) Justification: Breeding habitat information (Higgins, 1999)
Cercartetus nanus	Eastern Pygmy-possum	Intact	BioNet PCT associations	-	-	-	-	-	-
Chalinolobus dwyeri	Large-eared Pied Bat	Intact, Thinned, Scattered Trees	BioNet PCT associations	-	-	ROCK UNIT: ('Hawkesbury Sandstone', 'Minchinbury Sandstone')	-	-	Habitat restricted to within a 200 m buffer on "Cliffline" DEM layer. Justification: Species roost predominantly in caves and overhangs in sandstone cliffs and forage in nearby high-fertility forest or woodland near watercourses (DERM, 2011)

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	LiDAR – EM / CHM
Epacris purpurascens var. *purpurascens*	Epacris purpurascens var. purpurascens	Intact, Thinned	BioNet PCT associations	-	-	-	-	-	-
Eucalyptus benthamii	Camden White Gum	Intact, Thinned, Scattered Trees	BioNet PCT associations	-	Habitat restricted to within a 350 m buffer of the 'NEPEAN RIVER' Hydro Area Justification: Requires a combination of deep alluvial sands and a flooding regime to recruit seedlings (OEH, 2019c) and captures extent of species records	ROCK UNIT: ('Alluvium', 'Bringelly Shale', 'Hawkesbury Sandstone')	Between 25 to 300 m (OEH, 2019c)	-	-
Grevillea parviflora subsp. *Parviflora*	Small-flower Grevillea	Intact, Thinned	BioNet PCT associations	-	-	SOILS: ('Berkshire Park', 'Lucas Heights', ' Wianamatta (South Creek) ROCK UNIT: ('Alluvial channel deposits-in-channel bar', 'Alluvial floodplain deposits',	Between 25 to 300 m (OEH, 2019c)	-	-

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	LiDAR – EM / CHM
						'Alluvium', 'Mittagong Formation', 'Alluvial terrace deposits') Justification: Sydney region occurrences are usually on Tertiary sands and alluvium, and soils derived from the Mittagong Formation. Soil landscapes include Lucas Heights or Berkshire Park (OEH 2018c) Habitat also present where PCTs occur on or w/in 200 m of Hawkesbury soils AND sandstone geology (Hawkesbury Sandstone) (i.e. must satisfy both criteria) Justification: at least 80 of the 97 records of the			

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	LiDAR – EM / CHM
						species that occur outside Lucas Heights soils (around Wilton and GMAC) meet the above criteria			
Haliaeetus leucogaster	White-bellied Sea-Eagle	Intact	BioNet PCT associations	>5 ha Justification: Exclude small isolated patches of vegetation from habitat model	Habitat restricted to within 350 m around (Strahler order >3 or any waterbody include hydronametype IN ('BRANCH', 'DAM', 'LAKE', 'LAKES', 'RESERVOIR', 'RIVER', 'ARM')) Justification: Selection of nest site data (Dennis, McIntosh et al., 2011)	-	-	-	-

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	LiDAR – EM / CHM
Heleioporus australiacus	Giant Burrowing Frog	Intact	BioNet PCT associations	>5 ha Justification: Exclude small isolated patches of vegetation from habitat model	Habitat restricted to within 300 m of 1st , 2nd and 3rd order watercourses, excluding overlapping areas within 300 m from a 4th (or higher) order watercourse Justification: Burrows in the creek bank. Eggs are laid in burrows or under vegetation in small pools. Breeding habitat of this species is generally soaks or pools within first or second order streams. (up to 300 metres from breeding site (first and second order streams) (OEH, 2019c)	ROCK UNIT: ('Hawkesbury Sandstone', 'Minchinbury Sandstone') and SOILS: NOT in ('Blacktown', 'Glenorie', 'Luddenham', 'Picton', 'West Pennant Hills') Justification: Found in vegetation on a variety of soil types except those that are clay based (OEH, 2019c)	-	-	-

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	LiDAR – EM / CHM
Hieraaetus morphnoides	Little Eagle	Intact, Thinned	BioNet PCT associations	>5 ha Justification: Exclude small isolated patches of vegetation from habitat model	-	-	-	Habitat excluded from within 215 m of a dwelling and 65 m from industrial building Justification: Little Eagle expert report for WGA and GMAC (Saunders and Debus, 2018)	Minimum tree height restricted to 20m Justification: Nest trees height determined in WSA and GMAC expert report (Saunders and Debus, 2018)
Lophoictinia isura	Square-tailed Kite	Intact	BioNet PCT associations	>5 ha Justification: Exclude small isolated patches of vegetation from habitat model	Habitat restricted to within 350 m around Strahler order 3+ watercourses or any waterbody include hydronametype IN ('BRANCH', 'DAM', 'LAKE', 'LAKES', 'RESERVOIR', 'RIVER', 'ARM')) Justification: Species shows a particular preference for timbered watercourses, with nest sites generally located along or near	-	-	-	-

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	LiDAR – EM / CHM
					watercourses (OEH, 2019c)				
Marsdenia viridiflora subsp. *viridiflora* - endangered population	Marsdenia viridiflora subsp. viridiflora - endangered population	Intact, Thinned	BioNet PCT associations	-	-	-	-	LGAs IN ('BANKSTOWN', 'BLACKTOWN', 'CAMDEN', 'CAMPBELLTOWN', 'FAIRFIELD', 'HOLROYD', 'LIVERPOOL', 'PENRITH')	-
Maundia triglochinoides	-	Intact, Thinned	BioNet PCT associations	-		SOILS: (Berkshire Park, Birrong, Blacktown, Deep Creek, Freemans Reach, Glenorie, Lane Cove, Monkey Creek, Picton, Richmond, Wianamatta (South Creek), Teresa Park, Upper Castlereagh) Justification: Grows on heavy clay (OEH, 2019c)	-	-	-

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	LiDAR – EM / CHM
Micromyrtus minutiflora	-	Intact, Thinned	BioNet PCT associations	-	-	-	Up to 50 m (Doug & Lyn, 1998)	-	-
Myotis macropus	Southern Myotis	Intact, Thinned, Scattered Trees	BioNet PCT associations	-	All waterbodies in the Plan Area with pools/reaches of water 3 m or wider and areas of habitat within 200 m of these waterbodies where they occur on the subject land and coincide with the relevant PCTs (OEH, 2019c)	-	-	-	-
Ninox connivens	Barking Owl	Intact	BioNet PCT associations	>25 ha Justification: Moderate BAM patch size, removes isolated patches	Restricted to within 100 m of a watercourse Justification: Breeding habitat known to be similar and more restrictive than Powerful Owl (DEC, 2006)	-	-	-	Vegetation within "Gullies" DEM layer. Justification: Breeding habitat known to be similar and more restrictive than Powerful Owl (DEC, 2006)

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	LiDAR – EM / CHM
Ninox strenua	Powerful Owl	'Intact'	BioNet PCT associations	-	Restricted to within 100 m of a watercourse Justification: Nests in old hollow eucalypts in unlogged, unburnt gullies and lower slopes within 100 m of streams or minor drainage lines (DEC, 2006)	-	-	-	Vegetation within "Gullies" DEM layer. Justification: Nests in old hollow eucalypts in unlogged, unburnt gullies and lower slopes within 100 m of streams or minor drainage lines (DEC, 2006)
Persicaria elatior	-	Intact, Thinned, Scattered Trees, DNG	BioNet PCT associations	-	Habitat mapped within vegetation polygons occurring within 50m of the following Hydro Areas: Anabranch, Backwater, Billabong, Branch, Cowal, Creek, Pond, River, Stream, Swamp, Watercourse, Waterway Justification: Species grows in damp places, especially beside streams and	SOILS: ('Wianamatta (South Creek), 'Richmond', 'Freemans Reach', 'Berkshire Park', 'Upper Castlereagh) Justification: Species grows on sandy, alluvial soil (DEWHA, 2008c)	-	-	-

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	LiDAR – EM / CHM
					lakes, occasionally in swamp forest (OEH, 2019c)				
Persoonia bargoensis	Bargo Geebung	Intact, Thinned	BioNet PCT associations	-	-	ROCK UNIT: ('Hawkesbury Sandstone', 'Minchinbury Sandstone', 'Mount Hercules Sandstone Member', 'Razorback Sandstone Member') AND Blacktown, Glenorie, Picton, Luddenham soil landscapes within 80 m of the edge of the sandstone geology. Justification: Species favours interface soil landscapes such as between the Blacktown Soil Landscape and the complex Mittagong Formation soils (Lucas Heights	0 - 450 m Justification: As detailed in Cunninghamia Vol. 6(4): 2000, increased based on records around Bargo (Doug & Lyn, 1998)	-	-

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	LiDAR – EM / CHM
						Soil Landscape) with the underlying sandstone (OEH, 2019c)			
Petaurus norfolcensis	Squirrel Glider	Intact, Thinned, Scattered Trees	BioNet PCT associations	>4 ha Justification: Expected home range within the Plan Area (NSWSC, 2008)	-	-	-	-	Vegetation 10 m tall and higher, buffer all polygons by 12.5 m (to establish connected habitat within glide ratio of 1:2.5 for 10 m trees), clip the buffered polygons back to vegetation polygons, select patches that are 4 hectares and greater Justification: Connected habitats are those which the animals can reach by gliding, 10m tall trees are the minimum expected height for glide launch (Jackson, 2000; Vernes, 2001)

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	LiDAR – EM / CHM
Pimelea curviflora var. *curviflora*	-	Intact, Thinned	BioNet PCT associations	-	-	ROCK UNIT: ('Hawkesbury Sandstone', 'Minchinbury Sandstone') AND All Blacktown soil landscape within a 500m buffer on Wianamatta (South Creek), plus all Berkshire Park soil landscape Justification: Occurs on shaley/lateritic soils over sandstone and shale/sandstone transition soils (OEH 2018g)	Less than 300 m (Doug & Lyn, 2001)	-	Sandstone units selected only within a 100 m buffer on "Ridge and Crest" DEM layer Justification: Occurs on shale/sandstone transition soils on ridgetops and upper slopes amongst woodlands (OEH, 2019c)
Pomaderris brunnea	Rufous Pomaderris	Intact, Thinned	BioNet PCT associations	-	100 m around waterways Justification: Grows in moist woodland or forest on clay and alluvial soils of flood plains and creek lines (OEH, 2019c)	SOILS: ('Blacktown', 'Lucas Heights') Justification: Grows in moist woodland or forest on clay and alluvial soils of flood plains and creek lines (OEH, 2019c)	Up to 450 m (BioNet records)	-	-

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	LiDAR – EM / CHM
Pseudophryne australis	Red-crowned Toadlet	Intact	BioNet PCT associations	-	Restricted to 1st and 2nd order watercourses (OEH, 2019c)	ROCK UNIT: ('Hawkesbury Sandstone', 'Minchinbury Sandstone') inside Ridge and Crest Justification: Occurs in open forests, mostly on Hawkesbury and Narrabeen Sandstones (OEH, 2019c)	-	-	Habitat buffered to 50m above and 100m below "Ridge and Crest" DEM layer Justification: Species usually restricted to within 100 m of a ridgetop (NPWS, 2001)
Pultenaea parviflora	-	Intact, Thinned	BioNet PCT associations	-	-	-	Less than 120 m (Doug & Lyn, 1996)	-	-
Pultenaea pedunculata	Matted Bush-pea	Intact, Thinned, Scattered Trees	BioNet PCT associations	-	-	Occurs on Blacktown, Wianamatta (South Creek), Berkshire Park soil landscapes AND On, or within a 600 m buffer from, "Alluvium" in "GRPSUITE" field OR Within 500 m buffer from boundaries sandstone	Less than 150 m (Doug & Lyn, 1996)	-	-

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	LiDAR – EM / CHM
						derived soil landscapes Justification: Favours sites in clay or sandy-clay soils on Wianamatta Shale-derived soils, usually close to patches of Tertiary Alluvium, or at or near the Shale-Sandstone interface. All sites have a lateritic influence (OEH, 2019c)			
Tyto novaehollandiae	Masked Owl	Intact, Thinned	BioNet PCT associations	All "Intact" Vegetation or "Thinned" patches over 10 ha in area Justification: Removed scattered and isolated occurrences of "Thinned" vegetation not suitable for breeding habitat	-	-	-	-	Vegetation within "Gullies" DEM layer. Justification: Roosts and breeds in moist eucalypt forested gullies, using large tree hollows or sometimes caves for nesting (OEH, 2019c)

Table B-2: Cumberland subregion threatened species KBM parameters

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	Rainfall associations
Allocasuarina glareicola	-	Intact, thinned	BioNet PCT associations	>40 ha Justification: Exclusion of small patches of vegetation not meeting the known geographic extent of the species	-	-	Below 50 metres (Doug & Lyn, 1995)	Primarily restricted to the Richmond (NW Cumberland Plain) district, but with an outlier population found at Voyager Point, Liverpool (DAWE, 2020)	>800 mm (Doug & Lyn, 1995)
Anthochaera phrygia	Regent Honeyeater	Intact, Thinned, Scattered Trees	BioNet PCT associations	-	-	-	-	-	-
Botaurus poiciloptilus	Australasian Bittern	Intact, thinned	BioNet PCT associations	-	40 metre buffer applied to hydrolines. Justification: Preferred habitat is comprised of wetlands, often at the edges of pools or waterways, or from platforms or mats of vegetation over deep water (DAWE, 2020).	-	-	-	-

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	Rainfall associations
Chalinolobus dwyeri	Large-eared Pied Bat	Intact, thinned	BioNet PCT associations	-	-	Habitat restricted to within 2 kms of Rock Units ('Hawkesbury Sandstone', 'Minchinbury Sandstone', 'Mount Hercules Sandstone Member', 'Razorback Sandstone Member') Justification: species primarily roosts in caves and overhangs in sandstone cliffs and forage in nearby high-fertility forest or woodland near watercourses (DECC, 2007; Pennay, 2008; Pennay & Gosper, 2002)	-	-	-

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	Rainfall associations
Commersonia prostrata	Dwarf Kerrawang	Intact, Thinned, Scattered Trees	BioNet PCT associations	-	-	SOILS: ('Berkshire Park', 'Freemans Reach', 'Hawkesbury', 'Monkey Creek', 'Richmond', ' Wianamatta (South Creek), 'Theresa Park', 'Upper Castlereagh', 'Bakers Lagoon', 'Ettalong') ROCK UNIT: ('Hawkesbury Sandstone', 'Minchinbury Sandstone') Justification: Sandy/peat soils (OEH, 2020b)	-	-	-
Cynanchum elegans	White-flowered Wax Plant	Intact, thinned	BioNet PCT associations	-	-	-	Below 600 metres (DAWE, 2020)	All occurrences of PCT 830, 835, 849 and 850 within 1km of PCT 877, and all PCT 877 patches. Justification: Species occurs in ecotonal areas of dry rainforest and surrounding drier forest / woodland	-

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	Rainfall associations
Dasyurus maculatus maculatus	Spot-tailed Quoll	Intact, thinned	BioNet PCT associations	>1000 ha Justification: Restrict habitat to areas of very large intact bushland remnants around, and connected to, the edges of the Cumberland sub-region	-	-	-	-	>600 mm (DAWE, 2020)
Deyeuxia appressa	-	Intact, thinned	BioNet PCT associations	-	-	-	-	-	-
Genoplesium baueri	Yellow Gnat-orchid	Intact	BioNet PCT associations	-	-	-	Below 500 metres (Doug & Lyn, 2005)	-	-
Heleioporus australiacus	Giant Burrowing Frog	Intact	BioNet PCT associations	>5 ha Justification: Exclude small isolated patches of vegetation from habitat model	Habitat restricted to all PCTs within 300 m of 1st , 2nd and 3rd order watercourses, excluding overlapping areas within 300 m from a 4th (or higher) order watercourse. And wetland PCTs within 300m f watercourse irrespective of	ROCK UNIT: ('Hawkesbury Sandstone', 'Minchinbury Sandstone') and SOILS not in ('Blacktown', 'Glenorie', 'Luddenham', 'Picton', 'West Pennant Hills') Justification: Found in vegetation on a variety of soil types except	-	Northern population largely confined to the sandstone geology of the Sydney Basin and extending as far south as Ulladulla (OEH, 2019c)	-

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	Rainfall associations
					Strahler order. Justification: Burrows in the creek bank. Eggs are laid in burrows or under vegetation in small pools. Breeding habitat of this species is generally soaks or pools within first or second order streams. (up to 300 metres from breeding site (first and second order streams) (OEH, 2019c)	those that are clay based (OEH, 2019c)			
Hibbertia puberula subsp. *glabrescens* (also known as *Hibbertia sp. Bankstown)*	-	-	BioNet PCT associations	-	-	-	-	1 km around records Justification: Restrict habitat to known geographic extent of the species	-
Hoplocephalus bungaroides	Broad-headed Snake	Intact	BioNet PCT associations	>5 ha Justification: Excluded small isolated patches of vegetation from habitat model	-	-	-	-	-

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	Rainfall associations
Lathamus discolor	Swift Parrot	Intact, Thinned, Scattered Trees	BioNet PCT associations	-	-	-	-	-	-
Leucopogon exolasius	Woronora Beard-heath	Intact, thinned	BioNet PCT associations	-	200 metre buffer applied to Cataract River and Georges River: Justification: Restrict to known area of occurrence of the species, and the species' inhabits woodland on sandstone (and sandy alluvium) and prefers rocky hillsides along creek banks - prefers rocky hillsides along creek banks (DAWE, 2020).	SOILS: ('Berkshire Park', 'Freemans Reach', 'Hawkesbury', 'Monkey Creek', 'Richmond', Wianamatta (South Creek), 'Theresa Park', 'Upper Castlereagh') ROCK UNIT: ('Alluvial channel deposits-in-channel bar', 'Alluvial floodplain deposits', 'Alluvial terrace deposits', 'Alluvium', 'Hawkesbury Sandstone', 'Minchinbury Sandstone') Justification: Sandstone and sandy alluvium (DAWE, 2020).	Below 400 metres (DAWE, 2020)	-	1000-1400 mm (DAWE, 2020)

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	Rainfall associations
Macquaria australasica	Macquarie Perch	-	N/A	-	The waterways identified in the recovery plan (DoEE & DPI, 2018) that occur within and close to the Strategic Assessment Area that support self-sustaining native populations, or translocated and stocked populations Any additional waterways within the Strategic Assessment Area that support records of the species since 2000	-	-	-	-
Melaleuca deanei	Deane's Melaleuca	Intact, thinned	BioNet PCT associations	-	-	-	Below 400 metres (DAWE, 2020)	-	1000-1400 mm (DAWE, 2020)

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	Rainfall associations
Persicaria elatior	Tall Knotweed	All	BioNet PCT associations	-	Habitat mapped within vegetation polygons occurring within 50m of the following HydroAreas: Anabranch, Backwater, Billabong, Branch, Cowal, Creek, Pond, River, Stream, Swamp, Watercourse, Waterway Justification: Species grows in damp places, especially beside streams and lakes, occasionally in swamp forest (OEH, 2020b)	-	-	-	-
Persoonia glaucescens	Mittagong Geebung	Intact, thinned	BioNet PCT associations	-	-	-	250-650m (DAWE, 2020)	Restricted to within 7.5 kms of existing records	-
Petauroides volans	Greater Glider	Intact	BioNet PCT associations	>25 ha Justification: Restrict habitat to larger areas of vegetation. BioNet notes	-	-	-	-	-

Scientific name	Common name	Veg. condition	Veg. associations	Patch size	Waterways	Soil/ Geology restrictions	Elevation	Geographic	Rainfall associations
				species can occur in medium patches of 5-24ha, however this was returning many unsuitable areas as habitat					
Pimelea curviflora var. *curviflora*	-	Intact, thinned	BioNet PCT associations	-	-	ROCK UNIT: ('Hawkesbury Sandstone', 'Minchinbury Sandstone', 'Mount Hercules Sandstone Member', 'Razorback Sandstone Member') AND All Blacktown soil landscape within a 500 m buffer on Wianamatta (South Creek) plus all Berkshire Park soil landscape Justification: Occurs on shaley/lateritic soils over sandstone and shale/sandstone	Below 300 metres (DAWE, 2020)	-	-

C. Biological and important populations definitions

Table C-1: Biological populations and important populations definitions

Scientific Name	EPBC listing	Logic for Including/Excluding Records	How to Define Biological Population	Importance criteria used to identify important populations of this species
Acacia bynoeana	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat.	Limited information is available on the dispersal distance of *A. bynoeana*. The recovery plan for *A. pubescens* notes that dispersal over a distance of 300 m is considered likely for *Acacia* spp. (NSW NPWS, 2003a). Therefore, plants within 300 m of each other have been defined as one population.	Populations of *A. bynoeana* were considered important because they met one or more of the following criteria: • A large population • A population within a conservation area • A population that is site-managed species or iconic species targeted for conservation under the NSW Saving our Species program
Acacia pubescens	Vulnerable	All available BioNet records were used to identify populations, with no date restrictions.	Plants within 300 m of each other have been defined as one population, as dispersal is considered likely to occur over this distance in *Acacia* spp. (NSW NPWS, 2003a)	Populations of *A. pubescens* were considered important because they met one or more of the following criteria: • A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program • A large population • Is associated with a commitment made under the Sydney Growth Centres conservation program • A population within a conservation area
Allocasuarina glareicola	Endangered	All available BioNet records were used to identify populations, with no date restrictions.	Biological populations were defined based on clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollination	All populations of *A. glareicola* were considered important as the species is endangered.
Anthochaera phrygia	Critically Endangered	All available BioNet records were considered in the assessment.	The Regent Honeyeater comprises a single population (DoE, 2016b).	The population was considered to be important as the species is critically endangered.
Botaurus poiciloptilus	Endangered	Records restricted to post 2007 to account for estimated 11-year lifespan of the species.	The south-eastern Australian subpopulation of the species is considered as one population for this assessment. All records within the Strategic Assessment Area are therefore considered part of the same population.	All populations were considered to be important as the species is endangered.

Scientific Name	EPBC listing	Logic for Including/Excluding Records	How to Define Biological Population	Importance criteria used to identify important populations of this species
Chalinolobus dwyeri	Vulnerable	All BioNet records for the Strategic Assessment Area were included in the assessment.	The species is known to breed in very few locations across NSW and the distance bats move from the maternity roost to over wintering roosts has not been established, but is likely to be less than 100 km (DoEE, 2018). As such all records within the Cumberland subregion are considered likely to be from the same breeding population	The population of Large-eared Pied Bats was considered important within the Strategic Assessment Area because it met the following criteria: • A population identified or inferred in a Commonwealth conservation advice, recovery plan, final determination, or other relevant policy document as being important
Commersonia prostrata	Endangered	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat.	Populations were considered to constitute clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators.	All populations were considered to be important as the species is endangered.
Cynanchum elegans	Endangered	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat.	Little is known of the reproduction and dispersal ecology of *C. elegans* (DoEE, 2018). As part of this assessment, a population was considered to be clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators.	All populations were considered to be important as the species is endangered.
Dasyurus maculatus maculatus	Endangered	BioNet records from 1999 onwards were considered current for the assessment.	All records within an area covered by the average male home range (up to 5,512 ha) were considered a single population.	All populations were considered to be important as the species is endangered.
Deyeuxia appressa	Endangered	All available BioNet records were used to identify populations, with no date restrictions.	There are not thought to be any extant populations of this species, as there are no recent records of species, and it is considered possible that the species is now extinct.	All populations were considered to be important as the species is endangered.
Eucalyptus benthamii	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat.	There is limited information available regarding pollination and dispersal thresholds for *E. benthamii.* Therefore, a population was considered to constitute clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators.	Populations of *E. benthamii* were considered important because they met one or more of the following criteria: • A population identified or inferred in a Commonwealth conservation advice, plan, final determination, or other relevant policy document as being important • A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program

Scientific Name	EPBC listing	Logic for Including/Excluding Records	How to Define Biological Population	Importance criteria used to identify important populations of this species
				• A large population • A population within a conservation reserve • A population that is important for maintaining the Extent of Occurrence of a species
Genoplesium baueri	Endangered	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat.	Records within 500 m of each other have been considered to be a single population.	All populations of *G. baueri* have been considered as important as the species is endangered.
Grevillea parviflora subsp. *parviflora*	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat.	Little is known about the life cycle of *G. parviflora* subsp. *parviflora*. Flowers are insect pollinated, and it is likely that seeds have limited dispersal distances (probably <2 m) (DoEE, 2018). Populations were identified as clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators.	Populations of *G. parviflora* subsp. *parviflora* were considered important because they met one or more of the following criteria: • A population that is important for maintaining the Extent of Occurrence of a species • A population within a conservation reserve • A large population
Heleioporus australiacus	Vulnerable	BioNet records were used from 2008 onwards based on the approximate 10 year life-span of the species (noting that this only excluded two records from the assessment – both with limited accuracy from 1974 and 1913).	Records within 300 m were considered to be a population	The populations of Giant Burrowing Frog were considered important within the Strategic Assessment Area because they met the following criteria: • A population within a conservation reserve
Hibbertia puberula subsp. *glabrescens*	Critically Endangered	All available BioNet records were used to identify populations, with no date restrictions.	This species is known to occur in one location, as a single population. The translocation site has been planted with a number of individuals propagated from the Bankstown location.	All populations of *H. puberula* subsp. *glabrescens* have been considered as important as the species is critically endangered.
Hoplocephalus bungaroides	Vulnerable	Records of this species within the Strategic Assessment Area and Cumberland subregion were assessed to determine the age and accuracy of the record, the characteristics of the landscape in which the record is located, and the likelihood of persistence of the species in that locality due to subsequent	There is only one record of this species within the Strategic Assessment Area, which has been identified as a single population.	No important populations have been identified for this species (all non-important).

Scientific Name	EPBC listing	Logic for Including/Excluding Records	How to Define Biological Population	Importance criteria used to identify important populations of this species
		removal of, or disturbance to, habitat.		
Lathamus discolor	Critically Endangered	All available BioNet records were considered in the assessment.	The species is considered to be a single migratory population. All records within the Strategic Assessment Area are therefore considered part of the same population.	All populations were considered to be important as the species is critically endangered.
Leucopogon exolasius	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat.	Clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators.	No important populations were identified for *L. exolasius*. All populations are non-important.
Litoria aurea	Vulnerable	All available BioNet records from 1995 onwards were included in the assessment, based on the guidance in the EPBC Act Policy Statement 3.19 (DEWHA, 2009).	Populations were considered separate if records were more than 10km apart OR where landscape features interrupted connectivity, based on the guidance in the EPBC Act Policy Statement 3.19 (DEWHA, 2009).	The populations of Green and Golden Bell Frog were considered important within the Strategic Assessment Area because they met the following criteria: • A population identified or inferred in a Commonwealth conservation advice, plan, final determination, or other relevant policy document as being important
Macquaria australasica	Endangered	All BioNet records have been included in the assessment.	Populations in distinct rivers and streams are considered separate populations.	All populations were considered to be important as the species is endangered.
Melaleuca deanei	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat.	A population is considered to be individuals within 500 m of each other, as species dispersal is unlikely to occur beyond this distance (NSW DECCW, Goeth et al., 2010).	Populations of *M. deanei* were considered important because they met one or more of the following criteria: • A large population • A population within a conservation reserve • A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program
Micromyrtus minutiflora	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat.	Populations were defined by clustered records connected by relatively intact and continuous vegetation and not separated by a distance of >1 km (approx.). This is based on the distance travelled by insect pollinators and potential unrecorded individuals.	All populations of *M. minutiflora* were considered important within the Strategic Assessment Area because the species is identified as an SAII entity through the BC Act process.
Persicaria elatior	Vulnerable	All available BioNet records were used to identify populations.	Biological populations were defined based on clustered records connected by relatively intact and continuous	Populations of *P. elatior* were considered important because they met one or more of the following criteria:

Scientific Name	EPBC listing	Logic for Including/Excluding Records	How to Define Biological Population	Importance criteria used to identify important populations of this species
			vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollination.	• A large population (number of individuals)
Persoonia bargoensis	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat.	All recorded plants were mapped as a single population as occurrence of the species within the Plan Area spans 20 km, and genetic flow (fruit dispersal by birds and pollination) could potentially move across the population within the life span of each plant (expected to be 20 years (OEH, 2019a)).	Populations of *P. bargoensis* were considered important within the Strategic Assessment Area because they met one or more of the following criteria: • A large population (number of individuals) • Only known population of this species
Persoonia glaucescens	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat.	Individuals within 500 m of each other are likely to be interbreeding and are therefore considered to be the same population.	Populations of *P. glaucescens* were considered important because they met one or more of the following criteria: • A population that is important for maintaining the Extent off Occurrence of a species • A population within a conservation reserve • A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program
Persoonia hirsuta	Endangered	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat.	Clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators.	All populations of *P. hirsuta* are considered to be important as the species is endangered.
Persoonia nutans	Endangered	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat.	Populations were defined by clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators.	All populations of *P. nutans* are considered to be important as the population is endangered.
Petauroides volans	Vulnerable	BioNet records were restricted to post 2003 to account for the average 15 year lifespan of the species.	The species occupies a relatively small home range with an average size of 1 to 3 ha and they have a low dispersal ability. Records separated by several kilometres and/or cleared developed areas were identified as separate populations.	The populations of Greater Glider were considered important within the Strategic Assessment Area because they met the following criteria: • A population within a conservation reserve
Pimelea curviflora var. *curviflora*	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or	Populations were defined by clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent	Populations of *P. curviflora* var. *curviflora* were considered important because they met the following criteria:

Scientific Name	EPBC listing	Logic for Including/Excluding Records	How to Define Biological Population	Importance criteria used to identify important populations of this species
		disturbance to, habitat.	barriers likely to obstruct pollinators.	• A large population
Pimelea spicata	Endangered	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat.	Clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators.	All populations of *P. spicata* are considered to be important as the species is endangered.
Pomaderris brunnea	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat.	Records within 1 km of one another are considered a single population.	Populations of *P. brunnea* were considered important because they met one or more of the following criteria: • A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program • A population within a conservation reserve • A large population
Pommerhelix duralensis	Endangered	All available BioNet records were used to identify populations, with no lifespan restrictions.	Records have been grouped into populations based on geographic restrictions and connectivity between patches of suitable vegetation.	All populations were considered to be important as the species is endangered.
Pteropus poliocephalus	Vulnerable	Based on other bat species, the life expectancy is likely to be between two and ten years. BioNet records have been taken from 2008 onwards.	The Grey-headed Flying-fox is considered to be a single population across its range (DoEE, 2017)	The population of Grey-headed Flying-foxes was considered important within the Strategic Assessment Area because it met the following criteria: • A population identified or inferred in a Commonwealth conservation advice, recovery plan, final determination, or other relevant policy document as being important
Pterostylis saxicola	Endangered	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat.	Records within 500 m of one another considered a single population.	All populations of this species were considered to be important as the species is endangered.
Pultenaea parviflora	Vulnerable	Records in each population were interrogated to ascertain the likelihood of persistence based on the removal of, or disturbance to, habitat.	Records within 500 m of each other were considered to be a single population.	Populations of *P. parviflora* were considered important because they met one or more of the following criteria: • A population is important for maintaining the Extent of Occurrence of a species • A population within a conservation reserve • A large population

Scientific Name	EPBC listing	Logic for Including/Excluding Records	How to Define Biological Population	Importance criteria used to identify important populations of this species
				• Is associated with a commitment made under the Sydney Growth Centres conservation program • A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program
Rostratula australis	Endangered	Records restricted to post 2002 to account for estimated 16 year lifespan of the species.	All records within the Cumberland subregion are representative of a portion of the east coast population and therefore records in the Strategic Assessment Area have been grouped as one single population.	All populations were considered to be important as the species is endangered.

Part 4 Contents

Part 4 List of Figures

Part 4 List of Tables

This Part describes:

- Avoiding and minimising impacts under the Plan (Chapter 14)
- Managing indirect impacts of the urban and industrial, infrastructure, agribusiness, and transport development under the Plan (Chapter 15)
- Adaptive management for addressing uncertainty (Chapter 16)

This Part addresses the requirements for these matters under both the *Biodiversity Conservation Act 2016* (BC Act) and *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act), as well as for both Commonwealth-listed species and Threatened Ecological Communities (TECs) and NSW-listed species.

14 Avoiding and minimising impacts

The Department of Planning, Industry and Environment (the Department) and Transport for NSW have undertaken a strategic planning process to locate and design the urban capable land in the nominated areas and the transport corridors to avoid and minimise impacts on biodiversity values. This has been undertaken in accordance with:

- Guidance provided under section 8 of the Biodiversity Assessment Method (BAM)
- The draft *Guidelines for planning authorities for proposing conservation measures in strategic applications for biodiversity certification* (version 6) (EES, 2019)
- The Commonwealth Terms of Reference (ToR)

This Chapter:

- Discusses the importance of avoiding and minimising impacts to biodiversity values
- Defines the meaning of avoidance in the context of the strategic assessment
- Sets out the regulatory requirements for avoiding and minimising impacts under the BAM and ToR
- Describes the processes to avoid and minimise impacts of the transport corridors
- Describes the steps taken to locate and design the urban capable land within the nominated areas
- Identifies the avoidance outcomes for the nominated areas and justifies the location of the urban capable land

The avoidance and minimisation of impacts under the Plan in relation to other matters (such as other MNES) are provided in chapters specific to the assessments of those matters, including:

- Chapter 24 for prescribed impacts
- Chapter 25 for serious and irreversible impacts
- Chapters 29 to 31 for Commonwealth-listed species and TECs
- Chapters 32 to 35 for migratory species, Ramsar wetlands and World and National Heritage

14.1 WHY AVOIDING AND MINIMISING IMPACTS IS IMPORTANT

Avoiding and minimising impacts to biodiversity values is an important part of the planning and assessment process. It is a critical step in minimising the impacts of the development and reducing the need for commitments and actions to offset those impacts. It also provides opportunities to protect important areas of remaining biodiversity, through the application of commitments and actions (such as biodiversity stewardship agreements) to avoided lands.

Avoiding and minimising impacts on biodiversity values is fundamental to demonstrating that the commitments and actions proposed for a strategic biodiversity certification adequately address the impacts of the development under section 8.7 of the BC Act (see Part 7). Documenting the process is also a requirement of the ToR (section 4.5(2)).

14.2 DEFINITION OF AVOIDANCE

There may be several reasons why land is avoided and not impacted under the Plan, including because:

- Land has high biodiversity value and is avoided for biodiversity purposes

- Land is not suitable for development or biodiversity certification
- Land is excluded from the area proposed for development or biodiversity certification

Under the BAM, avoidance refers to land that is suitable for development and included in the area proposed for development or biodiversity certification, but has been avoided because of its biodiversity value. Land not impacted because it is not suitable for development or biodiversity certification, or land that has been excluded from the area proposed for development is not considered to have been avoided under the BAM.

Land that is avoided is not biodiversity certified under the Plan and is subject to separate site-by-site assessment and approval under the BC Act. Note that the Plan proposes that some development in some cases is able to be undertaken within avoided lands under the EPBC Act approval (see Chapter 7).

In accordance with the BAM, the Assessment Report determines avoidance outcomes for biodiversity values on the basis of the amount of land avoided because of its biodiversity value. The amount of land 'avoided' for other purposes (i.e. the land is not suitable for urban development) is also presented in this report for additional context.

14.2.1 DEFINITION OF LAND AVOIDED FOR OTHER PURPOSES

For the Assessment Report, the following land is considered to be avoided for other purposes:

- Riparian corridors consistent with the *Water Management Act 2000*:
  - Strahler stream order 2 - buffer 20 m either side
  - Strahler stream order 3 - buffer 30 m either side
  - Strahler stream order 4 and above - buffer 40 m either side
- State protected land (>18 degrees slope, considered too steep for urban development)

14.2.2 DEFINITION OF EXCLUDED LAND

Some land within the nominated areas was not considered for inclusion in the area proposed for development and has therefore been identified as 'excluded' land. These lands include:

- Existing protected land, including reserves and established offset sites
- Council owned land which is zoned for environmental conservation, environmental management or recreation
- Commonwealth land, such as Defence Establishment Orchard Hills
- Lands within the nominated areas already assessed as part of another development approval (Bingara Gorge), or lands progressing through an alternate assessment (Mount Gilead, Menangle Park, Sydney Metro Stage 1)
- Lands already developed (existing urban areas, urban land zones and roads)

PASSIVE RECREATION LANDS IN WESTERN SYDNEY AEROTROPOLIS

Some lands within Western Sydney Aerotropolis (WSA) have been identified as 'Environment and Recreation' lands within the updated Western Sydney Aerotropolis Stage 1 Structure Plan. These lands are shown in Figure 7-3, Part 2 and in the Plan as 'Non-certified – Western Sydney Aerotropolis' and are described in the Plan as 'land affected by the 1 per cent annual exceedance probability flood and…. other non-certified land'.

These lands have not been included in urban capable lands. However, the lands may be used for essential infrastructure or public open space or passive recreation, including supporting infrastructure such as information facilities, kiosks, or recreational areas (where this occurs, the Plan specifies that the objectives of the zoning for these lands will provide for both open space or recreation uses and the protection and enhancement of the natural environment).

For this reason, these lands are not considered avoided for either biodiversity or other purposes and have been included in the broad definition of excluded land for the purposes of the avoidance statistics in this Assessment Report.

The proposal to use 'Environment and Recreation' lands for essential infrastructure and public open space or passive recreation was made late in the development of the Plan and the potential impacts on these lands have not been assessed in the Assessment Report. This assessment will be completed following public exhibition of the report.

14.2.3 ALLOCATION OF LAND TO AVOIDANCE CATEGORIES

As land can be allocated to several categories (e.g. land can be allocated to both 'riparian corridor' and 'excluded land') a prioritisation process was used to allocate land to one of the four categories used.

The priority applied to the classification of land for avoidance calculations is provided in Table 14-1.

Table 14-1: Priority applied to classification of lands for avoidance calculations

Priority	Avoidance category	Input data
1	Biodiversity certified	Land proposed for urban development or transport corridors
2	Excluded/Non-certified – Western Sydney Aerotropolis	Land within the nominated areas already assessed as part of another development approval or lands progressing through an alternate development assessment (Bingara Gorge, Mount Gilead, Menangle Park, Sydney Metro Stage 1) Land already developed (existing urban areas, urban land zones and roads) Land not available to development (existing protected land, council owned land which is zoned for environmental conservation, environmental management or recreation, Commonwealth land and easements) Land identified as 'Environment and Recreation' lands within the updated Western Sydney Aerotropolis Stage 1 Structure Plan
3	Avoided for other purposes	Riparian corridors consistent with the *Water Management Act 2000* (Strahler stream order 2 and above) and state protected land (>18 degrees slope)
4	Avoided for biodiversity purposes	All other land (apart from land to be developed under the Plan)

14.2.4 METHOD TO CALCULATE AVOIDANCE OUTCOMES

The method to calculate avoidance outcomes for specific biodiversity values (e.g. a specific TEC, or group of TECs such as all critically endangered TECs) within the nominated areas is as follows:

- **Step 1:** determine the total existing area (in ha) of each biodiversity value within the assessed nominated areas.
- **Step 2:** determine the total area which could be impacted by urban development for each biodiversity value.
- **Step 3:** determine the total area which could be impacted by transport for each biodiversity value.
- **Step 4:** determine the area of each biodiversity value within excluded or non-certified – Western Sydney Aerotropolis.
- **Step 5:** determine the area avoided for other purposes, such as steep slopes or riparian corridors.
- **Step 6:** determine the area of land avoided for biodiversity purposes (this is done by subtracting the summed amount (ha) in steps 2, 3, 4 and 5 from step 1).

14.3 REGULATORY REQUIREMENTS

The BAM and ToR both require the Assessment Report to demonstrate how impacts to biodiversity values have been avoided and minimised. The BAM provides more detailed guidance than the ToR on how avoidance should be achieved.

14.3.1 BC ACT REQUIREMENTS

BAM

Section 8 of the BAM requires the BCAR to describe the actions taken to avoid and minimise impacts on biodiversity values through the location and design of the urban capable land and transport corridors on:

- Native vegetation and habitat

- Prescribed impacts

The BCAR must describe how actions taken to avoid and minimise impacts on biodiversity values have influenced both the project location and the design of the project. Specifically, the BCAR should explain how impacts on biodiversity values have influenced the location and design of the urban capable land and transport corridors, including the extent to which areas of higher biodiversity value have been identified and then excluded from the urban capable land and transport corridors.

The BAM provides that direct impacts on native vegetation and habitat can be avoided and minimised by:

- **Development location considerations:**
  - Locating development in areas where there are no or minimal biodiversity values
  - Locating development in areas where native vegetation or habitat is in the poorest condition (as measured by the Vegetation Integrity score for each vegetation zone)
  - Avoiding habitat for species with higher biodiversity risk weightings
  - Avoiding critically endangered or endangered TECs
  - Avoiding areas that maintain habitat connectivity between areas of nearby habitat
- **Development design considerations:**
  - Reducing the urban capable land and transport corridors of the project
  - Providing structures to enable species to move across barriers or habitat gaps
  - Making provision for the ecological restoration and ongoing maintenance of retained native vegetation

The BAM provides that prescribed impacts can be avoided and minimised by:

- **Development location considerations:**
  - Locating urban capable land or sub-surface works to avoid habitat features associated with prescribed impacts (such as caves, cliffs, water bodies, important non-native vegetation, or areas of habitat connectivity)
  - Avoiding areas that maintain habitat connectivity between areas of nearby habitat
- **Development design considerations:**
  - Designing project elements to minimise interactions with biodiversity values, such as designing fencing to prevent animal entry to roads or transport corridors or roads
  - Designing the project to maintain hydrological processes
  - Design the project to avoid and minimise downstream impacts on water bodies by controlling water quality

Section 8.1.1.4 and section 8.2.2.2 of the BAM requires the BCAR to:

- Analyse alternative locations for urban capable land that would further avoid or minimise impacts
- Justify the location of the final urban capable land

In justifying the selection of final urban capable land, a rationale should be provided for the location of the boundaries where they do not avoid areas of biodiversity value, such as strategic planning reasons.

GUIDELINES UNDER THE BAM

In addition to the BAM, the draft *Guidelines for planning authorities for proposing conservation measures in strategic applications for biodiversity certification* (version 6) (EES, 2019) provides a set of guiding principles for demonstrating that commitments and actions proposed for a strategic biodiversity certification adequately address impacts on biodiversity values.

The first principle relates to avoidance and requires that:

> *"Principle 1 – Potential serious and irreversible impacts are avoided and minimised"*

14.3.2 EPBC ACT REQUIREMENTS

Section 4.5(2) of the ToR requires the SAR to include an analysis of the likely adverse impacts of actions of the Plan on protected matters, including consideration of:

"How impacts on protected matters will be avoided through land use planning and other measures…"

14.4 PROCESSES TO AVOID AND MINIMISE IMPACTS OF TRANSPORT CORRIDORS

Avoidance and minimisation of impacts from the transport corridors is being undertaken in two stages:

- Processes to locate the transport corridors – this has already been undertaken
- Detailed design of the transport corridor footprints for each transport project to further avoid and minimise impacts

14.4.1 PROCESSES TO LOCATE THE TRANSPORT CORRIDORS

The process for identifying, selecting and designing future corridors and transport projects involves a detailed set of steps and processes to ensure optimum infrastructure, environmental, social and economic outcomes are achieved. The *Planning guideline for Major Infrastructure Corridors* (DPE, 2016) sets out the recommended processes for infrastructure agencies to follow through the different phases of corridor planning.

The guideline provides advice in relation to the three broad phases:

- Strategic planning – identification
- Corridor planning and selection
- Infrastructure delivery

The first two phases lead to the identification and protection of transport corridors. As part of this process, a Strategic Environmental Assessment (SEA) is prepared which provides an assessment of the environmental, economic and social impacts of reserving the corridor. SEAs are non-statutory documents that assist in the planning and decision-making process for the community and Government. They are subject to public consultation and include justification for a preferred corridor alignment and provide information on the assessment of alternative corridor alignments.

In making decisions on corridor selection, infrastructure agencies undertake a constraints analysis and multi-criteria comparison of options. These include consideration of a wide range of factors including:

- Aboriginal heritage
- Biodiversity
- Costs
- Engineering and construction limitations
- Land use and property impacts
- Landscape character and visual amenity
- Noise and vibration
- Non-Aboriginal heritage
- Socio-economic considerations
- Soils, geology and contamination
- Transport planning
- Water quality and hydrology

Box 1 provides an example of the process used to locate the Outer Sydney Orbital (OSO).

BOX 1: PROCESS USED TO LOCATE THE OSO

The Draft SEA for the OSO (AECOM, 2018) sets out the process that was followed to locate that transport corridor. Transport for NSW commissioned the OSO study "to identify the most appropriate location for the corridor and to protect land within that corridor for the future provision of critical road and freight rail infrastructure". The method for identifying the corridor involved (AECOM, 2018):

- *Identifying a study area – investigations commenced with a broad OSO study area to identify high-level constraints and opportunities*
- *Understanding constraints and opportunities – an analysis of constraints and opportunities within the study area included prioritisation of constraints as well as identification of key areas and values to avoid during corridor design development*
- *Developing guiding principles – a list of guiding principles was developed to inform the selection of a long list of corridor options. These principles followed the hierarchy of 'avoid, minimise, and mitigate impacts', to allow for the creation of a series of options*
- *Identifying corridor options – a range of tools, including computer software and specialist advice, was used to identify a long list of corridor options*
- *Evaluating corridor options – this included specialist investigations of identified options, comparative assessment and multi-criteria analyses*
- *Selecting a recommended OSO corridor – a continuation of the evaluation process where selection and refinement of a recommended corridor involved multi-criteria assessment, targeted stakeholder consultation and design development*
- *Consulting with the public on the recommended corridor – to obtain feedback on the recommended OSO corridor*

Potential impacts to biodiversity were a key consideration (amongst a range of considerations) in the SEA and the ultimate selection of the corridor. A similar process was followed for the other transport corridors.

14.4.2 DETAILED DESIGN OF TRANSPORT CORRIDOR FOOTPRINTS

The transport corridors included in the Plan have not completed the process to avoid and minimise impacts to biodiversity values as the alignments of the transport projects within each corridor are not currently certain (see Part 2).

The Plan includes commitments for further avoidance and minimisation of impacts to biodiversity values related to the transport corridors. This will be undertaken through:

- A process of strategic planning and detailed design, which will determine the final alignment of each transport project that will generally occur within each transport corridor
- NSW environmental assessment and approval process for each project current at the time the project is brought forward (this is currently the State Significant Infrastructure approval process)

COMMITMENTS FOR FURTHER AVOIDANCE WITHIN TRANSPORT CORRIDORS

Transport corridors within nominated areas

For the parts of the transport corridors within the nominated areas, the Plan commits to avoiding and minimising impacts to TECs, species and habitat (Commitment 3). This includes avoiding where possible:

- Areas of high biodiversity value (defined by the 'avoidance criteria' set out in section 14.5.3)
- Areas of potential habitat connectivity, particularly vegetation in riparian corridors, for the following species
  - Eastern Pygmy Possum
  - Green and Golden Bell-Frog
  - Spotted-tailed Quoll
  - Squirrel Glider
  - Yellow-bellied Glider
- Known flora populations within the OSO and M7/Ropes Crossing Link Road corridors, including:
  - *Dillwynia tenuifolia*
  - *Grevillea juniperina* subsp. *juniperina*

   - *Pultenaea parviflora*
   - *Persoonia nutans*

Commitment 3 also includes a requirement for the Outer Sydney Orbital waterway crossings to minimise structures within riparian areas, waterway re-alignments, and bulk earthworks on adjacent floodplain areas

The Plan includes further commitments under Commitment 3 that require:

- Impacts to be minimised as far as possible where an action cannot feasibly or practically avoid impacts
- Transport for NSW to determine the area of avoidance achieved on the basis of:
   - The final construction footprint/concept design plan for each infrastructure corridor
   - The Plan's data and mapping for threatened species, populations and communities

Actions under this commitment specify how Transport for NSW is to implement the commitment. In summary, the commitment will be implemented through Transport for NSW doing the following:

- Considering avoidance of areas of high biodiversity value (as defined by the avoidance criteria in section 14.5.3) during the strategic planning phase and detailed design of the project
- Including avoidance of biodiversity values as well as the costs of offsets, into the evaluation of the route options (e.g. multi-criteria analysis) during the planning phase of the project
- Reporting to the Department on development impacts and adjustments identified through the NSW State Significant Infrastructure approval (or equivalent) for each transport project. This will include specific reporting on avoidance achieved within the transport corridors and any further impacts that occur outside of the corridors

The Department will use this information from Transport for NSW to track impacts and adjust offset requirements through the Plan's reconciliation accounting process, and publish adjustments to the Plan's impacts to biodiversity values and offset requirements through the Plan's annual updates and five yearly reviews (see Part 2).

Transport corridors outside nominated areas

For the parts of the transport corridors outside the nominated areas, the Plan commits to avoiding and minimising impacts to species and TECs in accordance with the:

- Major infrastructure corridors class of action description
- BC Act, including the BAM (Commitment 4)

This includes avoiding disturbance to the following where possible:

- Known flora populations within the OSO and M7/Ropes Crossing Link Road corridors, including:
   - *Dillwynia tenuifolia*
   - *Grevillea juniperina* subsp. *juniperina*
   - *Pultenaea parviflora*
   - *Cynanchum elegans*
- Protected lands within and adjacent to the tunnel footprints:
   - Mater Dei BioBank site within the OSO footprint near Camden
   - Registered Property Agreement site within the OSO footprint at Camden Airport
   - Metro Offset site within the footprints for the OSO and Metro Rail Future Extension near Harrington Park
- Nepean River and associated riparian corridor within the OSO footprint
- Camden Golf Club at Narellan adjacent to the Metro Rail Future Extension footprint
- Mount Annan Botanic Gardens within the Metro Rail Future Extension footprint
- Populations and habitat within or adjacent to the OSO and Metro Rail Future Extension footprints for:
   - *Eucalyptus benthamii*
   - *Pomaderris brunnea*
   - *Pimelea spicata*
   - Cumberland Plain Land Snail

- Commonwealth land at:
  - Camden Airport
  - Western Sydney University (Campbelltown Campus)
  - 12 Werombi Road, Grassmere

Actions under this commitment specify how Transport for NSW is to implement the commitment. In summary, the commitment will be implemented through Transport for NSW doing the following:

- Undertaking surveys to confirm biodiversity values and MNES using the BAM (or equivalent), including targeted surveys for at-risk species, during strategic planning phase and detailed design of the project
- Including avoidance of biodiversity values as well as the costs of offsets, into the evaluation of the route options (e.g. multi-criteria analysis) during the planning phase and detailed design of the project
- Preparing a Biodiversity Certification Assessment Report or Biodiversity Development Assessment Report (or equivalent) under relevant NSW planning and assessment legislation at the time
- Avoiding and minimising biodiversity impacts in accordance with the BAM (or equivalent)

As for the process within the nominated areas, Transport for NSW will report to the Department on development impacts and adjustments identified through the NSW State Significant Infrastructure approval (or equivalent) for each transport project. The Department will use this information from Transport for NSW to track impacts and adjust offset requirements through the Plan's reconciliation accounting process (see Part 2).

14.5 STEPS TAKEN TO AVOID AND MINIMISE IMPACTS OF NOMINATED AREAS

Consistent with Section 8.1.1.2 of the BAM, the process to identify the urban capable land within the nominated areas was an iterative one that began early in the assessment process before the final data on biodiversity values was completed. The urban capable land was identified in three phases:

- Strategic planning to locate the nominated areas
- Initial development of footprints through Land Use and Infrastructure Implementation Plans (LUIIP)
- Iterative refinement of the footprints through development of the Plan and assessment of impacts

14.5.1 STRATEGIC PLANNING TO DETERMINE THE LOCATION OF THE NOMINATED AREAS

The location of the nominated areas was determined through various strategic planning strategies and investigations over many years. Two key planning strategies that informed the location of the nominated areas were:

- *A Plan for Growing Sydney* (DPE, 2014) – this identified the general location of Wilton Growth Area (Wilton) and Greater Macarthur Growth Area (GMAC) and the Badgerys Creek Airport precinct, which was subsequently refined further by the Department to become WSA
- *A Metropolis of Three Cities* (GSC, 2017) – this identified the general location of Greater Penrith to Eastern Creek Investigation Area (GPEC) and establishes a 40-year vision for Sydney as a global metropolis of three cities, including the Western Parkland City covering the nominated areas

The nominated areas were located based on a broad range of strategic planning considerations, including:

- Proximity to current and planned locations of employment
- The cost of infrastructure provision including roads, water, sewerage, public transport, schools and health facilities
- The economic and social cost to communities of having poor access to employment and services, including transport
- Environmental constraints, including biodiversity values

Action 2.4.2 of *A Plan for Growing Sydney* (DPE, 2014) aimed to develop a long-term framework for the identification of new nominated areas to improve the management of future land release in Sydney. In preparing a framework for the identification of nominated areas, Action 2.4.2 indicates that a range of issues should be considered, including:

- The value of land for drinking water supply, agriculture, environmental management and other purposes
- Constraints to development, including environmental constraints and natural hazards

The Department undertook investigations into the location of the nominated areas in accordance with Action 2.4.2.

14.5.2 LAND USE AND INFRASTRUCTURE IMPLEMENTATION PLANS

Land Use and Infrastructure Implementation Plans (LUIIP) are currently being prepared for the nominated areas (see Part 2). LUIIPs are high level plans for the growth and development of each nominated area. They identify the location of urban capable land, as well as broad land uses and the location of infrastructure across a nominated area, as well as housing and employment targets.

Indicative urban capable land had been developed as part of the early preparation of the LUIIPs, including for Wilton, GMAC and part of WSA. Urban capable land was identified largely on the basis of avoiding large patches of intact native vegetation (Eco Logical Australia, 2017), including:

- BIO Map core areas and corridors (OEH, 2015)
- Priority Conservation Lands identified as part of the Cumberland Plain Recovery Plan methodology report (DECCW, 2010)

The early LUIIP footprints provided the starting point for the iterative refinement of the footprints through development of the Plan (see section 14.5.3). Any changes made through this process are, or will ultimately be, reflected in the LUIIPs.

14.5.3 ITERATIVE REFINEMENT OF URBAN CAPABLE LAND THROUGH DEVELOPMENT OF THE PLAN

Development of the Plan provided an important opportunity to iteratively refine the initial urban capable land with the aim of avoiding and minimising impacts to biodiversity values. The process involved:

- Compilation of data on biodiversity values of each nominated area
- Development of criteria to identify priorities for avoidance of biodiversity values
- Workshops to apply the avoidance criteria to each nominated area and refine urban capable land
- Consultation with key stakeholders and resolution of issues
- Finalisation of initial urban capable land

COMPILATION OF DATA ON BIODIVERSITY VALUES

The best available data on the biodiversity values of each of nominated area was compiled and used to identify areas of high biodiversity value and inform the location and design of the urban capable land.

The data on biodiversity values was compiled into a series of GIS datasets and used in two phases:

- Initial urban capable land was identified based on preliminary data on biodiversity values
- Finalisation of initial urban capable land was undertaken based on final data on biodiversity values

The preliminary data used to inform the initial urban capable land comprised:

- Draft native vegetation maps of each nominated area showing:
    - Extent and condition of Plant Community Types (PCTs)
    - Extent and condition of NSW-listed TECs
- Threatened species records derived from BioNet for all species needing to be assessed in the Assessment Report (all Commonwealth-listed Category 1 matters and all NSW-listed candidate species – see Part 3)
- Draft habitat maps for threatened species where available. In particular, this included Koala habitat mapping

The data used to finalise the initial urban capable land comprised:

- Final native vegetation maps of each nominated area showing:
    - Extent and condition of PCTs
    - Extent and condition of Commonwealth-listed and NSW-listed TECs
- Threatened species records derived from BioNet for all species needing to be assessed in the Assessment Report (all Commonwealth-listed Category 1 matters and all NSW-listed candidate species – see Part 3)
- Final habitat maps for threatened species where available

A more detailed description of each dataset used to inform the urban capable land is provided in Part 3.

DEVELOPMENT OF AVOIDANCE CRITERIA

Criteria were developed to identify priorities for the avoidance of biodiversity values. The purpose of the criteria were to provide detailed guidance, consistent with the guidance provided in the BAM, to inform decisions about the location and design of the urban capable land through the series of workshops with precinct planners and ecologists.

The avoidance criteria identified priorities for avoidance within three main categories:

- TECs and PCTs, including condition
- Threatened species
- Ecological processes

In applying the criteria, the highest priority within each category was given equal weight (the TEC/PCT priority 1 was given equal weight to the threatened species priority 1).

The avoidance criteria are provided in Box 2.

BOX 2: AVOIDANCE CRITERIA AND CATEGORIES

(a) TECs and PCTs

1. Critically endangered ecological communities (CEECs) or PCTs ≥90% cleared in large patches and in good condition; or serious and irreversible impact (SAII) entities (TECs)
2. Endangered ecological communities (EECs) or PCTs ≥70% to <90% cleared in large patches and in good condition
3. PCTs ≥50% to <70% cleared in large patches and in good condition
4. PCTs <50% cleared in large patches and in good condition

(b) Threatened species

1. Known habitat^ for critically endangered species, SAII entities (species), Saving Our Species (SOS) species polygons (where species-specific habitat is present), or large populations of threatened species (relative to typical size for that species); or known primary koala habitat
2. Known habitat^ for endangered species or known secondary koala habitat
3. Known habitat^ for vulnerable species

(c) Ecological processes

1. Land identified as priority conservation lands, BIO Map core areas, or important local habitat corridors for key species including Koalas
2. Land identified as BIO Map regional corridors or as areas that provide significant opportunities to support important local habitat corridors for key species, including Koalas
3. Areas identified on the Biodiversity Values Map

Boundary rationalisation

Consider removing:

- Small nodes or isolated patches of features identified in (a), (b) or (c) if future land use change will lead to significant edge effects and low viability over the timeframe identified, and there is no feasible opportunity to enhance connectivity and extent
- Corridors that do not link important areas of habitat, including 'blind corridors'

^ As indicated by BioNet records or recent survey data

APPLICATION OF AVOIDANCE CRITERIA

The avoidance criteria were applied through a series of workshops to each nominated area to identify areas of high biodiversity value and priorities for avoidance. The workshops included the following participants:

- The Department's strategic assessment team
- Accredited assessors and other expert ecologists who advised on biodiversity values and priorities
- The Department's precinct planning team who advised on urban development priorities and targets

Urban capable land identified in the LUIIP processes for Wilton, GMAC and part of WSA was used as a starting point. The workshops involved:

- Reviewing the data on biodiversity values compiled into a series of GIS datasets. Accredited assessors and other expert ecologists reviewed the accuracy of the data and made adjustments where necessary. As part of this process, consultation was undertaken with field ecologists to verify the accuracy of data
- Identifying areas of high biodiversity value and priorities for avoidance based on the identified criteria. This work focused on identifying priority 1 and priority 2 avoidance areas within each nominated area
- Rationalising the urban capable land to remove areas of biodiversity value that comprised:
  - Small nodes or isolated patches where future land use change will lead to significant edge effects and low viability and in which the opportunity to enhance connectivity and extent are not feasible
  - Habitat corridors that do not link important areas of habitat, including 'blind corridors'
- Identifying where priorities for avoidance of biodiversity were inconsistent with:
  - Indicative urban capable land identified in current LUIIPs, and/or
  - The achievement of urban development priorities reflected in relevant planning strategies and plans, including LUIIPs. These priorities included matters such as:
    - Urban planning/urban structure and design principles
    - Housing provision and dwelling targets
    - Transport and infrastructure provision and accessibility targets
    - Employment areas and targets
    - Open space provision and targets

Where priorities for avoidance of biodiversity values were inconsistent with urban development priorities, further consideration of the specific urban development imperative and needs, and further desktop investigation and validation of the biodiversity values of the site, was undertaken. Potential alternatives were explored and negotiations undertaken between the Department's strategic assessment team and the Department's planning team to:

- Explain and justify urban development and biodiversity avoidance priorities
- Explore alternative development locations to achieve the urban development priorities
- Seek a balance between urban development and biodiversity priorities

Box 3 provides a case study of the application of the avoidance criteria.

BOX 3: CASE STUDY - MINIMISING IMPACTS TO BIODIVERSITY VALUES IN AN AREA TARGETED FOR URBAN GROWTH IN WILTON

Step 1: Map the biodiversity values in Wilton and integrate this information with development plans for the area

The development of lands in north Wilton precinct identified there was the opportunity for a recreation reserve comprising ovals and sports fields in the northern end of the precinct to support open space targets for the precinct

The land is largely pasture within a matrix of Shale Sandstone Transition Forest vegetation zones, which cover the full range of condition classes (intact, thinned, scattered trees and derived native grassland)

The forested portions of this community comprise the CEEC under both the BC Act and EPBC Act. In addition, the land had been identified as a component of the regional primary Koala corridor

Furthermore, as part of the work to develop the Plan, the area where the recreation reserve was proposed was identified as a priority for ecological restoration, including because the land contained a Koala corridor and the TEC

Step 2: Initial amendment of footprint to minimise impacts to biodiversity values

Discussions were undertaken between the Department and the landholder to explore opportunities to reduce impacts on biodiversity values while still providing for a recreational reserve to support open space targets

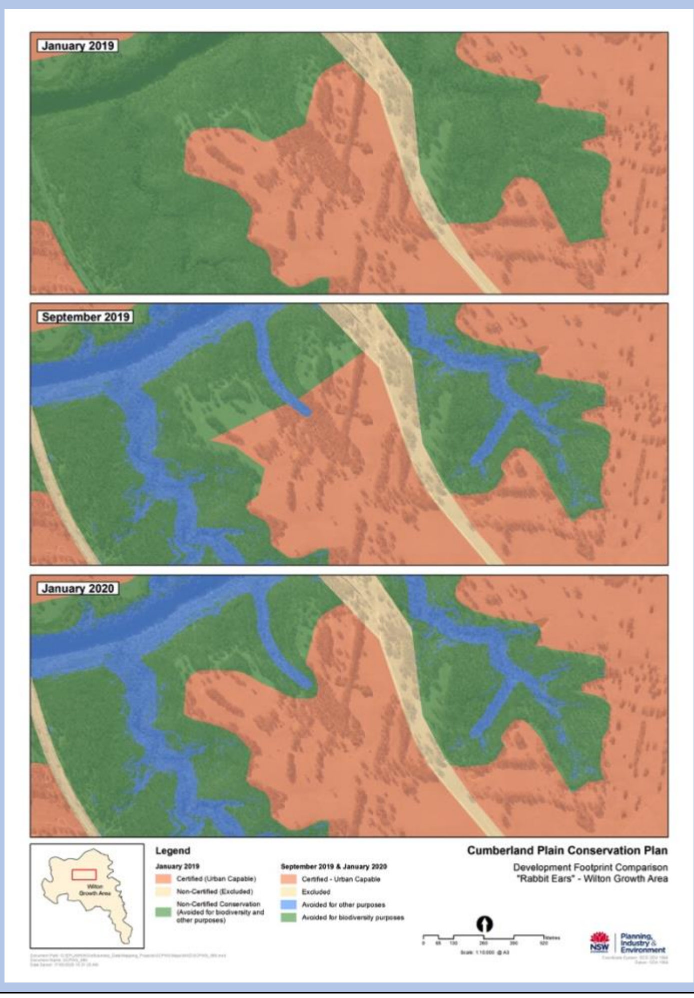
This led to reducing the footprint of the recreational reserve in key areas of biodiversity value, while still allowing for a road into the recreation area to provide and encourage public access to the area

Step 3: Further amend footprint and recreational design and use to further reduce impacts

The Department and the landholder met further to discuss opportunities to further amend the footprint and the recreational design and use of land to balance open space targets and impacts to biodiversity values

The agreed final design of the reserve will focus on passive, constructed play, and will retain of some of the original recreational land uses as well as potentially including car parking facilities. This allowed for a more effective wildlife corridor around the top of the Nepean River gorge to provide connectivity for animals such as Koala

These steps are reflected in the diagram below:



Consultation with key stakeholders

In some cases, consultation was undertaken with key stakeholders on indicative urban capable land.

Consultation occurred through:

- Public exhibition of draft LUIIPs that identified indicative urban capable land
- Targeted consultation with planning authorities, including Councils, to clarify urban development priorities particularly where these were inconsistent with avoidance priorities
- Consultation with accredited assessors and other expert ecologists to verify the accuracy of the data, particularly where urban development priorities were inconsistent with avoidance priorities
- Consultation with developers and landholders within the nominated areas to gain access to additional data

This consultation led to the adjustment of the urban capable land in some cases.

14.5.4 COMMITMENTS FOR AVOIDANCE RELATING TO URBAN CAPABLE LAND

The Plan includes a commitment (Commitment 2) to avoid and minimise impacts from urban and industrial, and infrastructure development, to at least 4,315 hectares of land within the nominated areas. This includes

- Avoiding 3,670 hectares of native vegetation comprising:
  - 2,735 hectares of native vegetation because of its biodiversity value
  - 935 hectares of riparian corridors and steep land
- Avoiding specific amounts of habitat for Commonwealth and NSW listed TECs
- Limiting cumulative direct impacts from essential infrastructure within non-certified land to the Commonwealth listed Shale Sandstone Transition Forest TEC and prioritising the avoidance of impacts from this infrastructure to specific known populations of flora species and important Koala corridors (see Chapter 37)

This commitment will be delivered through several actions, including:

- Introducing a planning provision to require that the urban capable lands in the precinct plans are consistent with the areas of certified land and avoided lands identified in the Plan
- Applying environment (E2) conservation zoning to land avoided for biodiversity or other purposes (see below)
- Applying further planning controls through the NSW planning system if the avoidance targets are not being met

The Plan also includes several commitments related to mitigation of indirect impacts that would lead to avoidance and minimisation of impacts on key habitat features within or adjacent to urban capable land. These include:

- Retain large trees (≥50cm DBH) during precinct planning where possible and avoid impacts to soil within the dripline of these trees during construction
- Retain areas of high density proteaceae shrubs where possible, particularly along riparian corridors
- If Green and Golden Bell Frog is confirmed present along Ropes Creek, consult with land managers of the riparian corridor to ensure key habitat features are protected and enhanced

Environmental protection zoning of avoided lands

The Plan will apply environment (E2) conservation zoning to land avoided for biodiversity and other purposes (riparian corridors, steep land) to strengthen the protection of avoided lands from the impacts of development. Note that avoided land will have environment (E2) conservation zoning applied except for land owned by LALCs or under claim by LALCs. LALC owned land and land under claim represents 90 ha of the 4,795 ha of avoided land[1]

[1] The total area of avoided land at the start of the Plan is 4,795 hectares. The avoidance target of 4,315 hectares has reduced this figure by 10% to allow for potential future development of essential infrastructure in non-certified land

Environmental zones are designed to protect land in NSW that is of important environmental value. The zoning aims to prevent or control development that may have an adverse effect on the biodiversity and other values of the area.

Zoning will be implemented through the proposed SEPP for strategic conservation planning or the relevant place based Environmental Planning Instrument (EPI), such as the Growth Centres SEPP or the draft Aerotropolis SEPP (see Part 2).

14.6 AVOIDANCE OUTCOMES AND JUSTIFICATION FOR THE LOCATION OF URBAN CAPABLE LAND IN THE NOMINATED AREAS

This section describes the outcomes achieved in relation to avoiding and minimising impacts within the nominated areas and justifies the location of the urban capable land. Avoidance outcomes are described in relation to:

- Native vegetation generally
- High-condition native vegetation
- Threatened ecological communities
- Species habitats
- Important populations
- Areas important for connectivity
- Matters that are subject to serious and irreversible impacts

Avoidance outcomes are shown in Figure 14-1 to Figure 14-4.

14.6.1 NOTE ON AVOIDANCE OUTCOME CALCULATIONS

EXCLUDED LAND

As described in section 14.2.2, avoidance statistics in this Assessment Report have been calculated without including excluded land. This includes avoidance calculations for land:

- Avoided for biodiversity purposes
- Avoided for other reasons
- Total land avoided
- Per cent (%) of land avoided

Excluded land has not been included in these avoidance calculations because this land is not part of the approvals under this Plan and avoidance outcomes on this land are not able to be influenced by the Plan.

Of the estimated 9,790 ha of native vegetation communities in the nominated areas, 4,331 ha (44.2per cent) is excluded land. The amounts of excluded land are identified in each Table in this section only for context.

Passive recreation lands in WSA are not considered avoided for either biodiversity or other purposes and have been included in the definition of excluded land for the purposes of the avoidance statistics (see section 14.2.2).

TRANSPORT CORRIDORS

Avoidance outcomes have also been calculated assuming the whole of the transport corridors within the nominated areas will be impacted. Avoidance outcomes are therefore likely to have been underestimated as further avoidance will be undertaken within the transport corridors during detailed design of the transport projects (see section 14.4.2).

ESSENTIAL INFRASTRUCTURE WITHIN AVOIDED LANDS

Planning for essential infrastructure to support the nominated areas, such as water and electricity utilities, is in various stages of development, and this infrastructure may need to be located outside urban capable lands.

The Plan is seeking approval under the EPBC Act (but not the BC Act) for certain essential infrastructure development to occur within the nominated areas outside urban capable lands (i.e. within avoided lands). The Plan specifies that:

- Every effort should be made to ensure that essential infrastructure development is limited to urban capable lands

- Where essential infrastructure occurs outside urban capable lands (i.e. within the avoided lands), the development must comply with the 'Guidelines for Development' in Appendix A of the Plan

The avoidance outcome statistics do not include the potential impacts of essential infrastructure development in avoided lands as the need for these projects to be located in avoided lands, and their location, is not currently known.

The potential impacts of essential infrastructure within avoided lands is assessed in Chapter 37.

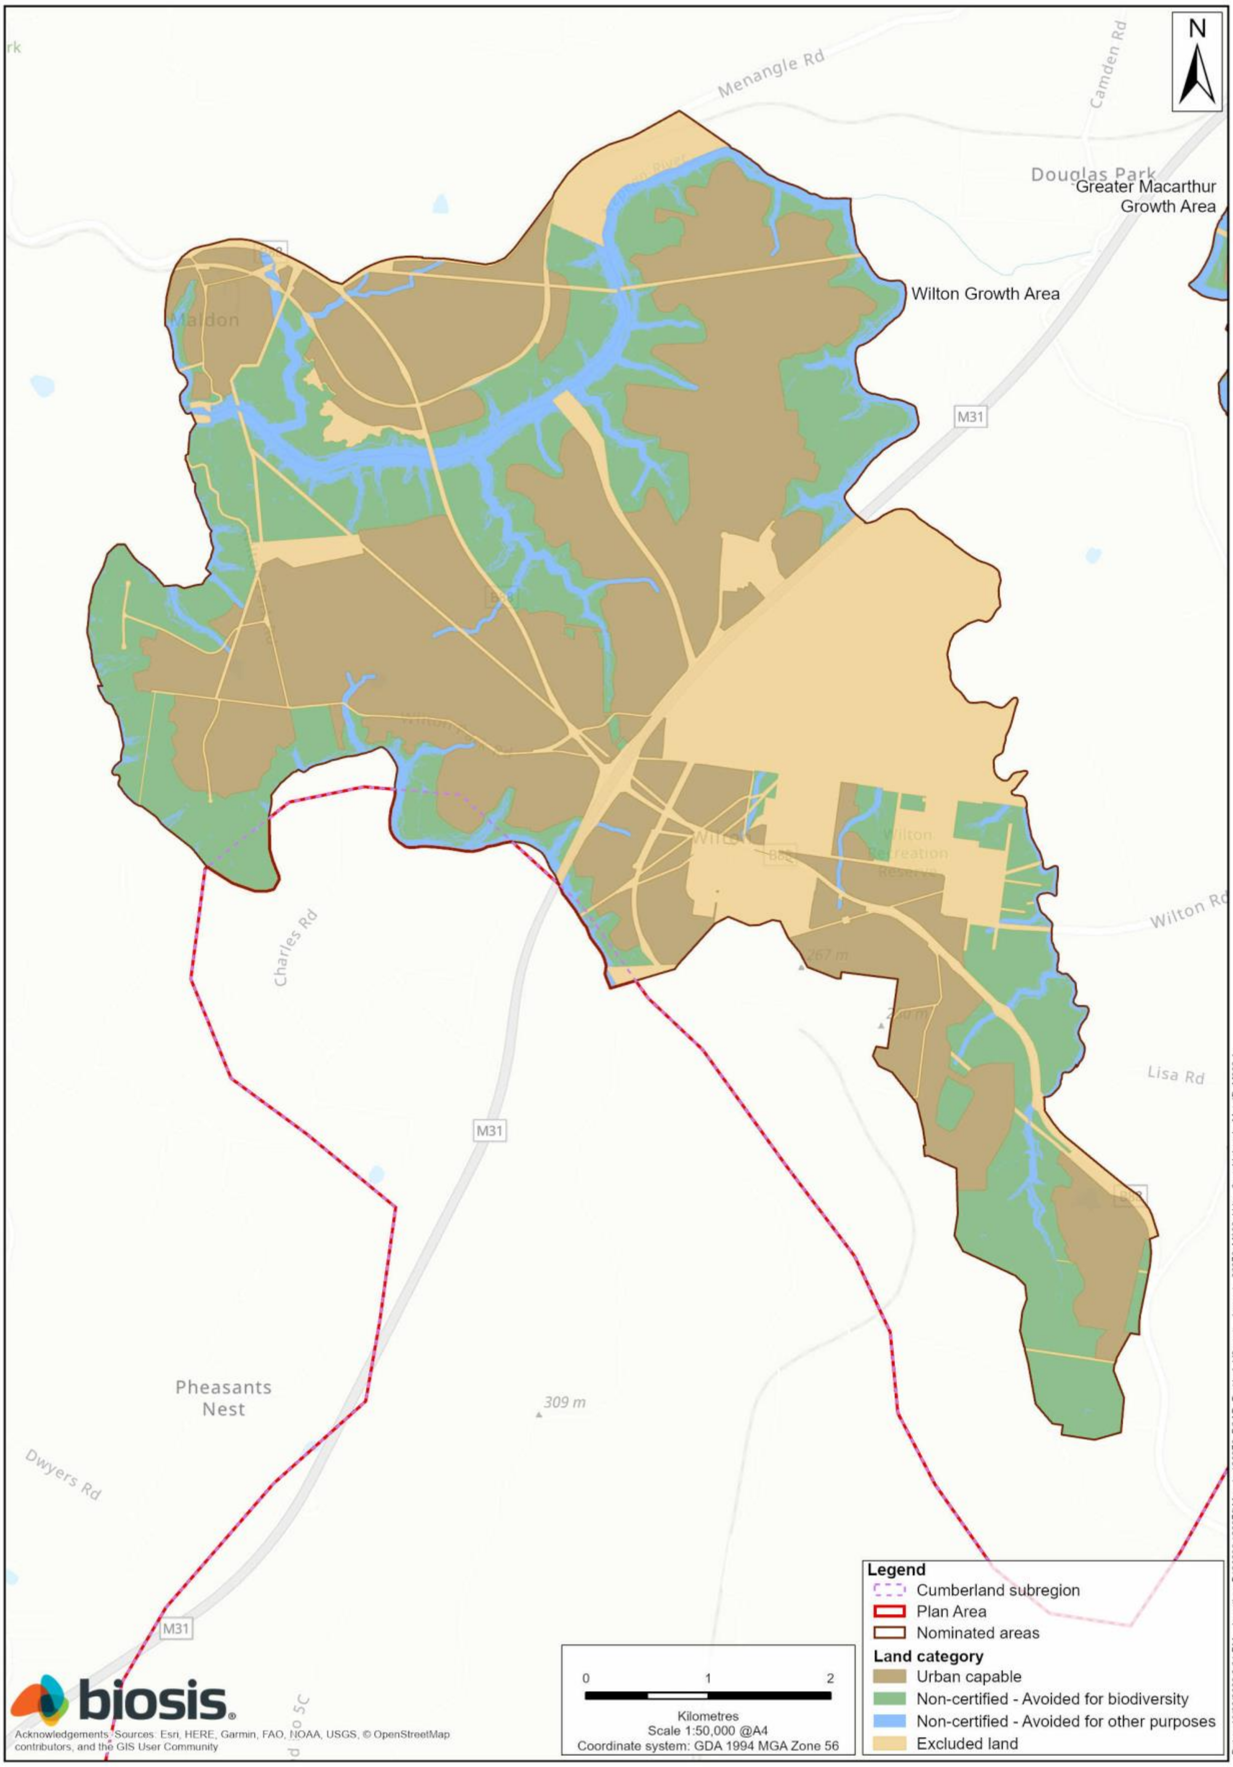


Figure 14-1: Avoidance outcomes – Wilton

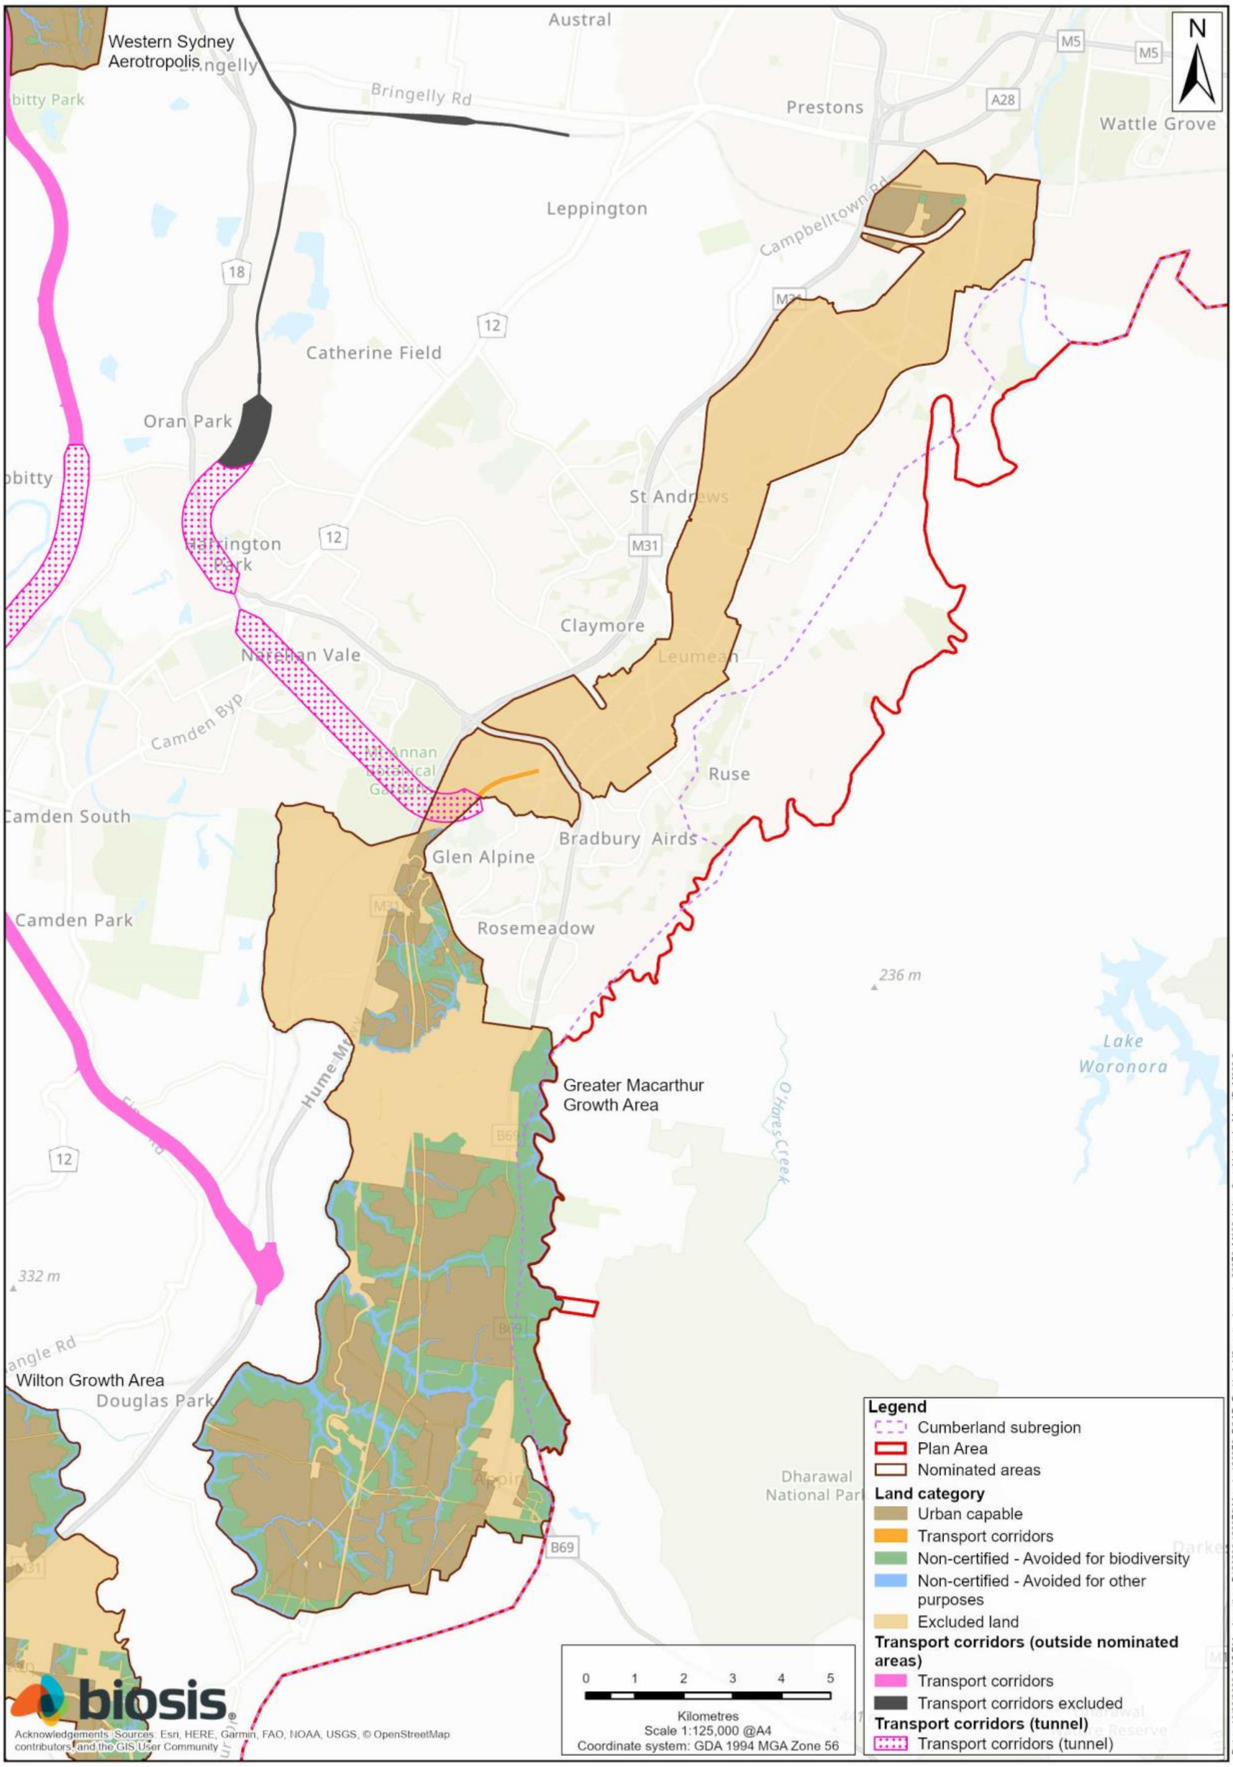

Figure 14-2: Avoidance outcomes – GMAC

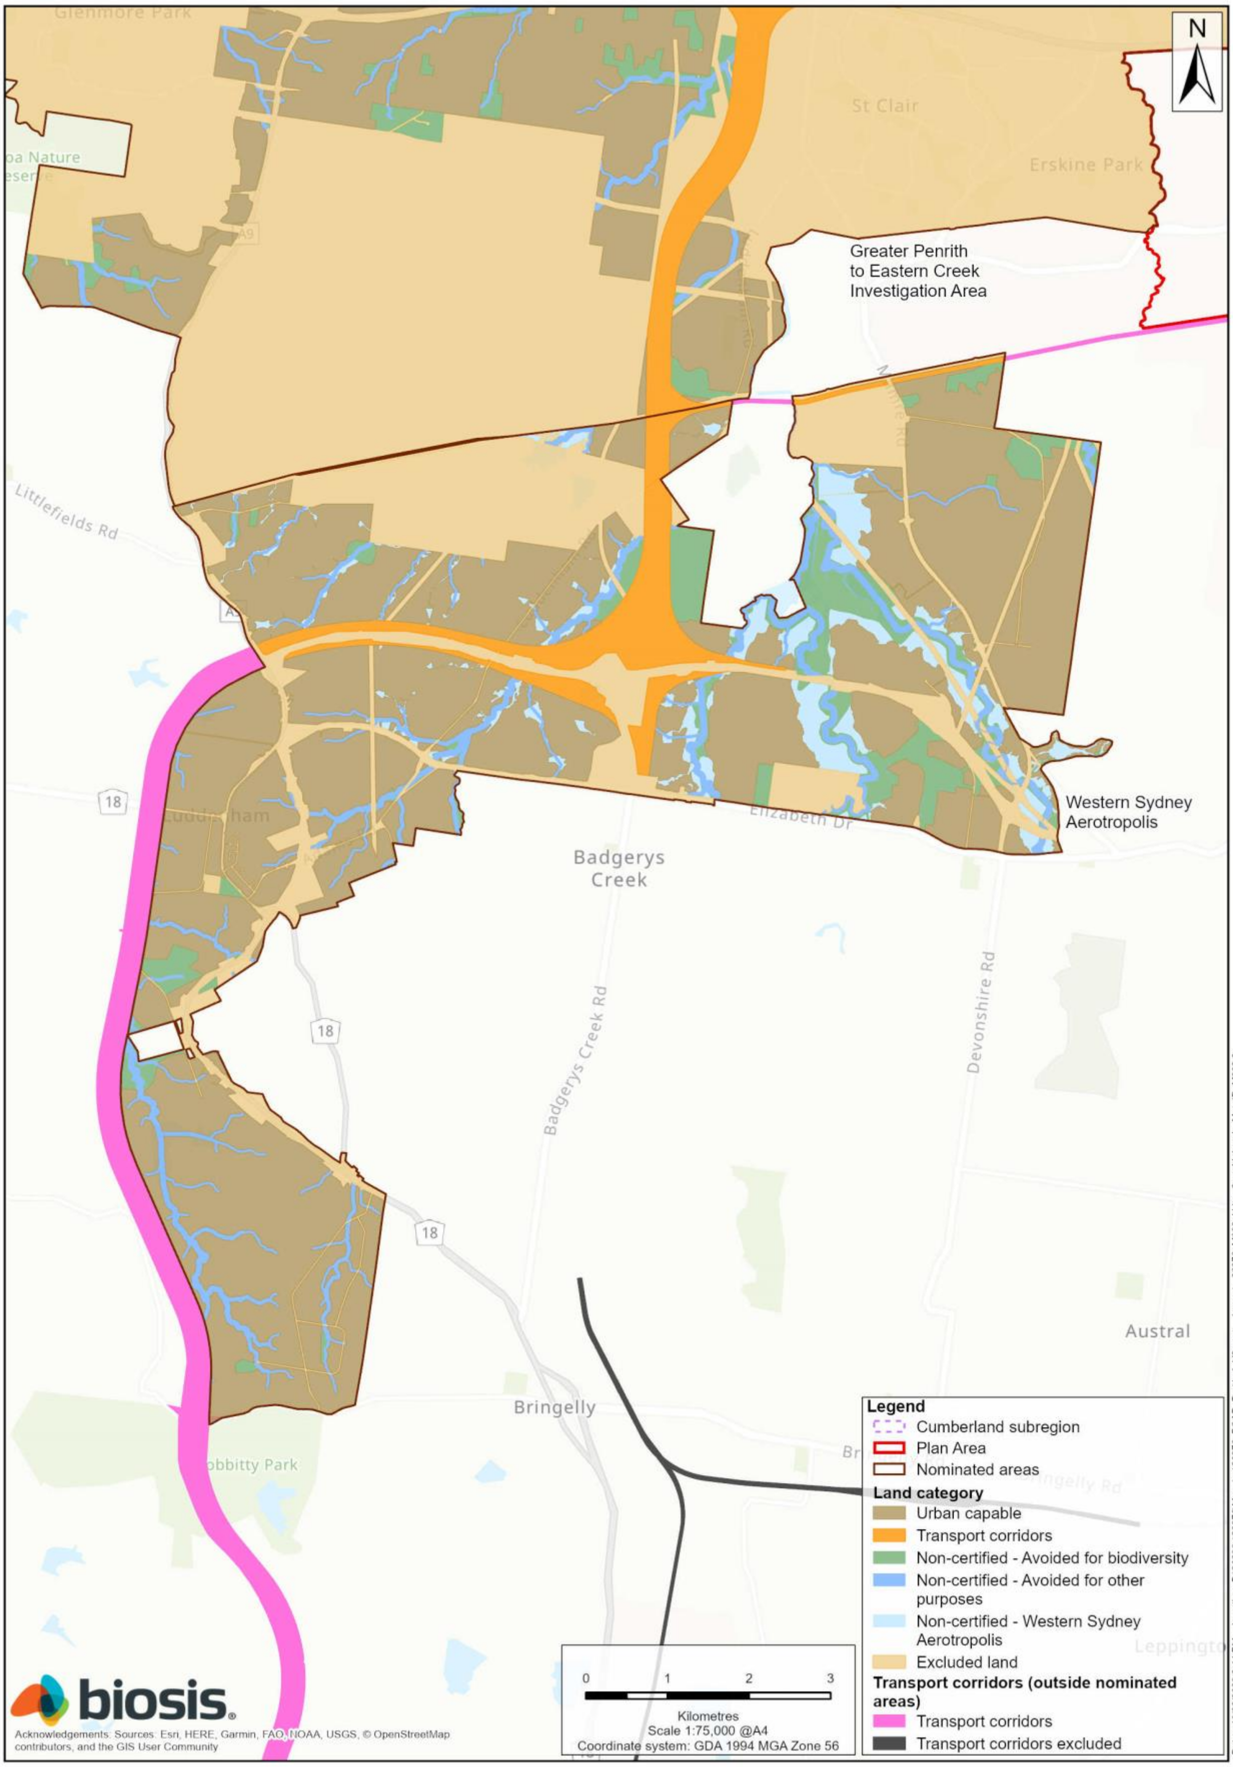

Figure 14-3: Avoidance outcomes – WSA

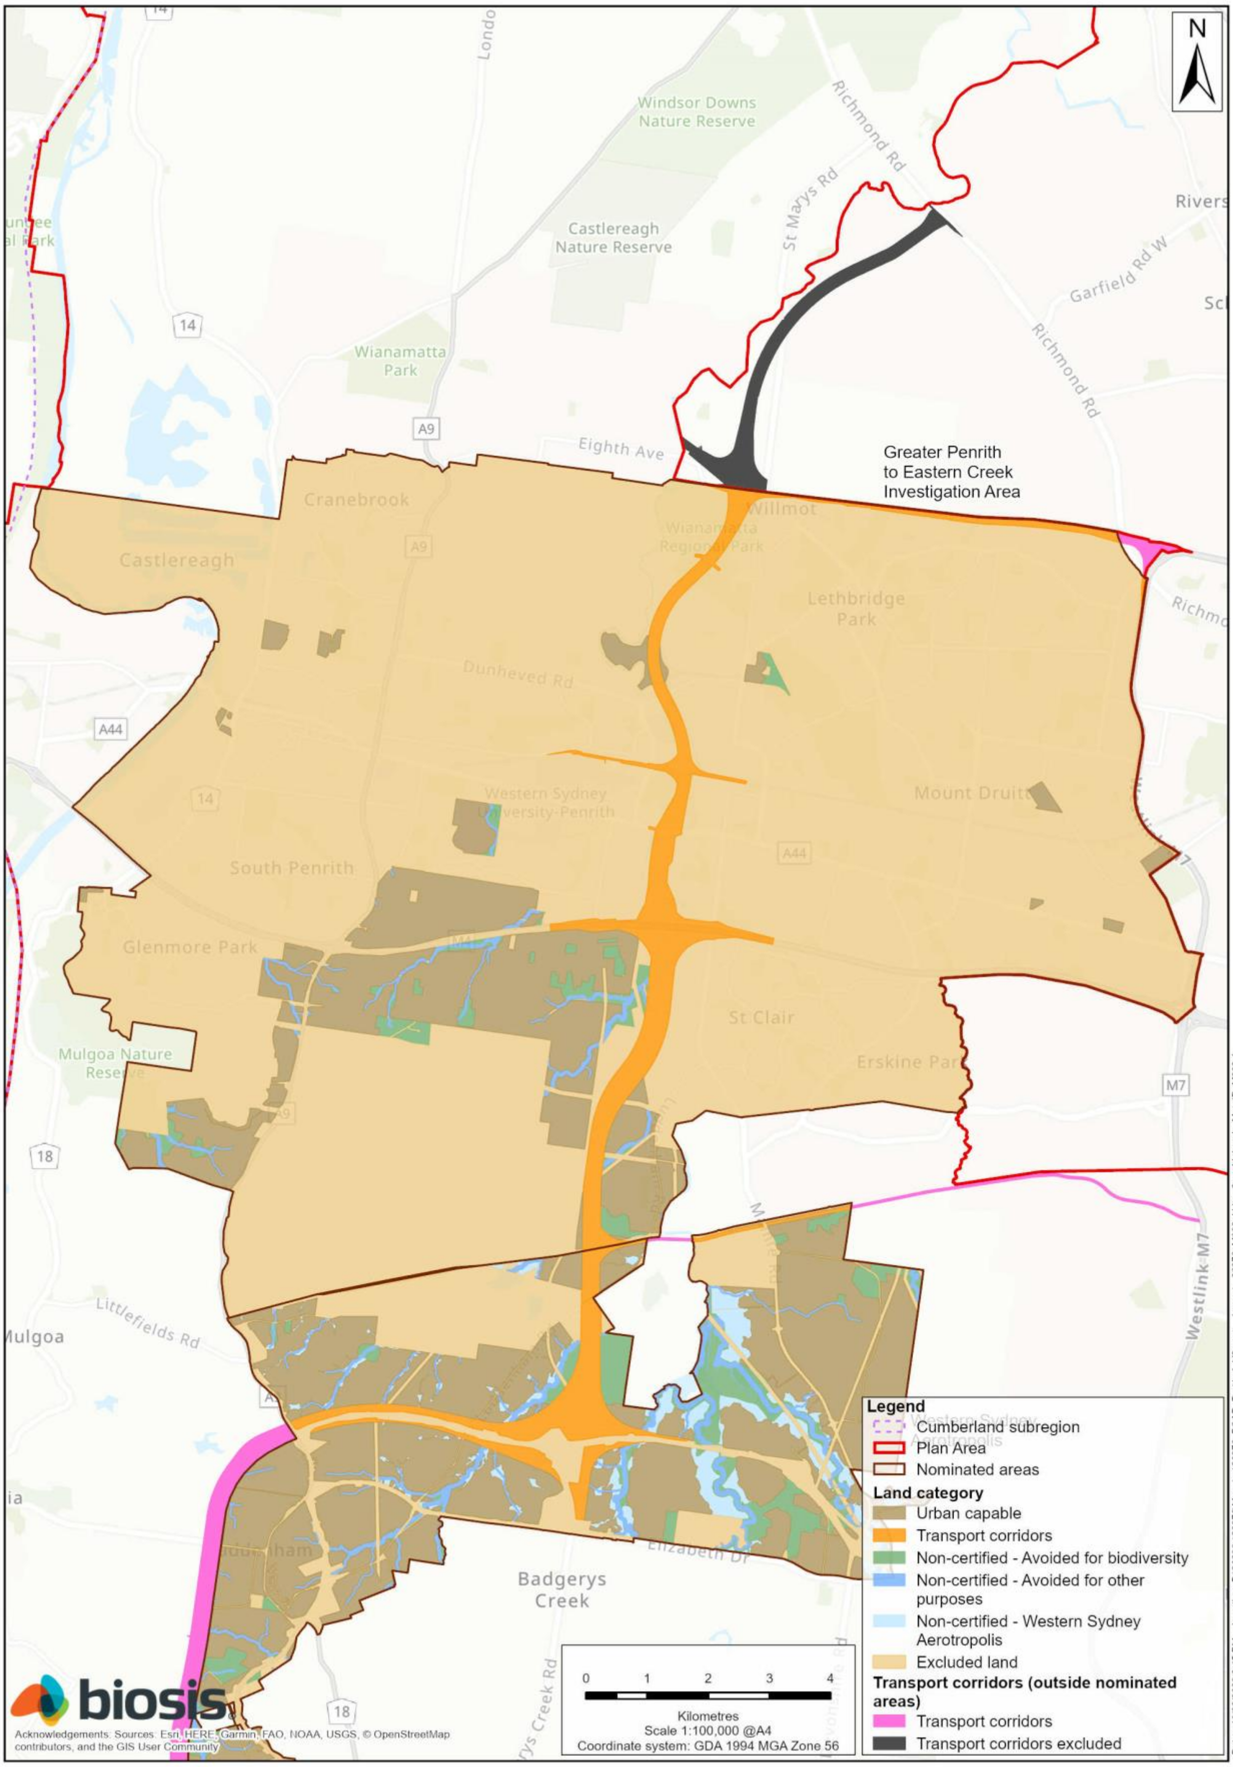

Figure 14-4: Avoidance outcomes – GPEC

14.6.2 NATIVE VEGETATION

Of the 5,460.5 ha of native vegetation occurring (not including excluded land) within the nominated areas:

- 2,734.7 ha (50.0 per cent) has been avoided for biodiversity purposes (as per the BAM definition)
- An additional 937.3 ha (17.2 per cent) has been avoided for other purposes and will not be directly impacted under the Plan

14.6.3 AVOIDANCE OF HIGH CONDITION NATIVE VEGETATION

Section 8.1.1.3 (b) of the BAM specifies that impacts can be avoided and minimised by locating development in areas where native vegetation is in the poorest condition, or by avoiding the highest condition native vegetation. For the purposes of this assessment high condition has been defined as vegetation mapped in the 'intact' condition state.

Table 14-2 indicates that the vast majority of the urban capable land for the nominated areas has been located in poorer condition native vegetation and avoided areas with the highest (intact) condition.

Of the high condition (intact) native vegetation in the nominated areas (2,472.5 ha, not including excluded lands):

- 1,678.5 ha (or 67.9 per cent) has been avoided for biodiversity purposes
- A total of 2,353.8 ha (or 95.2 per cent) has been avoided

AVOIDANCE IN GPEC

Avoidance outcomes of intact native vegetation for GPEC are lower than for other nominated areas. This is due to:

- The impacts of the transport corridors – the OSO within GPEC directly impacts about 36.9 ha of intact native vegetation (63.1 per cent of total area of intact vegetation in GPEC, not including excluded lands), while the urban capable land directly impacts about 2.1 ha of intact vegetation. It is important to note that avoidance within the transport corridors has not yet occurred (see section 14.4) and it is likely that further avoidance of intact native vegetation within the OSO footprint will occur during strategic planning and detailed design
- A relatively small urban capable land area within a nominated area that is largely already developed for urban purposes, meaning the opportunities for avoidance across the nominated area is generally more constrained

Despite this, it is considered that development under the Plan will generally avoid the areas that are most likely to be important for habitat connectivity within GPEC. The majority of BIO Map regional corridors/core areas have been avoided and will not be directly impacted. The main direct impacts occur:

- Within Wianamatta Regional Park where the OSO severs the eastern part of the regional park that is connected to Ropes Creek with the western part of the park
- Along Wianamatta (South Creek) where the OSO directly impacts the riparian corridor and severs the narrow connection along the corridor that links Wianamatta Regional Park and Orchard Hills

The other areas of potential habitat connectivity within GPEC comprise connected patches of vegetation (within 100 m of another patch) or isolated patches of vegetation (greater than 100 m from another patch) (there are no other areas of contiguous native vegetation forming habitat corridors outside Bio Map core areas/corridors). The development will result in the clearing of many small patches of connected vegetation, as well as the edges of several larger connected patches. This may reduce habitat connectivity across the area for more mobile species, such as bats and birds. Impacts to larger connected patches will reduce the size of the patches but will not generally sever connectivity between this connected vegetation and other areas of native vegetation, such as BIO Map corridors/core areas.

Table 14-2: Avoidance of high condition (intact) native vegetation in nominated areas

Nominated area	Area of high condition PCTs (ha) in nominated areas			Area of high condition PCTs avoided (ha) in nominated areas

14.6.4 AVOIDANCE OF THREATENED ECOLOGICAL COMMUNITIES

Section 8.1.1.3 (c) of the BAM specifies that impacts can be avoided and minimised by locating proposed development in areas that avoid critically endangered and endangered TECs.

Table 14-3 and Table 14-4 indicate that within the nominated areas:

- Of the 3,936.7 ha of critically endangered and endangered NSW-listed TECs (not including excluded land), 2,259.1 ha (or 57.4 per cent) has been avoided for biodiversity purposes, and a total of 2,823.8 ha (or 71.7 per cent) has been avoided
- Of the 2,416.7 ha of critically endangered and endangered Commonwealth-listed TECs (not including excluded land), 1,807.4 ha (or 74.8 per cent) has been avoided for biodiversity purposes, and a total of 2,114.1 ha (or 87.5 per cent) has been avoided

Table 14-3: Avoidance of endangered (E) and critically endangered (CE) NSW-listed TECs in nominated areas

14.6.5 AVOIDANCE OF SPECIES HABITATS

Section 8.1.1.3(c) of the BAM specifies that the proposed development should avoid areas of habitat for species with a high biodiversity risk weighting. Risk-weightings are identified by EES for each species and used in credit calculations as part of assessing the impacts of a development on each species. Risk-weightings are based on the combination of the sensitivity of the species to loss at the development site, and sensitivity of the species to potential gain at an offset site.

Table 14-5 sets out the amounts of potential habitat avoided for NSW-listed candidate species credit species (SCS) with a high or very high biodiversity risk weighting in the nominated areas. The table indicates that within the nominated areas the average avoidance of habitat:

- Is 77.8 per cent for the three candidate SCS with a very high risk weighting (not including excluded lands) (*Allocasuarina glareicola*, *Hibbertia fumana* and *Chalinolobus dwyeri*)
- Is 78.6 per cent for the 31 candidate SCS with a high risk weighting (not including excluded lands) where an impact occurs

Avoidance outcomes for each Commonwealth-listed species are further described in Chapters 29 and 30, including in relation to important populations (this is also summarised in section 14.6.6).

Table 14-5: Avoidance of species habitat in nominated areas, showing avoidance of species with very high or high biodiversity risk-weighting (BRW)

14.6.6 AVOIDANCE OF IMPORTANT POPULATIONS

Table 14-6 summarises the avoidance outcomes for important populations for each Commonwealth-listed species.

In total 20 species have mapped important populations within the nominated areas, of which the important populations identified for 14 species are not entirely included on excluded land. Of 14 species with important populations identified outside excluded land 12 have important populations represented (either wholly or partially) on land avoided for biodiversity purposes. It is important to note that in some cases, records that form part of the important population may be located across several land categories (urban capable land, excluded land, or avoided lands).

The avoidance outcomes and extent of direct impacts under the Plan to each important population are further described in the assessments for each Commonwealth-listed species in Chapters 29 and 30. The location of each important population is also shown in the habitat maps for each species provided in those chapters.

Table 14-6: Summary of avoidance of important populations for Commonwealth-listed species

Scientific name	Important populations in nominated areas			Important populations avoided in nominated areas			Location of avoided population records
	Total number	Number in excluded lands	Number not including excluded lands	Avoided for biodiversity purposes*	Avoided for other reasons	Total avoided	
Acacia bynoeana	1	1	0	0	0	0	N/A

Rostratula australis	1	1	0	0	0	0	N/A

* As per BAM definition of avoidance

Not including excluded lands

14.6.7 AVOIDANCE OF AREAS IMPORTANT FOR CONNECTIVITY

Section 8.1.1.3(d) of the BAM specifies that the development should avoid areas important for maintaining habitat connectivity. BIO Map core areas and corridors (OEH, 2015) provide a surrogate measure of habitat connectivity and a useful approach to evaluating avoidance outcomes in terms of connectivity.

The purpose of BIO Map is to identify areas on the Cumberland subregion where investment in conservation actions will have maximum benefit. It is acknowledged that BIO Map is not intended to be used for land-use planning, as it does not identify all significant vegetation. However, BIO Map core areas represent the habitat most likely to support species persistence and the maintenance of interactions between species and landscape scale ecological processes, and BIO Map corridors play a crucial role in maintaining connectivity between species populations.

Table 14-7 and Table 14-8 set out the amounts of Bio Map core areas and corridors avoided in the nominated areas. The tables indicate that of the Bio Map core areas and corridors within the nominated areas (not including excluded land):

- 68.6 per cent of core areas have been avoided for biodiversity purposes, and a total of 88.3 per cent has been avoided
- 56.5 per cent of corridors have been avoided for biodiversity purposes, and a total of 86 per cent has been avoided

Table 14-7: Avoidance of areas important for habitat connectivity (BIO Map core areas)

Nominated area	Area of Bio Map core areas in nominated areas (ha)			Area of Bio Map core areas avoided in nominated areas (ha)			Per cent avoided # (%)

14.6.8 AVOIDANCE OF SERIOUS AND IRREVERSIBLE IMPACTS

The BAM requires an assessment of avoidance for serious and irreversible impact (SAII) entities.

A total of 12 SAII entities were identified as potentially impacted by the proposed development and needing assessment in accordance with the BAM. The avoidance outcomes for each of these SAII entities is assessed in Chapter 25.

14.6.9 CONCLUSION

The urban capable land was located by establishing a planning process that took into account and biodiversity values and prioritised the avoidance of high biodiversity values through a set of criteria.

Where biodiversity priorities were inconsistent with urban development priorities, the decision-making process sought to balance these priorities. This was achieved through negotiations on options between the Department's strategic assessment team and the Department's planning team to:

- Explain and justify urban development and avoidance priorities
- Explore alternative development locations to achieve the urban development priorities
- Make decisions on final urban capable land boundaries (see Box 3)

The planning process to avoid and minimise impacts has led to substantial avoidance outcomes for native vegetation, TECs, species habitats, and habitat connectivity.

Urban capable land has generally avoided the vast majority of native vegetation and key areas of high biodiversity values, including NSW and Commonwealth-listed TECs, species habitats, important populations and habitat connectivity. Within the nominated areas, total avoidance (not including excluded lands) includes:

- Approximately 67.2 per cent of all native vegetation, including 95.2 per cent of high (intact) condition native vegetation
- Approximately 87.5 per cent of critically endangered and endangered Commonwealth-listed TECs and 71.7 per cent of critically endangered and endangered NSW-listed TECs
- An average of 77.8 per cent of potential habitat for three species with a very high biodiversity risk weighting (>3), and an average of 78.6 per cent of potential habitat for 31 species with a high biodiversity risk weighting (≥2)
- Of 14 species with important populations identified outside excluded land 12 have important populations represented (either wholly or partially) on land avoided for biodiversity purposes
- Approximately 88.3 per cent of Bio Map core areas and 86.0 per cent of Bio Map corridors

Note that these figures include the amount of land 'avoided' for other purposes and not just biodiversity purposes (i.e. the figures include land that is not suitable for urban development because it is steep land or riparian corridors).

It is considered these avoidance outcomes are adequate and generally consistent with the guidance under the BAM and requirements of the ToR. Furthermore, commitments under the Plan ensure:

- The amount of avoidance to be achieved is clear and transparent
- Precinct planning proceeds in a way that ensures avoided lands are clearly identified and avoided
- The protection of avoided lands from the impacts of development is strengthened through environmental zoning

15 Managing indirect impacts

15.1 INTRODUCTION

The BAM and the Commonwealth ToR require indirect impacts to be identified and assessed.

Indirect impacts are any impacts that could adversely affect biodiversity values, such as native vegetation, TECs and threatened species habitat, beyond the urban capable land. Indirect impacts may also result from changes to land-use patterns, such as an increase in vehicular access and human activity.

This Chapter:

- Sets out the regulatory requirements for managing indirect impacts under the BAM and ToR
- Describes the approach applied to identify and assess indirect impacts
- Describes the indirect impacts relevant to the Plan, including their nature, extent and duration
- Identifies the threatened species and TECs at risk of indirect impacts
- Describes the general mitigation measures and processes that will be implemented to address each indirect impact
- Assesses the potential indirect impacts on each species and TEC taking into account the general mitigation measures that will be implemented under the Plan, and identifies whether there are any residual impacts
- Describes any additional species or TEC specific mitigation measures to address any residual impacts
- Identifies the threat abatement plans under the EPBC Act relevant to the Plan and how they relate to the Plan

Detailed assessments of the potential indirect impacts on each Commonwealth-listed TEC and species, as well as other EPBC Act protected matters, are undertaken in the following chapters:

- Chapter 29 – Commonwealth-listed flora
- Chapter 30 – Commonwealth-listed fauna
- Chapter 31 – Commonwealth-listed TECs
- Chapter 32 – Migratory species
- Chapter 33 – Ramsar wetlands
- Chapter 34 – World and National Heritage
- Chapter 35 – Commonwealth Land

This Chapter covers the aspects of the indirect impacts assessment listed above, and in particular, describes the detail of the general and specific mitigation measures and processes that are referred to in these other chapters. This Chapter also covers the assessment of indirect impacts on NSW-listed TECs and species as required under the BAM and summarises the assessment undertaken for Commonwealth-listed TECs and species in Chapters 29 to 31.

15.2 REGULATORY REQUIREMENTS

15.2.1 BC ACT REQUIREMENTS

Section 9 of the BAM requires the Assessment Report to assess the potential indirect impacts of the Plan on biodiversity values. The Assessment Report must:

- Describe the nature, extent and duration of short-term and long-term impacts
- Identify the species and TECs likely to be affected
- Predict the consequences of the impacts for the bioregional persistence of the species and TECs
- Document mitigation measures proposed to manage impacts
- Identify any measures for which there is risk of failure
- Evaluate the risk and consequence of any residual impacts likely to remain after mitigation measures are applied
- Document any adaptive management strategy proposed (this is described in Chapter 16)

15.2.2 EPBC ACT REQUIREMENTS

Section 4.5 of the Commonwealth ToR requires the Assessment Report to consider potential indirect impacts on MNES and describe what mitigation will be implemented to reduce indirect impacts.

Section 5.3 of the ToR requires the Assessment Report to consider the likely effectiveness of the conservation measures under the Plan in protecting and managing MNES and any related risks and uncertainties.

15.3 APPROACH TO THE ASSESSMENT

The steps taken to assess indirect impacts involved:

Step 1: Identify the range of indirect impact types associated with the development and describe the nature, extent, and duration of each indirect impact type. This involved:

- Nature of impacts – qualitatively describe each indirect impact type, including cause and scope of the impact
- Extent of impacts – identify the general location and extent of indirect impacts
- Duration – identify whether the impacts are short-term or long-term

Step 2: Identify the species and TECs likely to be affected by each indirect impact within each nominated area and the transport corridors. This was done by drawing on ecological and life history information in BioNet profiles, conservation advices, recovery plans, as well as species records and habitat maps prepared for this Assessment Report

Step 3: Describe the general mitigation measures and processes that will be implemented to mitigate indirect impacts and the likely effectiveness of these measures

Step 4: Assess the potential impacts on each species and TEC taking into account the general mitigation measures in the Plan to address the impacts. This was done taking into account:

- Likely presence/abundance of species/TEC and importance of the location at a local and regional scale
- Life history traits and susceptibility of the species/TEC to the indirect impact
- Location of the species/TEC relative to the likely extent of the indirect impact
- Amount and quality of un-impacted habitat remaining
- Levels of existing protection

A conclusion is provided about whether any residual risks remain for each species and TEC.

Step 5: Describe any additional species or TEC specific mitigation measures identified under the Plan to address residual impacts

15.4 NATURE, EXTENT AND DURATION OF INDIRECT IMPACTS

15.4.1 SUMMARY OF DEVELOPMENT UNDER THE PLAN

The types of development under the Plan that have the potential to cause indirect impacts on biodiversity values are described in detail in Part 2 and include:

- Urban and industrial development in the nominated areas
- Infrastructure in the nominated areas
- Agribusiness in the Western Sydney Aerotropolis
- Transport corridors

URBAN AND INDUSTRIAL DEVELOPMENT

Urban and industrial development will occur within the urban capable land in the nominated areas. This development may include:

- Mixed residential, commercial and industrial development

- Major town centres including shops and recreational facilities, and smaller village centres
- Social infrastructure including education, cultural, sports and entertainment facilities
- Essential health and emergency services facilities
- General industrial facilities such as retail outlets, technology facilities, material supply centres and distribution centres
- Warehouses, freight transport facilities and heavy industrial storage establishments

INFRASTRUCTURE

Infrastructure development will predominantly be located within urban capable land and may include:

- Electricity transmission or distribution networks
- Gas pipelines
- Road or road infrastructure facilities including public transport facilities
- Water systems and facilities, such as for storage, treatment and supply
- Telecommunications facilities
- Stormwater management system
- Waste facilities, including organic waste and composting facilities
- Supporting infrastructure for parks and public reserves

AGRIBUSINESS

The Agribusiness Precinct in WSA will provide for the movement and storage of agricultural commodities at the northern and western edges of the Western Sydney International (Nancy-Bird Walton) Airport. Development in this area may include:

- Intensive plant agriculture, including protective cropping structures
- Businesses associated with the production, processing, marketing and distribution of agricultural products
- Advanced food manufacturing and logistics
- Wholesale markets, including retail, accommodation, and large distribution centres, and infrastructure such as cold stores, ripening rooms, treatment facilities and waste management

TRANSPORT CORRIDORS

Transport development includes all activities associated with the design, construction and operation of major transport infrastructure. These activities include, but are not limited to:

- Vegetation clearing
- Earthworks
- Utility works
- Landscaping
- Erosion and sediment control
- Laydown areas
- Road and rail construction
- Tunnel construction
- Construction of supporting infrastructure such as stations, car parks and pedestrian access
- Electricity infrastructure
- Site offices and access roads
- Dust and noise suppression
- Stormwater management (including detention basins, ponds and dams)
- Vehicle and train movements
- Maintenance and upgrade activities
- Installation and maintenance of traffic control and safety infrastructure

15.4.2 IMPACTS ASSOCIATED WITH EACH DEVELOPMENT TYPE

Table 15-1 identifies each indirect impact type associated with each type of development under the Plan, and the nature, extent and duration of the indirect impacts.

The nature, extent and duration of the impacts are described broadly. Due to the large scale of the development and the staging of construction precinct by precinct over the life of the Plan, it is not possible to be specific about the nature and extent of impacts in relation to specific vegetation zones at any particular location, or the exact timing of the development at any particular location.

The nature of each indirect impact type is described in more detail in Sections 15.4.3 to 15.4.12.

Table 15-1: Indirect impact types and nature, extent and duration of indirect impacts associated with the Plan

Indirect impact type	Development types relevant to the indirect impact				Nature of indirect impact	Extent/general location of indirect impact and/or high risk areas	Duration of indirect impact
	Urban and industrial	Infrastructure	Agribusiness	Transport corridors			
Hydrological/ soil disturbance	✓	✓	✓	✓	Changes to surface water and groundwater flows and water quality due to development and infrastructure disrupting natural flows and pollutants associated with urban areas and soil erosion/disturbance to contaminated soils	Waterways, wetlands, flood-prone areas within or downstream of development	Short term to long-term
Ground settling or subsidence				✓	Settlement/subsidence of ground in the vicinity of transport tunnels due to the tunnel void or groundwater removal, which may cause disturbance to the land surface	Land within or in vicinity of the transport tunnels	Long-term
Spread of infection/disease	✓	✓	✓	✓	Spread of pathogens from contaminated clothing and equipment or surface water runoff	Native vegetation retained within or adjacent to development	Likely long-term
Spread of weeds	✓	✓	✓	✓	Spread of invasive species due to edge effects, surface water run-off, or changed fire regimes	Native vegetation retained within or adjacent to development	Likely long-term
Predation/ competition by pest/domestic fauna	✓		✓	✓	Increased predation and competition of species by pest/domestic fauna	Habitat retained within or adjacent to development including well-connected habitat corridors	Likely long-term
Altered fire regimes	✓		✓	✓	Altered fire regimes as a result of increased burns for asset protection or reduced ability to burn due to risk to surrounding urban areas	Native vegetation retained within or immediately adjacent to development, particularly asset protection zones	Long-term

Indirect impact type	Development types relevant to the indirect impact				Nature of indirect impact	Extent/general location of indirect impact and/or high risk areas	Duration of indirect impact
	Urban and industrial	Infrastructure	Agribusiness	Transport corridors			
Disturbance from increased public access to natural areas	✓				Trampling of species or habitat, removal of wood or bush rock, damage from mountain-biking and four-wheel driving	Publicly accessible natural areas retained within or immediately adjacent to development	Short term to permanent
Fauna mortality, displacement and barriers to movement	✓	✓	✓	✓	Potential for mortality of threatened fauna species by vehicle strike and reduced movement and connectivity between habitat areas from barriers	Habitat intersected by roads	Long-term
Fauna disturbance due to noise, dust or light	✓	✓	✓	✓	Noise, dust or light created by equipment during construction or by new structures during operation	Habitat retained within or immediately adjacent to development	Short-term to long-term
Inadvertent impacts on adjacent habitat or vegetation	✓	✓	✓	✓	Damage to adjacent habitat during construction activities or during ongoing management	Native vegetation immediately adjacent to development	Short-term to long-term

15.4.3 HYDROLOGICAL/SOIL DISTURBANCE

Reduction in surface water quality and changes to surface water flows

Development under the Plan may lead to changes to hydrology and water quality. This is primarily related to:

- Disruption to natural flows and processes
- Increase of hard surfaces leading to an increased volume of water entering downstream waterways
- Introduction of contaminants into surface water, such as nutrients, chemicals and sediment from urban and other development and land uses, including disturbance of soils/contaminated soils during construction

Changes to surface water quality and hydrology can impact a range of listed species and TECs. Species that rely on aquatic environments such as swamps and riparian corridors are particularly at risk from these types of impacts.

Changes to groundwater

Development under the Plan may affect groundwater quality, including from salinity and contamination. This is primarily related to:

- Clearing for construction
- Construction works involving large excavations
- Dewatering or structures buried below the water table, including groundwater removal from the tunnel voids associated with the transport corridor tunnels
- Diversion of surface water, including installation of buildings and hard surfaces

Changes to groundwater can affect groundwater-sensitive species and habitats and dependent ecosystems.

Soil disturbance

Development under the Plan may cause soil erosion and sedimentation and disturbance to contaminated soils, which can lead to changes in water quality. This is primarily related to:

- Vegetation clearing
- Construction works involving large excavations
- The management of spoil during construction, particularly for the construction of the transport corridor tunnels

15.4.4 GROUND SETTLEMENT/SUBSIDENCE

Construction of the transport corridor tunnels involves the creation of a tunnel void and removal of groundwater from the void. This may cause ground settlement and subsidence to the land surface above and in the vicinity of the tunnel, causing disturbance to any biodiversity or other values in the affected area.

15.4.5 SPREAD OF INFECTION/DISEASE

Development under the Plan may increase the risk of the spread of infection/disease. This is primarily related to:

- Soil transportation on contaminated footwear, vehicles and machinery, and in residential garden establishment
- Increased site visitation rates
- Earthworks and activities conducted during construction
- Increased surface water runoff

Spread of infection/disease can affect species and have associated impacts on TECs.

Key threatening processes listed under the BC Act and EPBC Act relevant to this indirect impact type are:

- Infection of amphibians with chytrid fungus resulting in chytridiomycosis (EPBC Act)/infection of frogs by amphibian chytrid causing the disease chytridiomycosis (BC Act)
- Infection and dieback caused by the root-rot fungus *Phytophthora cinnamomi* (EPBC Act)/infection of native plants by *Phytophthora cinnamomi* (BC Act)

- Introduction and establishment of Exotic Rust Fungi of the order *Pucciniales pathogenic* on plants of the family *Myrtaceae* (BC Act)
- Novel biota and their impact on biodiversity (EPBC Act)
- Psittacine Circoviral (beak and feather) Disease affecting endangered psittacine species (EPBC Act/BC Act)

15.4.6 SPREAD OF WEEDS

Development under the Plan has the potential to increase the spread of invasive species and weeds. This is primarily related to:

- New environmental conditions at the edges of developments such as altered light levels, windspeed, and temperature, that may facilitate the spread of weeds
- Use of inappropriate species in landscaping and revegetation
- Accidental dispersal of weed seeds and plant material
- Altered fire regimes

Species are most susceptible to this threat where new urban growth or transport corridors occur adjacent to known populations or habitat. Weeds can reduce the viability of adjacent habitat or vegetation for listed species and TECs, and can reduce the health of important habitat features. Invasive species of particular concern are:

- African lovegrass (*Eragrostis curvula*)
- African olive (*Olea europaea* subsp. *cuspidata*)
- Asparagus fern (*Asparagus aethiopicus*)
- Black nightshade (*Solanum nigrum)*
- Bridal creeper (*Asparagus asparagoides*)
- Buffalo grass (*Stenotaphrum secundatum*)
- Castor-oil plant (*Ricinus communis*)
- Coolatai Grass (*Hyparrhenia hirta*)
- Kikuyu grass (*Cenchrus clandestinus*)
- Lantana (*Lantana camara*)
- Long-leaf willow primrose (*Ludwigia longifolia*)
- Rhodes grass (*Chloris gayana*)
- Whisky grass (*Andropogon virginicus*)

Key threatening processes listed under the BC Act and EPBC Act relevant to this indirect impact type are:

- Invasion and establishment of exotic vines and scramblers (BC Act)
- Invasion, establishment and spread of Lantana (*Lantana camara*) (BC Act)
- Invasion of native plant communities by African Olive *Olea europaea* subsp. *cuspidata* (BC Act)
- Invasion of native plant communities by exotic perennial grasses (BC Act)
- Loss and degradation of native plant and animal habitat by invasion of escaped garden plants (EPBC Act/BC Act)
- Novel biota and their impact on biodiversity (EPBC Act)

15.4.7 PREDATION/COMPETITION/LAND DEGRADATION BY PEST/DOMESTIC FAUNA

Development under the Plan has the potential to increase the spread of pest fauna and/or access to natural areas by domestic fauna, leading to increased predation and competition with native fauna. This is primarily related to:

- Clearing that creates new movement pathways that can be used by pest fauna to expand their range
- Clearing that changes conditions at the edges of habitat that favour pest fauna
- Direct predation of native fauna by pest/domestic fauna
- Pest fauna destroying habitat and spreading disease

Domestic animals in this context is primarily related to increased numbers of cats, dogs and rabbits.

Key threatening processes listed under the BC Act and EPBC Act relevant to this indirect impact type are:

- Aggressive exclusion of birds from potential woodland and forest habitat by abundant Noisy Miners *Manorina melanocephala* (EPBC Act/BC Act)
- Competition and land degradation by rabbits (EPBC Act)/Competition and grazing by European rabbit (BC Act)
- Competition and land degradation by unmanaged goats (EPBC Act)/Competition and habitat degradation by Feral Goats, *Capra hircus* (BC Act)
- Competition from feral honeybees (EPBC Act/BC Act)
- Herbivory and environmental degradation caused by feral deer (BC Act)
- Predation and hybridisation by Feral Dogs, *Canis lupus familiaris* (BC Act)
- Predation by feral cats (EPBC Act/BC Act)
- Predation by the European red fox (EPBC Act/BC Act)
- Predation by the plague minnow (*Gambusia holbrooki*) (BC Act)
- Predation, habitat degradation, competition and disease transmission by feral pigs (*Sus scrofa*) (EPBC Act/BC Act)
- The biological effects, including lethal toxic ingestion, caused by Cane Toads (*Rhinella marina*) (EPBC Act)/Invasion and establishment of the Cane Toad (*Rhinella marina*) (BC Act)

15.4.8 ALTERED FIRE REGIMES AND INCREASED FIRE RISK

Development under the Plan has the potential to alter fire regimes and increase fire risk. This is primarily related to:

- Arson or the accidental lighting of fires
- Increased burns for hazard reduction to protect assets, particularly within Asset Protect Zones
- Reduced burns in some areas due to risk to urban areas

Changed fire regimes can reduce habitat suitability for TECs and threatened species, affect foraging resources and prey species, and cause direct mortality from heat and smoke.

The key threatening process listed under the BC Act relevant to this indirect impact type is:

- Ecological consequences of high frequency fires (BC Act)

15.4.9 DISTURBANCE FROM INCREASED PUBLIC ACCESS TO NATURAL HABITAT AREAS

Development under the Plan will increase human activity in the vicinity of the nominated areas, which can impact avoided lands, conservation lands secured under the Plan and existing reserves. This is primarily related to:

- Trampling of threatened flora species/habitat for threatened fauna species
- Track creation
- Bush rock removal and disturbance
- Rubbish dumping and disturbance from associated clean-up activities
- Timber collection, removal of dead wood
- Illegal collection of threatened species
- Dog walking
- Recreational activities such as mountain-biking, four-wheel driving and fishing

Species and TECs most at risk from this threat occur on public land because these areas are publicly accessible.

Key threatening processes listed under the BC Act relevant to this indirect impact type are:

- Bushrock removal (BC Act)
- Removal of dead wood and dead trees (BC Act)

15.4.10 FAUNA MORTALITY AND INJURY, FAUNA DISPLACEMENT AND THE INTRODUCTION OF BARRIERS TO FAUNA MOVEMENT

Development under the Plan may increase the likelihood of fauna mortality and fauna displacement, and will introduce barriers to fauna movement. This is primarily related to:

- Direct mortality as a result of collisions with vehicles or new structures, shooting, poaching, or secondary poisoning during pest control
- Displacement due to clearing for the development
- Introduction of linear barriers such as fences, roads and railways, which can affect fauna movement and predation

Koala, birds, invertebrates and arboreal mammals are particularly susceptible to these impacts.

15.4.11 FAUNA DISTURBANCE DUE TO NOISE, DUST OR LIGHT

Development under the Plan will increase noise, dust and light. This is primarily related to:

- Clearing for the development
- Construction activities, including use of heavy vehicles and machinery
- Increased noise levels from traffic due to new roads or increased traffic on existing roads
- Artificial light from urban and commercial areas, and along transport routes

Increased noise can particularly impact on species that vocalise or rely on hearing for hunting or breeding. Artificial light can affect the behaviour of nocturnal and diurnal species, including disorientation, attraction to light sources resulting in collisions and mortality, and effects on light-sensitive life-cycles (e.g. flowering, breeding, and migration). Increased light can also influence the abundance, behaviour and movement of some predator species.

15.4.12 INADVERTENT IMPACTS ON ADJACENT HABITAT OR VEGETATION

Development under the Plan may cause inadvertent impacts on adjacent habitat, vegetation or important habitat features, such as hollow bearing trees. This could occur during construction or operation and is primarily related to:

- Impacts adjacent to construction sites
- Road, trail and powerline maintenance
- High frequency land management such as mowing and slashing or weed control

This can affect threatened species' habitat which is close to urban capable land and transport corridors.

15.5 SPECIES AND TECS LIKELY TO BE AFFECTED BY INDIRECT IMPACTS

Attachment A identifies the NSW and Commonwealth-listed threatened species and TECs potentially impacted by each indirect impact. Indirect impacts were identified as being relevant to a species or TEC if:

- The indirect impact is identified as a threat in a relevant profile, conservation advice or recovery plan, *and*
- The threat is present in the Cumberland subregion, *and*
- The Plan has the potential to exacerbate the threat

Relevant indirect impacts were identified by drawing on ecological and life history information in BioNet profiles, conservation advices and recovery plans, and species records and habitat maps prepared for this Assessment Report.

Note that ground settlement and subsidence is only relevant under the Plan to several species and TECs that occur in the vicinity of the transport corridor tunnels. The indirect impacts of the tunnels on these matters is assessed in Chapter 36.

15.6 GENERAL MITIGATION MEASURES

The Plan includes commitments to mitigate the indirect impacts of the urban, industrial, infrastructure, agribusiness and transport development on biodiversity values and other EPBC Act protected matters.

The types of mitigation measures and the processes to implement these mitigation measures are different for the types of development under the Plan. For the urban, industrial and agribusiness development, mitigation measures will be implemented through the NSW planning system. For infrastructure and transport corridors, mitigation measures will be implemented through the NSW environmental assessment and approval process current at the time of the development.

This section:

- Describes the relevant commitments and the actions under the Plan to mitigate indirect impacts and the processes to implement mitigation measures for each of the different types of development
- Summarises the general environmental controls that will be implemented through the NSW planning system to mitigate the indirect impacts of the urban, industrial and agribusiness development
- Summarises other commitments and actions under the Plan also relevant to addressing indirect impacts

15.6.1 REGULATION OF INDIRECT IMPACTS UNDER EXISTING LAWS

It is important to note that several potential indirect impacts associated with the urban, industrial, infrastructure, agribusiness and transport development are regulated in NSW under existing laws and additional mitigation measures under the Plan are not considered necessary to address any risks.

For example, the use of chemicals, fuels and other pollutants, including obligations to prevent spillage and leaks to the environment, is regulated under the *Protection of the Environment Operations Act 1997*. The Act is enforced by the NSW Environment Protection Authority and councils. This existing regulatory framework is considered adequate to manage the risk of spillage of pollutants and downstream impacts on environmental values such as the Towra Point Ramsar wetland (see Chapter 33) and migratory bird habitat (see Chapter 32).

15.6.2 MITIGATION MEASURES FOR URBAN, INDUSTRIAL, AND AGRIBUSINESS DEVELOPMENT

The Plan includes a commitment to mitigate indirect and prescribed impacts on TECs and species from development within the nominated areas to best practice standards (Commitment 5), including implementing development controls in the nominated areas to protected species, as prescribed in Appendix E of the Plan (Commitment 5.1)

Two broad types of development controls will be implemented:

- General environmental controls that will benefit the environment generally, including biodiversity values
- Specific controls that apply to specific species and TECs in specific locations or broader nominated areas. These controls have been identified through this Assessment Report and are needed to address residual risks to species or TECs that remain after implementation of the general environmental controls

The assessment of potential indirect impacts on each Commonwealth and NSW-listed species and TEC in section 15.7 was done taking into account the general environmental controls. Where these controls were not considered adequate to address the risks of indirect impacts to a particular species or TEC, additional specific controls were identified to be implemented under the Plan. These additional specific controls are set out in section 15.8.

PROCESS TO IMPLEMENT DEVELOPMENT CONTROLS

The commitment to manage indirect impacts of urban, industrial and agribusiness development within the nominated areas will be delivered primarily through the NSW planning system, and specifically, the nominated areas planning delivery framework. The overarching planning delivery framework is described in Chapter 9.

Implementation mechanisms

The key actions under the Plan to implement the development controls are set out in Table 15-2.

The key mechanism to implement the general environmental controls and the specific controls in the nominated areas is Development Control Plans (DCPs). DCPs will be prepared for each nominated area and set out the controls that need to be addressed by neighbourhood plans and development applications to mitigate indirect impacts.

Table 15-2: Actions taken under the Plan to mitigate indirect impacts within the nominated areas

Planning mechanism	Actions under the Plan to implement mitigation measures
State Environmental Planning Policies (SEPPs)	The Department is proposing a new SEPP as the key statutory mechanism to implement strategic conservation planning and to provide certainty that the Plan's commitments and actions to protect, enhance, maintain and restore biodiversity in Western Sydney will be met
Strategic land-use plans	Strategic land-use plans for nominated area precincts or neighbourhoods identify urban capable land and set out principles for protecting and managing biodiversity
DCPs	A DCP will be prepared for each nominated area Provisions will be incorporated in the DCPs for each nominated area setting out development controls that need to be addressed by neighbourhood plans and development applications to mitigate indirect and prescribed impacts on threatened species These provisions will include the list of controls in Appendix E of the Plan where relevant
Subdivision plans	Requirements to audit and monitor the implementation of development controls will be incorporated in standard conditions within subdivision plans
Support to councils	Provide ongoing support to councils in the application of DCP controls within the nominated areas, including the sharing of knowledge, maps and data

Implementation process

Who prepares the DCP?

In NSW, DCPs are typically prepared by councils for the purpose of regulating development and land use within a particular Local Government Area (LGA). Section 3.46 of the EPA Act provides that the purpose of a DCP is to:

- Give effect to the aims of any environmental planning instrument that applies to the development
- Facilitate development that is permissible under any such instrument
- Achieving the objectives of land zones under any such instrument

A DCP provides detailed guidelines and environmental standards for new development, which need to be considered when preparing a development application seeking approval for development.

DCPs are also used by councils in the assessment of development applications. When designing development proposals, applicants need to address the relevant requirements of any DCPs which apply to their land or proposal.

What is the process for preparing the DCP?

Each nominated area will be covered by a DCP prepared by either the Department (in the case of Department led precincts) or by the relevant councils in collaboration with the Department, and will be prepared in accordance with:

- Standard format for DCPs and a set of model provisions prepared by the Department to apply across NSW
- Any processes and guidelines for preparing DCPs specific to each council
- Current best practice standards, guidelines or targets (e.g. water quality standards for urban runoff)

Each DCP in the nominated area will also need to address:

- The Plan's draft DCP template prepared by the Department to apply to the nominated areas
- Information in the Assessment Report on the risks of indirect impacts to specific species and TECs and locations
- Data on biodiversity values collected as part of this Assessment Report, including:
  - Native vegetation
  - Extent and condition of TECs
  - Location of species records and potential habitat

Draft DCPs must be exhibited for public consultation, whether prepared by the council or the Department.

The Department will provide appropriate guidance and oversight of the development of DCPs to ensure each DCP is consistent with the commitments and actions under the Plan.

DCPs will be reviewed in five-year intervals and updated if necessary. This process allows new development controls to be incorporated into the DCP or controls to be amended to ensure they meet best practice standards.

General controls specified under this Plan in a draft DCP template

A draft DCP template is currently being prepared by the Department to support the Plan. The template will include:

- The key general environmental controls specific to the Plan to mitigate indirect impacts on biodiversity values and other EPBC protected matters, and which may not typically be included in DCPs by councils
- Any specific controls in section 15.8 for mitigating indirect impacts on certain species and TECs that are relevant to implementation through the planning system under a DCP

The purpose of the DCP template is to provide model provisions to ensure key general environmental controls specific to the Plan, as well as all specific controls for certain species and TECs, are applied consistently across the nominated areas and effectively address the mitigation requirements of the Plan.

The Department will work with councils to incorporate all of the controls in the draft DCP template where relevant and will include these controls in any DCPs developed by the Department for Department led precincts.

Other general environmental controls specified by councils

In preparing each DCP, councils typically incorporate a range of other general environmental controls (that are not included in the draft DCP template) relating to broader environmental, social and economic considerations. For example, councils typically include controls to manage:

- Water cycle and stormwater management, including water sensitive urban design principles
- Water quality, including water quality targets
- Soil erosion and sedimentation
- Disturbance to contaminated soils, saline soils, or acid sulphate soils

Councils will likely include this range of controls in each DCP for the nominated areas. For example, each of these types of controls were incorporated into the draft Wilton DCP that was publicly exhibited in 2019.

The specifics of each of these types of controls will be determined by councils during the preparation of each DCP.

How will the specific controls be incorporated in the DCP?

The specific controls are controls that have been identified through this Assessment Report as being needed to address residual risks to specific species or TECs that remain after implementation of the general environmental controls.

The draft DCP template will incorporate all the specific controls in section 15.8 that can be implemented through the NSW planning system (these do not include the controls related to the transport corridors). As described above, councils will be required to incorporate all of the controls in the draft DCP template where relevant into each DCP.

Implementation of the specific controls in the draft DCP template requires councils to make decisions around the circumstances, design specifics and exact locations where the controls should be applied. This is appropriate as the scale of the development and the long timeframe over which the development will be implemented does not allow these specific details to be determined as part of the Assessment Report.

The Department will support councils to make these decisions through providing:

- Information in the Assessment Report on the risks of indirect impacts to specific species and TECs and locations
- Data on biodiversity values collected as part of this Assessment Report
- Guidance on best practice standards, guidelines or targets
- Guidance on specific issues related to koala management and mitigation through the koala working group

How will the controls in the DCP be implemented?

Councils will be responsible for imposing conditions on developers requiring the implementation of development controls under the DCP through the development application process.

The Department will work with councils to ensure appropriate conditions are incorporated within each subdivision plan and development approval to support the implementation of the mitigation requirements in the DCPs by councils.

The Department will review how the DCP controls are working as part of the MER Framework under the Plan and provide feedback and support to precinct teams and councils.

What measures are in place to address any risk of failure of development controls?

The Plan puts in place several measures to address any uncertainty or risks of failure associated with the development controls in the DCPs. These measures include:

- Incorporate requirements to audit and monitor the implementation of development controls in the nominated areas
- Implement an MER Framework that will monitor and report and evaluate the delivery of actions and commitments and achievement of outcomes to inform adaptive management responses (see Chapter 9)
- An adaptive management approach linked to the MER framework that will adjust actions and other measures as necessary to ensure the Plan's outcomes are achieved (see Chapter 16)

Who will ensure compliance?

Councils or the relevant consent authority responsible for ensuring compliance with any conditions of consent that have been applied to a development based on the relevant controls in each DCP.

The NSW planning system provides an existing compliance framework under which councils can take action to ensure compliance with development conditions, including any requirements for managing indirect impacts under the Plan.

The Plan provides further support to this existing framework through:

- Preparing a draft DCP template that clearly set out details of the development controls to be addressed by neighbourhood plans and development applications to mitigate indirect impacts
- Incorporating provisions into relevant statutory land-use plans for the nominated areas, such as Precinct Plans to give legal effect to specific development standards as required

These actions that will be undertaken under the Plan means that development controls are clearly defined and understood and there is an existing process in place to enforce the controls where they are incorporated as conditions of consent in a development application.

A compliance strategy will also be prepared under the Plan to ensure that the development occurs in accordance with the Plan and conditions of approval (see Chapter 9). The compliance strategy will identify relevant compliance mechanisms, compliance monitoring and auditing priorities and processes, and roles and responsibilities for compliance monitoring and action. The Plan will also provide funding for at least three Council-based surveillance officers.

SUMMARY OF GENERAL ENVIRONMENTAL CONTROLS

This section summarises:

- Examples of general environmental controls typically incorporated into DCPs by councils in NSW
- General environmental controls specific to the Plan that are included in the draft DCP template

General environmental controls typically specified by councils

As described above, councils typically incorporate a range of general environmental controls in DCPs relating to broader environmental, social and economic considerations.

Examples of these types of controls included in the draft Wilton DCP are provided in Table 15-3.

These controls will be important to manage potential indirect impacts of the urban and industrial, and agribusiness development to the general environment, including downstream impacts on environmental values such as the Towra Point Ramsar wetland (see Chapter 33) and Commonwealth land (see Chapter 35).

Table 15-3: Examples of general environmental controls incorporated by council in the draft Wilton DCP

Control type	Summary of example control in draft Wilton DCP
Water cycle management	• Water management measures must comply with council's requirements for detention, drainage and water sensitive urban design principles • Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
Water quality	• Stormwater systems must be constructed and maintained to achieve EES water quality targets
Soil erosion and sedimentation	• Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development • Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom, 2004) and submitted with each subdivision development application
Disturbance to saline soils	• Salinity Management Plans must be prepared in accordance with the Western Sydney Salinity Code of Practice 2004 (WSROC, 2004) and submitted with each subdivision development application
Contaminated soils	• All subdivision development applications must be accompanied by a Stage 1 Preliminary Site Investigation. Where this identifies potential site contamination, a Stage 2 detailed site investigation must be prepared • A Remediation Action Plan (RAP) must be prepared for areas identified as contaminated land in the Stage 2 Site Investigation
Air quality	• Development must comply with the Protection of the Environment Operations Act 1997 and supporting regulations. Submit an Odour Impact Assessment when required • Provide a barrier such as dense landscaping to mitigate dispersion of air pollutants, noise or odour where necessary
Noise	• Provide a barrier such as dense landscaping to mitigate dispersion of air pollutants, noise or odour • Development to include buffers (as outlined in the DCP) to limit noise impacts on surrounding areas • Provide an acoustic report to address the impact of noise generation from development on the surrounding area
Traffic/construction traffic	• Ensure the road networks are designed to control traffic speeds to appropriate limits • Provide a traffic report/statement to address the impact of the development on the local road system and address traffic safety issues

General environmental controls in the draft DCP template

The general environmental controls included in the draft DCP template are summarised in:

- Table 15-4 for mitigation of construction impacts
- Table 15-5 for protection of waterways and riparian corridors
- Table 15-6 for mitigation of the spread of disease/infection
- Table 15-7 for mitigation of spread of weeds
- Table 15-8 for mitigation of pest/domestic fauna impacts
- Table 15-9 for mitigation of altered fire regimes

- Table 15-10 for mitigation of fauna mortality, fauna displacement and impacts from linear barriers
- Table 15-11 for mitigation of fauna disturbance due to noise, dust and light
- Table 15-12 for mitigation of inadvertent impacts on adjacent habitat or vegetation
- Table 15-13 for retention of key habitat features

Construction impacts

Table 15-4: Development controls specific to mitigation of indirect impacts from construction

Summary of key controls	Relevant standards, targets or guidelines
• Prepare a Construction Environmental Management Plan (CEMP) setting out measures to protect the environment during construction, including: o Pre-clearance assessment for native fauna prior to any clearing native vegetation o Best practice site hygiene protocols to minimise spread of *Phytophthora* and Myrtle Rust o Site rehabilitation and installation of nest boxes for development adjacent to natural areas o Tree felling protocol to avoid impacts to species relying on tree hollows, dreys, dens, and other nests in trees that are to be cleared • Submit a weed eradication and management plan with development applications for subdivision outlining weed control measures during and after construction • Construction traffic to utilise clearly defined access and egress points to and from a development site to avoid remnant wildlife corridors and native vegetation communities • Parking and equipment and laydown areas to be located away from land with biodiversity values • Temporary fencing to be erected to manage inadvertent impacts on adjacent natural areas	Relevant council specifications Arrive Clean, Leave Clean: Guidelines (Commonwealth of Australia, 2015)

Waterways and riparian corridors

Table 15-5: Development controls to manage waterways and riparian corridors

Summary of key controls	Relevant standards, targets or guidelines
• Maintain waterways of Strahler order 2 or higher in a natural state, including the maintenance and restoration of riparian corridors • Where development will affect a waterway of Strahler order 2 or higher, rehabilitate the waterway to return it to a natural state • Design road crossings of waterways to minimise impacts to vegetated riparian corridors and species movements Note under the EPA Act, development within 40 m of a watercourse is Integrated Development and requires approval under the *Water Management Act 2000*	• Relevant councils design and construction specifications • Strahler ordering scheme for waterways

Spread of infection/disease

Table 15-6: Development controls to manage the spread of infection/disease

Summary of key controls	Relevant standards, targets or guidelines
• Prepare a Construction Environmental Management Plan (CEMP) setting out the measures methods to protect the environment during construction, including: o Best practice site hygiene protocols to minimise spread of *Phytophthora* and Myrtle Rust	Arrive Clean, Leave Clean: Guidelines (Commonwealth of Australia, 2015)

Spread of weeds

Table 15-7: Development controls to manage the spread of weeds

Summary of key controls	Relevant standards, targets or guidelines
• Submit a weed eradication and management plan with development applications for subdivision outlining weed control measures during and after construction • Subdivision design and bulk earthworks to minimise environmental weed spread and include measures to eradicate these weeds in accordance with relevant council weed policies • Weeds of National Significance and on the National Environmental Alert List under the National Weeds Strategy to be managed and eradicated. Proponent to reference NSW Weed Wise for current weed identification and management approaches	Relevant council weed policies National Weeds Strategy NSW Weed Wise Plan's weed control strategy

Predation/competition/land degradation by pest/domestic fauna

Table 15-8: Development controls to manage the impacts from pest/domestic fauna

Summary of key controls	Relevant standards, targets or guidelines
Domestic animals • Ensure that domestic animals are appropriately contained at urban/bushland interfaces • Property boundaries should have appropriate fencing to contain domestic animals within the landholders' property	
Pest animals • Appropriately manage and control pest animals as relevant to the site • Pest control techniques implemented during and post construction to be in accordance with regulatory requirements for chemical use	Plan's pest animal control strategy

Altered fire regimes and increased fire risk

Table 15-9: Development controls to manage impacts from altered fire regimes and increased fire risk

Summary of key controls	Relevant standards, targets or guidelines
• APZs for bushfire protection purposes are to be located wholly within the urban capable land for new development and not within land with biodiversity values As part of commitment 2, the Plan includes an action that specifies APZs are to be located wholly within urban capable land. The appropriate APZ distance is determined by the Rural Fire Service Standards for Asset Protection based on vegetation type, slope and the nature of the development and is measured from the edge of the retained habitat	RFS Standards for Asset Protection

Fauna mortality and injury, fauna displacement and the introduction of linear barriers

Table 15-10: Development controls to manage fauna mortality, fauna displacement and impacts from the introduction of linear barriers

Summary of key controls	Relevant standards, targets or guidelines
• Implement traffic calming measures in development areas not subject to koala exclusion fencing, including speed limit restrictions for areas adjacent to land with biodiversity values, and installation of wildlife signposting and speed humps and audible surfacing in accordance with relevant standards • Install and maintain fauna-friendly road design structures in appropriate areas adjacent to fauna habitat, such as underpasses, fauna bridges and overpasses	TfNSW Biodiversity Guidelines Relevant council guidelines Relevant Australian Standards

Fauna disturbance due to noise, dust or light

Table 15-11: Development controls to manage fauna disturbance due to noise and light

Summary of key controls	Relevant standards, targets or guidelines
• Where noise or light impacts from development on land adjacent to natural areas may affect wildlife, mitigation measures to manage impacts should be implemented, such as managing the timing of activities and/or installing appropriate noise barriers • High-intensity outdoor lighting, including commercial lighting, or sports fields lighting, should be designed to avoid light spill into adjoining natural areas • Development within 100 m of known microbat colonies or habitat likely to support microbat colonies must include street lighting that does not attract insects	Australian Standard AS 4282 Commonwealth's *Draft Light Pollution Guidelines for Wildlife*

Inadvertent impacts on adjacent habitat or vegetation

Table 15-12: Development controls to manage inadvertent impacts on adjacent habitat or vegetation

Summary of key controls	Relevant standards, targets or guidelines
• Parking and equipment and laydown areas to be located away from land with biodiversity values • Temporary fencing to be erected to manage inadvertent impacts on adjacent natural areas	

Retention of key habitat features or important sites

Table 15-13: Development controls to retain key habitat features

Summary of key controls	Relevant standards, targets or guidelines
• Establish ecological setbacks in accordance with distances in the DCP to provide a buffer to adjacent development for: o Raptor nests o Grey-headed Flying Fox camps	

Other relevant development controls

Asset protection zones

An asset protection zone (APZ) is a buffer zone between a bushfire hazard and buildings or other infrastructure that needs to be protected. It is managed to minimise fuel loads and reduce potential radiant heat levels, flames, localised smoke and ember attack. The width of the APZ is between generally between a minimum of 20 m and 60 m. This is determined based on vegetation type, slope and the nature of the development, in accordance with Rural Fire Service standards. As part of the subdivision design, the APZ may include perimeter roads or open space areas.

Commitment 2 of the Plan includes an action that specifies APZs are to be located wholly within urban capable land when preparing new precinct plans for nominated areas.

APZs will act as a buffer between the urban, industrial and agribusiness development under the Plan and biodiversity values, including avoided lands and other areas containing TECs and species populations. This buffer will reduce the risk, and support the mitigation of, several indirect impacts, including:

- Waterways and riparian corridors
- Water quality
- Weed invasion
- Altered fire regimes
- Inadvertent impacts on adjacent habitat or vegetation

Environmental protection zoning of avoided lands

Commitment 2 of the Plan includes an action to apply environment (E2) conservation zoning to land avoided for biodiversity purposes and other purposes (riparian corridors and steep land), to strengthen the protection of avoided lands from the impacts of development. Note that avoided land will have environment (E2) conservation zoning applied except for land owned by LALCs or under claim by LALCs. LALC owned land and land under claim represents 90 ha of the 4,795 ha of avoided land.[2]

This environmental zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will reduce the risk, and support the mitigation of, several indirect impacts, including:

- Removal of key habitat features, such as trees, firewood and bush rock
- Habitat disturbance from increased public access, including recreational activities

15.6.3 MITIGATION MEASURES FOR INFRASTRUCTURE

The Plan includes a commitment to mitigate indirect and prescribed impacts on TECs and species from development to best practice standards (Commitment 5), including the construction and operation of infrastructure projects (Commitment 5.3), as prescribed in Appendix E of the Plan.

Implementation mechanisms

This commitment will be delivered through future environmental assessment and approval processes that will apply to each infrastructure project under the EP&A Act current at the time the project is brought forward.

Infrastructure projects covering the broad types under the Plan (see Part 2) are subject to different environmental assessment and approval processes under the EP&A Act. The processes are summarised in Table 15-14. State Environmental Planning Policy (SEPP) (Infrastructure) 2007 provides a framework for determining how most types of infrastructure are assessed and approved under the EPA Act. The SEPP sets out:

- What type of infrastructure is approved by council, the Minister for Planning, or Department under a traditional development consent process under Part 4 of the EP&A Act (this is known as 'development with consent')
- What type of infrastructure development is approved by a public authority under a separate process under Part 5 of EP&A Act (this is known as 'development without consent')
- What type of development is exempt from requiring approval (known as 'except development') or may be undertaken provided certain conditions are met (known as 'complying development')

Table 15-14: Potential assessment and approval processes for infrastructure under the Plan

	Approval	Assessment	Assessment mechanism	Approval body
Part 4	Approval required under Part 4 of EP&A Act	Must include an assessment of the 'likely impacts of the development, including environmental impacts on both the natural and built environments and social and economic impacts…' (s 79C(1)	Environmental Impact Statement (for State Significant Development) Statement of Environmental Effects (for other development)	Normally council For State Significant Development, may be: • Minister for Planning • Planning Assessment Commission • The Department
Part 5	Approval required under Part 5 of EP&A Act	Must 'examine and take into account to the fullest extent possible all matters affecting or likely to affect the environment by reason of that activity' (s 111)	Review of Environmental Factors Environmental Impact Statement	Normally a public authority

[2] The total area of avoided land at the start of the Plan is 4,795 hectares. The avoidance target of 4,315 hectares has reduced this figure by 10 per cent to allow for potential future development of essential infrastructure in non-certified land

	Approval	Assessment	Assessment mechanism	Approval body
SSI	Approval required under Part 5.1 of EP&A Act	Must prepare an Environmental Impact Statement in accordance with assessment requirements specified by the Department	Environmental Impact Statement	Minister for Planning

The key actions under the Plan to implement the commitment for infrastructure are set out in Table 15-15.

Table 15-15: Assessment and approval processes for infrastructure under the Plan

Legislative mechanism	Actions under the Plan to address indirect impacts
NSW environmental assessment and approval process under the EP&A Act for each project current at the time the project is brought forward	• The department will establish guidelines that will include the mitigation measures for indirect and prescribed impacts on biodiversity in the nominated areas, and these will need to be considered by the determining authority for activities assessed under Part 5 of the EP&A Act. These mitigation measures are described in Appendix E of the Plan

The indirect impacts of the infrastructure projects within urban capable land on biodiversity values under the EPBC Act and BC Act have been assessed as part of this Assessment Report, and the Plan includes mitigation measures for specific species and TECs to address these risks (see section 15.8). Public authorities will be required to take these mitigation measures into account when constructing and operating infrastructure projects.

The future processes of environmental assessment and approval summarised in Table 15-14 will assess and identify mitigation measures to manage the other potential environmental impacts of the infrastructure projects. This process will, for example, assess the potential for the project to result in soil erosion and sedimentation based on the detailed design of the infrastructure project, and identify mitigation measures to address this risk.

This future assessment process therefore provides a process through which:

- The specific mitigation measures identified in this Assessment Report and the Plan for species and TECs (see section 15.8) can be implemented based on the detailed design of the infrastructure project
- General mitigation measures to manage the risks to the environment generally (for example, soil erosion and sedimentation, or construction impacts) will be identified and implemented

Essential infrastructure

Some infrastructure to support the development in the nominated areas (called 'essential infrastructure') may be located within non-certified land in the nominated areas (i.e. within avoided or non-certified land but not excluded lands) provided it complies with specific guidelines under the Plan. The Plan is seeking approval under the EPBC Act (but not the BC Act) for essential infrastructure development to occur within these areas.

Planning for essential infrastructure is in various stages of development, and the location of this infrastructure has not yet been determined. The guidelines to avoid, mitigate and offset the potential direct and indirect impacts of essential infrastructure are described, along with an assessment of impacts, in Chapter 37.

15.6.4 MITIGATION MEASURES FOR THE TRANSPORT CORRIDORS

The Plan includes a commitment to mitigate indirect and prescribed impacts from transport corridors on TECs and species (Commitment 6), including implementing mitigation measures as prescribed in Appendix E of the Plan.

Implementation mechanisms

The commitment to manage indirect impacts of the transport corridors will be delivered through the NSW environmental assessment and approval process (currently the State Significant Infrastructure approval process under the EP&A Act).

The key actions under the Plan to implement the commitment are set out in Table 15-16.

As described in Part 2, each transport project will be subject to future strategic planning and detailed design and a process of environmental assessment and approval:

- For the transport corridors within the nominated areas (where biodiversity impacts under both the EPBC Act and BC Act have already been assessed in this Assessment Report – see Part 1), this process will involve assessment under the State Significant Infrastructure approval process (or equivalent)
- For the transport corridors outside the nominated areas (where biodiversity impacts have only been assessed under the EPBC Act - see Part 1), this process will involve assessment under both:
  - State Significant Infrastructure approval process (or equivalent)
  - BC Act and BAM (or equivalent)

The biodiversity impacts of the transport corridors under the EPBC Act and BC Act (except for the transport corridors outside the nominated areas under the BC Act) have been assessed under this Assessment Report, and the Plan includes mitigation measures for specific species and TECs to address these risks (see section 15.8). Transport for NSW will be required to take these mitigation measures into account when constructing and operating transport projects.

The process under the State Significant Infrastructure approval process (or equivalent) will assess the other environmental impacts and matters that need to be considered prior to construction and operation of the transport project. This will include an assessment of risks to the environment and the identification of mitigation measures to manage these risks, such as impacts related to hydrological disturbance, noise, air quality, and construction.

This future assessment process therefore provides a process through which:

- The specific mitigation measures identified in this Assessment Report and the Plan for species and TECs (see section 15.8) can be implemented based on the detailed design of the transport project
- General mitigation measures to manage the risks to the environment generally (for example, groundwater drawdown from tunnels, or construction impacts) will be identified and implemented

Table 15-16: Actions taken under the Plan to mitigate indirect impacts from the transport corridors

Legislative mechanism	Actions under the Plan to address indirect impacts
NSW environmental assessment and approval process for each project current at the time the project is brought forward (this is currently the State Significant Infrastructure approval process under the EPA Act)	Transport for NSW will undertake the following: • Assess indirect impacts on biodiversity (for transport corridors outside the nominated areas) and other environmental values based on detailed design • Implement mitigation measures based on the outcomes of the assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the TfNSW Biodiversity Guidelines • Identify potential design options for major watercourse crossings to reduce disruption to connectivity and the risk of vehicle strikes • Undertake ongoing monitoring of high-value environmental areas, and review and adjust mitigation measures (where practical) in response to monitoring outcomes • Apply further mitigation according to BAM requirements for transport corridors outside the nominated areas • Report to the Department on mitigation measures proposed to manage impacts of each infrastructure project, including proposed techniques, timing, frequency and responsibility for implementing each measure

Implementation process

How does the process work?

Currently the EP&A Act provides the primary legislative basis for assessing and approving the impacts of transport development on the environment. The EP&A Act includes provisions to ensure that all potential environmental impacts of a development, including indirect impacts, are rigorously assessed and considered in the decision-making process.

Major road and rail projects are typically dealt with under the State Significant Infrastructure provisions (Division 5.2 of the EP&A Act) and require approval of the Minister for Planning. Under this Division, proponents must:

- Prepare an Environmental Impact Statement (EIS) for the project that assesses the impacts of the development
- Prepare the EIS in accordance with the Planning Secretary's environmental assessment requirements

The Department has prepared a standard set of environmental assessment requirements for State Significant Infrastructure Projects (DPIE, 2020b). The SEARs reflect the Department's preferred approach to conditioning projects through the provision of performance or outcome focused conditions, and currently requires the assessment to:

- Assess and identify impacts, including indirect impacts
- Propose measures to mitigate impacts
- Nominate and commit to performance outcomes for managing impacts
- Identify the detail of proposed management plans and monitoring programs

These actions that will be undertaken under the Plan means that mitigation measures to be applied to transport development are clearly defined and understood and the process to implement them is legally robust and enforceable.

Will all relevant indirect impacts be mitigated?

The Plan ensures all relevant indirect impacts will be mitigated by utilising the environmental impact assessment process under NSW planning and assessment legislation current at the time of construction.

This process currently requires the environmental impact assessment to identify all relevant indirect impacts, propose measures to mitigate those impacts and commit to performance outcomes for managing the impacts, and identify the detail of proposed management plans and monitoring programs (DPIE, 2020b).

Under the current process, the Department has prepared indicative standard conditions for linear State Significant Infrastructure Projects (DPIE, 2020b). These conditions include requirements to prepare a Construction Environmental Management Plan and Operational Environmental Management Plan to set out how performance outcomes, commitments and mitigation measures identified in the environment impact assessment, including in relation to managing indirect impacts, will be implemented and achieved. The plans must include:

- A program for ongoing analysis of the key environmental risks associated with the development
- Details of how the development will be undertaken to meet the performance outcomes identified in the environmental impact assessment and manage the risks identified in the risk analysis
- A protocol for managing and reporting any non-compliances with the approval

In addition to these legislative requirements for mitigating indirect impacts, Transport for NSW has prepared *Biodiversity Guidelines: Protecting and managing biodiversity on RTA projects* (Roads and Maritime Service, 2011). These guidelines provide detailed guidance on how to minimise and mitigate impacts on biodiversity during construction and maintenance of transport projects, including in relation to managing indirect impacts.

Are mitigation standards best practice and can they be adapted over time?

The environmental impact assessment process provides a mechanism to identify and implement best practice mitigation approaches and standards at the time of the construction of the transport projects.

The Department's current preferred approach to conditioning major development projects such as transport projects is through performance or outcome focused conditions where appropriate. Under this approach, performance outcomes are identified that must be complied with to achieve an appropriate environmental outcome, but how those outcomes are best achieved through mitigation measures is flexible. An advantage of this approach is that it allows flexibility over time about what mitigation measures are implemented to best achieve the outcome.

The Department has prepared guidelines for identifying mitigation measures to manage impacts in environmental impact assessments, including guidance on implementing performance-based approaches to mitigation (DPE, 2017). Furthermore, the *Biodiversity Guidelines: Protecting and managing biodiversity on RTA projects* (Roads and Maritime Service, 2011), are not static and will be updated at regular intervals to ensure they reflect best practice.

As set out below, the indicative standard conditions for linear State Significant Infrastructure Projects (DPIE, 2020b) require development of monitoring programs during construction and operation of major projects so that adjustments to performance outcomes, commitments and mitigation measures can be made if necessary.

What measures are in place to address any risk of failure of mitigation measures?

By undertaking environmental impact assessments under NSW planning and assessment legislation, the Plan ensures a detailed process is put in place to address any risk of failure of mitigation measures.

Under the current process, the Department has prepared indicative standard conditions for linear State Significant Infrastructure Projects (DPIE, 2020b). These conditions include requirements to prepare a Conservation Monitoring Program and Operational Monitoring Program to monitor performance outcomes, commitments and mitigation measures identified in the environmental impact assessment. The purpose of the monitoring is to enable a comparison of actual performance against the predicted performance in the environmental impact assessment so that adjustments to performance outcomes, commitments and mitigation measures can be made if necessary.

The monitoring programs must provide details of:

- Baseline data to be obtained
- Parameters of the project to be monitored
- Frequency and location of monitoring
- Reporting on monitoring results
- Procedures to identify and implement additional mitigation measures where necessary

The Plan also puts in place several measures to address any uncertainty or risks of failure associated with mitigation measures to manage indirect impacts. These measures include:

- Implement an MER Framework that will monitor and report and evaluate the delivery of actions and commitments and achievement of outcomes to inform adaptive management responses (see Chapter 9)
- An adaptive management approach linked to the MER framework that will adjust actions and other measures as necessary to ensure the Plan's outcomes are achieved (see Chapter 16)

Who will ensure compliance?

Under the current environmental impact assessment process, the indicative standard conditions for linear State Significant Infrastructure Projects (DPIE, 2020b) provide a detailed set of conditions for each state significant infrastructure project. Any breach of these conditions is a breach of the approval and is enforceable under EP&A Act.

The set of conditions require the preparation of compliance reports that report on the monitoring and compliance program and the compliance status of a project in relation to compliance with the conditions of approval. Compliance reports must be prepared in accordance with detailed guidelines on compliance reporting (DPE, 2018a). The Department will review the compliance report and respond to any non-compliances in accordance with powers under the EP&A Act and processes outlined in the Department's Compliance Policy (DPE, 2018b).

A compliance strategy will also be prepared under the Plan to ensure that the development occurs in accordance with the Plan and conditions of approval (see Chapter 9).

15.6.5 MITIGATION MEASURES FOR KOALA

The Plan includes a commitment to mitigate indirect impacts from urban, infrastructure and transport development on the Southern Sydney Koala population to best practice standards and in line with the Chief Scientist Koala Report (Commitment 7). A set of actions under the commitment specify how this will be done, including:

- Constructing exclusion fencing between important koala habitat and urban capable land in Wilton and GMAC
- Applying development controls within 60 m of koala habitat in accordance with the *Koala Habitat Protection Guideline* (DPIE, 2020a) (made under State Environmental Planning Policy (Koala Habitat Protection) 2019)

The key actions under the Plan to implement the commitment are set out in Table 15-17.

Table 15-17: Actions taken under the Plan to mitigate indirect impacts from urban, infrastructure and transport development on the Southern Sydney Koala Population

Actions under the Plan to address indirect impacts
• Install koala exclusion fencing between important koala habitat and urban capable land within GMAC and Wilton, except where exclusion fencing is not feasible due to slope, heritage or water courses • Ensure all koala exclusion fencing is at least 3 metres from koala habitat trees • In areas where exclusion fencing is not feasible, apply mitigation actions 60 metres from koala habitat. These actions include implementing controls from the *Koala Habitat Protection Guideline* and including design requirements in relevant DCPs. Specific locations are identified in the Plan • Install koala exclusion fencing on both sides of Appin Road between Rosemeadow and Appin to mitigate koala vehicle strikes at roadkill hotspots • Where fencing must cross existing or planned linear infrastructure such as gas and electricity transmission, consider appropriate access treatments such as gates to ensure the integrity of the koala exclusion fencing • Establish a koala working group including koala experts and relevant government agencies to determine priorities for koala conservation consistent with the objectives of the NSW Koala Strategy

<u>Exclusion fencing</u>

The exclusion fencing will be implemented through a program administered by the Department and funded under the Plan. Exclusion fencing will separate Koalas from urban capable land. The exact location of exclusion fencing will be determined during implementation of the Plan. Further details of the fencing program are provided in sub plan B.

<u>Development controls</u>

Where exclusion fencing is not possible due to topography, roads, waterways or heritage constraints, development controls will be applied within 60 m of koala habitat in accordance with the *Koala Habitat Protection Guideline*.

Design requirements and development controls specified in the koala guideline will be incorporated into relevant DCPs and implemented through the NSW planning system. The development and implementation of controls will be informed by the koala working group where appropriate.

15.6.6 OTHER COMMITMENTS RELEVANT TO INDIRECT IMPACTS

The Plan includes several other commitments and actions which support the mitigation of indirect impacts from the development under the Plan. These commitments are:

- Commitment 16 to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Areas. This commitment will be implemented through:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land

- Commitment 17 to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the Strategic Conservation Areas. This commitment will be implemented through:
  - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
  - Preparation of a Pest Animal Control Implementation Strategy
  - A process to enter into written agreements with delivery partners to implement the pest animal control program
  - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Commitment 18 to manage fire in strategic locations across the Strategic Assessment Area. This commitment will be implemented through:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a Fire Management Strategy for the Strategic Conservation Areas that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- Commitment 19 to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This commitment will be implemented through:
  - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
  - Entering into written agreements with delivery partners to implement priority disease control programs
- Commitment 21 to provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas
- Commitment 23 to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the Weed Implementation Strategy
- Commitment 28 to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal rubbish dumping and vegetation clearing

15.7 ASSESSMENT OF POTENTIAL INDIRECT IMPACTS

The potential indirect impacts from the urban, industrial, infrastructure, agribusiness and transport development on each Commonwealth and NSW-listed species and TEC are assessed in this section.

This assessment was done taking into account:

- The general mitigation measures to address indirect impacts, where these are relevant to a species or TEC
- Likely presence/abundance of species and TEC and importance of the location at a local and regional scale
- Life history traits and susceptibility of the species and TEC to the indirect impact
- Location of the species and TEC relative to the likely extent of the indirect impact
- Amount and quality of un-impacted habitat remaining
- Levels of existing protection

A conclusion is provided about whether any residual risks remain for each species and TEC. Additional species or TEC specific mitigation measures under the Plan to address residual risks are described in Section 15.8.

The assessment of potential indirect impacts is set out in the following tables:

- Fauna – Table 15-18
- Flora – Table 15-19
- TECs – Table 15-20

Detailed assessments of the potential indirect impacts on each Commonwealth-listed TEC and species, as well as other EPBC Act protected matters, are undertaken in the following chapters:

- Chapter 29 – Commonwealth-listed flora
- Chapter 30 – Commonwealth-listed fauna
- Chapter 31 – Commonwealth-listed TECs
- Chapter 32 – Migratory species
- Chapter 33 – Ramsar wetlands
- Chapter 34 – World and National Heritage
- Chapter 35 – Commonwealth Land

This section covers the assessment of indirect impacts on NSW-listed TECs and species as required under the BAM and summarises the assessment undertaken for Commonwealth-listed TECs and species in Chapters 29 to 31.

15.7.1 FAUNA

Table 15-18: Assessment of indirect impacts – fauna

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
BIRDS							
Anthochaera phrygia	Regent Honeyeater	CE	CE	ECS SCS	Removal of trees and firewood collection Spread of weeds Inappropriate fire regimes	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in each nominated area As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because this species is reliant on large mature trees, an additional specific mitigation measure has been identified to mitigate residual risks to this species	Yes
Artamus cyanopterus cyanopterus	Dusky Wood-swallow	N/A	V	ECS	Weed invasion	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in each nominated area. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur throughout the bioregion • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion. These measures are expected to manage any residual impacts to the species	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Botaurus poiciloptilus	Australasian Bittern	E	E	ECS	Hydrological changes Predation by introduced vertebrates Weed invasion Inappropriate fire regimes	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Most records of the species surround the subregion, and the subregion does not appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including hydrological changes, predation, weed invasion, inappropriate fire regimes. These measures are expected to manage any residual impacts to the species	No
Calidris canutus	Red Knot, Knot	E Mig.	N/A	N/A	None	As discussed in the Migratory Species Impact Assessment – Chapter 32, there are no important habitat areas for the species which are at risk of indirect impacts from development under the Plan	N/A
Calidris ferruginea	Curlew Sandpiper	CE Mig.	E	ECS	None	As discussed in the Migratory Species Impact Assessment – Chapter 32, there are no important habitat areas for the species which are at risk of indirect impacts from development under the Plan	N/A

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Callocephalon fimbriatum	Gang-gang Cockatoo	N/A	V	ECS SCS	Inappropriate hazard reduction burns Weed invasion	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in GPEC, Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Most records of the species surround the subregion, and the subregion does not appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and weed invasion. These measures are expected to manage any residual impacts to the species	No
Calyptorhynchus lathami	Glossy Black-cockatoo	N/A	V	ECS SCS	Loss of hollow bearing trees due to land management Weed invasion	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Most records of the species surround the subregion, and the subregion does not appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion. These measures are expected to manage any residual impacts to the species	No
Charadrius leschenaultii	Greater Sand Plover, Large Sand Plover	V Mig.	N/A	N/A	None	As discussed in the Migratory Species Impact Assessment – Chapter 32, there are no important habitat areas for the species which are at risk of indirect impacts from development under the Plan	N/A

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Chthonicola sagittata	Speckled Warbler	N/A	V	ECS	Weed invasion Nest failure due to predation by native and non-native birds, cats, dogs and foxes	The Plan has the potential to exacerbate threats in areas of habitat for this species (as indicated by records) that occur adjacent to urban capable land and transport corridors in the nominated areas. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Many records of the species surround the subregion or occur in protected lands in the subregion, and the subregion does not appear to be a stronghold for the species As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and predation. These measures are expected to manage any residual impacts to the species	No
Circus assimilis	Spotted Harrier	N/A	V	ECS	Loss of mature trees from rural landscapes Secondary poisoning from the use of pindone in rabbit control and rodenticides	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas This species is reliant on mature trees and at risk from secondary poisoning, therefore specific mitigation measures have been identified to mitigate potential residual impacts	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Climacteris picumnus victoriae	Brown Treecreeper	N/A	V	ECS	Weed invasion Degradation of habitat, particularly loss of tree hollows	The Plan has the potential to exacerbate threats in areas of habitat for this species (as indicated by records) that occur adjacent to the urban capable land and transport corridors in the nominated areas. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur throughout the bioregion • The subregion does not appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion. In addition, there is a specific measure in the Plan for some other species to retain large trees during precinct planning, which is likely to benefit the Brown Treecreeper. These measures are expected to manage any residual impacts to the species	No
Daphoenositta chrysoptera	Varied Sittella	N/A	V	ECS	Weed invasion Inappropriate fire regimes	The Plan has the potential to exacerbate threats in areas of habitat for this species (as indicated by records) that occur adjacent to the urban capable land and transport corridors in the nominated areas. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur throughout the bioregion • Many records in the subregion occur in protected lands • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and inappropriate fire regimes. These measures are expected to manage any residual impacts to the species	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Ephippiorhynchus asiaticus	Black-Necked Stork	N/A	E	ECS	Modification or degradation of wetlands	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in WSA. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur throughout the bioregion; the subregion doesn't appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including impacts to hydrological processes. These measures are expected to manage any residual impacts to the species	No
Epthianura albifrons	White-Fronted Chat	N/A	V	ECS	None	While the Plan has the potential to exacerbate several threats to the species, this species is unlikely to be indirectly impacted because the species is wide-ranging with areas of habitat (as indicated by records) occurring some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted	N/A
Glossopsitta pusilla	Little Lorikeet	N/A	V	ECS	Weed invasion Inappropriate fire regimes Loss of old hollow-bearing trees	The Plan has the potential to exacerbate threats in areas of habitat for this species (as indicated by records) that occur adjacent to urban capable land and transport corridors in Wilton and GMAC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because this species is reliant on large mature trees, an additional specific mitigation measure has been identified to mitigate residual risks to this species	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Grantiella picta	Painted Honeyeater	V*	V	ECS	Removal of large, old trees with heavy mistletoe infestations Inappropriate fire regimes	The Plan has the potential to exacerbate threats in areas of habitat for this species (as indicated by records) that occur adjacent to urban capable land and transport corridors in the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because this species is reliant on large mature trees, an additional specific mitigation measure has been identified to mitigate residual risks to this species	Yes
Haliaeetus leucogaster	White-bellied Sea-Eagle	N/A	V	ECS SCS	Reduction of suitable nesting habitat Non-target poisoning during vertebrate pest control Disturbance by humans or human activity when nesting	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species. In particular, development controls to establish ecological setbacks between development and raptor nests These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because this species is reliant on mature trees for nesting and at risk from secondary poisoning, additional specific mitigation measures have been identified to mitigate residual risks to this species	Yes
Hieraaetus morphnoides	Little Eagle	N/A	V	ECS SCS	Degradation of breeding habitat Secondary poisoning from rabbit baiting	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas This species is reliant on mature trees and at risk from secondary poisoning, therefore additional specific mitigation measures have been identified to mitigate potential residual impacts	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Hirundapus caudacutus	White-throated Needletail	V	N/A	N/A	None	As discussed in the Migratory Species Impact Assessment – Chapter 32, the species is known to forage above a wide range of habitats and is unlikely to be disrupted or displaced by development	N/A
Irediparra gallinacea	Comb-Crested Jacana	N/A	V	ECS	Loss and degradation of wetland habitat Predation on breeding birds and their nests by feral predators such as the European red fox	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in WSA. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur elsewhere in the bioregion; the subregion doesn't appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including impacts to hydrological processes and predation. These measures are expected to manage any residual impacts to the species	No
Ixobrychus flavicollis	Black Bittern	N/A	V	ECS	Impacts to riparian vegetation Predation by foxes and feral cats	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The species is wide-ranging and the subregion does not appear to be a stronghold for the species • Many records in the subregion occur in existing conservation areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including impacts to riparian vegetation and predation. These measures are expected to manage any residual impacts to the species	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Lathamus discolor	Swift Parrot	CE	E	ECS SCS	Collision mortality Inappropriate fire regimes Predation by feral cats	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land in the nominated areas and transport corridors As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and predation These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because this species is reliant on large mature trees, an additional specific mitigation measure has been identified to mitigate residual risks to this species	Yes
Limicola falcinellus	Broad-Billed Sandpiper	N/A	V	ECS	None	While the Plan has the potential to exacerbate several threats to the species, this is unlikely to result in indirect impacts to the species because there are no records of the species in the subregion and areas of habitat (as indicated by records) occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted	N/A
Limosa lapponica baueri	Bar-tailed Godwit	V Mig.	N/A	N/A	None	As discussed in the Migratory Species Impact Assessment – Chapter 32, there are no important habitat areas for the species which are at risk of indirect impacts from development under the Plan	N/A
Limosa limosa	Black-tailed Godwit	Mig.	V	ECS	None	As discussed in the Migratory Species Impact Assessment – Chapter 32, there are no important habitat areas for the species which are at risk of indirect impacts from development under the Plan	N/A

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Lophoictinia isura	Square-tailed kite	N/A	V	ECS SCS	Disturbance to or removal of potential nest trees near watercourses Secondary poisoning	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in WSA and GPEC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species. In particular, development controls to establish ecological setbacks between development and raptor nests These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because this species is reliant on mature trees for nesting and at risk from secondary poisoning, additional specific mitigation measures have been identified to mitigate residual risks to this species	Yes
Melanodryas cucullata cucullata	Hooded Robin (South-Eastern Form)	N/A	V	ECS	Weed invasion Inappropriate fire regimes	The Plan has the potential to exacerbate threats in areas of habitat for this species (as indicated by records) that occur adjacent to the urban capable land and transport corridors in the nominated areas. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The species is wide-ranging and records occur throughout the bioregion • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and inappropriate fire regimes. These measures are expected to manage any residual impacts to the species	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Melithreptus gularis gularis	Black-Chinned Honeyeater (Eastern subsp.)	N/A	V	ECS	Weed invasion Inappropriate fire regimes Removal of large trees	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because this species is reliant on large mature trees, an additional specific mitigation measure has been identified to mitigate residual risks to this species	Yes
Neophema pulchella	Turquoise Parrot	N/A	V	ECS	Loss of hollow-bearing trees hollows and critical habitat feature degradation Weed invasion Inappropriate fire regimes Predation by foxes and cats	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in each nominated area. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The species is wide-ranging and the subregion does not appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion, inappropriate fire regimes and predation. In addition, there is a specific measure in the Plan for some other species to retain large trees during precinct planning, which is likely to benefit the Turquoise Parrot. These measures are expected to manage any residual impacts to the species	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Ninox connivens	Barking Owl	N/A	V	ECS SCS	Removal of old, hollow-bearing trees	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in GPEC, Wilton and GMAC This species is reliant on mature trees and the specific measure in Table 15-21 to retain large trees may benefit the species to some extent, particularly in areas adjacent to large patches of potential habitat. This is expected to manage any residual impacts to the species	Yes
Ninox strenua	Powerful Owl	N/A	V	ECS SCS	Loss of hollow-bearing trees High frequency hazard reduction burning Predation of fledglings by foxes, dogs and cats	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in GPEC, Wilton and GMAC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and predation These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because this species is reliant on large mature trees, an additional specific mitigation measure has been identified to mitigate residual risks to this species	Yes
Numenius madagascariensis	Eastern Curlew, Far Eastern Curlew	CE Mig.	N/A	N/A	None	As discussed in the Migratory Species Impact Assessment – Chapter 32, there are no important habitat areas for the species which are at risk of indirect impacts from development under the Plan	N/A
Pandion cristatus	Eastern Osprey	N/A	V	ECS	None	While the Plan has the potential to exacerbate several threats to the species, this is unlikely to result in indirect impacts to the species because the species favours coastal areas and usually nests within 1 km of the coast. The majority of areas of habitat (as indicated by records) occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted	N/A

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Petroica boodang	Scarlet Robin	N/A	V	ECS	Weed invasion Predation by feral cats (*Felis catus*)	The Plan has the potential to exacerbate threats in areas of habitat for this species (as indicated by records) that occur adjacent to urban capable land and transport corridors in each nominated area. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur throughout the bioregion; the subregion does not appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and predation. These measures are expected to manage any residual impacts to the species	No
Petroica phoenicea	Flame Robin	N/A	V	ECS	Weed invasion	The Plan has the potential to increase weed invasion in areas of habitat for this species (as indicated by records) that occur adjacent to urban capable land and transport corridors in each nominated area. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur throughout the bioregion; the subregion does not appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion. These measures are expected to manage any residual impacts to the species	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Rostratula australis	Australian Painted Snipe	E	E	ECS	Loss or degradation of wetlands Predation by feral animals Vegetation changes caused by introduced plants Inappropriate fire regimes	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The species occurs elsewhere in the bioregion, with relatively few records in the subregion • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including impacts to hydrological processes, predation, weed invasion and inappropriate fire regimes. These measures are expected to manage any residual impacts to the species	No
Stagonopleura guttata	Diamond Firetail	N/A	V	ECS	Weed invasion	The Plan has the potential to increase weed invasion in areas of habitat for this species (as indicated by records) that occur adjacent to urban capable land and transport corridors in each nominated area. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur throughout the bioregion • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion. These measures are expected to manage any residual impacts to the species	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Stictonetta naevosa	Freckled Duck	N/A	V	ECS	Hydrological disturbance	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in WSA. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur elsewhere in the bioregion; there are very few recent records in the subregion • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including hydrological disturbance. These measures are expected to manage any residual impacts to the species	No
Tyto novaehollandiae	Masked Owl	N/A	V	ECS SCS	Loss of mature hollow-bearing trees	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas This species is reliant on mature trees and the specific measure in Table 15-21 to retain large trees may benefit the species to some extent, particularly in areas adjacent to large patches of potential habitat. This is expected to manage any residual impacts to the species	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
MAMMALS							
Cercartetus nanus	Eastern Pygmy-possum	N/A	V	SCS	Changed fire regimes that affect the abundance of flowering proteaceous and myrtaceous shrubs Predation from cats, dogs and foxes Road mortality	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and predation These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because this species is reliant on nectar and pollen from Proteaceae shrubs and at risk of predation from cats, additional specific mitigation measures have been identified to mitigate residual risks to this species	Yes
Chalinolobus dwyeri	Large-eared Pied Bat	V	V	SCS	Disturbance of roosts from human recreational activities Fire in the proximity of roosts	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land in the nominated areas and transport corridors. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The species occurs across the bioregion, the subregion does not appear to be a stronghold for the species • There are no known roost or breeding sites close to areas at risk of indirect impacts from the development As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including disturbance and increased fire risk. These measures are expected to manage any residual impacts to the species	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Dasyurus maculatus maculatus (SE mainland population)	Spot-tailed Quoll, Spotted-tailed Quoll	E	V	ECS	Competition and predation from introduced predators Road mortality Inappropriate fire regimes	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in GMAC, Wilton and the OSO transport corridor As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including road mortality and inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because this species is reliant on nectar and pollen from Proteaceae shrubs and at risk of predation from cats, additional specific mitigation measures have been identified to mitigate residual risks to this species	Yes
Falsistrellus tasmaniensis	Eastern False Pipistrelle	N/A	V	ECS	Loss of roosting habitat, primarily hollow-bearing eucalypts	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in Wilton and GMAC This species is reliant on mature trees, therefore a specific mitigation measure has been identified to mitigate potential residual impacts	Yes
Micronomus norfolkensis	Eastern Coastal Free-tailed Bat	N/A	V	ECS	Loss of hollow-bearing trees Artificial light sources spilling on to foraging and/or roosting habitat Hazard reduction burns on foraging and/or roosting habitat	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including light pollution and inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because this species is reliant on large mature trees for roosting and sensitive to disturbance, additional specific mitigation measures have been identified to mitigate residual risks to this species	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Miniopterus australis	Little Bent-winged Bat	N/A	V	ECS	Disturbance to and loss of known maternity and roost sites such as caves, and roosts within culverts, tunnels and under bridges Hazard reduction fires Predation from cats and foxes	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and predation These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because this species is reliant on large mature trees for roosting and sensitive to disturbance, additional specific mitigation measures have been identified to mitigate residual risks to this species	Yes
Miniopterus orianae oceanensis	Large Bent-winged Bat	N/A	V	ECS	Disturbance by general public accessing caves and adjacent areas Hazard reduction fires Predation by feral cats	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including disturbance, inappropriate fire regimes and predation These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because this species is reliant on large mature trees for roosting and sensitive to disturbance, additional specific mitigation measures have been identified to mitigate residual risks to this species	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Myotis macropus	Southern Myotis	N/A	V	SCS	Loss or disturbance of roosting sites Reduction in stream water quality	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including disturbance and impacts to hydrological processes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because this species is reliant on large mature trees for roosting and sensitive to disturbance, additional specific mitigation measures have been identified to mitigate residual risks to this species	Yes
Petauroides volans	Greater Glider	V	N/A	N/A	Inappropriate fire regimes Habitat loss or degradation from *Phytophthora* root fungus	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because roosting habitat for the species may be affected by *Phytophthora cinnamomi*, an additional specific mitigation measure has been identified to mitigate residual risks to this species	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Petaurus australis	Yellow-bellied Glider	N/A	V	ECS	Loss of hollow-bearing trees	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur elsewhere in the bioregion; there are very few recent records in the subregion • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development). There is a specific measure in the Plan for some other species to retain large trees during precinct planning, which is likely to benefit the Yellow-bellied Glider. These measures are expected to manage any residual impacts to the species	No
Petaurus norfolcensis	Squirrel Glider	N/A	V	SCS	Loss of hollow-bearing trees Inappropriate fire regimes Road mortality	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in GPEC, Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur elsewhere in the bioregion; there are very few recent records in the subregion • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and road mortality. In addition, there is a specific measure in the Plan for some other species to retain large trees during precinct planning, which is likely to benefit the Squirrel Glider. These measures are expected to manage any residual impacts to the species	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Phascolarctos cinereus	Koala	V	V	ECS SCS	Vehicle strike Effects of urban development including predation by dogs Disruption of connectivity Fire Disease (Chlamydiosis caused by infection with Chlamydia)	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in Wilton and GMAC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including road mortality, impacts from domestic animals and inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because the species is at risk from vehicle strike and loss of key habitat features additional specific mitigation measures have been identified to mitigate residual risks to this species (see section 15.6.4 and Chapter 30 for the full Koala impact assessment)	Yes
Pteropus poliocephalus	Grey-headed Flying-fox	V	V	ECS	Camp disturbance Loss of large trees for foraging and roosting	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas This species is reliant on large mature trees and sensitive to camp disturbance, therefore specific mitigation measures have been identified to mitigate residual risks to this species	Yes
Saccolaimus flaviventris	Yellow-bellied Sheathtail-bat	N/A	V	ECS	Disturbance to roosting and summer breeding sites Loss of hollow-bearing trees	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address indirect impacts This species is reliant on large mature trees for roosting and sensitive to disturbance, therefore additional specific mitigation measures have been identified to mitigate residual risks	Yes

Scoteanax rueppellii	Greater Broad-nosed Bat	N/A	V	ECS	Disturbance to roosting and summer breeding sites Loss of hollow-bearing trees	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in Wilton and GMAC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts This species is reliant on large mature trees for roosting and sensitive to disturbance, therefore additional specific mitigation measures have been identified to mitigate residual risks	Yes
REPTILES							
Hoplocephalus bungaroides	Broad-headed Snake	V	E	ECS	Bush rock removal Inappropriate fire regimes Predation by cats Road mortality	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because • There are no current records of the species in the Strategic Assessment Area, greater densities of records occur in surrounding areas, in particular to the south east of the subregion • The removal of bush rock in many reserves is prohibited and management plans for reserves typically include measures to control public access within reserves, which may reduce the risk of bush rock removal for the species As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and predation. These measures are expected to manage any residual impacts to the species	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Varanus rosenbergi	Rosenberg's Monitor	N/A	V	ECS	Removal of habitat elements, such as termite mounds and fallen timber Predation by cats and dogs	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to urban capable land and transport corridors in Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • There are no records of the species in the nominated areas and very few records in the subregion • Greater densities of records occur elsewhere in the bioregion • The species is considered unlikely to rely on the habitat at risk of indirect impacts for persistence in the subregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including predation. These measures are expected to manage any residual impacts to the species	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
AMPHIBIANS							
Heleioporus australiacus	Giant Burrowing Frog	V	V	SCS	Hydrological changes Inappropriate fire regimes Predation by foxes and cats Vehicle strike Infection with amphibian chytrid fungus	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • There are limited records of the species in the Strategic Assessment Area and a lack of suitable habitat in the subregion • Greater densities of records occur in surrounding areas, in particular to the south east of the subregion • The species does not appear to rely on the habitat at risk of indirect impacts for persistence in the subregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including impacts to hydrological processes, inappropriate fire regimes, predation and disease. These measures are expected to manage any residual impacts to the species	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Litoria aurea	Green and Golden Bell Frog	V	E	SCS	Changes to the structure and diversity of aquatic vegetation Changes to hydrology and water quality Intensification of public access to habitat Predation cats Inappropriate fire regimes Infection with amphibian *chytrid* fungus	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the OSO transport corridor in GPEC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including impacts to hydrological processes and predation These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because the population associated with Ropes Creek corridor is on the edge of the western range for the species and could be potentially impacted by development under the Plan, therefore species-specific commitments are required to address potential residual impacts	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Pseudophryne australis	Red-crowned Toadlet	N/A	V	SCS	Changes to hydrology and pollution/ degradation of water quality Inappropriate fire regimes Habitat degradation through four-wheel driving and trail bikes Bush rock removal	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • Records occur throughout the bioregion and the subregion does not appear to be a stronghold for the species • The species does not appear to rely on the habitat at risk of indirect impacts for persistence in the subregion • The removal of bush rock in many reserves is prohibited and management plans for reserves typically include measures to control public access within reserves, which may reduce the risk of bush rock removal for the species As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including impacts to hydrological processes, and inappropriate fire regimes. These measures are expected to manage potential residual impacts	No
INVERTEBRATES							
Meridolum corneovirens	Cumberland Plain Land Snail	N/A	E	SCS	Weed invasion Inappropriate fire regimes Removal of fallen logs for firewood Loss of ground shelter habitat by slashing Ground subsidence	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in each nominated area As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because the species is restricted to the subregion, additional species-specific commitments are required to address potential residual impacts and to support critical actions for the species under the Saving our Species program	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Pommerhelix duralensis	Dural Land Snail	E	E	N/A	Inappropriate fire regimes Disturbance due to weed control activities	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in WSA and GPEC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • There are no records close to urban capable land or transport corridors, or in areas at risk of indirect impacts from development • The species does not appear to rely on the habitat at risk of indirect impacts for persistence in the subregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and disturbance from weed control activities. These measures are expected to manage potential residual impacts	No
FISH							
Macquaria australasica	Macquarie Perch	E	N/A	N/A	Hydrological changes Degradation caused by bushfires Recreational fishing	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur in Erskine Creek, Glenbrook Creek, Georges River and Cordeaux River As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including impacts to hydrological processes and inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because recreational fishing is identified as a threat to the species, additional species-specific commitments are required to address potential residual impacts	Yes

15.7.2 FLORA

Table 15-19: Assessment of indirect impacts – flora

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Acacia bynoeana	Bynoe's Wattle, Tiny Wattle	V	E	SCS	Inappropriate habitat disturbance Weed invasion Inappropriate fire regimes	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GMAC and Wilton. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of records occur away from urban capable land and transport corridors • Some habitat for the species is subject to approval conditions to protect and manage it from indirect impacts, under an existing EPBC Act approval in the Bingara area. As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and weed invasion. These measures are expected to manage potential residual impacts	No
Acacia pubescens	Downy Wattle, Hairy Stemmed Wattle	V	V	SCS	Weed invasion Habitat disturbance through illegal track creation and maintenance activities Inappropriate fire regimes	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in the nominated areas and transport corridors outside the nominated areas. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of records occur away from urban capable land and transport corridors • The species does not appear to rely on the habitat at risk of indirect impacts for persistence in the subregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion, disturbance and inappropriate fire regimes. These measures are expected to manage potential residual impacts	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Allocasuarina glareicola		E	E	SCS	Habitat degradation from increased public access Inappropriate fire regimes Weed invasion	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GPEC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of records and potential habitat occur away from urban capable land and transport corridors • Several areas of potential habitat and records are managed in existing conservation reserves As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including habitat degradation, inappropriate fire regimes and weed invasion. These measures are expected to manage potential residual impacts	No
Commersonia prostrata	Dwarf Kerrawang	E	E	N/A	None	While the Plan has the potential to exacerbate some threats to the species, this is unlikely to result in indirect impacts to the species because the majority of areas of habitat occur some distance away from the urban capable land and transport corridors and away from associated areas that could be impacted	N/A
Cynanchum elegans	White-flowered Wax Plant	E	E	N/A	Degradation of habitat due to weed invasion, grazing and inappropriate fire management Hydrological disturbance	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur near to the OSO transport corridor near Cobbitty, south of WSA As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because an important population occurs close to the OSO transport corridor, additional species-specific commitments are required to address potential residual impacts	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Deyeuxia appressa		E	E	N/A	None	While the Plan has the potential to exacerbate some threats to the species, this is unlikely to result in indirect impacts to the species because all three records of the species (if extant) and potential habitat occur outside the Strategic Assessment Area and some distance from the urban capable land and transport corridors and transport corridors and away from associated areas that could be impacted	N/A
Dillwynia tenuifolia		N/A	V	SCS	Inappropriate fire regimes Disturbance from human activity such as rubbish dumping and uncontrolled vehicular access Weed invasion	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in WSA and GPEC. As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion, disturbance and inappropriate fire regimes These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, the subregion is a key location for the species and records and potential habitat occurs close to urban capable land and transport corridors, additional species-specific commitments are required to address potential residual impacts	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Epacris purpurascens var. *purpurascens*		N/A	V	SCS	Urban run-off Inappropriate fire regimes Disturbance from human activity such as rubbish dumping, trampling and uncontrolled vehicular access Weed invasion	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of the records in the subregion occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion or subregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including impacts to hydrological processes, disturbance, inappropriate fire regimes and weed invasion. These measures are expected to manage potential residual impacts	No
Eucalyptus benthamii	Camden White Gum, Nepean River Gum	V	V	SCS	Inappropriate fire regimes Changed hydrology Weed invasion Myrtle rust Ground subsidence	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to GPEC, GMAC and the OSO transport corridor As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes, impacts to hydrological processes, weed invasion and spread of disease These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, the species has been identified as being at risk from indirect impacts from the OSO tunnel, and additional specific measures are required to address potential residual impacts	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Genoplesium baueri	Yellow Gnat-orchid	E	E	N/A	Habitat disturbance from recreational use, rubbish dumping, and nearby urban areas	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GMAC There are very few records of this species in the subregion, however, a population (no. 21) occurs close to the urban capable land in GMAC and an additional species-specific commitment is required to address potential residual impacts in this location	Yes
Grevillea juniperina subsp. *juniperina*	Juniper-leaved Grevillea	N/A	V	SCS	Inappropriate fire regimes Disturbance from human activity such as rubbish dumping, trampling and increased fire risk Weed invasion	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in WSA and GPEC. As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and weed invasion These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, the subregion is a key location for the species, records and potential habitat occur close to urban capable land and transport corridors, so additional species-specific commitments are required to address potential residual impacts	Yes
Grevillea parviflora subsp. *parviflora*	Small-flower Grevillea	V	V	SCS	Road maintenance Weed invasion Habitat disturbance from recreational activities and rubbish dumping Inappropriate fire regimes	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur near to the urban capable land and transport corridors in Wilton As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and weed invasion. In addition, some habitat for the species is subject to approval conditions to protect and manage it from indirect impacts, under an existing EPBC Act referral (EPBC 2014/7400) in the Bingara area These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because an important population occurs close to the urban capable land in Wilton, additional species-specific commitments are required to address potential residual impacts in that location	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Hibbertia fumana		N/A	CE	SCS	Inappropriate fire regimes Weed invasion Habitat disturbance from uncontrolled movement of vehicles	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in Wilton and GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of the records in the subregion occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted • A large number of records occur in protected areas in Moorebank to the north of GMAC, which is a proposed priority management site under the NSW Saving our Species strategy • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion or subregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes, weed invasion and disturbance. These measures are expected to manage potential residual impacts	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Hibbertia puberula		N/A	E	SCS	Weed invasion Disturbance from human activity such as from trailbikes, 4WDs and mountain bikes	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GPEC, in particular the northern boundary adjacent to Shanes Park. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of the records in the subregion occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted • A large number of records occur in protected areas in Moorebank to the north of GMAC, which is a proposed priority management site under the NSW Saving our Species strategy • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion or subregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and disturbance. These measures are expected to manage potential residual impacts	No
Hibbertia puberula subsp. *glabrescens*		CE	N/A	N/A	None	While the Plan has the potential to exacerbate some threats to the species, this is unlikely to result in indirect impacts to the species because the species is only known from one location outside the Strategic Assessment Area in Bankstown, some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted	N/A

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Leucopogon exolasius	Woronora Beard-heath	V	V	N/A	Inappropriate fire regimes Weed invasion	The Plan has the potential to exacerbate some threats in areas of habitat for this species that occur adjacent to GMAC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of the records in the subregion occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion or subregion • The populations nearest to the nominated area have been classified as non-important populations As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and weed invasion. These measures are expected to manage potential residual impacts	No
Marsdenia viridiflora subsp. *viridiflora*		N/A	E	SCS	Stochastic events (e.g. fire) due to small population size	The Plan has the potential to exacerbate some threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GMAC, WSA and GPEC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including undertaking bushfire reduction measures close to the urban capable land, which is likely to reduce the likelihood of stochastic events such as wildfires affecting the species	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Maundia triglochinoides		N/A	V	SCS	Hydrological changes Weed invasion	The Plan has the potential to exacerbate some threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GMAC and WSA. As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including impacts to hydrological processes and weed invasion	No
Melaleuca deanei	Deane's Melaleuca	V	V	SCS	Inappropriate fire regimes and mechanical methods of bushfire removal Inappropriate habitat disturbance from construction and maintenance of tracks and easements, unrestricted access and rubbish dumping Weed invasion	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in Wilton and GMAC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and weed invasion. However, because the species is sensitive to inappropriate habitat disturbance from construction and maintenance of tracks and easements, unrestricted access and rubbish dumping, an additional species-specific commitment is required to address potential residual impacts	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Micromyrtus minutiflora		V	E	SCS	Inappropriate fire regimes Weed invasion Habitat degradation through arson, grazing, trail bike riding, and rubbish dumping	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GPEC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of the records in the subregion occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion or subregion • Many records occur in existing conservation reserves in the north of the subregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes, weed invasion and disturbance. These measures are expected to manage potential residual impacts	No
Persicaria elatior	Tall Knotweed	V	V	SCS	Hydrological changes Inappropriate habitat disturbance, such as through road, track and trail maintenance Weed invasion	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to GMAC, WSA, GPEC and transport corridors. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The majority of the records in the subregion are protected in an existing conservation reserve some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion or subregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including impacts to hydrological processes, disturbance and weed invasion. These measures are expected to manage potential residual impacts	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Persoonia bargoensis	Bargo Geebung	V	E	SCS	Inappropriate fire regimes and fire maintenance activities Inappropriate habitat disturbance Infection by *Phytophthora cinnamomi*	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur near to the urban capable land and transport corridors in Wilton and GMAC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and weed invasion. In addition, some habitat for the species is subject to approval conditions to protect and manage it from indirect impacts, under an existing EPBC Act referral (EPBC 2014/7400) in the Bingara area These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because the species is sensitive to inappropriate fire regimes, disturbance from habitat maintenance and at risk from *Phytophthora cinnamomi*, additional species-specific commitments are required to address potential residual impacts	Yes
Persoonia glaucescens	Mittagong Geebung	V	E	N/A	None	While the Plan has the potential to exacerbate some threats to the species, this is unlikely to result in indirect impacts to the species because the records and majority of areas of habitat occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted	N/A
Persoonia hirsuta	Hairy Geebung, Hairy Persoonia	E	E	N/A	Inappropriate fire regimes Disturbance from recreational users Altered hydrology Weed invasion Infection by *Phytophthora cinnamomi*	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to all nominated areas and the OSO transport corridor As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes, altered hydrology and weed invasion. In addition, all known populations are on privately owned land which reduces the risk of disturbance from recreational users These measures are expected to address potential indirect impacts from development under the Plan on this species, and are expected to manage potential residual impacts	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Persoonia nutans	Nodding Geebung	E	E	SCS	Inappropriate fire regimes Habitat degradation and rubbish dumping related to unrestricted access Infection by root-rot fungus *Phytophthora cinnamomi* Weed invasion	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur near to the urban capable land and transport corridors in WSA and GPEC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and weed invasion These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, because an important population and potential habitat occur close to the OSO transport corridor within Wianamatta Regional Park in GPEC, additional specific measures are required to address potential residual impacts in that area	Yes
Pimelea curviflora var. *curviflora*		V	V	SCS	Weed invasion Habitat degradation from recreational activities, road and trail maintenance, and bush rock removal Inappropriate fire regimes	The Plan has the potential to exacerbate threats in areas of habitat for this species (as indicated by records) that occur adjacent to the urban capable land and transport corridors in GMAC, Wilton and GPEC. Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The species occurs elsewhere in the bioregion • The majority of the records in the subregion occur some distance away from the urban capable land and transport corridors, and away from associated areas that could be impacted • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion or subregion • Many records are protected in existing conservation reserves As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes, disturbance and weed invasion. These measures are expected to manage potential residual impacts	No

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Pimelea spicata	Spiked Rice-flower	E	E	SCS	Illegal dumping of rubbish and garden waste Weed invasion and competition High frequency land-use/management activities Inappropriate fire regimes Hydrological disturbance Ground subsidence	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur near to the urban capable land and transport corridors in all nominated areas and transport corridors outside the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes, impacts to hydrological processes and weed invasion These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, the species has been identified as being at risk from human disturbance and indirect impacts from the OSO tunnel, so additional specific measures are required to address potential residual impacts	Yes
Pomaderris brunnea	Rufous Pomaderris	V	E	SCS	Weed invasion Disturbance from trampling and recreational vehicle use Stormwater run-off Altered fire regimes Ground subsidence	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GMAC and Wilton and transport corridors outside the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes, impacts to hydrological processes and weed invasion These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, the species has been identified as being at risk from indirect impacts from the OSO tunnel, and additional specific measures are required to address potential residual impacts	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Pterostylis saxicola	Sydney Plains Greenhood	E	E	SCS	Weed invasion Inappropriate fire regimes Inappropriate habitat disturbance Unrestricted access	The Plan has the potential to exacerbate in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GPEC, GMAC and Wilton Should this occur, the consequence for the persistence of the species in the bioregion is likely to be minor because: • The species is cryptic and hard to identify • The species does not appear to rely on the habitat at risk of indirect impacts from the development for persistence in the bioregion As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including weed invasion and inappropriate fire regimes. However, the species has been identified as being at risk from indirect impacts associated with habitat disturbance, and additional specific measures are required to address potential residual impacts	Yes
Pultenaea parviflora		V	E	SCS	Inappropriate habitat disturbance from uncontrolled vehicle access and rubbish dumping Inappropriate fire regimes Weed invasion	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GPEC and WSA As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and weed invasion These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, the subregion is a key location for the species, records and potential habitat occur close to urban capable land and transport corridors, so additional species-specific commitments are required to address potential residual impacts	Yes

Scientific name	Common name	Cth status	NSW status	BAM species type	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Pultenaea pedunculata	Matted Bush-pea	N/A	E	SCS	Inappropriate fire regimes Disturbance from human activity Weed invasion	The Plan has the potential to exacerbate threats in areas of habitat for this species that occur adjacent to the urban capable land and transport corridors in GMAC As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this species, including inappropriate fire regimes and weed invasion These measures are expected to address the majority of potential indirect impacts from development under the Plan on this species. However, the subregion is a key location for the species, records and potential habitat occur close to urban capable land in GMAC, so additional species-specific commitments are required to address potential residual impacts	Yes

15.7.3 THREATENED ECOLOGICAL COMMUNITIES

Table 15-20: Assessment of indirect impacts – TECs

Cth TEC name	NSW TEC name	Cth status	NSW status	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Castlereagh Scribbly Gum and Agnes Banks Woodlands of the Sydney Basin Bioregion	*Castlereagh Scribbly Gum Woodland in the Sydney Basin Bioregion*	E	V	Inappropriate fire regimes Weed invasion Invasive fauna Diseases, pathogens and dieback Damage caused by human disturbance	While areas of mapped TEC occur some distance from the urban capable land and transport corridors, the Plan has the potential to exacerbate several threats to the TEC. As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this TEC. These measures are expected to manage any residual impacts to the TEC	No
Coastal floodplain eucalypt forest of eastern Australia (previously referred to as *River-flat Eucalypt Forest on Coastal Floodplains of New South Wales*)	*River-flat Eucalypt Forest on Coastal Floodplains of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions*	FPAL	E	Inappropriate fire regimes Weed invasion Changes to hydrology Invasive fauna Diseases, pathogens and dieback Damage caused by human disturbance Ground subsidence	The Plan has the potential to exacerbate threats in areas of the TEC that occur adjacent to the urban capable land in the nominated areas and in the transport corridors As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this TEC These measures are expected to address the majority of potential indirect impacts from development under the Plan on this TEC. However, because the TEC is at risk from dieback caused by *Phytophthora cinnamomi*, an additional specific mitigation measure has been identified to mitigate residual risks	Yes

Cth TEC name	NSW TEC name	Cth status	NSW status	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland ecological community	*Swamp Oak Floodplain Forest of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions*	E	E	Inappropriate fire regimes Weed invasion Inappropriate habitat disturbance Changes to hydrology Diseases, pathogens and dieback Invasive fauna	The Plan has the potential to exacerbate threats in areas of the TEC that occur adjacent to the urban capable land and transport corridors in WSA and GPEC. As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this TEC These measures are expected to address the majority of potential indirect impacts from development under the Plan on this TEC. However, because the TEC is at risk from dieback caused by *Phytophthora cinnamomi*, an additional specific mitigation measure has been identified to mitigate residual risks	Yes
Cooks River/Castlereagh Ironbark Forest of the Sydney Basin Bioregion	*Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion*	CE	E	Inappropriate fire regimes Weed invasion Inappropriate habitat disturbance Changes to hydrology Diseases, pathogens and dieback Invasive fauna	The Plan has the potential to exacerbate threats in areas of the TEC that occur adjacent to urban capable land and transport corridors in WSA and GPEC. As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this TEC These measures are expected to address the majority of potential indirect impacts from development under the Plan on this TEC. However, because the TEC is at risk from dieback caused by *Phytophthora cinnamomi*, an additional specific mitigation measure has been identified to mitigate residual risks. In addition, there is a TEC-specific commitment to undertake all control measures in line with the *Best Practice Guidelines: Cooks River/Castlereagh Ironbark Forest* and *Recovering Bushland on the Cumberland Plain: best practice guidelines on the management and restoration of bushland*	Yes

Cth TEC name	NSW TEC name	Cth status	NSW status	Key relevant indirect impacts / threats	Assessment of indirect impacts	Residual impacts
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest		CE		Inappropriate fire regimes Weed invasion Inappropriate habitat disturbance Changes to hydrology Diseases, pathogens and dieback Invasive fauna Ground subsidence	The Plan has the potential to exacerbate threats in areas of the TEC that occur adjacent to the urban capable land in the nominated areas and transport corridors As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this TEC These measures are expected to address the majority of potential indirect impacts from development under the Plan on this TEC. However, because the TEC is at risk from dieback caused by *Phytophthora cinnamomi*, an additional specific mitigation measure has been identified to mitigate residual risks	Yes
	Cumberland Plain Woodland in the Sydney Basin Bioregion		CE	Inappropriate fire regimes Weed invasion Inappropriate habitat disturbance Changes to hydrology Diseases, pathogens and dieback Invasive fauna Ground subsidence	The Plan has the potential to exacerbate threats in areas of the TEC that occur adjacent to the urban capable land in the nominated areas and transport corridors inside and outside the nominated areas As described in section 15.6, mitigation measures will be implemented through development controls (for urban, industrial and agribusiness development) or future environmental assessment processes (for transport and infrastructure development) that will address relevant indirect impacts to this TEC These measures are expected to address the majority of potential indirect impacts from development under the Plan on this TEC. These measures are expected to manage any residual impacts to the TEC	No

15.8 ADDITIONAL SPECIFIC MITIGATION TO ADDRESS RESIDUAL RISKS

This section identifies additional specific mitigation measures considered necessary to address residual risks from the potential indirect impacts of the urban, industrial, infrastructure, agribusiness and transport development on Commonwealth and NSW-listed TECs and species, and other EPBC Act protected matters.

These mitigation measures are provided in Appendix E of the Plan, and are incorporated into several commitments and actions under the Plan. The measures will be implemented as described above in section 15.6 though either:

- The draft DCP template
- An environmental impact assess process (for infrastructure and transport development)
- An action under the Plan

These additional mitigation measures, along with the package of relevant commitments in the Plan (see section 15.6) are considered to adequately address residual risks to each of these matters.

15.8.1 FAUNA

The specific mitigation measures to address residual risks to flora are provided in Table 15-21.

Table 15-21: Specific mitigation measures to address residual risks – fauna

Relevant impact	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
HABITAT FEATURES AND CONNECTIVITY						
Urban and industrial, infrastructure, agribusiness	Retain large trees (including dead trees) (≥50cm DBH) during precinct planning where possible and avoid impacts to soil within the dripline of these trees during construction	Large trees within urban landscapes are likely to be important for the persistence of several species within the subregion. Microbats benefit directly through roosting opportunities and indirectly through foraging opportunities. Flying-foxes and nectivorous birds benefit directly through foraging opportunities (high volumes of nectar). Owls and raptors benefit indirectly through large trees providing habitat for prey species	**Microbats:** Southern Myotis, Little Bent-winged Bat, Eastern Coastal Free-tailed Bat, Large Bent-winged Bat, Yellow-bellied Sheathtail-bat, Eastern False Pipistrelle, Greater Broad-nosed Bat **Flying-foxes and nectivorous birds:** Grey-headed Flying-fox, Regent Honeyeater, Swift Parrot, Little Lorikeet, Painted Honeyeater, and Black-chinned Honeyeater **Owls and raptors:** Barking Owl, Powerful Owl, Masked Owl, Little Eagle, White-bellied Sea Eagle, Square-tailed Kite, Spotted Harrier	All nominated areas	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations and communities to best practice standards	DCP EIA process for infrastructure

Relevant impact	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
Urban and industrial, infrastructure, agribusiness	Retain areas of high density proteaceae shrubs where possible, particularly along riparian corridors	Proteaceae shrubs such as banksias are a favoured foraging resource for the species and the species is likely to use riparian corridors as habitat or for movement between other areas of suitable habitat	Eastern Pygmy-possum	All nominated areas	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations and communities to best practice standards	DCP EIA process for infrastructure
Urban and industrial, infrastructure	If Green and Golden Bell Frog is confirmed present along Ropes Creek, consult with land managers of the riparian corridor to ensure key habitat features are protected and enhanced	Aims to protect an important population of the species (if confirmed present) at Ropes Creek in GPEC	Green and Golden Bell Frog	GPEC (mapped potential habitat along Ropes Creek)	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations and communities to best practice standards	N/A
Urban and industrial, infrastructure, agribusiness	Undertake pre-construction surveys prior to removal or disturbance (seasonally dependent, before torpor) to human made structures to ensure any roosting habitat for microbat species including mine shafts, storm water tunnels, old or derelict buildings, bridges and culverts are retained where possible	Minimises the potential impacts of urban development to human-made structures that may be used by microbats for roosting or breeding	Eastern Coastal Free-tailed Bat Little Bent-winged Bat Large Bent-winged Bat Southern Myotis Yellow-Bellied Sheathtail-Bat	All nominated areas	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations and communities to best practice standards	DCP EIA process for infrastructure
Transport corridors	Incorporate artificial breeding and roosting habitat (e.g. bat boxes, structural cavities) in the design of bridges associated with the transport corridors in accordance with relevant	Minimises the potential impacts of the transport corridors to human-made structures that may be used by microbats for roosting or breeding	Eastern Coastal Free-tailed bat Large Bent-winged Bat Southern Myotis Yellow-Bellied Sheathtail-	All transport corridors within and outside nominated areas	Commitment 6: Mitigate indirect and prescribed impacts on threatened species from major infrastructure	EIA process for transport

Relevant impact	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
	guidelines or standards		bat		(transport) development on threatened species and their habitat	
PEST/DOMESTIC ANIMALS						
Urban and industrial, infrastructure, agribusiness	Modify pest control techniques implemented during construction and operation of the development and under the pest control strategy to reduce the risk of secondary poisoning (e.g. from Pindone or second-generation rodenticides)	There is a risk of pest control measures causing secondary poisoning of raptors	White-bellied Sea-Eagle Little Eagle Square-tailed kite Spotted Harrier	All nominated areas	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations and communities to best practice standards	DCP EIA process for infrastructure
				SCAs	Commitment 17: Manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the strategic conservation area	Pest control strategy
Urban and industrial, infrastructure	Where permitted and appropriate, contain domestic cats and dogs in new residential areas during operation of the development at the urban/bushland interface consistent with relevant Council guidelines	Increased numbers of domestic cats and dogs associated with urban development increases the threat of predation to native animals	Eastern Pygmy-possum Spotted-tailed Quoll	Wilton GMAC	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations and communities to best practice standards	DCP

Relevant impact	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
HUMAN DISTURBANCE						
Urban and industrial, infrastructure, agribusiness	Establish minimum setbacks for urban development around flying fox camps	Minimises disturbance to known populations	Grey-headed Flying-fox	All nominated areas	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations and communities to best practice standards	DCP
Urban and industrial, infrastructure, agribusiness	Consult with relevant resource managers to consider: • Prohibiting recreational fishing along the stretches of habitat associated with Erskine Creek, Glenbrook Creek, Georges River and Cordeaux River known to support the species • Installing signs/interpretive displays at appropriate sites used to access fishing locations at Erskine Creek, Glenbrook Creek, Georges River and Cordeaux River to assist with identification and awareness of threats	Minimises the risk of increased recreational fishing affecting the species due to larger urban populations associated with urban development	Macquarie Perch	Erskine Creek Glenbrook Creek Georges River Cordeaux River	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations and communities to best practice standards	N/A

Relevant impact	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
DISEASE						
Urban and industrial, infrastructure	If Green and Golden Bell Frog is confirmed present along Ropes Creek, incorporate best practice site hygiene protocols to manage the potential spread of chytrid fungus	Minimises the risk of the spread of chytrid fungus due to construction activities within potential habitat for the species	Green and Golden Bell Frog	GPEC (mapped potential habitat along Ropes Creek)	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations and communities to best practice standards	DCP EIA process for infrastructure
Transport corridors				OSO within GPEC (mapped potential habitat along Ropes Creek)	Commitment 6: Mitigate indirect and prescribed impacts on threatened species from major infrastructure (transport) development on threatened species and their habitat	EIA process for transport
Urban and industrial, infrastructure, agribusiness	Incorporate best practice site hygiene protocols to manage the potential spread of pathogens, such as *Phytophthora* and Myrtle Rust within or adjacent to potential habitat for relevant species	Minimises the risk of the spread of pathogens due to construction activities adjacent to potential habitat for the species	Greater Glider	All nominated areas All transport corridors within and outside nominated areas	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations and communities to best practice standards	DCP EIA process for infrastructure
Transport corridors					Commitment 6: Mitigate indirect and prescribed impacts on threatened species from major infrastructure (transport) development on	EIA process for transport

Relevant impact	Mitigation measure	Rationale for measure	Relevant species	General location of measure	Relevant commitment	Implementation mechanism
					threatened species and their habitat	
OTHER						
Urban and industrial, infrastructure, agribusiness	Consult with relevant land managers to implement critical actions for Cumberland Plain Land Snail under the Save our Species program (EES, 2020) on public land adjacent to urban development during construction and operation of the development, taking into account relevant guidance in the Weed Control Implementation Strategy and the Fire Management Strategy	Minimises indirect impacts and supports maintenance of known populations adjacent to urban capable land	Cumberland Plain Land Snail	All nominated areas	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations and communities to best practice standards	N/A
Urban and industrial, infrastructure, agribusiness development	Implement 'open structure design' when designing structures such as roads adjacent to known populations of Cumberland Plain Land Snail where possible, consistent with the critical actions for this species under the Save our Species program (EES, 2020)	Development in the nominated areas may isolate patches of habitat. This action is consistent with a critical action for this species under the Save our Species program (EES, 2020)	Cumberland Plain Land Snail	All nominated areas	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations and communities to best practice standards	DCP

15.8.2 FLORA

The specific measures to address residual risks to flora are provided in Table 15-22.

Table 15-22: Specific mitigation measures to address residual risks – flora

15.8.4 OTHER PROTECTED MATTERS

The specific measure to address residual risks to other EPBC Act protected matters (Commonwealth land) is provided in Table 15-24.

A detailed assessment of potential indirect impacts relevant to Commonwealth land is provided in Chapter 35.

Table 15-24: Specific mitigation measures to address residual risks – other protected matters

Relevant impact	Mitigation measure	Rationale for measure	Key relevant protected matter	General location of measure	Relevant commitment	Implementation mechanism
Urban and industrial, infrastructure, agribusiness	Ensure development adjacent to the southern and western boundaries of Commonwealth land comprising the Orchard Hills Defence Establishment mitigates impacts to surface water flows and the water quality of Blaxland Creek	Minimises the risk of indirect impacts from hydrological disturbance on an important waterway on Commonwealth land that occurs adjacent to urban development	Commonwealth land	Orchard Hills Defence Establishment	Commitment 5: Mitigate indirect and prescribed impacts on threatened species, populations and communities to best practice standards	DCP EIA process for infrastructure

15.9 ANALYSIS OF THREAT ABATEMENT PLANS

15.9.1 INTRODUCTION

Under the EPBC Act, the impact assessment should address whether the actions under the Plan are inconsistent with any approved Threat Abatement Plans (TAPs).

TAPs have been developed under the EPBC Act to address listed KTPs and include actions to reduce their impact on threatened species and TECs.

There are seven TAPs which address KTPs that are potentially relevant to the Plan, which are discussed below.

15.9.2 THREAT ABATEMENT PLAN FOR COMPETITION AND LAND DEGRADATION BY UNMANAGED GOATS

The goal of this is TAP is to minimise the impact of competition and land degradation by unmanaged goats (*Capra hircus*) on biodiversity. Unmanaged goats are free-living and not owned, identified, restrained or managed. Unmanaged goats can affect threatened species and TECs by:

- Grazing on threatened native vegetation and therefore preventing regeneration
- Overgrazing and causing soil erosion
- Competing with threatened fauna species for food and shelter
- Introducing weeds through seeds carried in their dung
- Polluting watercourses (DEWHA, 2008)

OBJECTIVES AND ACTIONS UNDER THE TAP

The TAP sets out five objectives to achieve the goal, they are:

- Prevent unmanaged goats occupying new areas and eradicate them from high conservation-value 'islands'
- Promote the maintenance and recovery of native species and ecological communities that are affected by competition and land degradation by unmanaged goats
- Improve knowledge and understanding of unmanaged goat impacts and interactions with other species and ecological processes
- Improve the effectiveness, target specificity and humaneness of control options for unmanaged goats
- Increase awareness of all stakeholders of the objectives and actions of the TAP, and of the need to control unmanaged goats (DEWHA, 2008)

A set of actions accompanies each objective to help achieve the goal of the TAP. There are four actions to prevent unmanaged goats occupying new areas. These relate to collating data on areas of high conservation value, and developing and implementing management plans for these areas.

There are three actions to promote the maintenance and recovery of native species and ecological communities that are affected by this threat. These relate to identifying priority areas to control unmanaged goats, and conducting and monitoring goat control.

There are four actions to improve knowledge and understanding of unmanaged goat impacts and interactions. These relate to developing methods for assessing and monitoring the impact of unmanaged goats, and improving knowledge of interactions between unmanaged goats and other key species.

There are seven actions to improve the control options for unmanaged goats. These relate to investigating ways to improve control methods and programs including:

- Improving self-mustering trap systems
- Assessing goat toxins for undesirable side effects
- Testing exclusion fence designs
- Developing training programs to help land managers
- Promoting the adoption and adaptation of the model codes of practice

There are two actions to increase awareness of stakeholders of the objectives and actions of the TAP which relate to the promotion of the objectives and actions in the TAP.

Relevance of the TAP to the Plan

There is little information to suggest that unmanaged goats are a problem in the Strategic Assessment Area and there are no activities under the Plan which are likely to lead to the introduction of unmanaged goats in the area.

The Plan has the potential to exacerbate the threat of goats to some extent, and includes a commitment to manage priority pest animals in strategic locations in the Cumberland Subregion to reduce threats to land within the SCAs.

Consistency with the TAP

The Plan is not inconsistent with the TAP on the basis that:

- The Plan will not prevent any of the actions of the TAP from being implemented
- The measures under the Plan are consistent with the intent behind the actions to deliver on Objective 2, to "promote the maintenance and recovery of native species and ecological communities that are affected by competition and land degradation by unmanaged goats"

15.9.3 THREAT ABATEMENT PLAN FOR COMPETITION AND LAND DEGRADATION BY RABBITS

The goal of this TAP is to minimise the impact of competition and land degradation by rabbits (*Oryctolagus cuniculus*) on biodiversity. Rabbits are abundant in Australia and cause damage to native flora and fauna, vegetation communities and crops. Rabbits can affect threatened species and TECs by:

- Grazing on threatened native vegetation and therefore preventing regeneration
- Competing with threatened fauna species for food and shelter
- Reversing the normal processes of plant succession
- Altering ecological communities and changing soil structure and nutrient cycling, leading to significant erosion
- Removal of critical habitat for arboreal mammals and birds, leading to increased predation
- Supporting elevated population densities of pest predators such as foxes and feral cats
- Promoting growth of introduced and unpalatable species such as weeds (DoEE, 2016a)

Objectives and actions under the TAP

The TAP sets out four objectives to achieve the goal, they are:

- Strategically manage rabbits at the landscape scale and suppress rabbit populations to densities below threshold levels in identified priority areas
- Improve knowledge and understanding of the impact of rabbits and their interactions with other species and ecological processes
- Improve the effectiveness of rabbit control programs
- Increase engagement of the community of the environmental impacts of rabbits and the need for integrated control

A set of actions have been identified to achieve the objectives of the TAP. There are five actions to support the strategic management of rabbits at a landscape scale. These relate to identifying priority areas for rabbit control on a regional scale, coordinating efforts across all land tenures such as private land and urban areas, and developing regular monitoring and reporting mechanisms to track progress.

There are three actions to improve knowledge and understanding of the impact of rabbits. These relate to further investigating the interaction of rabbits with other species and threats to improve rabbit control measures.

There are eight actions to improve the effectiveness of rabbit control programs through further research.

There are four actions to increase communication with stakeholders around the impacts caused by rabbits. These relate to developing training programs for land managers, promoting and seeking engagement from all people in the community and promoting adoption of model codes of practice for rabbit control (DoEE, 2016a).

Relevance of the TAP to the Plan

There is no likelihood of national rabbit eradication, so rabbit control is an ongoing issue across Australia. Current rabbit control programs focus on long-term management and suppression of rabbit populations.

The Plan has the potential to exacerbate the threat of rabbits to some extent, and includes a commitment to manage priority pest animals in strategic locations in the Cumberland Subregion to reduce threats to land within the SCAs.

Consistency with the TAP

The Plan is not inconsistent with the TAP on the basis that:

- The Plan will not prevent any of the actions of the TAP from being implemented
- The measures under the Plan are consistent with the intent behind the actions to deliver on Objective 1, to "strategically manage rabbits at the landscape scale and suppress rabbit populations to densities below threshold levels in identified priority areas"

15.9.4 Threat abatement plan for disease in natural ecosystems caused by *Phytophthora cinnamomi*

The goal of this TAP is to minimise the impacts of Phytophthora on EPBC-listed threatened species, TECs and MNES. The TAP applies to *Phytophthora cinnamomi*, however, other species of *Phytophthora* can also be found in Australia and may benefit from the same controls.

Phytophthora cinnamomi (Phytophthora) is a soil-borne plant pathogen, infection in plants can result in:

- Inability of infected plants to develop new shoots, flowers, fruit and seed
- Extinction of populations of some flora species
- A dramatic modification of the native plant community's structure and composition
- A significant reduction in primary productivity and functionality
- Habitat loss and degradation of dependent flora and fauna
- Local extinction and a significant loss of genetic diversity
- Major declines in some animal species due to the loss of shelter and nesting sites or food (DoEE, 2018b)

Objectives and actions under the TAP

The TAP sets out four objectives to achieve the goal, they are:

- Identify and prioritise for protection biodiversity assets that are, or may be, impacted by Phytophthora. Prioritised biodiversity assets may include:
    - Listed threatened species and ecological communities
    - Areas where there is potential for Phytophthora to cause unlisted native species or ecological communities to become eligible for listing under the EPBC Act (in any category other than conservation dependent)
- Reduce the spread and mitigate the impacts of Phytophthora to protect:
    - Priority biodiversity assets
    - Areas where there is potential for Phytophthora to cause native species or ecological communities not yet listed to become eligible for listing under the EPBC Act (in any category other than conservation dependent)
- Inform and engage the community by promoting information about Phytophthora, its impacts on biodiversity and actions to mitigate these impacts
- Encourage research on Phytophthora species and options to manage infestations and protect biodiversity assets

A set of actions have been identified to achieve the objectives of the TAP. There are five actions to identify and prioritise for protection biodiversity assets that are, or may be, impacted by Phytophthora which relate to developing a list of flora, fauna and communities that are at risk and areas at risk of infection spatially to inform threat management.

There are seven actions to reduce the spread and mitigate the impacts of Phytophthora which relate to safeguarding priority biodiversity assets through adherence to hygiene protocols, integrating management of Phytophthora dieback with other natural resource management systems (in particular fire management), and including management actions in National Recovery Plans for EPBC-listed threatened species and TECs.

There are six actions to inform and engage the community about the impacts of Phytophthora which relate to developing communication and training strategies for relevant stakeholder groups and ensuring the currency and accessibility of the relevant mapping, guidelines and signage.

There are nine actions to encourage research on Phytophthora species which relate to:

- Learning more about the Phytophthora genus
- Developing new and effective treatments for the disease
- Developing resistance and resilience in vulnerable species and communities
- Developing improved techniques for rapid diagnosis of Phytophthora infestation
- Developing restoration methods for priority sites that are degraded by Phytophthora dieback

RELEVANCE OF THE TAP TO THE PLAN

There is no effective mechanism to remove the Phytophthora pathogen from an area, and therefore the TAP aims to minimise the spread of the disease, especially when undertaking high-risk activities, such as:

- Land development
- Road construction
- Construction and maintenance of recreational tracks and walking trails
- Construction of straight-line infrastructure (for example power lines and telecommunication structures)
- Soil and gravel extraction
- Fencing
- Installation of drainage (DoEE, 2018a)

The activities above will be undertaken as part of the Plan and could exacerbate the threat of Phytophthora.

While there is a risk of the spread of Phytophthora as a result of the activities proposed in the Plan, there are commitments to manage the risk of indirect impacts due to the development under the Plan, including managing the risk of spread of Phytophthora at construction sites, and to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion.

CONSISTENCY WITH THE TAP

The Plan is not inconsistent with the TAP on the basis that:

- The Plan will not prevent any of the actions of the TAP from being implemented
- The measures under the Plan are consistent with the intent behind the actions to deliver on Objective 2, to “protect priority biodiversity asses through reducing the spread and mitigating the impacts of *Phytophthora cinnamomi*”

15.9.5 THREAT ABATEMENT PLAN FOR INFECTION OF AMPHIBIANS WITH CHYTRID FUNGUS RESULTING IN CHYTRIDIOMYCOSIS

The goal of this TAP is to minimise the impacts of amphibian chytrid fungus (*Batrachochytrium dendrobatidis*) on affected native species and ecological communities.

Chytrid fungus causes chytridiomycosis in amphibians which is a highly infectious disease that can be found in all areas in Australia except the Northern Territory. The fungus invades the surface layers of the skin and disrupts its normal function which results in electrolyte depletion and osmotic imbalance. This can affect the nervous system of some animals and paralysis, and ultimately death, occurs. Susceptibility to the disease varies between populations but the reasons for this are unknown. (DoEE, 2016b)

OBJECTIVES AND ACTIONS UNDER THE TAP

The TAP sets out four objectives to help achieve the goal, they are:

- Improve understanding of the extent and impact of infection by amphibian chytrid fungus and reduce its spread to uninfected areas and populations
- Identify and prioritise key threatened amphibian species, populations and geographical areas and improve their level of protection by implementing coordinated, cost-effective on-ground management strategies
- Facilitate collaborative applied research that can be used to inform and support improved management of amphibian chytrid fungus
- Build scientific capacity and promote communication among stakeholders

A set of actions have been identified to achieve the objectives of the TAP. There are four actions to improve the understanding of infection by chytrid fungus and reduce its spread which relate to monitoring at-risk species, mapping the distribution of chytridiomycosis (and chytrid fungus), including control measures in amphibian translocation strategies, and ensuring appropriate hygiene protocols are implemented in chytrid-free areas.

There are six actions to support the identification and prioritisation of key threatened species, populations and geographical areas and the implementation of management strategies, which relate to completing risk assessments for high-priority species, implementing biosecurity measures around high-priority areas, and coordinating conservation efforts.

There are seven actions to facilitate research to improve management of chytrid fungus which include obtaining knowledge on:

- Assisted colonisation strategies
- The mechanisms for resistance
- The severity of chytrid fungus
- The best treatment protocols

There are three actions to build scientific capacity and promote communication among stakeholders which relate to developing an effective communication strategy, supporting a central information storage site, and encouraging participation in the National Chytrid Working Group.

RELEVANCE OF THE TAP TO THE PLAN

Most of populations susceptible to chytrid fungus that occur adjacent to or within proximity to proposed development, such as the Green and Golden Bell Frog, already exist within a highly built up and urbanised environment. Development under the Plan is unlikely to change the current level of risk in these areas in relation to chytrid fungus.

Despite this, there are commitments to manage the risk of indirect impacts due to the development under the Plan, including managing the risk of spread of chytrid fungus at Ropes Creek should a population of Green and Golden Bell Frog occur at that location, and to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion.

CONSISTENCY WITH THE TAP

The Plan is not inconsistent with the TAP on the basis that:

- The Plan will not prevent any of the actions of the TAP from being implemented
- The measures under the Plan are consistent with the intent behind the actions to deliver on Objective 2, to "identify and prioritise key threatened amphibian species, populations and geographical areas and improve their level of protection by implementing coordinated, cost-effective, on-ground management strategies"

15.9.6 THREAT ABATEMENT PLAN FOR PREDATION BY EUROPEAN RED FOX

The goal of this TAP is to minimise the impact of the European red fox (*Vulpes Vulpes*) on biodiversity in Australia.

The European red fox can be found all over the Australian mainland, apart from in the far North. Fox predation is a threat to many threatened fauna species, in particular terrestrial mammals and ground-nesting birds.

Objectives and actions under the TAP

The TAP sets out four objectives to achieve the goal, they are:

- Prevent foxes occupying new areas in Australia and eradicate foxes from high-conservation-value 'islands'
- Promote the maintenance and recovery of native species and ecological communities that are affected by fox predation
- Improve knowledge and understanding of fox impacts and interactions with other species and other ecological processes
- Improve the effectiveness, target specificity, integration and humaneness of control options for foxes
- Increase awareness of all stakeholders of the objectives and actions of the TAP, and of the need to control and manage foxes

A set of actions have been identified to help achieve the objectives of the TAP. There are four actions to prevent foxes occupying new areas in Australia which relate to collating data on areas with high conservation values, developing and implementing management plans, and eradicating populations of foxes from lands adjacent to priority areas.

There are three actions to promote the recovery of native species and ecological communities that are affected by fox predation which relate to identifying priority areas for fox control and undertaking and monitoring fox control at these locations.

There are five actions to improve the knowledge and understanding of fox impacts which relate to developing methods for monitoring foxes, exploring the interactions between foxes, feral cats, wild dogs and rabbits, and estimating the costs of impacts from foxes.

There are seven actions to improve the control options for foxes which relate to investigating existing and new control techniques, developing training programs for land managers and promoting best practice standards.

There is one action to increase awareness of the need to control and manage foxes which relates to ensuring that the actions in the TAP are better communicated.

Relevance of the TAP to the Plan

The Plan has the potential to exacerbate the threat of foxes to some extent, and includes a commitment to manage priority pest animals in strategic locations in the Cumberland Subregion to reduce threats to land within the SCAs.

Consistency with the TAP

The Plan is not inconsistent with the TAP on the basis that:

- The Plan will not prevent any of the actions of the TAP from being implemented
- The measures under the Plan are consistent with the intent behind the actions to deliver on Objective 2, to "promote the maintenance and recovery of native species and ecological communities that are affected by fox predation"

15.9.7 THREAT ABATEMENT PLAN FOR PREDATION BY FERAL CATS

The goal of this TAP is to minimise predation of native species by feral cats (*Felis catus*).

Feral cats are found throughout all habitats in mainland Australia and Tasmania and on some offshore islands. They are known to have a devastating effect on native fauna, predominantly from predation but also through competition and disease transmission (DoE, 2015).

Objectives and actions under the TAP

The TAP sets out four objectives to achieve the goal, they are:

- Effectively control feral cats in different landscapes
- Improve effectiveness of existing control options for feral cats
- Develop or maintain alternative strategies for threatened species recovery
- Increase public support for feral cat management and promote responsible cat ownership

A set of actions have been identified to help achieve the objectives of the TAP. There are nine actions to improve the control of feral cats in different landscapes which relate to further research and development of current and new feral cat control options, improving understanding of the interactions between feral cats and other predators, and development of Code of Practice and/or Standard Operating Procedures for new tools.

There are four actions to improve the effectiveness of existing feral cat control options which relate to understanding how best to encourage land managers to include cat management programs within their activities, providing information regarding best practice methods and standard operating procedures, and implementing a consistent regulatory approach across all state and territory governments.

There are five actions to support the investigation of alternative strategies for threatened species recovery which include eradicating or controlling cats in priority areas, implementing or improving biosecurity measures in cat-free areas, and creating fenced reserves to support the recovery of threatened species.

There are four actions to increase public support for cat management which relate to increasing awareness and understanding about:

- The threat to biodiversity posed by cats
- The need for responsible cat ownership
- The containment of cats where their roaming may impact priority areas

RELEVANCE OF THE TAP TO THE PLAN

Total eradication of feral cats is not currently feasible and cat control is an ongoing issue across Australia. Current control programs focus on long-term management and suppression of feral cat populations.

Existing land use within the nominated areas and surrounding region includes residential areas and farming, which means cats are unlikely to pose a novel threat to native fauna in the area. However, the extent of proposed new urban development under the Plan means the threat is likely to be exacerbated. The main areas of concern relate to new urban development in Wilton and the southern section of GMAC, where the current density of houses is low.

The Plan includes a commitment to manage indirect impacts due to the development under the Plan, including to restrict the keeping of domestic animals where there is unacceptable residual risk and ensure property boundaries have appropriate fencing to contain domestic animals within the landholders' property.

CONSISTENCY WITH THE TAP

The Plan is not inconsistent with the TAP on the basis that:

- The Plan will not prevent any of the actions of the TAP from being implemented
- The measures under the Plan are consistent with the intent behind the actions to deliver on Objective 4, to "increase public support for feral cat management and promote responsible car ownership"

15.9.8 THREAT ABATEMENT PLAN FOR PREDATION, HABITAT DEGRADATION, COMPETITION AND DISEASE TRANSMISSION BY FERAL PIGS (*SUS SCROFA*)

The goal of this TAP is to prevent further species and ecological communities from becoming threatened or extinct due to the impacts of feral pigs.

Feral pigs are widespread throughout Australia and can affect threatened species and ecological communities by:

- Consuming threatened fauna species
- Destroying threatened flora species
- Altering ecological parameters such as plant species composition and succession, nutrient and water cycles, and water quality
- Changing the composition of threatened plant communities
- Altering soil structure
- Increasing the spread of weeds
- Spreading animal diseases such as leptospirosis, brucellosis and plant pathogens such as *Phytophthora cinnamomi*

OBJECTIVES AND ACTIONS UNDER THE TAP

The TAP sets out six objectives to achieve the goal, they are:

- Prioritise key species, ecological communities, ecosystems and locations across Australia for strategic feral pig management
- Encourage the integration of feral pig management into land management activities at regional, state and territory, and national levels
- Encourage further scientific research into feral pig impacts on nationally threatened species and ecological communities, and feral pig ecology and control
- Record and monitor feral pig control programs, so their effectiveness can be evaluated
- Build capacity for feral pig management and raise feral pig awareness amongst landholders and land managers
- Improve public awareness about feral pigs and the environmental damage and problems they cause, and the need for the feral pig control

A set of actions have been identified to help achieve the objectives of the TAP. There are two actions to support strategic feral pig management which include identifying priority species, ecological communities, ecosystems and locations for priority protection, and implementing control measures in these areas.

There is one action to support the integration of feral pig management into land management activities which relates to encouraging government departments and agencies, and regional groups, to integrate feral pig management into their land management activities.

There are four actions to encourage further scientific research into feral pig impacts which include undertaking more research into:

- Feral pig impacts
- Feral pig population dynamics and ecology
- Special and temporal use of landscapes by feral pigs
- The effectiveness of feral pig control methods

There are three actions to evaluate the effectiveness of feral pig control programs which relate to developing better monitoring techniques and encouraging centralised recording of feral pig control actions.

There are two actions to raise feral pig awareness amongst landholders and land managers which relate to increased delivery of training programs to build feral pig management skills and improve the understanding of special impediments to feral pig control.

There are two actions to improve public awareness about feral pigs which include developing a public education program about feral pigs and the environmental damage and problems they could cause.

RELEVANCE OF THE TAP TO THE PLAN

Feral pigs are widely established in Australia and it is not currently possible to completely eradicate them (DoEE, 2017).

The Plan has the potential to exacerbate the threat of feral pigs to some extent, and includes a commitment to manage priority pest animals in strategic locations in the Cumberland Subregion to reduce threats to land within the SCAs.

CONSISTENCY WITH THE TAP

The Plan is not inconsistent with the TAP on the basis that:

- The Plan will not prevent any of the actions of the TAP from being implemented
- The measures under the Plan are consistent with the intent behind the actions to deliver on Objective 2, to "encourage the integration of feral pig management into land management activities at regional, state and territory, and national levels"

16 Adaptive management for addressing uncertainty

This Chapter:

- Discusses what is adaptive management and why it is important
- Sets out the regulatory requirements for adaptive management under the BAM and ToR
- Identifies key uncertainties and risks in implementation
- Describes the Plan's approach to adaptive management
- Assesses the adequacy of the Plan's approach to adaptive management

The analysis in this Chapter is supported by the detailed evaluation of the Plan in Part 7.

16.1 WHAT IS ADAPTIVE MANAGEMENT AND WHY IS IT IMPORTANT

Adaptive management is a process for improving management practices through learning from the outcomes of previous management (DSEWPC, 2011). It is based on information derived from monitoring and can be applied anywhere uncertainty in management exists. Adaptive management typically involves the following steps:

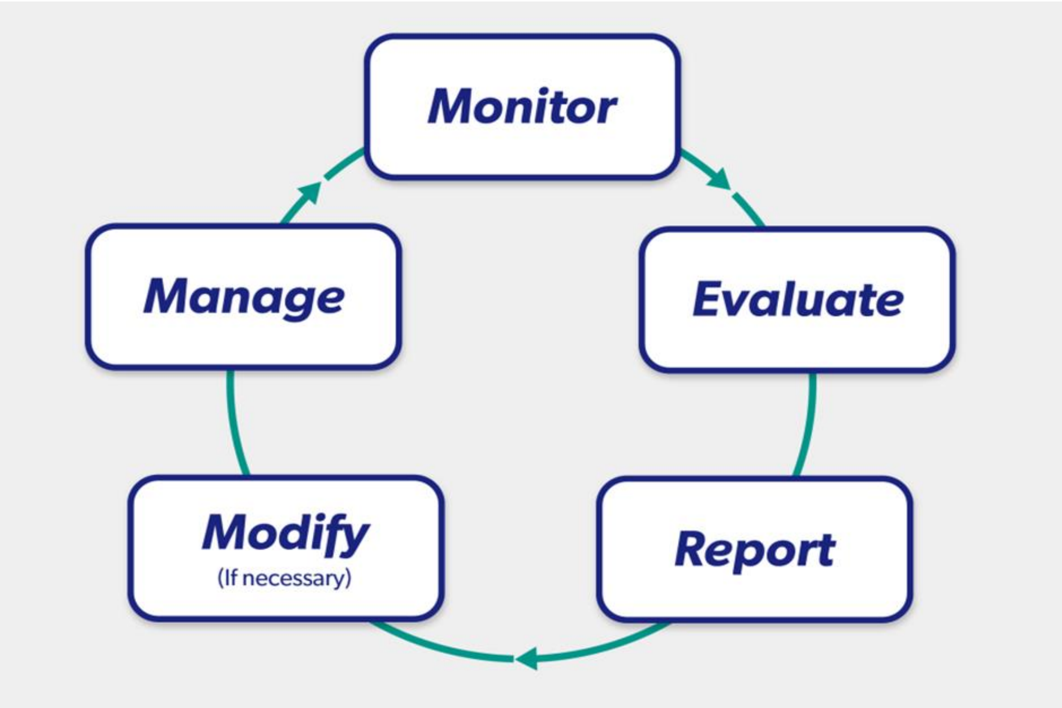

Figure 16-1: Adaptive management steps (taken from Sub-Plan B)

Adaptive management is an essential part of the implementation framework for strategic assessments. It is important because:

- The scale and complexity of strategic assessments means that there may be uncertainty relating to some impacts during the assessment process that need to be addressed during implementation
- The timeframes for strategic assessments are long and implementing agreed outcomes will be subject to a range of uncertainties over the life of the Plan
- Factors relating to the environment are likely to change over the life of a strategic assessment and an adaptive approach to management will be important for achieving the Plan's outcomes
- Changes to State and Commonwealth legislation, policies, plans and advice will occur over the life of the Plan

Providing a process to address uncertainty and deal with changing circumstances during the life of the Plan is therefore critical.

16.2 REGULATORY REQUIREMENTS

The BAM and ToR both require the Assessment Report to demonstrate how uncertainty will be addressed through adaptive management during implementation.

The BAM applies a narrower focus around just dealing with uncertain impacts, while the ToR has a broader focus on addressing uncertainty across all elements of implementation (including conservation commitments and actions).

16.2.1 BC ACT REQUIREMENTS

BAM

Section 9.4 of the BAM requires the BCAR to outline the adaptive management strategy proposed for minimising impacts that are uncertain. The BAM identifies the following impacts on biodiversity that are uncertain:

- Impacts related to damage to karst, caves, crevices, cliffs and other geological features of significance
- Impacts related to subsidence and upsidence resulting from underground mining
- Impacts related to wind turbine strikes
- Impacts related to vehicle strikes

Impacts related to vehicle strikes is the only relevant consideration for development within the nominated areas. Mining and the construction of wind turbines are not within the scope of the project and are not considered further.

Chapter 24 (Prescribed Biodiversity Impacts) examines the potential for impacts related to karst, caves, crevices, cliffs and other geological features of significance. It concludes that impacts to these features will not occur within the nominated areas and it is therefore not considered further in this chapter.

GUIDELINES

In addition to the BAM, the draft *Guidelines for planning authorities for proposing conservation measures in strategic applications for biodiversity certification* (version 6) provide a set of guiding principles for demonstrating that commitments and actions proposed for a strategic biodiversity certification adequately address impacts on biodiversity values.

The last principle relates to certainty of implementation and requires that:

> *"Principle 8 – The delivery of conservation measures is timely and certain"*

16.2.2 EPBC ACT REQUIREMENTS

Section 6 of the ToR requires the SAR to identify key uncertainties and risks associated with implementing the Plan, and describe and assess the adequacy of the procedures proposed in the Plan to ensure an adaptive approach to implementation of the Plan.

The relevant ToR are:

> *6.1 The Report must identify key uncertainties and risks associated with implementing the Plan, responses to these and proposed adaptations to changing circumstances. Key uncertainties may include:*
>
> - *Knowledge gaps in scientific understanding and responding to new knowledge.*
> - *Assumptions made in assessing potential impacts and benefits.*
> - *How changes to State and Commonwealth legislation, policies, plans and advice is to be accounted for in the management of the areas impacted by the Plan.*
> - *Effectiveness or capacity to ensure the Plan is implemented.*
>
> *6.2 The Report must describe and assess the adequacy of the procedures proposed in the Plan to ensure an adaptive approach to implementation of the Plan. This must include:*
>
> 1. *How the results of monitoring will be used to understand the effectiveness of conservation outcomes for protected matters and improve implementation.*

2. *How new information relating to protected matters and biodiversity, including legislative changes, may be assessed and accounted for in implementation of the Plan.*

16.3 KEY UNCERTAINTIES AND RISKS IN IMPLEMENTATION

The ToR (Clause 6.1) provide a framework for identifying the key uncertainties and risks in implementation. This framework includes BAM requirements around uncertain impacts and is addressed below.

16.3.1 KNOWLEDGE GAPS IN SCIENTIFIC UNDERSTANDING AND RESPONDING TO NEW KNOWLEDGE

KNOWLEDGE GAPS IN SCIENTIFIC UNDERSTANDING

There are two key types of gaps in scientific understanding relevant to the assessment:

- Data gaps
- Gaps in understanding of ecological processes

Data gaps

Data gaps for this assessment can be defined as a lack of information about a particular element of the environment. For example, presence or absence information for a threatened species at a particular site may not be available at the time required.

Given the large spatial scale of the Plan, it is not possible to have perfect information about the environment and some level of uncertainty in data is inherent in the project. However, the requirements of the BAM and the ToR define what is an acceptable level of data to understand the environment and to conduct the assessment. As outlined in Part 3, a comprehensive data set has been collected for the assessment which addresses the BAM and ToR.

The data that has been used in the assessment and any limitations are discussed in detail in:

- Chapter 13: Data and limitations
- Individual assessment chapters for protected matters

Understanding of ecological processes

Sufficient understanding of ecological processes is a key challenge for all environmental impact assessments. There is commonly a lack of information about issues such as:

- Species distribution
- Species habitat requirements
- Species population numbers and dynamics
- The effects of key threatening processes (e.g. climate change)
- The best approaches for minimising and mitigating potential impacts

The assessment addresses these uncertainties through:

- Gathering the best available information from scientific literature, expert knowledge, on-ground surveys
- Applying a precautionary approach to understanding and evaluating potential impacts. An analysis of the application of the precautionary principle is provided in Part 7

The Plan addresses uncertainty through its monitoring, evaluation and reporting (MER) framework combined with ongoing adaptive management.

RESPONDING TO NEW KNOWLEDGE

Given the long timeframe of the Plan, new knowledge about environmental issues will become available through:

- New scientific research
- Monitoring as part of implementation of the Plan

It will be critical that the Plan can consider this information and respond appropriately. The Plan's approach to this is discussed below in Section 16.4.

16.3.2 ASSUMPTIONS MADE IN ASSESSING POTENTIAL IMPACTS AND BENEFITS

One of the key risks in environmental impact assessment is making incorrect assumptions about the nature of potential impacts and benefits of a project. In particular, it is important that the consequences of potential impacts are not understated and the benefits of conservation measures are not overstated.

To address this risk, the assessment report takes a precautionary approach to identifying and analysing impacts and benefits. For example, the habitat mapping for threatened species generally overestimates the amount of habitat in the Plan Area which means the impacts that are assessed are likely to be larger than what will ultimately occur on the ground.

The assumptions made in assessing potential impacts and benefits are:

- Outlined in Part 3 – Assessment Approach which describes the methods used in the assessment
- Set out in relation to each protected matter in the individual assessment chapters

The application of the precautionary principle to the assessment is evaluated in Part 7.

16.3.3 HOW CHANGES TO STATE AND COMMONWEALTH LEGISLATION, POLICIES, PLANS AND ADVICE IS TO BE ACCOUNTED FOR IN THE MANAGEMENT OF THE AREAS IMPACTED BY THE PLAN

Given the long timeframes of the Plan, changes to legislation, policies, plans and advice are inevitable. These changes may lead to risks around:

- Implementation processes. For example, changes to State planning policies may affect the approaches to addressing indirect impacts
- Conservation priorities for threatened species and ecological communities. For example, changes to a Conservation Advice may provide new information about the key threats to a species and the recommended mitigation strategies
- Compliance. For example, changes to legislation may have implications for compliance under what would then be an approval under outdated legislation

The Plan addresses these risks through:

- Clearly establishing outcomes and commitments that will be delivered despite any changes to legislation, policies, plans and advice
- Its approach to MER and adaptive management (discussed below in Section 16.4) which will provide a way of responding to any changes to legislation, policies, plans and advice

16.3.4 EFFECTIVENESS OR CAPACITY TO ENSURE THE PLAN IS IMPLEMENTED

Effective implementation is particularly important for strategic assessments because of the size and complexity of the programs, the long timeframes over which they are implemented, the number of stakeholders and the diversity of their interests, the amount of money the programs cost, and the complexity of the legal frameworks they operate within.

Lessons learnt from other strategic assessments around Australia suggest that effective implementation requires:

- Clear and feasible outcomes that the Plan will deliver
- Clarity about the delivery framework and mechanisms to implement the Plan
- Appropriate flexibility within the Plan to ensure it remains relevant over time
- Clear governance arrangements, including certain funding
- Comprehensive processes to monitor and report on implementation, and adapt implementation as needed

The Plan has been designed to address these issues. A detailed evaluation of the implementability of the Plan is provided in Chapter 41.

16.4 THE PLAN'S APPROACH TO ADAPTIVE MANAGEMENT

The Plan includes a commitment (Commitment 27) to "implement an evaluation program for the Plan that sets out requirements for monitoring, evaluation, reporting and adaptive management". The approach to adaptive management is set out in Sub-Plan A. The approach is designed around:

- Clearly defining outcomes through program logic
- Undertaking regular data collection/monitoring to track progress
- Completing regular evaluations to investigate cause and effect, efficiency and effectiveness, and test assumptions
- Establishing programs of research to test and improve management interventions

Adaptive management will be applied across the entire conservation program. It will use the data sourced through monitoring and the findings of program evaluation to determine if actions need to be revised to more-effectively deliver the Plan's commitments (and consequently the Plan's outcomes). Evaluations will consider any new information that becomes available over the life of the Plan (in addition to monitoring data). Information about the Plan's approach to MER is provided in Part 2 and evaluated in Part 7.

Where evaluation suggests a commitment is not tracking as planned, it will trigger a review and potential modification to the required action or delivery of action. This process will include delivery partners as appropriate.

Changes to actions may be made in the case that:

- Targets are not being met
- The program logic does not adequately translate into the desired outcomes (i.e. the commitments are not leading to the outcomes as anticipated)
- External factors arise that affect the assumptions, logic or delivery of the Plan. This may relate to large-scale changes (e.g. unpredicted climate variation) or smaller scale changes (e.g. local events such as fires, floods or disease)

One particularly important part of the adaptive management process will be a series of adaptive management steps that will be triggered in the case that biodiversity offsets are not secured in line with development impacts. Where the total amount of secured offsets is less than 80 per cent of the offset liability at a point in time, the following remediation actions will be considered:

- Encourage uptake of conservation lands by:
  - Incentivising landowners to enter into Biodiversity Stewardship Agreements
  - Engaging with the community and landowners
  - Working with delivery partners to strengthen the effectiveness of the Biodiversity Stewardship Agreement and reserve programs
- Invest in active restoration technologies and projects
- Manage for new and emerging threats to biodiversity
- Undertake research to better understand how species and communities respond to change, and implement relevant management practices
- Review data needs and update conservation priority mapping as required

16.5 ADEQUACY OF THE PLAN'S APPROACH TO ADAPTIVE MANAGEMENT

The Plan's approach to adaptive management is considered appropriate because:

- There is a clear commitment in the Plan to take an adaptive approach to ensure the outcomes and commitments are delivered
- The approach addresses the key uncertainties and risks in implementation of the Plan
- The approach is supported by:
  - Clear processes and steps as part of the MER framework
  - The broader governance arrangements of the Plan which identify roles and responsibility for implementation
  - Commitments to fund implementation of the Plan

Part 4 Attachment Contents

Part 4 Attachment List of Tables

A. Indirect impacts relevant to each species and TEC

Identification of indirect impacts relevant to each matter is presented in:

- Table A-1 – NSW and Commonwealth-listed threatened fauna
- Table A-2 – NSW and Commonwealth-listed threatened flora
- Table A-3 – NSW and Commonwealth-listed TECs

Table A-1: Potential indirect impacts which may affect threatened fauna

Scientific name	Common name	Cth status	NSW status	BAM species type	Hydrology / soil disturbance	Ground subsidence	Spread of infection / disease	Spread of weeds	Pest / domestic animals	Altered fire regimes	Increased public access / disturbance	Fauna mortality / barriers to movement	Fauna disturbance due to noise, dust or light	Inadvertent impacts on adjacent habitat
BIRDS														
Anthochaera phrygia	Regent Honeyeater	CE	CE	ECS SCS				✓		✓	✓			✓
Artamus cyanopterus cyanopterus	Dusky Wood-swallow	N/A	V	ECS				✓						
Botaurus poiciloptilus	Australasian Bittern	E	E	ECS	✓			✓	✓	✓				
Calidris canutus	Red Knot	E Mig.	N/A	N/A	As discussed in the Migratory Species Impact Assessment – Chapter 32, there are no important habitat areas for the species which are at risk of indirect impacts from development under the Plan									
Calidris ferruginea	Curlew Sandpiper	CE Mig.	N/A	ECS	As discussed in the Migratory Species Impact Assessment – Chapter 32, there are no important habitat areas for the species which are at risk of indirect impacts from development under the Plan									
Callocephalon fimbriatum	Gang-gang Cockatoo	N/A	V	ECS SCS				✓						

Scientific name	Common name	Cth status	NSW status	BAM species type	Hydrology / soil disturbance	Ground subsidence	Spread of infection / disease	Spread of weeds	Pest / domestic animals	Altered fire regimes	Increased public access / disturbance	Fauna mortality / barriers to movement	Fauna disturbance due to noise, dust or light	Inadvertent impacts on adjacent habitat
Calyptorhynchus lathami	Glossy Black-cockatoo	N/A	V	ECS SCS				✓		✓				✓
Charadrius leschenaultii	Greater Sand Plover, Large Sand Plover	V Mig.	V	N/A	As discussed in the Migratory Species Impact Assessment – Chapter 32, there are no important habitat areas for the species which are at risk of indirect impacts from development under the Plan									
Chthonicola sagittata	Speckled Warbler	N/A	V	ECS				✓	✓					
Circus assimilis	Spotted Harrier	N/A	V	ECS								✓		✓
Climacteris picumnus victoriae	Brown Treecreeper	N/A	V	ECS				✓						✓
Daphoenositta chrysoptera	Varied Sittella	N/A	V	ECS				✓		✓				
Ephippiorhyn-chus asiaticus	Black-necked Stork	N/A	E	ECS	✓									
Epthianura albifrons	White-Fronted Chat	N/A	V	ECS	No relevant threats to bioregional persistence identified. The species is wide-ranging and habitat is away from areas that could be impacted									
Glossopsitta pusilla	Little Lorikeet	N/A	V	ECS				✓		✓				✓
Grantiella picta	Painted Honeyeater	V	V	ECS						✓				✓
Haliaeetus leucogaster	White-bellied Sea-Eagle	N/A	V	ECS SCS							✓	✓		✓

Scientific name	Common name	Cth status	NSW status	BAM species type	Hydrology / soil disturbance	Ground subsidence	Spread of infection / disease	Spread of weeds	Pest / domestic animals	Altered fire regimes	Increased public access / disturbance	Fauna mortality / barriers to movement	Fauna disturbance due to noise, dust or light	Inadvertent impacts on adjacent habitat
Hieraaetus morphnoides	Little Eagle	N/A	V	ECS SCS								✓		✓
Hirundapus caudacutus	White-throated Needletail	V	N/A	N/A	As discussed in the Migratory Species Impact Assessment – Chapter 32, the species is known to forage above a wide range of habitats and is unlikely to be disrupted or displaced by development									
Irediparra gallinacea	Comb-crested Jacana	N/A	V	ECS	✓				✓					
Ixobrychus flavicollis	Black Bittern	N/A	V	ECS					✓					✓
Lathamus discolor	Swift Parrot	CE	E	ECS SCS					✓	✓		✓		
Limicola falcinellus	Broad-billed Sandpiper	N/A	V	ECS	No relevant threats to bioregional persistence identified. There are no records in the subregion and habitat is away from areas that could be impacted									
Limosa lapponica baueri	Bar-tailed Godwit	V Mig.	N/A	N/A	As discussed in the Migratory Species Impact Assessment – Chapter 32, there are no important habitat areas for the species which are at risk of indirect impacts from development under the Plan									
Limosa limosa	Black-tailed Godwit	Mig.	V	ECS	As discussed in the Migratory Species Impact Assessment – Chapter 32, there are no important habitat areas for the species which are at risk of indirect impacts from development under the Plan									
Lophoictinia isura	Square-tailed kite	N/A	V	ECS SCS								✓		✓

Part 5A Contents

Part 5A List of Figures

Part 5A List of Tables

17 Introduction

This Part describes the existing biodiversity values within the nominated areas for matters listed under the *Biodiversity Conservation Act 2016* (BC Act) in accordance with the Biodiversity Assessment Method (BAM), including:

- Landscape features and site context
- Native vegetation, including native vegetation extent, type and condition
- NSW listed Threatened Ecological Communities (TECs)
- NSW listed threatened species and habitat

The BAM uses the term Subject Land to mean land to which the BAM is applied in Stage 1 to assess the biodiversity values of the land, including land within urban capable land or proposed for biodiversity certification. In this Assessment Report, the terms 'nominated areas' and 'urban capable land' are used instead of the term Subject Land.

18 Landscape features and site context

This Chapter provides an assessment of the landscape features and site context of the nominated areas in accordance with section 4 of the BAM, including:

- Interim Biogeographic Regionalisation of Australia (IBRA) bioregions and subregions
- Native vegetation extent – buffer area
- NSW (Mitchell) Landscapes
- Rivers and streams
- Wetlands
- Habitat connectivity and fragmentation
- Areas of geological significance and soil hazards
- Areas of outstanding biodiversity value
- Site context

These landscape features are shown in the site and location maps for each nominated area:

- Wilton: Figure 18-1 (site map) and Map 10.1 (location map)
- GMAC: Figure 18-2 (site map) and Map 10.2 (location map)
- WSA: Figure 18-3 (site map) and Map 10.3 (location map)
- GPEC: Figure 18-4 (site map) and Map 10.4 (location map)

18.1 IBRA BIOREGIONS AND SUBREGIONS

The nominated areas occur within the Sydney Basin IBRA bioregion (version 7) and the Cumberland and Cataract subregions. The percentages of each subregion within each nominated area is shown in Table 18-1.

Table 18-1: Per cent of nominated areas representing each subregion

Nominated area	Subregion	Per cent of nominated area within each subregion
Wilton Growth Area (Wilton)	Cumberland	98.46
	Sydney Cataract	1.54
Greater Macarthur Growth Area (GMAC)	Cumberland	96.45
	Sydney Cataract	3.55
Western Sydney Aerotropolis (WSA)	Cumberland	100.00

Nominated area	Subregion	Per cent of nominated area within each subregion
Greater Penrith to Eastern Creek Growth Area (GPEC)	Cumberland	100.00

The Sydney Basin bioregion lies on the central east coast of NSW and covers an area of approximately 3,624,008 hectares. It occupies about 4.53 per cent of NSW and is one of three bioregions contained wholly within the State.

The Sydney Basin bioregion extends from just north of Batemans Bay to Nelson Bay on the lower North Coast, and west to Merriwa. It is bordered to the north mostly by the NSW North Coast and Brigalow Belt South bioregions, to the south by the South East Corner bioregion and to the west by the South Eastern Highlands and NSW South Western Slopes bioregions. The bioregion is one of the most species-diverse in Australia (OEH, 2016).

The Cumberland subregion geology is dominated by Triassic age Wianamatta Group shales and lithic sandstones. Quaternary alluvium occurs along the main streams and a large plume of Tertiary-era sandy and gravelly alluvium occurs in the northern end between Wianamatta (South Creek) and the Nepean/Hawkesbury River. The characteristic landform is low rolling hills and wide valleys within a rain shadow area between the Blue Mountains and the coast. There are also swamps and lagoons on the floodplain of the Nepean and Hawkesbury Rivers and major creeks including Wianamatta (South Creek).

Typical soils of the Cumberland subregion are red and yellow texture contrast soils on slopes, becoming harsher and sometimes affected by dryland salinity in tributary valley floors. There is uniform red to brown clays and poor uniform stony soils, often with texture contrast profiles on older gravels with high quality loams on modern floodplain alluvium (DPIE, 2019).

Characteristic landforms of the Cumberland subregion include low rolling hills and wide valleys in a rain shadow area below the Blue Mountains. At least three terrace levels are evident in the gravel splays which occur within the subregion. Swamps and lagoons occur on the floodplain of the Nepean River. Typical vegetation of the Cumberland subregion includes Grey Box, Forest Red Gum, Narrow-Leaved Ironbark woodland to open forest with some Spotted Gum on the shale hills. Hard-leaved Scribbly Gum, Narrow-leaved Apple and Old Man Banksia occur on alluvial sands and gravels. Broad-Leaved Apple, Cabbage Gum and Forest Red Gum with abundant Swamp Oak occur on low-lying flats. Tall Spike Rush, and *Juncus* sp. with Swamp Oak occur in lagoons and swamps (OEH, 2016).

The Sydney Cataract subregion occurring to the south east of Wilton and the east of GMAC is Triassic era geology with Hawkesbury Sandstone on the coastal edge of the Sydney Basin above the Illawarra escarpment. The characteristic landform is a sandstone plateau with shallow creeks flowing through hanging swamps in the highest parts, ramping down to low hills in the Georges River and Botany Bay. There are coastal cliffs north of the Illawarra and a large barrier system with beach, dunes, swamps, and estuary at the westernmost edge of Kurnell.

Typical soils of the Sydney Cataract subregion are deep sands and clayey sands with peat in hanging swamps, yellow earths on better drained sandstone ridges. Siliceous sands occur in younger dunes and well-developed podzols occur in older dunes.

Characteristic landforms of the Sydney Cataract include a sandstone plateau with shallow creeks flowing through hanging swamps in the highest part of the subregion, ramping down to low hills in the Georges River and Botany Bay areas. Coastal cliffs occur to the north of the Illawarra and a large barriers system with dunes, swamps and estuary occurs at Kurnell. Vegetation of the Sydney Cataract subregion is typically Red Bloodwood and Silvertop Ash Woodland with abundant shrubs on sandstone and extensive *Gahnia* and *Banksia* in hanging swamps. There is a coastal dune sequence of Tea-Tree, Coast Wattle, Smooth-Barked Apple, Blackbutt and Swamp Mahogany on the barrier system (OEH, 2016).

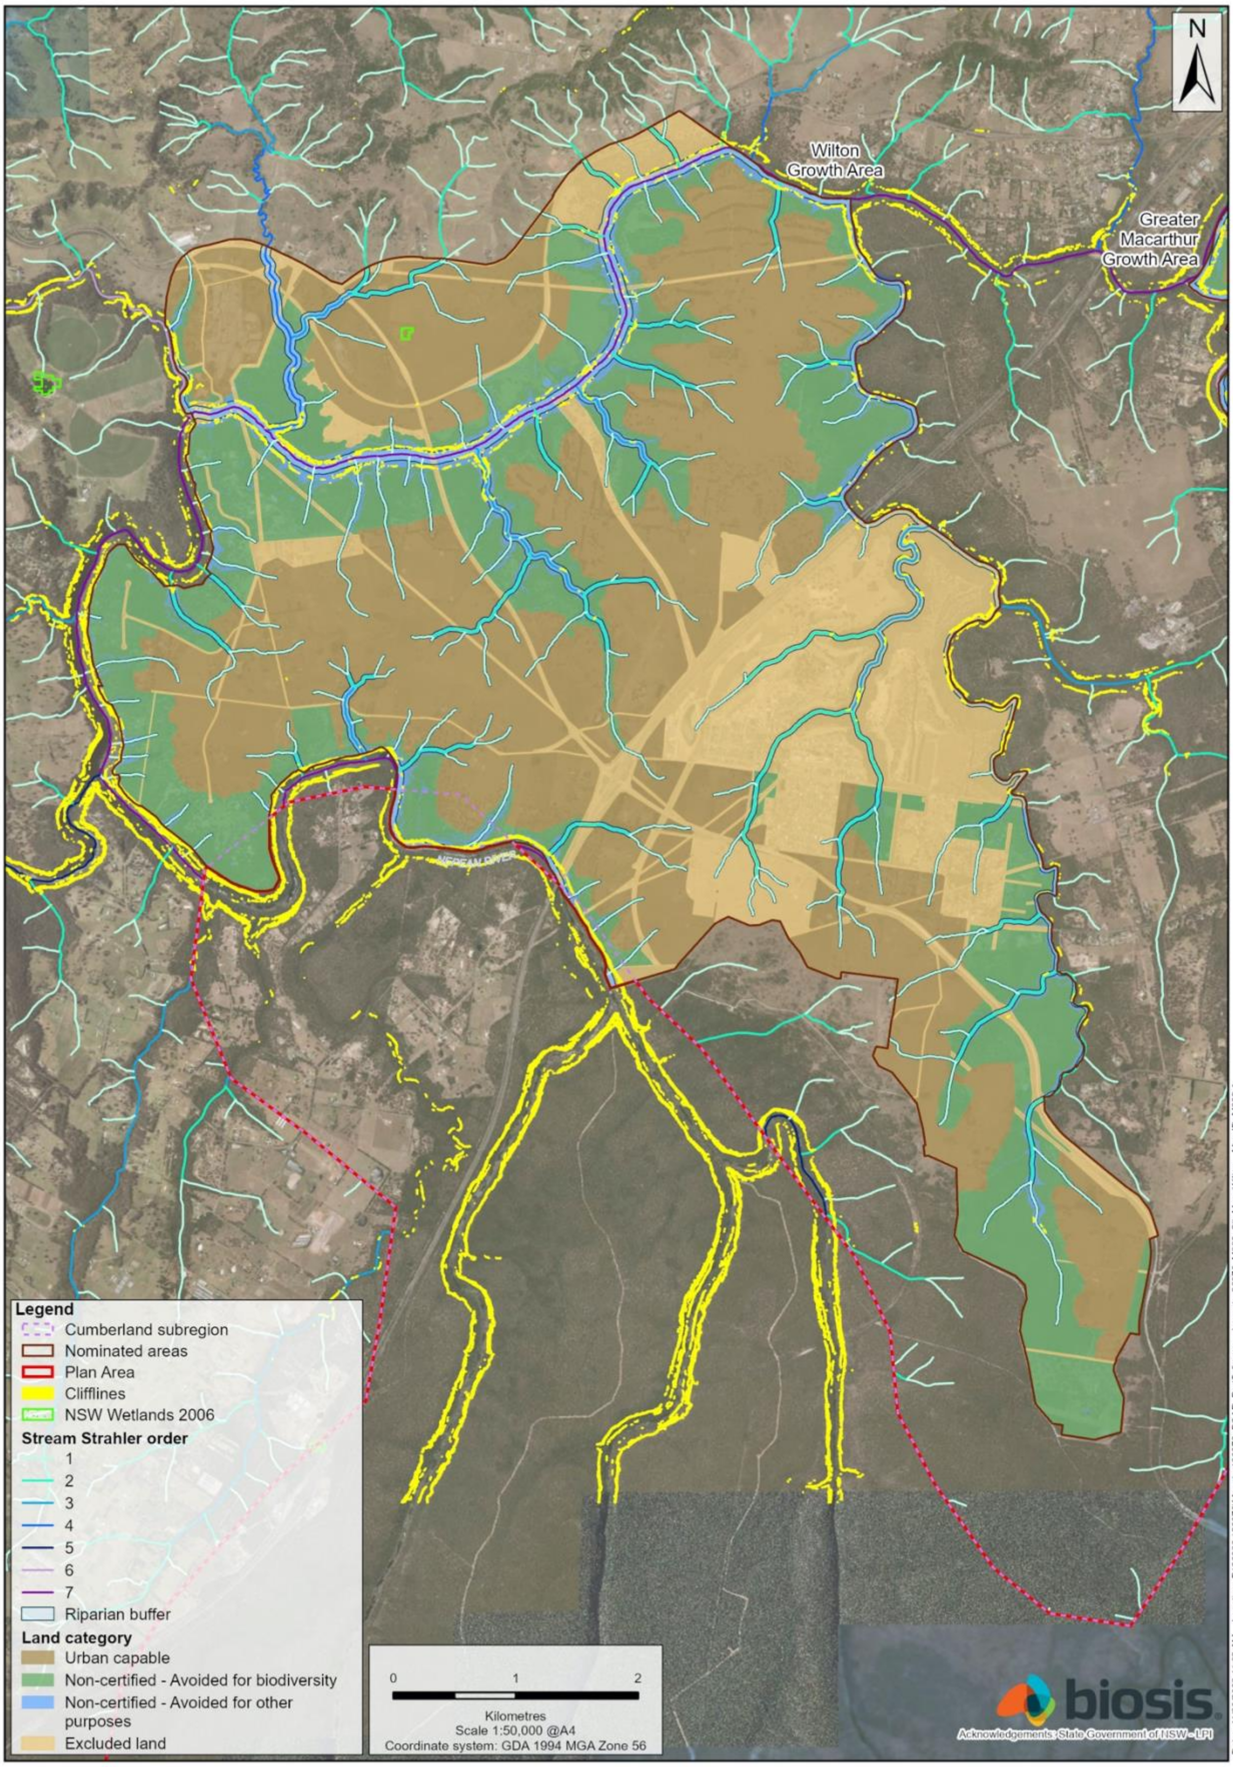

Figure 18-1: Site map – Wilton

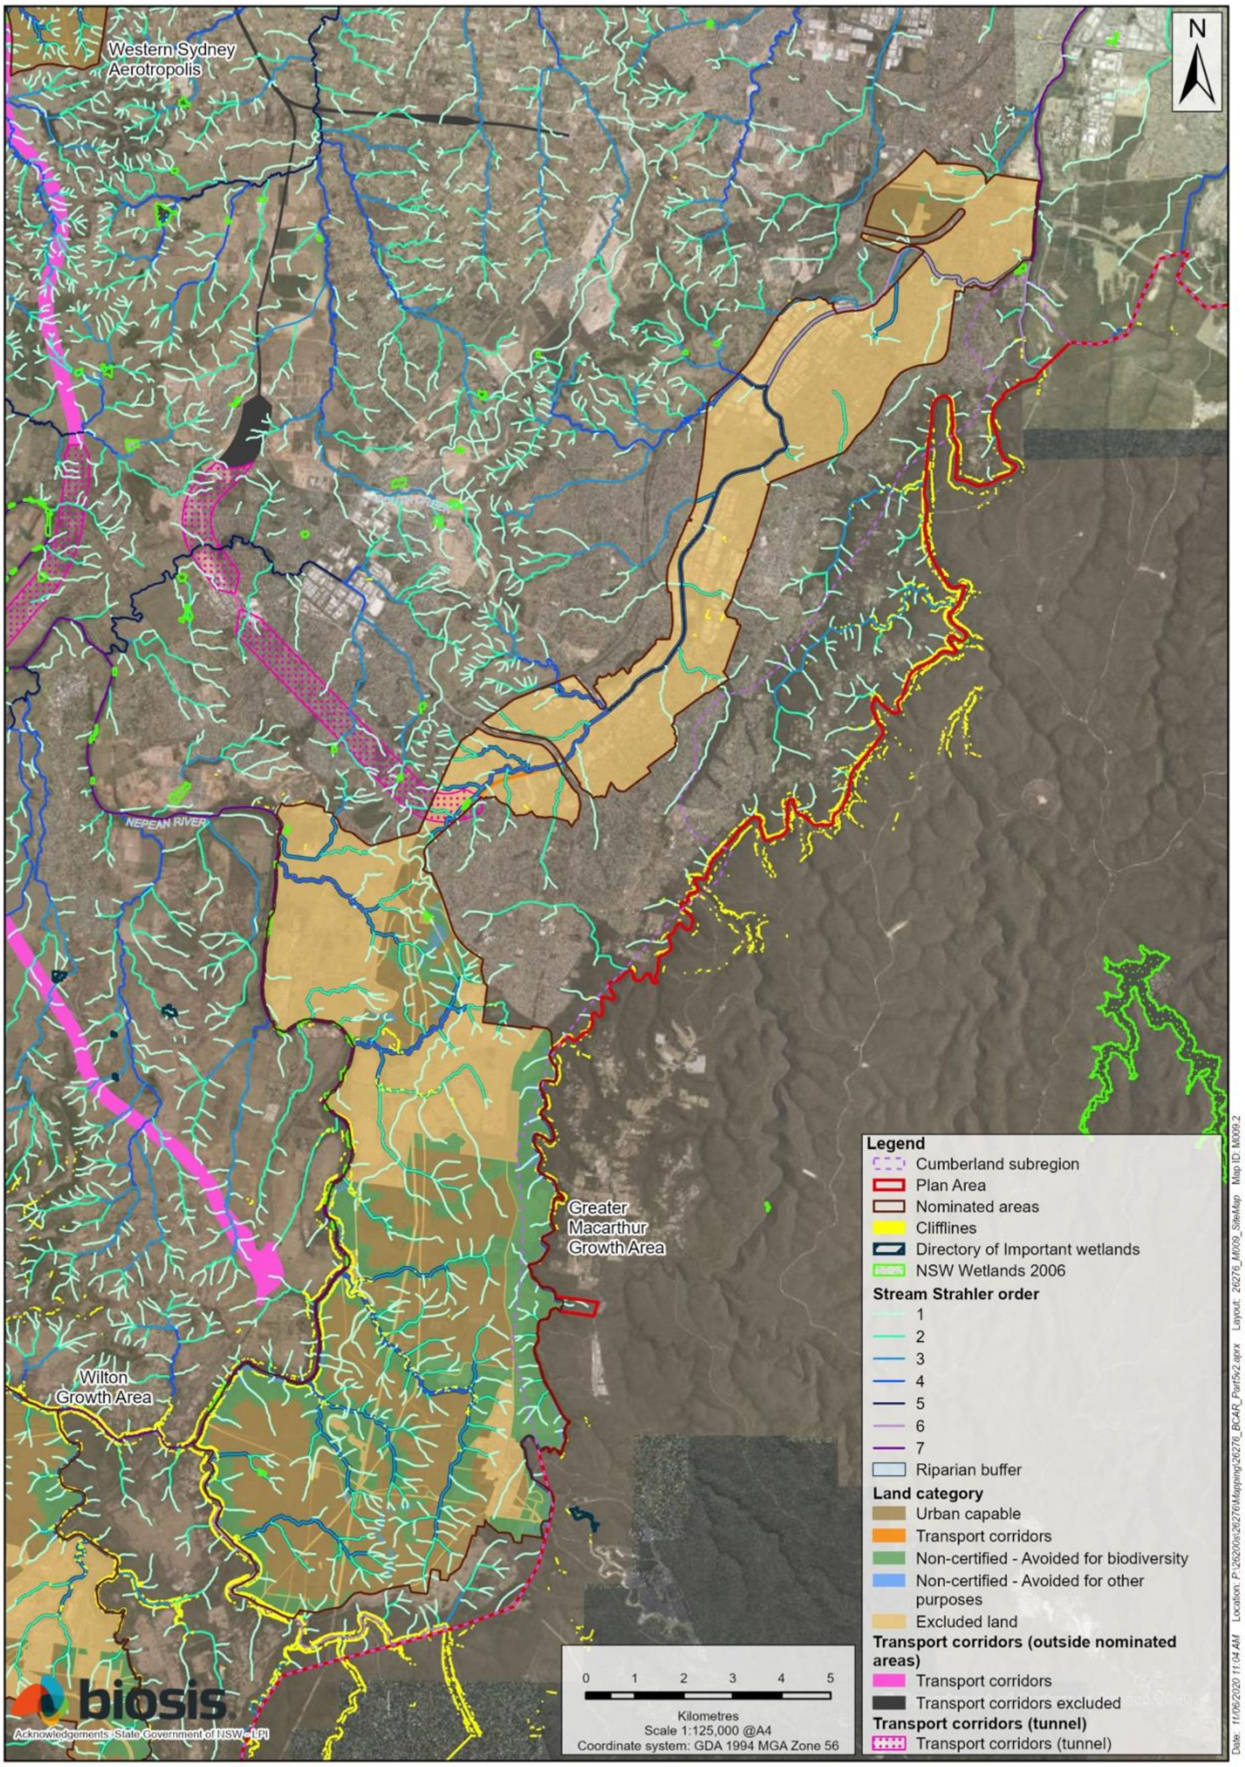

Figure 18-2: Site map – GMAC

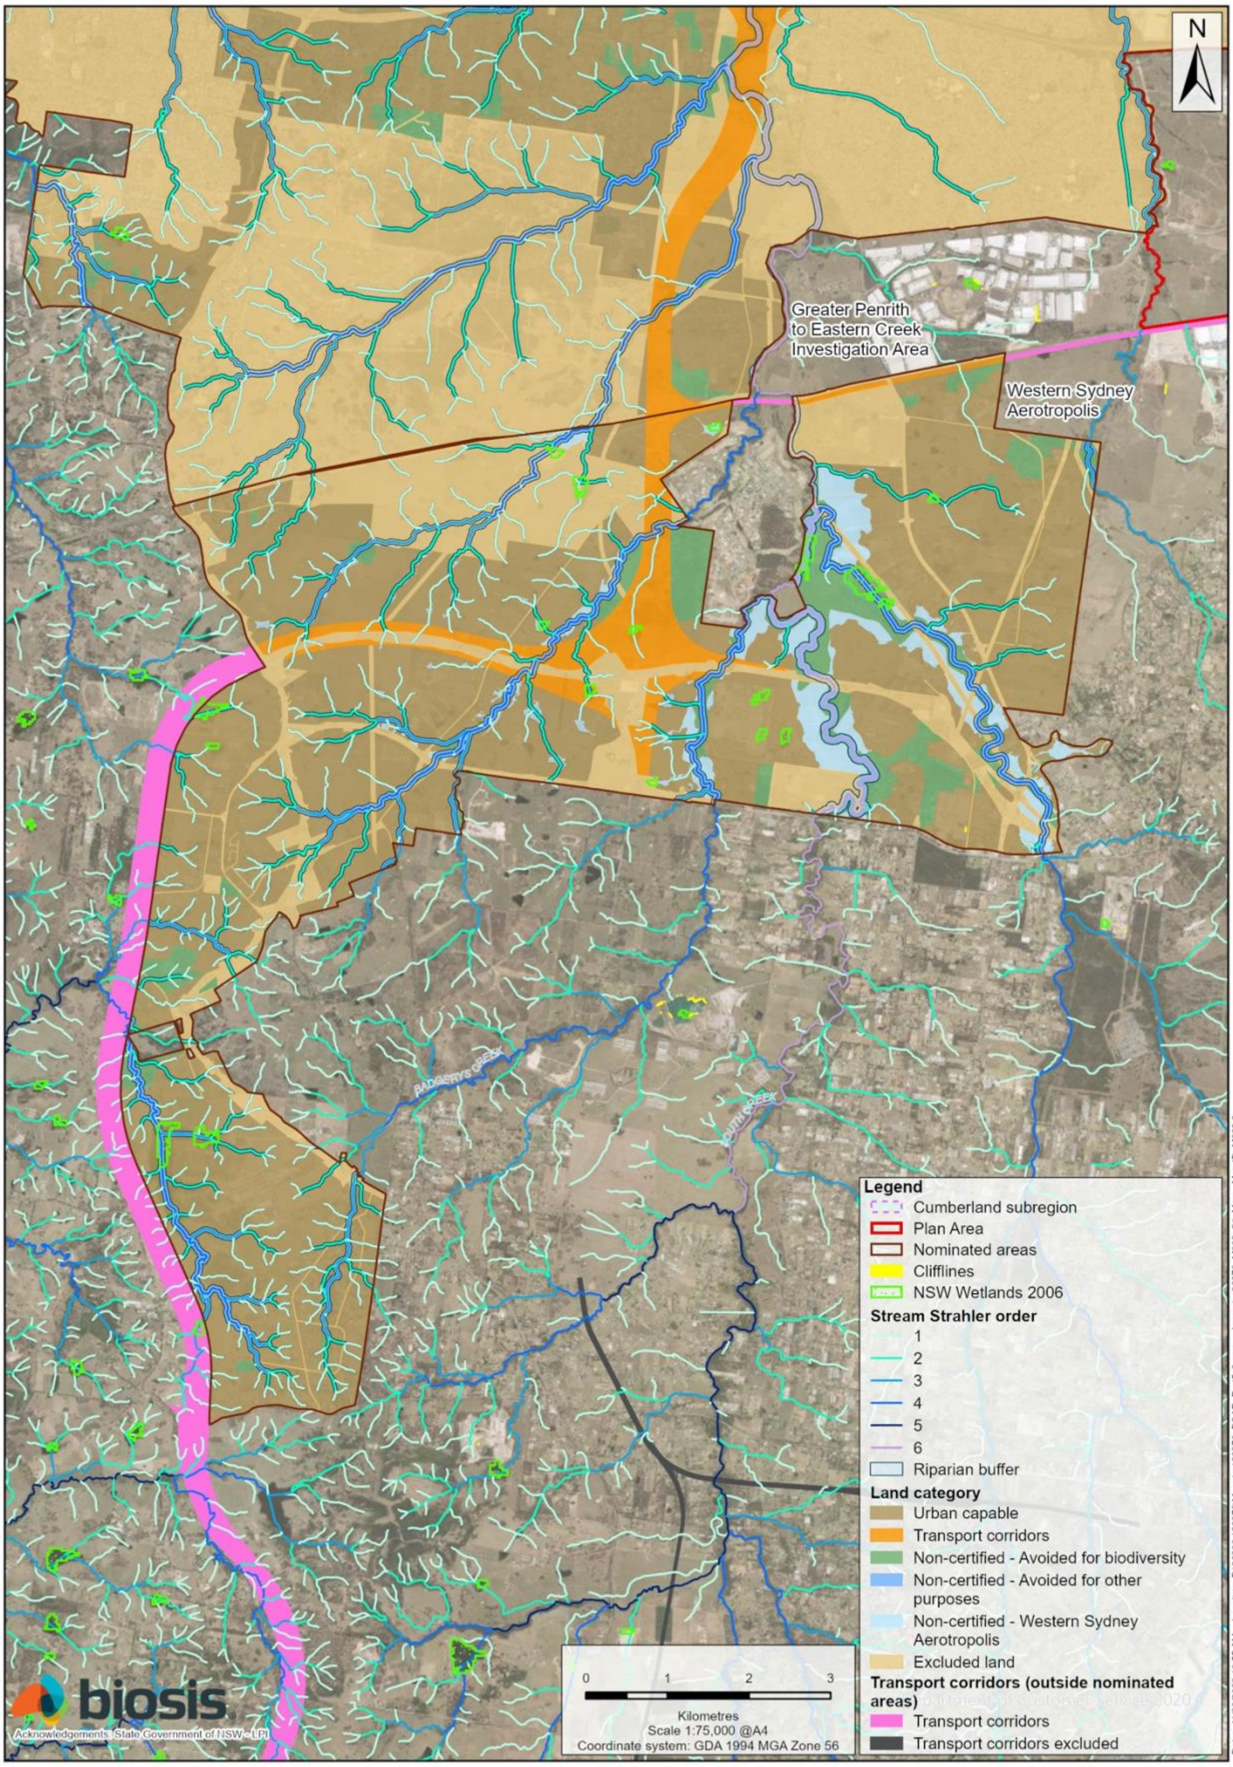

Figure 18-3: Site map – WSA

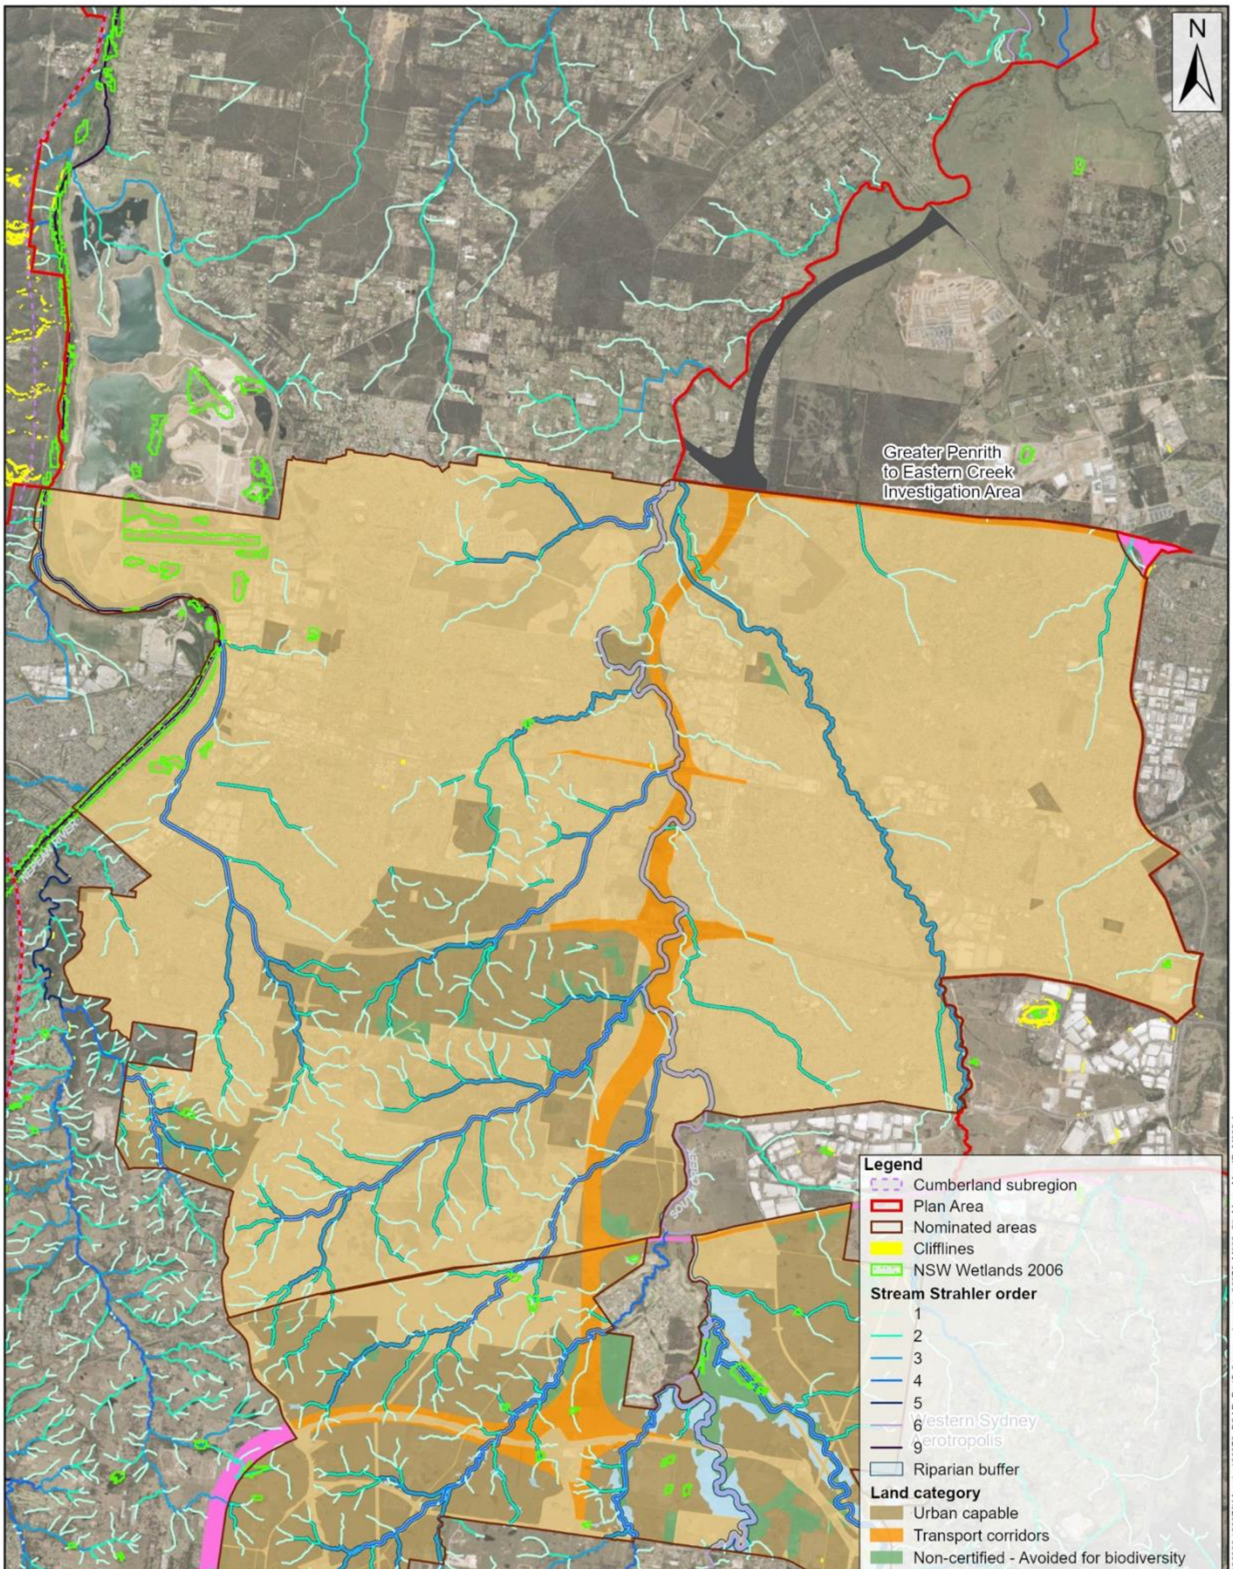

Figure 18-4: Site map – GPEC

18.2 NATIVE VEGETATION EXTENT – BUFFER AREA

Table 18-2 provides the percentage cover of native woody and derived grassland vegetation within the urban capable land of each nominated area, and the 1,500 m buffer. The vegetation mapping within the 1,500 m buffer was undertaken using existing vegetation mapping only, therefore the native vegetation extent for derived grasslands is likely to be under-represented.

Table 18-2: Native vegetation cover

Nominated area	Native vegetation extent (ha) (%)	Native vegetation extent (%) within urban capable land*		Native vegetation extent (%) within 1,500 m buffer*		
		Woody	Derived grasslands	Woody	Derived grasslands	Cover Class
Wilton	2,354 (58%)	11	28	55	7	>30-70%
GMAC	3,284 (30%)	11	3	40	1	>30-70%
WSA	901 (15%)	8	2	21	1	>10-30%
GPEC	3,255 (18%)	14	1	21	1	>10-30%

* Percentages rounded to whole numbers

18.3 NSW (MITCHELL) LANDSCAPES

NSW landscapes (also known as Mitchell Landscapes (Mitchell, 2002)) that occur within the nominated areas are described in Table 18-3. The landscape entered into the BAM calculator for each nominated area is the landscape in which most of the likely impacts within a nominated area occur, and is marked with an asterisk in the table.

Table 18-3: NSW (Mitchell) landscapes

NSW (Mitchell) landscape	Subregion	Nominated area	Area of landscape in nominated area (ha)	Description
Upper Nepean Gorges	Cataract	Wilton	1,476	The Upper Nepean Gorges landscape is characterised by steep-sided benched slopes of the Nepean River tributaries on Triassic age quartz sandstones, with elevation of 250 to 350 m and local relief of 80 m. The landscape has shallow, well-drained sands with limited development of yellow texture-contrast soils on benches underlain by clayey sandstone of thin shale units
		GMAC	1,433	
Picton-Razorback Hills	Cumberland and Cataract	Wilton	2,496*	The Picton-Razorback Hills landscape is a plateau ridge with steep slopes on horizontal upper Triassic shale, carbonaceous claystone, and lithic sandstone, subject to extensive earthflows on slopes above 120 m. General elevation is 180 to 300 m with local relief of 90 m. Soils are harsh, red, brown or yellow texture-contrast soils with reactive clay subsoils
		GMAC	3,127	
Cumberland Plain	Cumberland and Cataract	Wilton	109	The Cumberland Plain landscape is characterised by low, rolling hills and valleys in a rain shadow area between the Blue Mountains and the coast on horizontal Triassic shales and lithic sandstones forming a down-warped block on the coastal side of the Lapstone monocline. It is partly covered by Tertiary river gravels and sands (Hawkesbury-Nepean Terrace Gravels landscape). Quaternary alluvium occurs along the mains streams. General elevation is 30 to 120 m, with local relief of 50 m. The landscape is sometimes affected by dryland salinity in tributary valley floors. Soils are pedal uniform red to brown clays on volcanic hills, and red and brown texture-contrast soils on crests grading to yellow harsh texture-contrast soils in valleys
		GMAC	3,810*	
		WSA	5,361*	
		GPEC	14,499*	
Hawkesbury - Nepean Channels and Floodplains	Cumberland	GMAC	450	The Hawkesbury –Nepean Channels and Floodplains landscape is a meandering channel and moderately wide floodplain of the Hawkesbury and Nepean rivers on Quaternary sand and gravel. Sand is dominant upstream of the Warragamba River junction with general elevation 0 to 20 m and local relief of less than 10 m. Soils are characterised as undifferentiated alluvial sand to poorly structured gradation profiles of sandy loam or clay loam
		WSA	873	
		GPEC	3,347	
Woronora Plateau	Cataract and Cumberland	GMAC	353	The Woronora Plateau landscape is an extensive plateau developed on Triassic quartz sandstone with benched, low angle slopes and a marked break to steep sided, deep valleys controlled by joint patterns. General elevation is 400 to 500 m with local relief of 100 m. There are small areas of nodular ironstone on ridge crests, with deep uniform sands or texture-contrast soils on slopes and deep, uniform, grey or white organic sands on swampy valley floors. Rock outcrop is common on ridgelines and in creeks, and absent from most slopes

NSW (Mitchell) landscape	Subregion	Nominated area	Area of landscape in nominated area (ha)	Description
Ashfield Plains	Cumberland	GMAC	723	The Ashfield Plains landscape is a coastal extension of the Cumberland Plain landscape and is characterised by undulating hills and valleys on horizontal Triassic shale and siltstone, and occasional quartz sandstones, especially near the margin of the Port Jackson landscape. General elevation is 0 to 45 m with local relief of less than 20 m. Soils are red and brown texture-contrast on crests, grading to yellow harsh texture-contrast soils in valleys
Georges River Alluvial Plain	Cumberland	GMAC	1,134	Georges River Alluvial Plain comprises channel, floodplain and terraces of the Georges River on Quaternary and Tertiary alluvial sediments. Mostly clayey sand and sand with limited gravel on the highest terrace, general elevation 0 to 30 m, local relief 10 m. Massive uniform or gradational profiles on yellow brown to orange clayey sand. Podzols with well-developed double pans on limited areas of deep quartz sand, stony, harsh, yellow, texture-contrast soils on higher terraces
Sydney Basin Diatremes	Cumberland	GMAC	12	Sydney Basin Diatremes are widely distributed across the Sydney Basin and distinguished as a landscape because they always contain locally different landform, soil and vegetation. Diatremes are circular volcanic vents filled with layered, brecciated country rock cemented by a fine-grained basaltic matrix. Some contain a core of basalt. In sandstone country the volcanic breccia weathers and erodes more rapidly than the sandstone and the landform is circular with the appearance of a crater. Soils in the crater are dominated by sandstone detritus from the surrounding slopes but the subsoils are a fertile well, structured clay derived from the breccia and these protected sites carry more mesic variants of the local vegetation. In shale country the breccia is more resistant than the shale and the diatremes form a low rounded hill with red-brown gradational profiles of clay loam and structured clay with moderate to high fertility. General elevation varies considerably across the basin
		WSA	5	
		GPEC	28	
Hawkesbury - Nepean Terrace Gravels	Cumberland	GPEC	719	Hawkesbury - Nepean Terrace Gravels comprise three levels of river terrace dating into the Tertiary. General elevation is 20 to 45 m, local relief 10 m. Planar, poorly drained terraces with harsh texture-contrast soils and heavy clays in swamps and cut-off meanders
Kurrajong Fault Scarp	Cumberland	GPEC	3	Kurrajong Fault Scarp dissected and broken slopes on Triassic Quartz sandstone and shale across the Lapstone monocline and Kurrajong fault scarp. Local dips on the sedimentary rocks up to 300, general elevation 100 to 250 m, local relief 100 m. Abundant rock outcrop with pockets of yellow-brown sand and occasional yellow texture-contrast soils

*NSW (Mitchell) Landscape entered into the BAM calculator for each nominated area

18.4 RIVERS AND STREAMS

The nominated areas are located within two catchments (OEH, 2010):

- Hawkesbury
- Port Jackson/Georges River

Within the nominated areas, the watercourses and creeks provide riparian connectivity, and connections to the major watercourses of the Georges River (to the east) and the Hawkesbury-Nepean River (to the west).

Major watercourses of each nominated area are described in Table 18-4. Unnamed and minor tributaries are numerous throughout the nominated areas and are not listed in the tables.

Table 18-4: Watercourses of the nominated areas

Nominated areas	General Information	Major watercourses	Watercourse Strahler order*
Wilton	Wilton is located at the southern end of the Cumberland subregion. Four major watercourses run through the area, which generally have a south to north flow regime. There are several creeks that junction into the major watercourses	Nepean River, flowing west then north of Wilton	The Strahler order of the watercourses across Wilton is as follows: • One seventh-order watercourse • Three fourth-order watercourses • Six third-order watercourses • 26 second-order watercourses • 110 first order watercourses
		Allen's Creek, starting just south east of Wilton, flowing north into the Nepean River	
		Other smaller creeks include Sand Gully Creek, a second-order tributary as well as Clements Creek, a third order tributary	
		Stringybark Creek, a third-order tributary situated downstream of Clements Creek	
GMAC	GMAC stretches from Glenfield to Appin. There are three major watercourses that have a south to north flow regime	Bow Bowing Creek, a major watercourse that runs north east through northern GMAC The creek has several lower-order tributaries associated with it including: Smith's Creek, McBarron Creek, Leumeah Creek, Fishers Ghost Creek, Birunji Creek and Keanes Creek Georges River is generally east of GMAC	The Strahler order of the watercourses across GMAC is as follows: • Three seventh-order watercourses • Four sixth-order watercourses • One fifth-order watercourse • 11 fourth-order watercourses • 16 third-order watercourses • 68 second-order watercourses • 245 first-order watercourses
		Nepean River borders the south west portion of GMAC, it is the major watercourse flowing south to north There are four creeks that converge into the Nepean River that run through the southern portion of GMAC: • Menangle Creek, a fourth-order tributary, flowing west • Leafs Gully Creek, a second-order tributary, flowing north west • Ousedale Creek, a fourth-order tributary flowing north west • Simpsons Creek, a third-order	

Nominated areas	General Information	Major watercourses	Watercourse Strahler order*
		tributary, flowing north-west into the Nepean River	
		The Cataract River forms the southern border of GMAC Rocky Ponds Creek, a third-order tributary, converges into Cataract River	
WSA	The WSA contains five major watercourses. All watercourses have several tributaries	Ropes Creek forms the eastern border of WSA, it is a perennial creek, flowing northwards. Wianamatta (South Creek) which also flows northwards has four high-order tributaries (some listed below) and two third-order creeks that junction into it. Badgerys Creek is a fourth-order watercourse that has several unnamed tributaries	The Strahler order of the watercourses across the WSA is as follows: • One sixth-order watercourse • Four fourth-order water courses • 15 third-order watercourses. • 59 second-order watercourses • 208 first-order watercourses
		Kemps Creek, flows in a north-west direction, it is a perennial creek that converges into Wianamatta (South Creek). Kemps Creek has three unnamed tributaries that come from an easterly direction	
		Cosgroves Creek flows through WSA in a north-east direction. It has several creeks and tributaries that converge with it, including Oaky Creek	
		Duncans Creek drains the south west corner of WSA and junctions into the Nepean River in the west	
GPEC	The GPEC has three major watercourses. There are several creeks that junction into these major watercourses	Nepean River forms the western border for GPEC, flowing from south to north Four creeks flow into the Nepean River: • Boundary Creek, a second-order tributary with a westerly flow • Peach Tree Creek, a fourth-order tributary with a northern flow • Surveyors Creek, which junctions just north of the western motorway School House Creek is the most southern creek to junction into the Nepean River	The Strahler order of the watercourses across GPEC is as follows: • One ninth-order watercourse • Two sixth-order watercourses • Seven fourth-order water courses • 15 third-order watercourses • 53 second-order watercourses • 193 first-order watercourses
		Ropes Creek, runs through GPEC and is a major watercourse	
		Wianamatta (South Creek) flows south to north through the middle of GPEC. It has several smaller	

Nominated areas	General Information	Major watercourses	Watercourse Strahler order*
		tributaries that feed into the large watercourse including: • Werrington Creek • Claremont Creek • Blaxland Creek • Byrnes Creek	
		Kemps Creek, flows in a north-west direction, it is a perennial creek that converges into Wianamatta (South Creek). Kemps Creek has three unnamed tributaries that come from an easterly direction	
		Cosgroves Creek flows through WSA in a north-east direction. It has several creeks and tributaries that converge with it, including Oaky Creek	
		Duncans Creek drains the south west corner of WSA and junctions into the Nepean River in the west	

* This stream order system was originally developed by Strahler (1964). It functions by adding two streams of equal order at their confluence to form a higher order stream. As stream order increases, so does the likelihood that it would be a perennial source of water

18.5 WETLANDS

There are no wetlands protected under the Coastal Management State Environmental Planning Policy (SEPP) within the nominated areas. These wetlands were previously listed as SEPP 14 – Coastal Wetlands.

Locally occurring wetlands that provide wetland habitats include areas of floodplain wetland along the Nepean River, Wianamatta (South Creek) and Werrington Creek, farm dams and reservoirs. There are more than 60 of these types of wetland habitats mapped across the nominated areas (OEH, 2011a).

There are no nationally important wetlands or Ramsar-listed wetlands within the nominated areas. The closest nationally important wetlands to the nominated areas are (DoEE, 2018):

- Towra Point (Ramsar site) 25 kilometres east of Glenfield
- Lake Illawarra, 30 kilometres to the south-east of Wilton
- Bicentennial Park, Newington Wetlands, Silverwater Nature Reserve, 17 kilometres east of Prospect Reservoir
- Pitt Town Lagoon, Pitt Town
- Longneck Lagoon, Pitt Town

The closest Ramsar wetland is located at the Towra Point Nature Reserve, in Botany Bay.

18.6 HABITAT CONNECTIVITY AND FRAGMENTATION

The soils of the Cumberland subregion are relatively fertile, particularly when compared to the surrounding Hawkesbury Sandstone landscapes. This fertility has resulted in extensive clearing of native vegetation for agriculture, market gardens and orchards. More recently, clearing has occurred for urban development.

Only approximately 13 per cent of the pre-1970 extent of native vegetation in the Cumberland subregion remains intact and in good condition, with an additional 12 per cent occurring as scattered trees in disturbed areas (DECCW, 2011).

Remaining native vegetation is often highly fragmented. In 2010, an estimated 2,446 individual native vegetation remnants remained in the subregion, ranging from less than 1 hectare to 3,598 hectares in area (DECCW, 2010). Eighty one of the largest patches (those greater than 50 hectares) represent 51 per cent of the remaining native vegetation (DECCW, 2011).

Fragmentation of habitats across and between the nominated areas mirrors this general pattern of clearing and development in the Cumberland subregion, with significant areas of native vegetation community restricted to reserves, major riparian corridors, sandstone geologies and areas not suited to agriculture, such as steep slopes and escarpments.

The impacts of the development on habitat connectivity is assessed in Chapter 24.

18.6.1 WILTON

Connectivity of intact vegetation within Wilton is generally in the hilly, gorge and riparian corridors on the fringes of the nominated area. There is intact vegetation creating connectivity along Allens Creek from the west of the nominated area towards the areas of more intact vegetation south of the nominated area. Habitat for native species within the central parts of the nominated area (predominantly on shale soils) is restricted to scattered trees and derived grasslands or small native remnants of less than 5 hectares, which are under pressure from weed invasion, edge impacts and ongoing agricultural practices.

Map 19 shows habitat connectivity within Wilton.

18.6.2 GMAC

Fragmentation of habitat within GMAC is also typical of that seen in the Cumberland subregion, with clearing of vegetation from the fertile crests, and the low-lying and alluvial soils. However, due to the presence of riparian corridors and sandstone geologies there is some connectivity of intact habitats along a number of east-west corridors in the southern portion of GMAC. These connections reach from the Nepean River riparian corridor on the western boundary, to near the eastern boundary, where the habitats of the Georges River riparian corridor are located.

Habitat connectivity within the highly developed northern portion of the nominated area is restricted to small local connections such as largely cleared riparian corridors and urban bushland parks. Scattered trees and urban native vegetation are also present in this area, providing some connectivity for highly mobile species.

Map 19 shows habitat connectivity within GMAC.

18.6.3 WSA

WSA is characterised predominantly by an agricultural landscape with limited small acreage subdivision in the far south and larger acreage and small residential subdivisions in the centre and northern parts. Some small acreage subdivisions contain native vegetation, providing local connections for native fauna and flora species.

Other native vegetation habitats are present along the many riparian corridors that cross WSA, including Wianamatta (South Creek), Duncans Creek and Badgerys Creek corridors and tributaries. There are remnant patches of vegetation located between Willowdene Avenue and the Northern Road in the central part of the nominated area around Duncans Creek, providing some limited connectivity east-west. There are also many waterbodies within WSA that provide habitat connectivity for species dependent on these environments for dispersal and reproduction.

Map 19 shows habitat connectivity within WSA.

18.6.4 GPEC

GPEC has been extensively developed for housing. Intact native vegetation and habitats are restricted to the far north of the nominated area around the Wianamatta Regional Park, and the Orchard Hills Defence Establishment in the far south of the nominated area. These two areas of remnant habitats are connected via the riparian corridors of Wianamatta (South Creek). The Ropes Creek corridor reaches from the Wianamatta Regional Park through to the south east of the nominated area. Both of these major riparian corridors have been subject to varying levels of clearing and disturbance. However, they provide the only vegetated link within the local and regional landscape for native flora and fauna species.

Map 19 shows habitat connectivity within GPEC.

18.7 AREAS OF GEOLOGICAL SIGNIFICANCE AND SOIL HAZARDS

Areas of geological significance occur outside urban capable land on the edges of some of the nominated areas, including rocky escarpments associated with surrounding sandstone landscapes. These areas may be important for species that have specific habitat constraints and associations. Areas of potential soil hazard within the nominated areas include:

- Acid Sulfate Soils
- Sodic soils
- Salinity
- Land contamination
- Soil compaction
- Unstable soils

The impacts of the development on karst, caves, crevices and cliffs is assessed in Chapter 24.

18.7.1 ACID SULFATE SOILS

Table 18-5 provides a description of the soil hazard map units identified in the Atlas of Australian Acid Sulfate Soils (Fitzpatrick, Powell et al., 2011).

Areas of high probability Acid Sulfate Soils within the nominated areas are shown in Map 11.

Table 18-5: Acid Sulfate Soils within the nominated areas

Map Units	Probability of occurrence	Map unit	Subscript	Confidence	Nominated area
Bn(p4)	B - Low (6-70%)	n - Inland landscapes in wet/riparian corridors associated with sodosols, chromosols and dermosols. Acid Sulfate Soils generally within upper 1 m of wet / riparian corridors	p - Potential acid sulfate soil (PASS) = sulfidic material	4- Classification is provisional	GMAC GPEC
Cq(p4)	C- Extremely low (1-5%)	q - Inland landscapes in wet/riparian corridors associated with kandosols, tenosols and rudosols. Acid Sulfate Soils generally within 1 m of wet/riparian corridor	p - Potential acid sulfate soil (PASS) = sulfidic material	4- Classification is provisional	Wilton GMAC WSA GPEC
Cu(--)	C- Extremely low (1-5%)	u - unclassified Not Acid Sulfate Soils	Not Acid Sulfate Soils	Not Acid Sulfate Soils	GMAC GPEC
An(p4)	A - High (>70%)	n - Inland landscapes in wet/riparian corridors associated with sodosols, chromosols and	p - Potential Acid Sulfate Soil (PASS) = sulfidic material	4- Classification is provisional	WSA GPEC

Map Units	Probability of occurrence	Map unit	Subscript	Confidence	Nominated area
		dermosols. Acid Sulfate Soils generally within upper 1 m of wet / riparian corridors			
Aq(p4)	A - High (>70%)	q - Inland landscapes in wet/riparian corridors associated with kandosols, tenosols and rudosols. Acid Sulfate Soils generally within 1 m of wet/riparian corridor	p - Potential acid sulfate soil (PASS) = sulfidic material	4- Classification is provisional	WSA GPEC
Cn(p4)	C- Extremely low (1-5%)	n - Inland landscapes in wet/riparian corridors associated with sodosols, chromosols and dermosols. Acid Sulfate Soils generally within upper 1 m of wet / riparian corridors	p - Potential Acid Sulfate Soil (PASS) = sulfidic material	4- Classification is provisional	WSA GPEC

18.7.2 SODIC SOILS

Sodicity refers to the proportion of exchangeable sodium cations held on the surface of clay particles. The greater the proportion of sodium in the total exchangeable cations, the greater the sodicity of the soil.

Sodic soils cause clay dispersion, an undesirable condition.

Sodic soils could occur within the nominated areas, most likely in riparian corridors and near dams. A site assessment would be necessary to determine extent at specific locations.

18.7.3 SALINITY

Salinity refers to the amount of dissolved salt in the soil. A large concentration of salt gives high salinity and increasing salinity makes it difficult for plant roots to absorb water.

The Western Sydney Hydrogeological Landscape maps show the majority of Western Sydney as having high land salinity. Wilton is mapped as having low to moderate land salinity, while parts of the assessment area north of Wilton are predominantly high land salinity areas (OEH, 2011b).

Site assessments would be required to determine the salinity of individual sites.

18.7.4 LAND CONTAMINATION

Land contamination can threaten human health and the environment, limit land use potential or increase development costs. Contaminated sites are typically found in areas that have been used for heavy industry or agriculture, chemical storage areas and service stations and dry cleaning sites (NSW EPA, 2019).

Declarations of significantly contaminated lands have been made for various sites across each of the nominated areas, primarily relating to industrial sites. The list of current declarations for each Local Government Area (LGA) within the nominated areas is available through the NSW Environment Protection Authority website.

18.7.5 SOIL COMPACTION

Compaction of soils can occur through movement of stock, machinery or vehicles. When soil becomes compacted, air and water movement through the soil are restricted, limiting their use.

Compacted soils within the nominated areas are most likely to be found in areas used for grazing or agriculture. Areas of susceptibility are likely to occur on the alluvial plains and the Cumberland Plain Mitchell Landscape.

Site assessments would be required to determine soil compaction levels at individual sites.

18.7.6 UNSTABLE SOILS

Unstable soils are referred to as 'dispersible soils' and are often associated with high levels of salt. They are vulnerable to compaction, surface sealing and erosion. Areas of potential high land salinity within the nominated areas are more likely to exhibit unstable soils. Potential areas of instability and potential for gully erosion within the nominated areas are most likely to occur in areas of high slope, salinity and reduced vegetation ground cover.

Within the nominated areas, the Wianamatta (South Creek) soil landscape has high to extreme potential for erosion, and stream bank and gully erosion in this landscape can result from concentrated water flows. The Luddenham Soil Landscape has a moderate to very high potential for erosion, with minor gully erosion and sheet erosion in disturbed areas.

18.8 AREAS OF OUTSTANDING BIODIVERSITY VALUE

No areas identified as Areas of Outstanding Biodiversity Value occur within the nominated areas (OEH, 2020).

18.9 SITE CONTEXT

This section describes the site context, in accordance with section 4.3 of the BAM, for each of the nominated areas.

18.9.1 PER CENT NATIVE VEGETATION COVER

Per cent native vegetation cover is shown in Table 18-6 for the:

- Nominated areas
- Urban capable land
- 1500 m buffer areas

Table 18-6: Native vegetation cover

Nominated area	Native vegetation cover (%)	Cover Class	Native vegetation cover (%) – urban capable land*	Cover Class	Native vegetation cover (%) – 1,500 m buffer*	Cover Class
Wilton	58	>30-70%	39	>30-70%	62	>30-70%
GMAC	30	>10-30%	14	>10-30%	41	>30-70%
WSA	15	>10-30%	10	0-10%	22	>10-30%
GPEC	18	>10-30%	15	>10-30%	22	>10-30%
Average	30	>10-30%	20	>10-30%	37	>30-70%

* Percentages rounded to whole numbers

18.9.2 CHANGES TO THE MAPPED NATIVE VEGETATION EXTENT

Several areas of native vegetation shown on the existing native vegetation maps (OEH, 2013, 2016) have been cleared since the maps were prepared and no longer exist. These areas were discernible on Nearmap aerial imagery (Nearmap, 2018) and were excluded from the updated vegetation maps. Areas of urban vegetation such as roadside plantings were also excluded. These areas were ground-truthed during surveys where possible to positively identify them as being non-native vegetation or native vegetation with a cultivated origin.

18.9.3 PATCH SIZE

Patch size for BAM credit calculations was defined as greater than 100 hectare for all vegetation zones in the nominated areas. This served to not limit the potential threatened species that could be recorded or identified in the assessment for consideration.

19 Native vegetation

This Chapter describes the native vegetation communities in the nominated areas, including vegetation extent, PCTs and vegetation condition (native vegetation integrity).

The method for identifying and mapping native vegetation within the nominated areas is provided in Chapter 11.

19.1 NATIVE VEGETATION EXTENT

The total extent of vegetation within the nominated areas is 11,806 hectares (see Table 19-3). This includes:

- 9,791 ha of native vegetation, including areas with native dominated ground cover and canopy area of trees
- 2,015 ha of 'Urban Native/Exotic' vegetation, which comprises areas of exotic vegetation or with few native species, as well as planted vegetation, landscaped areas, gardens, and other areas that are not considered representative of 'native vegetation' and/or a PCT

Map 12 shows the extent of native vegetation within the nominated areas, including the extent of the 'Urban Native/Exotic' vegetation.

19.2 PLANT COMMUNITY TYPES

A total of 15 different PCTs occur within the nominated areas. In addition to these 15 PCTs, a category of vegetation called 'Urban Native/Exotic' vegetation also occurs (see Table 19-1).

A description of the PCTs that occur within the nominated areas, including the percentage of each PCT that has been cleared (up to 2018) (OEH, 2018) is provided in Table 19-1.

Table 19-2 provides a justification for the identification of each PCT in accordance with section 5.2.1.12 of the BAM. Table 19-3 provides the amount (hectares) of each PCT within the nominated areas.

The five most extensive PCTs (including the Urban Native/Exotic category of vegetation) within the nominated areas are:

- 1395 Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest – 3,326 ha
- 849 Grey Box - Forest Red Gum grassy woodland on flats – 3,049 ha
- Urban Native/Exotic – 2,015 ha
- 835 Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats – 1,170 ha
- 1181 Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes – 780 ha

Map 13.1, Map 13.2, Map 13.3 and Map 13.4 show the distribution of PCTs within the nominated areas.

Table 19-1: PCTs within the nominated areas

PCT	Name	Vegetation formation	Vegetation class	Description*	Per cent cleared value (2018)
724	Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion	Dry Sclerophyll Forest	Cumberland Dry Sclerophyll Forest	This community is associated with shale-influenced sandy soils that support a component of ironstone gravels. The vegetation typically consists of an open eucalypt forest with an understorey that varies between dense shrubs and a low sparse shrub cover with an abundant ground cover of grasses. The canopy typically includes Broad-leaved Ironbark *Eucalyptus fibrosa* along with a wide variety of other eucalypts depending on location. White Feather Honeymyrtle *Melaleuca decora* is sometimes present above a lower open shrub layer of Blackthorn *Bursaria spinosa* and Gorse Bitter Pea *Daviesia ulicifolia*. The ground cover is a mix of grasses, sedges and herbs. On the basis of floristic composition alone, Castlereagh Shale-Gravel Transition Forest is closely related to Castlereagh Ironbark Forest	75%
725	Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion	Dry Sclerophyll Forest (Shrub/grass sub-formation)	Cumberland Dry Sclerophyll Forest	This community is associated with clay soils derived from Tertiary alluvial deposits (Tozer 2003). It is one of two closely related ironbark shrub-grass forests found in western Sydney. The structure ranges from a moderately tall open eucalypt forest or woodland to a low dense thicket of paperbarks with low emergent eucalypts. Human-induced changes to the original forest structure have resulted in the presence of varying structures of the community Benson and Howell (1994a). Broad-leaved Ironbark is the most commonly recorded eucalypt although at some sites it may be absent Woollybutt *Eucalyptus longifolia* is also common although sites often have a diverse canopy composition which reflects subtle grades between substrates sourced from Tertiary sand, sandstone bedrock, shale and ironstone gravels. For this reason, there are localised occurrences of Hard-leaved Scribbly Gum *Eucalyptus sclerophylla*, Smooth-barked Apple *Angophora costata* and Narrow-leaved Apple *Angophora bakeri*, species more typically associated with siliceous soils of sand deposits and the sandstone plateau. A prominent small tree layer of White Feather Honeymyrtle features above a dense cover of shrubs that include *Melaleuca nodosa*, Blackthorn and Peach Heath *Lissanthe strigosa* The ground layer is a sparse cover of grasses and forbs. These may be very depauperate in locations where dense shrub layers exclude light	95%

PCT	Name	Vegetation formation	Vegetation class	Description*	Per cent cleared value (2018)
781	Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion	Freshwater Wetlands	Coastal Freshwater Lagoons	This community is associated with freshwater lagoons and swamps on alluvial flats and sand depressions across the NSW east coast. Lagoons have fluctuating levels of standing water that gives rise to a varied assemblage of species. They include a range of sedges, rushes and aquatic herbs with woody shrubs and small trees found only on the margins of the wetlands in low abundance. Tall reedlands (reaching over 3 m in height) may dominate individual wetlands. Cumbungi *Typha orientalis* is typically dominant in urban wetlands and may be joined by Common Reed *Phragmites australis*. Other tall reeds include *Eleocharis sphacelata* and tall sedges such as Twig-rushes *Baumea* spp. The margins of open water carry a range of aquatic herbs such as *Isachne gibbosa* and *Persicaria decipiens*. Less frequently inundated wetlands support only a few species of sedges or rushes such as *Carex appressa* and *Baumea* spp. which do not reach the height of the taller reedlands found elsewhere	74%
830	Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Grassy Woodlands	Coastal Valley Grassy Woodlands	This community occurs on protected aspects on steeper shale hills and rises of the southern half of the Cumberland Plain. It differs from the grassy woodlands found in Western Sydney by the prevalence of waxy-leaved shrubs and small trees in the understorey and a ground cover of herbs, fleshy twiners and grasses. Some of these species, such as Hairy Clerodendrum *Clerodendrum tomentosum* and Slender Grape *Cayratia clematidea*, are features of the Hinterland Dry Rainforest, a community that occasionally occurs in more protected situations nearby. Across its range in Western Sydney the canopy is mostly dominated by Forest Red Gum *Eucalyptus tereticornis* and Grey Box *Eucalyptus moluccana*. Much of this habitat has been extensively cleared, with remaining stands commonly choked by dense thickets of African Olive *Olea europaea* subsp. *cuspidata* and Lantana *Lantana camara*. This reduces species diversity and in chronic situations it may be difficult to correctly diagnose the community due to low numbers of native species	75%
835	Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	Forested Wetlands	Coastal Floodplain Wetlands	This community is located on broad alluvial flats of the Hawkesbury and Nepean river systems. It also forms narrower ribbons alongside streams and creeks that drain the Cumberland Plain. The canopy typically includes one of either Rough-barked Apple *Angophora floribunda* or Broad-leaved Apple *Angophora subvelutina* and one or both of Forest Red Gum and Cabbage Gum *Eucalyptus amplifolia*. However, eucalypt species will vary between localities, including Blue Box *Eucalyptus baueriana*, Sydney Blue Gum *Eucalyptus saligna* and Blackbutt *Eucalyptus pilularis*. The understorey within this community is characterised by an occasional sparse to open small tree stratum of Paper Bark *Melaleuca* spp. and Wattles *Acacia* spp. A sparse lower shrub layer features Blackthorn *Bursaria spinosa* at most sites. The ground layer is characterised by an abundant cover of grasses with herbs and ferns	93%

PCT	Name	Vegetation formation	Vegetation class	Description*	Per cent cleared value (2018)
849	Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	Grassy Woodlands	Coastal Valley Grassy Woodlands	This community is one of two grassy woodlands that comprise Cumberland Plain Woodland listed under the BC Act. The community includes an open grassy woodland dominated by Grey Box, Forest Red Gum and Narrow-leaved Ironbark and Broad-leaved Ironbark. Like the related community Cumberland Shale Hills Woodland, it is typified by a sparse to moderate cover of shrubs and a high cover of grasses and forbs	93%
850	Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Grassy Woodlands	Coastal Valley Grassy Woodlands	This community is one of two grassy woodlands that comprise the Cumberland Plain Woodland listed under the BC Act. The community is an open woodland of Grey Box and Forest Red Gum with Narrow-leaved Ironbark also common. Hickory Wattle *Acacia implexa* occurs amongst the small tree layer, often amongst regrowth stands. This species is one of the more distinctive floristic attributes that helps distinguish between the two components of the EEC. Other features are similar in that the two woodland units are characterised by an open shrub layer and a grassy ground cover. Fire history can have an important influence on the abundance of shrubs (Watson et al. 2009), with density of Blackthorn *Bursaria spinosa* increasing with time since fire	88%
883	Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion	Dry Sclerophyll Forests (Shrubby sub-formation)	Sydney Sand Flats Dry Sclerophyll Forests	This community is one of several unique dry shrub woodland communities found on poorly consolidated sand deposits on hinterland plains and valleys of the Sydney region. The woodland comprises an open, low-growing eucalypt cover dominated by Hard-leaved Scribbly Gum *Eucalyptus sclerophylla*, Narrow-leaved Apple and Drooping Red Gum *Eucalyptus parramattensis* subsp. *parramattensis*. A sparse cover of White Feather Honeymyrtle is often present. Banksias, hakeas, wattles, tea-trees and paperbarks provide a well-developed shrub layer. The ground cover is usually a diverse mix of species typically including a high cover of grasses and sedges	50%
1081	Red Bloodwood - Grey Gum woodland on the edges of the Cumberland Plain, Sydney Basin Bioregion	Dry Sclerophyll Forests (Shrubby sub-formation)	Sydney Hinterland Dry Sclerophyll Forests	This community is equivalent to DSF 146 identified by Tindall et al. (2004) and is a eucalypt woodland with an open understorey of sclerophyll shrubs, sedges, forbs and grasses. This transition woodland encircles the Cumberland Plain rainshadow, on loamy soils typically derived from sediments belonging to the Hawkesbury or Mittagong formations. 40 per cent of this community's original distribution has been cleared, and clearing continues in localised areas of suburban expansion. However, considerable areas are represented within conservation reserves	40%

PCT	Name	Vegetation formation	Vegetation class	Description*	Per cent cleared value (2018)
1105	River Oak open forest of major streams, Sydney Basin Bioregion and South East Corner Bioregion	Forested Wetlands	Eastern Riverine Forests	Open *Casuarina* forest, 10-40 m tall, with a variable non-sclerophyll shrub stratum and patchy groundcover of sedges and herbs, interspersed with leaf litter, cobbles and open sand. Restricted to narrow bands along rivers of the coast and tablelands north from Bega continuing into central Queensland	40%
1181	Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion	Dry Sclerophyll Forests (Shrubby sub-formation)	Sydney Coastal Dry Sclerophyll Forests	This community is equivalent to DSF 142 identified by Tindall et al. (2004) and is an open eucalypt forest with an abundant sclerophyll shrub stratum and a groundcover dominated by sedges. This community grades from Hinterland Sandstone Gully Forest into Sandstone Riparian Scrub immediately adjacent to creeklines and is replaced by Coastal Sandstone Ridgetop Woodland or Wingecarribee-Burragorang Sandstone Forest on upper slopes and exposed positions. Dominant trees include; Smooth-barked Apple, Red Bloodwood *Corymbia gummifera*, Sydney Peppermint *Eucalyptus piperita*. As rainfall increases toward the coast, it is replaced by Coastal Sandstone Gully Forest. Much of this community's original distribution has been cleared. Large areas remain, including examples in conservation reserves, though edge effects such as weed invasion and high fire frequency are evident in some locations	20%
1292	Water Gum - Coachwood riparian scrub along sandstone streams, Sydney Basin Bioregion	Forested Wetlands	Eastern Riverine Forests	This low scrub comprises a mix of hardy shrubs growing on rocky creek lines or shallow alluvial soils at the base of deep sandstone gully systems. The vegetation cover is highly variable as it is interspersed by rock pools, rock pavements and open sandy banks. It is a zone of occasional flooding and plants must survive fast-moving waters to persist. Water gums *Tristaniopsis laurina* and *Tristania neriifolia* are invariably present, often in combination with wattles, hakeas, grevilleas, tea-trees and casuarinas. Two shrub species, River Lomatia *Lomatia myricoides* and Blunt-leaved Wattle *Acacia obtusifolia*, are particularly common in this community; both are easily distinguished by their long leaves. Small moisture-loving ferns and sedges may form dense clumps on or near stream banks. A sparse cover of overhanging eucalypts may also be present, though these are often rooted in the adjoining slopes rather than the creek line itself	10%

PCT	Name	Vegetation formation	Vegetation class	Description*	Per cent cleared value (2018)
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion	Grassy Woodlands	Coastal Valley Grassy Woodlands	This community is found on the fringes of the Cumberland Plain. It is one of a suite of forests that are associated with the subtle intergrade between clay-rich shale soil and the coarse sandy substrates of the sandstone plateau. It is a moderately tall eucalypt forest with a mixed understorey of sclerophyll shrubs and grasses (Tozer et al. 2010). Sites invariably have one of two species of Ironbark, Narrow-leaved Ironbark and Broad-leaved Ironbark, present in the canopy along with Grey Gum *Eucalyptus punctata* and Red Bloodwood. A sparse cover of tall Casuarinas *Allocasuarina littoralis*/*Allocasuarina torulosa* is common. The understorey supports a mix of shrubs that are common on shale substrates such as Blackthorn *Bursaria spinosa* and those more commonly associated with sandstone soils such as Geebungs (*Persoonia* spp). Beneath this diverse mix of shrubs is a high cover of grass and forbs. The grass layer includes a wide range of species, most of which occur more extensively on the Cumberland Plain	80%
1790	Red Bloodwood - Grey Gum - Stringybark open forest on enriched sandstone ridges of the western Woronora plateau and lower Blue Mountains	Dry Sclerophyll Forest (shrubby formation)	Sydney Hinterland Dry Sclerophyll Forests	This forest is primarily found on the broad ridges associated with Mittagong formation sandstone in the western stretches of the Woronora Plateau between Appin and Holsworthy. These bedrocks have interbanding layers of shale and sandstone material that erode to a sandy soil with a gentle shale influence. It is most extensive within the Campbelltown and Liverpool LGAs. Outside of the Plan Area it is likely to occur on the fringes of the Cumberland Plain in north-west Sydney and the lower Blue Mountains. The community consists of a tall open eucalypt forest dominated by Grey Gum *Eucalyptus punctata* and Red Bloodwood *Corymbia gummifera*. A sparse small tree layer of Casuarina *Allocasuarina littoralis* and *Allocasuarina torulosa* is common. The understorey is typically shrubby with a diverse mix of plants common on sandstone soils including Wattles, Tea-trees, Banksias and Geebungs. Unlike sandstone woodlands however, the ground layer supports a relatively high number of grass species including Kangaroo Grass *Themeda triandra* and Spear Grass *Austrostipa pubescens* and are indicative of the presence of shale in the soil	40%
1800	Swamp Oak open forest on river flats of the Cumberland Plain and Hunter valley	Forested Wetlands	Coastal Floodplain Wetlands	This community is found on the river flats of the Cumberland Plain in western Sydney. The distinguishing feature is the prominent stands of Swamp Oak *Casuarina glauca* found along or near streams. Often these are relatively young trees, swarming amongst a mix of old and young eucalypts such as Rough-barked Apple *Angophora floribunda*, Forest Red Gum and Grey Box. This community features an open grassy and herbaceous understorey, as is typical of river flat forests	60%
	Urban Native/Exotic			Vegetation that is not consistent with floristic composition and landscape positions for native plant community types as defined by the NSW BioNet Vegetation Classification system; most commonly communities comprise of very few native species or consist of an assorted mix of planted natives	

*Adapted from the BioNet Vegetation Information System (VIS) database

Table 19-2: Justification for the identification of PCTs

PCT	Name	Species relied on for identification of the PCT*	Justification of evidence to identify the PCT
724	Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion	*E. fibrosa, M. decora*	Associated with shale-gravelly soils. This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as an open eucalypt forest with an understorey that may vary between dense shrubs and a low sparse shrub cover with an abundant ground cover of grasses, sedges and herbs, consistent with the species assemblage for this PCT
725	Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion	*E. fibrosa, E. longifolia, Melaleuca decora* and *M. nodosa*	Associated with clay soils derived from Tertiary alluvial deposits and laterized deeply weathered shale. This PCT was found in varying degrees of condition and species composition. In intact condition, the structure ranges from a moderately tall open eucalypt forest or woodland to a low dense thicket of paperbarks with low emergent eucalypts, consistent with the species assemblage for this PCT
781	Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion	*Typha orientalis, Phragmites australis, Eleocharis sphacelata, Baumea* spp. and *Persicaria decipiens*	Associated with freshwater lagoons and swamps on alluvial flats, found generally at low elevations less than 20 m above sea level, and up to 50 m above sea level. This PCT was found in varying degrees of condition and species composition. In intact condition, the lagoons consist of a range of sedges, rushes and aquatic herbs with woody shrubs and small trees, consistent with the species assemblage for this PCT
830	Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	*E. tereticornis, E. moluccana, Corymbia maculata, Clerodendrum tomentosum* and *Breynia oblongifolia*	Associated with protected aspects on steeper shale hills and rises of the southern half of the Cumberland Plain. This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as an open grassy woodland with prevalence of waxy-leaved shrubs and small trees in the understorey and a ground cover of herbs, fleshy twiners and grasses, consistent with the species assemblage for this PCT
835	Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	*Angophora floribunda, A. subvelutina, Eucalyptus tereticornis, E. amplifolia, Melaleuca* spp. and *Acacia* spp.	Associated with broad alluvial flats, streams and creeks at altitudes between one and 160 m above sea level. This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as an open eucalypt forest, with occasional sparse to open small tree stratum and a sparse lower shrub layer, with an abundant cover of grasses, small herbs and ferns, consistent with the species assemblage for this PCT

PCT	Name	Species relied on for identification of the PCT*	Justification of evidence to identify the PCT
849	Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	*E. moluccana, E. tereticornis, E. crebra* and *E. fibrosa*	Associated with gentle topography generally at less than 150 m above sea level, and can occur over 300 m above sea level in some locations. This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as an open grassy eucalypt woodland with a sparse to moderate cover of shrubs and a high cover of grasses and forbs, consistent with the species assemblage for this PCT
850	Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	*E. moluccana, E. tereticornis* and *E. crebra*	Associated with elevations between 50 m and 350 m above sea level in more rugged landforms separating this from more gentle landforms occupied by PCT 849. This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as an open woodland with an open shrub layer and a grassy ground cover, consistent with the species assemblage for this PCT
883	Hard-leaved Scribbly Gum - Parramatta Red Gum heathy woodland of the Cumberland Plain, Sydney Basin Bioregion	*E. sclerophylla, Angophora bakeri, E. parramattensis* subsp. *parramattensis* and *Melaleuca decora*	Associated with soils derived from Tertiary alluvium, or on sites located on adjoining shale or Holocene alluvium, with sandy deposits. This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as a shrubby woodland with an open, low-growing eucalypt cover, well developed shrub layer, and a diverse mix of species typically including a high cover of grasses and sedges, consistent with the species assemblage for this PCT
1081	Red Bloodwood - Grey Gum woodland on the edges of the Cumberland Plain, Sydney Basin Bioregion	*Corymbia gummifera, E. punctata,* and *Angophora costata*	This community is present on loamy soils on dry ridges in the rainshadow zone surrounding the Cumberland Plain. It occurs at elevations below 400 m above sea level. This PCT was predominantly found in moderate condition, with an intact native canopy over ground and midstorey layers subject to weed incurrence. The species composition was consistent with the species assemblage for this PCT and Proteaceae (particularly banksias) are often present
1105	River Oak open forest of major streams, Sydney Basin Bioregion and South East Corner Bioregion	*Casuarina cunninghamiana*	Associated with sand or gravel alluvium along rivers and streams between 1 m and 600 m. This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as an open or tall open forest with an open shrub layer and a dense or patchy groundcover of grasses and forbs, consistent with the species assemblage for this PCT
1181	Smooth-barked Apple - Red Bloodwood - Sydney Peppermint heathy open forest on slopes of dry sandstone gullies of western and southern Sydney, Sydney Basin Bioregion	*Angophora costata, Corymbia gummifera, E. piperita, E. pilularis, E. punctata* and *Syncarpia glomulifera*	Associated with lower slopes of dry sandstone gullies up to 600 m above sea level. This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as an open eucalypt forest with an abundant sclerophyll shrub stratum and a groundcover dominated by sedges, consistent with the species assemblage for this PCT

PCT	Name	Species relied on for identification of the PCT*	Justification of evidence to identify the PCT
1292	Water Gum - Coachwood riparian scrub along sandstone streams, Sydney Basin Bioregion	*Tristaniopsis laurina, Ceratopetalum apetalum, Tristania neriifolia,* and *Lomatia myricoides*	This community is present on sandy banks and sandstone beds of streams draining sandstone plateaux below 450 m elevation. It was mainly present in good condition within the Plan Area, with a species composition and structure that aligns with the descriptive characteristics for the PCT
1395	Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion	*E. crebra, E. fibrosa, E. punctata* and *Corymbia gummifera*	Associated with clay-rich shale soil and the coarse sandy substrates of sandstone plateaus. This PCT was found in varying degrees of condition and species composition. In intact condition, it occurs as a moderately tall eucalypt forest with a mixed understorey of sclerophyll shrubs and grasses, consistent with the species assemblage for this PCT. Generally with few to no Proteaceae present, which distinguishes the community from PCT 1081
1790	Red Bloodwood - Grey Gum - Stringybark open forest on enriched sandstone ridges of the western Woronora plateau and lower Blue Mountains	*Corymbia gummifera, E. punctata, E. oblonga and E. pilularis*	Primarily found on the broad ridges associated with Mittagong formation sandstone in the western stretches of the Woronora Plateau between Appin and Holsworthy. The community is associated with bedrocks of interbanding layers of shale and sandstone material that erode to a sandy soil with a gentle shale influence. Restricted to a narrow band of rainfall of 850-1050 mm per annum at elevations between 23 and 275 m above sea level
1800	Swamp Oak open forest on river flats of the Cumberland Plain and Hunter valley	*Casuarina glauca, Angophora floribunda, E. tereticornis* and *E. moluccana*	Associated with grey-black clay-loams and sandy loams, on drainage lines, lake margins and estuarine fringes associated with coastal floodplains, generally below 20 m elevation but up to 60 m ASL in the upper Wianamatta (South Creek) reaches. This PCT was found in varying degrees of condition and species composition. In intact condition it occurs as an open grassy and herbaceous understorey, consistent with the species assemblage for this PCT
	Urban Native/Exotic	Exotic species	This PCT is associated with exotic species, and the species assemblage was not associated with a PCT

*All plot data were entered into the BioNet PCT ID tool and the Tozer vegetation identification tool and then reviewed by ecologists with experience in the vegetation of the Cumberland Plain

19.3 NATIVE VEGETATION CONDITION

Vegetation zones have been identified within the nominated areas in accordance with the method described in Chapter 11. A vegetation zone is an area of native vegetation that is the same PCT and has a similar condition state (BAM 5.3.1.1).

There is a total of 39 vegetation zones within the nominated areas.

Table 19-4 identifies the area of each vegetation zone within each nominated area. A description of the vegetation condition categories shown in Table 10 is provided in Chapter 11.

Table 19-5 identifies the area of Non-Offsettable Grassland (NOG) in the nominated areas.

The current vegetation integrity score (a measure of vegetation condition) of each vegetation zone within the nominated areas is provided in Table 19-6. The vegetation integrity score has not been calculated for each nominated area separately as the nominated areas comprise a single biodiversity certification area over which all plots were collected.

Map 14.1, Map 14.2, Map 14.3 and Map 14.4 show the vegetation zones within each nominated area.

Table 19-4: Vegetation condition and amount (ha) of each PCT and condition type within the nominated areas

*Vegetation integrity scores are only calculated for zones impacted by the proposed development. Of the 39 zones in the nominated areas, 30 are impacted

20 Threatened ecological communities

A total of nine NSW-listed TECs occur within the nominated areas.

The method to determine the TECs that occur within the nominated areas is explained in Chapter 11.

Identification of the NSW-listed TECs that occur within the nominated areas, as well as the extent of each TEC within each nominated area, is provided in Table 20-1.

Table 20-1 also indicates whether a PCT is notionally associated with a Commonwealth-listed TEC. It is important to note that Commonwealth-listed TECs often do not align exactly to a PCT and are usually defined differently to NSW-listed TECs. Commonwealth-listed TECs are described and assessed in Chapter 31.

The five most extensive NSW TECs within the nominated areas are:

- Cumberland Plain Woodland – 3,573 ha (this comprises 3,049 ha of PCT 849, and 524 ha of PCT 850)
- Shale Sandstone Transition Forest – 3,326 ha
- River-flat Eucalypt Forest on Coastal Floodplains – 1,170 ha
- Swamp Oak Floodplain Forest – 233 ha
- Shale Gravel Transition Forest – 191 ha

Map 15.1, Map 15.2, Map 15.3 and Map 15.4 show the distribution of TECs within each nominated area.

Table 20-1: TECs and amount (ha) of each TEC within the nominated areas

PCT	NSW TEC name	NSW status^	Area (ha)					Commonwealth TEC name	Cth status^

21 Threatened species and habitat

This Chapter identifies the NSW-listed ecosystem credit species (ECS) and candidate species credit species (SCS) predicted to occur within the nominated areas and provides maps of the locations of the habitat for candidate SCS.

The method to predict the ECS and SCS within the nominated areas is explained in Chapter 9.

21.1 ECOSYSTEM CREDIT SPECIES

The ECS predicted to occur within the nominated areas are provided in Table 21-1.

The method to predict the ECS within the nominated areas is explained in Chapter 11.

A total of 45 ECS are predicted to occur within the nominated areas.

For this assessment, it was assumed that all ECS predicted to occur within the nominated areas are present, and no ECS were excluded from the assessment as allowed under section 6.4 of the BAM.

Table 21-1: Ecosystem credit species predicted to occur within the nominated areas

Scientific name	Common Name	NSW status^	Cth status^	Habitat constraints	Sensitivity to gain class	Predicted location			
						Wilton	GMAC	WSA	GPEC
*Anthochaera phrygia**	Regent Honeyeater	CE	CE	N/A	High	Yes	Yes	Yes	Yes
Artamus cyanopterus cyanopterus	Dusky Woodswallow	V	N/A	N/A	Moderate	Yes	Yes	Yes	Yes
Botaurus poiciloptilus	Australasian Bittern	E	E	Waterbodies; brackish or freshwater wetlands.	Moderate	No	Yes	Yes	Yes

*These species are ECS in relation to foraging habitat only

21.1.1 SPECIES CREDIT SPECIES

Section 6.4 of the BAM sets out a process for determining the SCS that need to be assessed in the Assessment Report. The method to predict the candidate SCS within the nominated areas is explained in Chapter 11.

In summary, the steps involve:

- Generating a list of SCS predicted to occur within the nominated areas according to the BAM calculator
- Identifying candidate SCS that require further assessment by considering whether any SCS can be excluded on the basis of specific considerations under the BAM. Where this occurs, adequate justification must be provided

A SCS may be excluded from needing further assessment because:

- Ecological information about a species provided in BioNet or published, peer reviewed literature, suggests that the SCS is unlikely to occur, or habitat is unlikely to be suitable (BAM section 6.1.1.2)
- Habitat constraints (defined in Threatened Biodiversity Data Collection) are not present (BAM section 6.4, step 2)
- Habitat is not suitable because it is substantially degraded (BAM section 6.4, step 3)
- An expert report determines that habitat for the species is unlikely to be present (BAM section 6.4, step 3)

For any SCS not excluded from needing further assessment, section 6.4.1.21 of the BAM requires a determination of whether the SCS is present, or likely to use suitable habitat, within the urban capable lands, by either:

- Assuming the species is present (this was done using a knowledge-based method (KBM) (see Chapter 11)
- Undertaking a threatened species survey
- Providing an expert report

Table 21-2 identifies the list of SCS predicted to occur according to the BAM calculator, and:

- The nominated area that the SCS is predicted to occur within (marked with a tick or cross)
- Whether the SCS has been removed from needing further assessment within a nominated area (marked with an 'R')
- The remaining list of candidate SCS
- The method used to determine the presence of each candidate SCS

Attachment A in Chapter 11 provides a justification for each SCS removed from needing further assessment and identifies the relevant section of the BAM under which a SCS was removed. Section 6.1.1.2 of the BAM was the primary basis used for removing a SCS from needing further assessment.

A total of 84 SCS were predicted to occur within the nominated areas.

Of these, 40 SCS were determined to be candidate SCS needing further assessment, and 44 were removed.

Table 21-3 identifies the amount of habitat for each candidate SCS in the nominated areas.

The following maps show the distribution of habitat within the nominated areas for each candidate SCS:

- Map 16.1 – *Acacia bynoeana*

Part 5B Contents

Part 5B List of Tables

22 Introduction

This Part provides an assessment of the impacts of the urban, industrial, infrastructure, agribusiness and transport development under the Plan within the nominated areas for matters listed under the BC Act in accordance with the BAM, including:

- Direct impacts on Plant Community Types (PCTs), threatened ecological communities (TECs), and threatened species and habitat (Chapter 23)
- Prescribed impacts (Chapter 24)
- Serious and irreversible impacts (SAII) (Chapter 25)
- Impact summary, including the number of credits that would be required to be retired to offset the impacts (Chapter 26)

Direct impacts described in Chapter 23 are identified in terms of:

- Impacts of urban, industrial, infrastructure, and agribusiness development within each nominated area and total impacts across all nominated areas
- Total impacts of the transport development across all nominated areas
- Total impacts of the urban, industrial, infrastructure, agribusiness and transport development across all nominated areas

Note that the only development types in Wilton Growth Area (Wilton) are urban, industrial and infrastructure development.

Avoidance and minimisation of impacts on biodiversity values is described in Chapter 14.

Indirect impacts on native vegetation and habitat are described in Chapter 15.

23 Direct impacts on native vegetation and habitat

23.1 APPROACH TO THE ASSESSMENT

The BAM defines in detail the method for addressing direct impacts. In summary, this involved:

- Assessing the direct impacts that will result from the clearing of native vegetation, TECs and threatened species habitat (Section 9.1.2 of the BAM)
- Calculating:
  - The change in vegetation integrity for each vegetation zone and species polygon (Section 9.1.3 of the BAM)
  - The required number of ecosystem credits for direct impacts (Section 11.2.3 of the BAM)
  - The required number of species credits for direct impacts (Section 11.2.4 of the BAM)
- Identifying the credit class for ecosystem credits and species credit (Section 11.3 of the BAM)

23.2 NATIVE VEGETATION

23.2.1 VEGETATION ZONES

Table 23-1 summarises the amount (hectares) of each vegetation zone that will be directly impacted within the nominated areas, including:

- Urban, industrial, infrastructure, and agribusiness development
- Transport development
- Total impacts from the urban, industrial, infrastructure, agribusiness and transport development

A total of 1,777.79 ha of native vegetation occurs within the urban capable land and transport corridors and will be impacted by the development. The five most impacted vegetation zones (excluding non-offsettable grassland) are:

- PCT 849_Thinned – 335.61 ha
- PCT 849_DNG – 239.17 ha
- PCT 1395_DNG – 237.30 ha
- PCT 850_DNG – 188.45 ha
- PCT 1395_Thinned – 155.05 ha

Table 23-1: Direct impacts on vegetation zones within each nominated area

^ While hollow-bearing trees were not recorded within plots used to assess that vegetation zone, they may occur elsewhere within the vegetation zone

* Totals highlighted in blue are based on raw vegetation data outputs. Some rounding errors may occur between the impact areas quoted for each nominated area and the summed total for each vegetation zone.

23.2.2 NON-OFFSETTABLE GRASSLAND

Table 23-2 provides a summary of impacts to non-offsettable grassland vegetation types within the nominated areas.

Non-offsettable grassland comprises grassland vegetation zones with a vegetation integrity score of <15 and does not require offsetting for the associated PCT under the BAM. However, where non-offsettable grasslands support species credit species habitat, offsets may be required for those species.

Table 23-2: Direct impacts on non-offsettable grassland (NOG) within the nominated areas

Vegetation zone			Area (ha) impacted					
Vegetation zone ID	PCT	Condition	Wilton	GMAC	WSA	GPEC	Transport development	Total*
835_NOG	835	NOG	0.0	14.42	432.24	285.24	209.69	**941.59**
849_NOG	849	NOG	653.31	1,283.23	2,266.76	619.44	312.34	**5,135.07**
850_NOG	850	NOG	12.27	441.48	9.96	219.05	0.0	**682.75**
1395_NOG	1395	NOG	331.06	447.38	0.0	0.0	0.0	**778.44**

* Totals highlighted in blue are based on raw vegetation data outputs. Some rounding errors may occur between the impact areas quoted for each nominated area and the summed total for each vegetation zone.

23.2.3 VEGETATION INTEGRITY

Table 23-3 shows the change in vegetation integrity as a result of the urban, industrial, infrastructure, agribusiness and transport development within the nominated areas. Change in vegetation integrity is a measure of the direct impact on native vegetation and species habitat.

It has been assumed that all vegetation will be removed within the urban capable land of each nominated area and within the transport corridors and therefore the future vegetation integrity score will be zero.

In practice some vegetation will likely be retained through Development Control Plans and other instruments, including hollow-bearing trees and other vegetative features required for the threatened species habitat be retained across the landscape (see Chapter 15).

Table 23-3: Change in vegetation integrity due to urban, industrial, infrastructure, agribusiness and transport development

Vegetation zone			Area (ha) impacted	Current vegetation integrity score before development	Future vegetation integrity score after development	Change in vegetation integrity score

23.3 THREATENED ECOLOGICAL COMMUNITIES

Table 23-4 summarises the amount (hectares) of each TEC that will be directly impacted within the nominated areas, including:

- Urban, industrial, infrastructure and agribusiness development
- Transport development
- Total impacts from the urban, industrial, infrastructure, agribusiness and transport development

A total of 1,777.79 ha of TECs occurs within the urban capable land and transport corridors and will be impacted by the development. The TEC mapping method used is generally conservative and is more likely to over-predict distribution of TECs. Limitations to the mapping are further discussed in Chapter 13.3.

The five most impacted TECs are:

- Cumberland Plain Woodland – 1,014.52 ha
- Shale Sandstone Transition Forest – 487.72 ha
- River-flat Eucalypt Forest on Coastal Floodplains – 165.14 ha
- Shale Gravel Transition Forest – 52.20 ha
- Cooks River/Castlereagh Ironbark Forest – 36.85 ha

23.4 THREATENED SPECIES AND SPECIES HABITAT

Table 23-5 identifies the amount of habitat (in hectares) of each candidate species credit species (SCS) that will be directly impacted within the nominated areas, including:

- Urban, industrial, infrastructure, and agribusiness development
- Transport development
- Total impacts from the urban, industrial, infrastructure, agribusiness and transport development

The five SCS with the largest area of potential habitat impacted are:

- *Pimelea spicata* – 847.75 ha
- *Myotis macropus* – 745.24 ha
- *Meridolum corneovirens* – 736.40 ha
- *Acacia pubescens* – 734.15 ha
- *Grevillea juniperina* subsp. *juniperina* – 457.75 ha

It is important to note that the knowledge-based method used to determine habitat for some species is based on assuming presence within areas of potential habitat. The method is therefore likely to greatly overestimate the amount of actual or known habitat for these species impacted by the development (see Chapter 11).

The BAM requires certain candidate SCS to be assessed by a count of the species individuals directly impacted, rather than the area of habitat. One candidate SCS, *Epacris purpurascens* var. *purpurascens* requires assessment by a count of individuals. As the KBM process is limited to modelling habitat based on area, a modelled count of individuals is not possible. To address this for *Epacris purpurascens* var. *purpurascens* the following process was used to derive a biodiversity credit requirement for impacts to the species:

- The ratio of credits per hectare required for impacts to all species credit species was determined by dividing the number of credits by the area of impact (in hectares)
- The Biodiversity Risk Weighting (BRW) was assessed for all candidate species credit species. This included *Epacris purpurascens* var. *purpurascens* which was found to by 1.5
- The average credits per hectare ratio was calculated for all other species with a BRW of 1.5
  - Little Eagle and Square-tailed Kite were excluded due to an over-representation of impacts associated with Non-offsettable Grassland, which brings down the ratio of credits per hectare
- Modelled impact to *Epacris purpurascens* var. *purpurascens* habitat were multiplied by the average credits per hectare ratio for all other species with a BRW of 1.5 to determine the biodiversity credit for *Epacris purpurascens* var. *purpurascens*
  - This calculation was undertaken separately for the Wilton and Greater Macarthur Growth Areas (GMAC) due to a difference in the average credits per hectare ratio
- This biodiversity credit requirement was then used to determine the stem count required to be entered into the BAM Calculator by dividing the number of credits required by *Epacris purpurascens* var. *purpurascens'* offset multiplier of 1.5

Note that Little Eagle and Square-tailed Kite are candidate SCS for breeding habitat only. Expert reports were prepared for these species that mapped areas of 'breeding and foraging habitat' (equating to potential breeding habitat) within Wilton and GMAC. An additional 1,322.98 ha of foraging habitat for Little Eagle and 510.84 ha of foraging habitat for Square-tailed Kite were mapped within the expert reports which have not been included in the candidate SCS calculations, as they are not considered to be impacts to the species as required by the BAM and include mainly grassed paddocks. Potential breeding habitat is generally restricted to heavily vegetated areas outside urban capable lands, however there is considerable overlap between potential forage habitat and urban capable land. In addition, impacts of 0.80 ha to a buffer around a confirmed stick nest (species not known) in GPEC, associated with grassed paddocks commensurate with the habitat mapped as potential forage habitat by the expert in Wilton and GMAC, has also been excluded from the candidate SCS calculations.

^CE = critically endangered; E = endangered; V = vulnerable; E.pop. = endangered population

*These species are SCS in relation to breeding habitat or mapped "important habitat" only

+7.58 hectares of impact to Green and Golden Bell Frog is associated with vegetation removal and hence has been entered into the BAM Calculator to determine the resultant credit requirement. The remaining 5.76 hectares of impact is associated with man-made structures and has been assessed under Prescribed Impact in Section 16.3 of the BCAR

#839.18 hectares of impact to *Pimelea spicata* is associated with vegetation removal and hence has been entered into the BAM Calculator to determine the resultant credit requirement. The remaining 8.6 hectares of impact (as mapped by the species expert) is associated with Non-Native Vegetation and has been assessed under Prescribed Impact in Section 16.3 of the BCAR

~ Totals highlighted in blue are based on raw habitat data outputs. Some rounding errors may occur between the impact areas quoted for each nominated area and the summed total for each species

24 Prescribed biodiversity impacts

24.1 INTRODUCTION

The BAM requires prescribed impacts to be identified and assessed.

This Chapter sets out:

- The definition of prescribed impacts
- The approach taken to assessing prescribed impacts
- Identification of relevant prescribed impacts
- Assessment of the impacts of the urban, industrial, infrastructure, agribusiness and transport development within the nominated areas under the Plan in relation to each relevant prescribed impact

24.2 DEFINITION OF PRESCRIBED IMPACTS

Prescribed impacts can be defined generally as impacts on biodiversity values that do not comprise direct clearing of native vegetation that are assessed through credits. Prescribed impacts can be direct impacts (e.g. impacts on species' habitat of a type that is not native vegetation, such as rocks) or indirect impacts (e.g. impacts on species associated with the severing of a habitat corridor). Prescribed impacts comprise impacts on (Clause 6.1, BC Regulation):

- Habitat features for threatened species or TECs:
  - Karst, caves, crevices, cliffs and other geological features of significance
  - Rocks
  - Human-made structures
  - Non-native vegetation
- Connectivity of habitat of threatened species that facilitates the movement of those species across their range
- Movement of threatened species that maintains their lifecycle
- Water quality, water bodies and hydrological processes that sustain threatened species and TECs
- Wind turbine strikes on protected fauna
- Vehicle strikes on threatened fauna or fauna that is part of a TEC

24.3 APPROACH TO THE ASSESSMENT

The BAM requires the BCAR to identify and assess prescribed impacts within the nominated areas.

Section 6.7 of the BAM requires the BCAR to:

- Identify occurrences of habitats associated with prescribed impacts
- List the candidate SCS or ecosystem credit species (ECS) or TECs associated with those habitats
- Undertake targeted surveys for any relevant candidate SCS

Section 9.1.1.2 and 9. 2 of the BAM requires the BCAR to:

- Describe the nature, extent, frequency, duration and timing of prescribed impacts relevant to the proposed development, including impacts during construction and operation
- Evaluate the consequences of prescribed impacts

The steps taken to assess prescribed impacts involved:

Step 1: Identify the relevant species and TECs (including ECS and candidate SCS) associated with each prescribed impact type within the nominated areas. This was done by drawing on ecological and life history information in BioNet profiles, as well as species records, habitat maps, and surveys undertaken for this assessment.

The following was described for each species or TEC:

- Likely presence/abundance of species/TEC in the nominated areas
- Use and importance of the prescribed impact type for the TEC/species

A combination of targeted surveys and habitat assessments was undertaken within urban capable land by senior ecologists for the range of species associated with prescribed impacts where land access was granted. Survey effort and species subject to targeted surveys (based on tracks or survey points) is set out in Chapter 11.

Step 2: Map the occurrence of each prescribed impact type within the nominated areas where possible. Where mapping was not possible (human-made structures, vehicle strikes) or not necessary (rock outcrops – see Section 24.7), the occurrence of the prescribed impact type in each nominated area was described and assessed qualitatively.

Mapping was undertaken for:

- Karst, caves, crevices, cliffs and other geological features of significance
- Non-native vegetation
- Habitat connectivity and movement
- Water bodies and hydrological processes

The mapping of each prescribed impact type was overlayed on the urban capable land within each nominated area to provide impact data and other information on the nature, extent and duration of impacts

Step 3: Describe the nature, extent, and duration of each prescribed impact type:

- Nature of impacts – qualitatively describe any direct impacts (e.g. removal or destruction of habitat) or indirect impacts (e.g. reduction in habitat connectivity, human use/disturbance, urban run-off)
- Extent of impacts – quantify the amount of direct impacts where possible (e.g. the amount of habitat removed or destroyed (ha)) or the general location and extent of indirect impacts
- Duration – identify whether the impacts are permanent or temporary

Step 4: Describe the commitments and general environmental controls that will be implemented under the Plan through the NSW planning system to mitigate the prescribed impacts

Step 5: Assess the likelihood of residual prescribed impacts on each TEC and species taking into account the general environmental controls to mitigate the impacts. This was done taking into account matters such as:

- Likely presence/abundance of species/TEC and importance of the location at a local and regional scale
- Life history traits and susceptibility of the species/TEC to the prescribed impact
- Location of the species/TEC relative to the likely extent of the prescribed impact
- Amount and quality of unimpacted habitat remaining and levels of existing protection

Step 6: Describe any additional specific mitigation measures for particular species/TECs that will be implemented under the Plan to address residual prescribed impacts remaining after the application of general environmental controls

24.4 RELEVANT PRESCRIBED IMPACTS

The following prescribed impact types are relevant to the development:

- Karst, caves, crevices, cliffs and other geological features of significance
- Rocks
- Human-made structures
- Non-native vegetation
- Habitat connectivity and movement
- Water bodies and hydrological processes
- Vehicle strikes

Prescribed impacts may be associated with direct or indirect impacts. Table 24-1 sets out the potential types of impacts associated with each prescribed impact type that are relevant to the development.

The prescribed impact type 'wind turbine strikes on protected fauna' is not relevant to the development and has not been considered further in this Assessment Report.

Table 24-1: Types of impacts associated with each prescribed impact type

Prescribed impact type	Associated potential direct impacts	Associated potential indirect impacts
Karst, caves, crevices, cliffs	Removal or destruction (e.g. cracking or collapse) of habitat	Recreational use/disturbance Noise or light disturbance
Rocks	Removal of habitat (rocks)	
Human-made structures	Removal of habitat (structures)	Human disturbance Noise or light disturbance
Non-native vegetation	Removal of habitat (non-native vegetation)	Recreational use/disturbance Weed invasion Spread of plant/animal disease Pest animals/predation/competition Soil erosion/sedimentation Urban run-off (water quality)
Habitat connectivity/movement	N/A	Reduction in habitat connectivity
Water bodies/hydrological processes	Removal of habitat (water bodies)	Change in water flows/quantity Urban run-off (water quality)
Vehicle strikes	Death of species individuals	N/A

24.5 PRESENCE/ABUNDANCE OF RELEVANT SPECIES

Table 24-2 identifies the presence and abundance of species and TECs associated with each prescribed impact type.

Note about Koala: development under the Plan within the nominated areas has the potential to impact the Southern Sydney Koala population. The direct, indirect and prescribed impacts from the development within the Plan Area on Koala has been assessed in detail in Chapter 30 and is not covered in this chapter.

Table 24-2: Relevant species/TECs potentially subject to prescribed impacts

Scientific name	Common name	Presence/abundance in nominated areas	Relevant prescribed impact type
Plants			
Acacia bynoeana	Bynoe's Wattle	Records occur to the north of GPEC where there are a significant number of populations, and in Wilton in avoided/excluded lands	• Non-native vegetation
Grevillea juniperina subsp. *Juniperina*	Juniper-leaved Grevillea	Records occur in Western Sydney Aerotropolis (WSA) and Greater Penrith to Eastern Creek Investigation Area (GPEC). Most records for the species occur just north of GPEC. The species is known to occur in disturbed land at Marsden Park (Weston, 2019)	• Non-native vegetation

Scientific name	Common name	Presence/abundance in nominated areas	Relevant prescribed impact type
Hibbertia fumana		Species is only known from the Moorebank and Bankstown areas outside the nominated areas. However, the species is recently described and if present, could have been recorded under a different name in previous studies	• Non-native vegetation
Hibbertia puberula		There are no records within the Plan Area. This species is only known from Bankstown Airport and has not been recorded at any other sites, despite targeted surveys throughout the Bankstown area	• Non-native vegetation
Persoonia bargoensis	Bargo Geebung	Records occur on the edge of Wilton within avoided/excluded lands. These records are part of a single population of the species that spans from Bargo, to Picton in the north west, through to Appin in the east	• Non-native vegetation
Pimelea spicata	Spiked Rice-flower	Records occur in GPEC and GMAC in avoided/excluded lands. Most records occur in the Blacktown, Prospect, Bankstown and Narellan districts. One population in GMAC occurs within roadside vegetation	• Non-native vegetation
Bats			
Chalinolobus dwyeri	Large-eared Pied Bat	Records occur throughout the Cumberland subregion. Breeding habitat is associated with sandstone caves, crevices and cliffs. Most records occur in the south of the subregion around Wilton. Interrogation of BioNet records suggests no roost sites occur in the nominated areas	• Karsts, caves, crevices and cliffs • Non-native vegetation • Habitat connectivity
Falsistrellus tasmaniensis	Eastern False Pipistrelle	Records occur within and surrounding the Cumberland subregion. Most records in the subregion occur in the eastern and northern parts. Few records occur in the nominated areas. The species has not been recorded in WSA	• Human-made structures • Non-native vegetation • Habitat connectivity
Miniopterus australis	Little Bentwing-bat	Few records occur within the Cumberland subregion. The species has been recorded in three of the nominated areas (not WSA), including recently (< 5 years ago) in Wilton. Most records surrounding the subregion occur in coastal areas to the north	• Karsts, caves, crevices and cliffs • Human-made structures • Non-native vegetation • Habitat connectivity
Miniopterus orianae oceanensis	Large Bent-winged Bat	Records are widespread within and surrounding the Cumberland subregion. The species has been recorded in all four nominated areas, including recently (< 5 years ago)	• Karsts, caves, crevices and cliffs • Human-made structures • Non-native vegetation • Habitat connectivity
Mormopterus norfolkensis	Eastern Freetail-bat	Records are widespread within and surrounding the Cumberland subregion. The species has been recorded in all four nominated areas, including recently (< 5 years ago) in Wilton and GPEC	• Human-made structures • Non-native

Scientific name	Common name	Presence/abundance in nominated areas	Relevant prescribed impact type
			vegetation • Habitat connectivity
Myotis macropus	Southern Myotis	Records are widespread within and surrounding the Cumberland subregion. The species has been recorded in all four nominated areas, including recently (< 5 years ago) particularly in Wilton and GPEC and just outside the northern part of GMAC. Suitable habitat has been mapped within each of the nominated areas. Suitable habitat occurs as scattered small to moderate size patches associated with native vegetation, including vegetation in low to moderate condition	• Human-made structures • Habitat connectivity • Water bodies
Pteropus poliocephalus	Grey-headed Flying-fox	The Plan Area supports significant numbers of the species across a number of camps. The location of breeding and roosting camps within the Cumberland subregion has been monitored since 2012 (Geoscience Australia, 2015). There are no known camps in the urban capable lands	• Non-native vegetation • Habitat connectivity
Saccolaimus flaviventris	Yellow-bellied Sheathtail-bat	Records occur within and surrounding the Cumberland subregion. Few records occur in the nominated areas. The species has not been recorded in WSA. Roost requirements are poorly known	• Human-made structures • Non-native vegetation • Habitat connectivity
Scoteanax rueppellii	Greater Broad-nosed Bat	Records occur within and surrounding the Cumberland subregion. Most records for the species in the subregion occur in the eastern part. Few records occur in the nominated areas	• Human-made structures • Non-native vegetation • Habitat connectivity
Marsupials			
Cercartetus nanus	Eastern Pygmy-possum	No records occur in the nominated areas. Records occur to the south and east of Wilton and east of GMAC outside the Cumberland subregion. Suitable habitat for the species is generally restricted to the gorges and gullies on the edges of Wilton, on the edges and through the middle of the southern part of GMAC, along riparian corridors in WSA and GPEC, and associated with larger patches of native vegetation within Wianamatta Regional Park and Orchid Hills	• Habitat connectivity • Vehicle strikes
Dasyurus maculatus	Spotted-tailed Quoll	Several important populations for the species have been identified within the vicinity of the nominated areas. Suitable habitat is generally restricted to the gorges and gullies on the edges of the nominated areas and along waterways	• Non-native vegetation • Habitat connectivity • Vehicle strikes
Petaurus australis	Yellow-bellied Glider	No records occur in the nominated areas. Closest record occurs < 1 km away from Wilton. There are 6 records north of GPEC, 3 records west of Wilton, and one record east of Wilton, all within the Plan Area. The majority of records occur outside the Plan Area to the north-east and south-west	• Habitat connectivity • Vehicles strikes

Scientific name	Common name	Presence/abundance in nominated areas	Relevant prescribed impact type
Petaurus norfolcensis	Squirrel Glider	Records in the nominated areas are limited. There are 2 records in Wilton and one in GPEC, all of which occur on avoided lands	• Habitat connectivity • Vehicles strikes
Frogs			
Litoria aurea	Green and Golden Bell Frog	Records in the nominated areas are limited. There are 12 records within GPEC and two records within GMAC. Suitable habitat has been mapped along Ropes Creek in GPEC in the vicinity of 6 records made between 1998 and 2012. It has not been confirmed whether this population still exists. However, there are a series of other records from nearby habitat associated with Ropes Creek more broadly and areas of suitable habitat remain along the corridor in the form of a high density of water bodies (Lemckert, 2019)	• Non-native vegetation • Habitat connectivity • Water bodies • Vehicle strikes
Pseudophryne australis	Red-crowned Toadlet	There are no records within the nominated areas. Closest records occur within a few kilometres of the nominated areas. Mapped suitable habitat occurs in scattered patches within the vicinity of gorges and gullies that occur mainly around the edges of the nominated areas	• Rocky areas • Habitat connectivity
Reptiles			
Hoplocephalus bungaroides	Broad-headed Snake	There are no recent records in the nominated areas. There is one historical record from 1970 in the Appin area. Mapped suitable habitat occurs along riparian corridors in gorges and gullies that occur mainly around the edges of the nominated areas	• Karsts, caves, crevices and cliffs • Rocky areas • Vehicle strikes
Varanus rosenbergi	Rosenberg's Monitor	No records occur in the nominated areas and very few records occur in the Cumberland subregion. Records occur at the edges of the subregion near Gordon and Dharawal National Park. The species is associated with sandstone areas, particularly to north-east, south-east and north-west of Sydney (OEH, 2017i) and is considered unlikely to occur in the nominated areas, and is not considered further in this Chapter	N/A
Birds			
Anthochaera phrygia	Regent Honeyeater	There are 78 records in the Plan Area which mostly occur in larger patches of woodland in the Londonderry area. Records in the nominated areas are limited, with one occurring in east Wilton and 3 occurring in north-east GPEC	• Habitat connectivity
Artamus cyanopterus cyanopterus	Dusky Woodswallow	There are 96 records in the nominated areas. The species is abundant in and around the Cumberland subregion	• Non-native vegetation • Habitat connectivity
Botaurus poiciloptilus	Australasian Bittern	Records in the nominated areas are limited to one record in the north of GPEC. Six records occur to the north of GPEC and 4 are scattered between WSA, GMAC and Wilton within the Plan Area	• Habitat connectivity • Water bodies

Scientific name	Common name	Presence/abundance in nominated areas	Relevant prescribed impact type
Calidris ferruginea	Curlew Sandpiper	The species occurs in and around the Cumberland subregion, most frequently closer to the coast. There are 40 records in the Plan Area, the majority of which are concentrated around Windsor. One record occurs in GMAC, within avoided/excluded lands	• Habitat connectivity
Callocephalon fimbriatum	Gang-gang Cockatoo	The species occurs in and around the Cumberland subregion. Records within the nominated areas are limited. One record occurs in the north of GPEC, 3 in Wilton along the boundary, and 10 in GMAC	• Habitat connectivity
Calyptorhynchus lathami	Glossy Black Cockatoo	The species occurs in and around the Cumberland subregion. Records in the nominated areas are limited. There are 2 records in the north of GPEC, 4 in Wilton, and 3 in GMAC	• Habitat connectivity
Circus assimilis	Spotted Harrier	Records in the nominated areas are limited. One record occurs in GPEC and 2 in GMAC. The majority of records in the Plan Area occur in the north-east around the Richmond area	• Habitat connectivity
Climacteris picumnus victoriae	Brown Treecreeper	This species occurs sparsely in the Cumberland subregion with the highest density of records occurring in the Blue Mountains and Wolgan Valley regions. Records within the nominated areas are limited. There are 2 records in the north-east of GPEC, 3 in the east of Wilton, and 5 throughout GMAC	• Habitat connectivity
Daphoenositta chrysoptera	Varied Sittella	The species occurs in and around the Cumberland subregion. There are 17 records in GPEC, 3 in WSA, 1 in Wilton, and 8 in GMAC	• Habitat connectivity
Ephippiorhynchus asiaticus	Black-necked Stork	Records in the nominated areas are limited. There are 3 records in GPEC and 1 record in GMAC. Outside the nominated areas within the Plan Area there are a further 9 records, the majority of which are located in and around Windsor	• Water bodies
Epthianura albifrons	White-fronted Chat	Records within the nominated areas are limited. There is only 1 record in the nominated areas, located in GMAC. There are a further 3 records outside the nominated areas within the Plan Area, which are located in Liverpool, Windsor, and Scheyville National Park	• Habitat connectivity
Glossopsitta pusilla	Little Lorikeet	The species is abundant and wide-spread in and around the Cumberland subregion. There are 17 records in Wilton, 8 in GPEC, and 22 in GMAC	• Habitat connectivity
Grantiella picta	Painted Honeyeater	The species occurs sparsely in the Cumberland subregion. There are 5 records within the Plan Area, none of which occur in the nominated areas. Four records occur north of GPEC and one east of WSA in Smithfield	• Non-native vegetation • Habitat connectivity

Scientific name	Common name	Presence/abundance in nominated areas	Relevant prescribed impact type
Haliaeetus leucogaster	White-bellied Sea-eagle	There are several records in the nominated areas. There is one old record in GPEC and two records in the central part of WSA, including a recent (2017) record. There is a cluster of relatively recent records (2013) within or just outside the central part of GPEC, and several other records in the southern part of GPEC. There are several recent (2018) records just outside the northern part of the GPEC to the east. There are no records in Wilton	• Habitat connectivity • Water bodies
Hieraaetus morphnoides	Little Eagle	There are 35 records of the species within the nominated areas or within 5 km of their boundaries. Most records are associated with large patches of open woodland that occur within open grassland areas. Some records are found close to the edges of forests along watercourses. A few records are from woodlands associated with wetlands (Saunders and Debus, 2018a)	• Non-native vegetation • Habitat connectivity
Irediparra gallinacean	Comb-crested Jacana	There are 18 records of the species in the Plan Area, 17 of which occur north of GPEC, with 1 just north of GMAC. There are no records in the nominated areas	• Habitat connectivity • Water bodies
Ixobrychus flavicollis	Black Bittern	The species occurs sparsely in the Cumberland subregion with the majority of records occurring closer to the coast. There are 15 records in the Plan Area, 2 of which occur in GPEC	• Habitat connectivity • Water bodies
Lathamus discolor	Swift Parrot	The species is abundant and wide-spread in and around the Cumberland subregion. There are 135 records in the Plan Area, 25 of which occur in GPEC and 5 in GMAC	• Habitat connectivity
Limicola falcinellus	Broad-billed Sandpiper	There are no records of the species in the Plan Area. The closest record is approximately 9 km east towards the coast	• Habitat connectivity
Limosa limosa	Black-tailed Godwit	There are no records in the nominated areas. Eight records occur in the Plan Area, with the closest approximately 2 km west of GPEC	• Habitat connectivity
Lophoictinia isura	Square-tailed Kite	There are 32 records in the nominated areas, including 12 within Wilton and the southern part of GMAC. Another 15 records occur within 5 km of the nominated areas, with 11 occurring just outside the northern part of GMAC. The majority of records are from January to April, which represents the post-breeding dispersal phase (Saunders and Debus, 2018b)	• Non-native vegetation • Habitat connectivity
Melithreptus gularis gularis	Black-chinned Honeyeater	The species is wide-spread in and around the Cumberland subregion, with a higher abundance further north around Glen Davis and the Hunter. There are 48 records in the Strategic Assessment Area; 1 in Wilton, 2 in GPEC and 2 in GMAC	• Habitat connectivity

Scientific name	Common name	Presence/abundance in nominated areas	Relevant prescribed impact type
Neophema pulchella	Turquoise Parrot	The species occurs in and around the Cumberland subregion with higher densities of records found in Glen Davis, Mellong, and near Yerranderie State Conservation Area. There are 28 records in the Plan Area, 6 of which occur in GMAC and 1 in Wilton	• Habitat connectivity
Ninox connivens	Barking Owl	The species occurs in and around the Cumberland subregion. There are 16 records in the Plan Area, 2 of which occur in Wilton and GMAC	• Non-native vegetation • Habitat connectivity
Ninox strenua	Powerful Owl	The species occurs in and around the Cumberland subregion. There are 121 records in the Plan Area, including 18 records in GMAC, 10 in GPEC and 3 in Wilton	• Non-native vegetation • Habitat connectivity
Pandion cristatus	Eastern Osprey	There are 4 records in the Plan Area, one of which occurs in GPEC. Relatively more records occur to the east of the Plan Area along the coast	• Habitat connectivity • Water bodies
Rostratula australis	Australian painted-snipe	The species is sparsely distributed in and around the Cumberland Plain. There are 19 records in the Plan Area, of which 1 occurs in GPEC and 1 in GMAC	• Water bodies
Stagonopleura guttata	Diamond Firetail	The species occurs in and around the Cumberland subregion. There are 93 records in the Plan Area of which 15 occur in GPEC, 6 in GMAC, and 1 in Wilton	• Habitat connectivity
Stictonetta naevosa	Freckled Duck	The species is sparsely distributed in and around the Cumberland subregion. There are 30 records for the species in the Plan Area, mostly concentrated around Windsor. Of which 7 occur in GPEC and 1 in WSA	• Habitat connectivity • Water bodies
Tyto novaehollandiae	Masked Owl	The species occurs in and around the Cumberland subregion, with higher concentrations occurring around the Central Coast and Nowra. There are 34 records in the Plan Area, of which 3 occur in GMAC and 1 in GPEC	• Non-native vegetation • Habitat connectivity
Snail			
Meridolum corneovirens	Cumberland Plain Land Snail	The species is largely endemic to the Cumberland subregion, with a few records occurring just outside. There are 976 records in the Plan Area, of which 210 occur in GPEC, 66 in GMAC, 13 in WSA and 3 in Wilton. Records are scattered across the subregion. Most records occur outside the nominated areas or on excluded land	• Habitat connectivity

24.6 ASSESSMENT OF KARST, CAVES, CREVICES, CLIFFS

24.6.1 LIST OF RELEVANT SPECIES AND TECS

The list of species associated with karst, caves, crevices and cliffs is shown in Table 24-3.

Table 24-3: Species associated with karst, caves, crevices, cliffs and other geological features

Relevant species	Use and importance of habitat type
Broad-headed Snake	Broad-headed Snake may use rocky areas and crevices for refuge. Adults shelter in rocky outcrops under flat sandstone rocks on exposed cliff edges during autumn, winter and early spring, then move to adjacent woodland within 500 m of rocky areas during late spring and summer. Pregnant females and juveniles remain in rocky habitat, using cooler, shaded rocks and crevices (DoEE, 2018a)
Large Bent-winged Bat	Large Bent-winged Bat mainly roosts in caves with very specific temperature and humidity regimes. It can also use mines, storm water tunnels, buildings and other human-made structures. The species disperses widely from breeding colonies (within 300 km. Interrogation of BioNet records suggests no roost sites occur in the nominated areas
Large-eared Pied Bat	Large-eared Pied Bat roosts in sandstone caves, crevices, cliffs and old mine workings. Habitat within the nominated areas is likely to be used for foraging. Interrogation of BioNet records suggests no roost sites occur in the nominated areas
Little Bentwing-bat	Little Bentwing-bat can roost in the following human-made structures: tunnels, abandoned mines, stormwater drains, culverts, bridges and sometimes buildings during the day. It also roosts in caves and tree hollows. Forages in densely vegetated habitats (OEH, 2019f). Interrogation of BioNet records suggests no roost sites occur in the nominated areas

24.6.2 OCCURRENCE OF HABITAT OR PRESCRIBED IMPACT TYPE

Locations where karst, caves, crevices, cliffs and other geological features are most likely to occur in the nominated areas are shown in Map 17.

These areas are associated with the gorges and gullies around the edges and northern part of Wilton and the southern part of GMAC, including along the Nepean and Cataract rivers. All these areas occur outside the urban capable land and transport corridors within the nominated areas.

Karst, caves, crevices, cliffs and other geological features were mapped by:

- Manipulation of a bare earth Digital Elevation Model to produce a layer that showed the mean elevation within a 30 m x 30 m grid surrounding each 1 m elevation grid cell
- Creation of a Topographic Position Index to identify the height of each 1 m cell above/below local mean elevation
- Reclassification of the Topographic Position Index to identify only areas that were high enough above the local mean elevation to create a topographic brake that might support cliffs
- Overlay the cliffs layer with a sandstone geology layer to exclude areas outside sandstone geology

The cliffs layer was validated through inspection of aerial photos and knowledge of the topography and landscape of the nominated areas, as well as site observations during surveys.

24.6.3 NATURE, EXTENT AND DURATION OF IMPACTS

Impacts to karsts, caves, crevices and cliffs are unlikely to occur as a result of the urban, industrial, infrastructure, agribusiness or transport development under the Plan within the nominated areas.

Map 17 shows that the areas where karst, caves, crevices, cliffs and other geological features are most likely to occur have been avoided and do not occur within urban capable land or transport corridors within the nominated areas.

The steps taken to avoid and minimise impacts of the development in the nominated areas are set out in Chapter 14.

24.7 ASSESSMENT OF ROCKY AREAS

24.7.1 LIST OF RELEVANT SPECIES AND TECS

The list of species associated with rocky areas is shown in Table 24-4.

Table 24-4: Species associated with rocky areas

Relevant species	Use and importance of habitat type
Broad-headed Snake	Broad-headed Snake may use rocky areas for refuge. Adults shelter in rocky outcrops under flat sandstone rocks on exposed cliff edges during autumn, winter and early spring, then move to adjacent native vegetation (woodland communities) within 500 m of rocky areas during late spring and summer. Pregnant females and juveniles remain in rocky habitat, using cooler, shaded rocks and crevices (DoEE, 2018a)
Red-crowned Toadlet	Red-crowned Toadlet may use rocky areas for breeding and refuge, and is largely restricted to the immediate vicinity of these areas. Breeding habitat comprises dense vegetation and debris beside ephemeral creeks and gutters (OEH, 2019h). The species deposits eggs in terrestrial nests beneath rocks and logs or in leaf litter (NSW Scientific Committee, 2002). Outside the breeding period, the species disperses to refuge areas close to breeding sites, which comprise rocks and masses of dense vegetation or thick piles of leaf litter generally on sandstone ridges (OEH, 2019h)

24.7.2 OCCURRENCE OF HABITAT OR PRESCRIBED IMPACT TYPE

The potential occurrence of rocky areas in each nominated area is described in Table 24-5.

No obvious rock outcrops were observed during targeted surveys done as part of this project (see Chapter 11). However, some areas were not surveyed due to land access restrictions and rock outcrops have the potential to occur.

Table 24-5: Potential occurrence of rocky areas

Nominated area	Potential occurrence of rocky areas
Wilton	Rocky areas may occur on the edges of the nominated area and in the gully lines where the underlying sandstone is exposed
GMAC	Northern part: A few rocky areas comprising small exposures of shale and lithic sandstone may occur
	Southern part: Rocky areas may occur on the edges of the southern section of the nominated area where the underlying sandstone is exposed. Some exposure may also occur along the main gully lines
WSA	A few rocky areas comprising small exposures of shale and lithic sandstone may occur
GPEC	A few rocky areas comprising small exposures of shale and lithic sandstone may occur. In the Eastern Creek area there are possible outcrops of basalt and other igneous intrusion

24.7.3 NATURE, EXTENT AND DURATION OF IMPACTS

The nature, extent and duration of the impacts of the urban, industrial, infrastructure, agribusiness and transport development on rocky areas are set out in Table 24-6.

Table 24-6: Nature, extent and duration of impacts – rocky areas

Species	Nature	Extent	Duration
Broad-headed Snake Red-crowned Toadlet	**Direct impacts:** Rocky areas utilised by these species generally only occur within areas of native vegetation Direct impacts are therefore addressed through impacts to native vegetation and habitat (see Chapter 23) rather than as a prescribed impact	N/A	N/A
	Indirect impacts: The development has the potential to increase bush rock removal in areas of potential habitat for these species as a result of increased human populations in the nominated areas	Risk is highest in publicly accessible habitat areas within and adjacent to the nominated areas	Long-term

24.7.4 COMMITMENTS AND GENERAL MITIGATION MEASURES TO ADDRESS IMPACTS

The Plan will apply environmental conservation zoning to all areas avoided for biodiversity purposes as well as riparian corridors to strengthen the protection of avoided lands from the impacts of development.

This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will reduce the risk, and support the mitigation of, several indirect and prescribed impacts, including:

- Removal of key habitat features, such as trees, firewood and bush rock
- Habitat disturbance from increased public access, including recreational activities

Furthermore, the collection of bush rock is regulated in NSW. For example, the removal of bush rock in national parks and nature reserves, as well as state forests and Crown land reserves, is prohibited. Some councils also regulate bush rock removal in council reserves and other bushland areas (Department of Environment and Climate Change, 2009).

Furthermore, councils or other public authorities prepare management plans for many reserves which typically include measures to control public access within reserves, which may reduce the risk of bush rock removal.

24.7.5 ASSESSMENT OF POTENTIAL IMPACTS

An assessment of the potential prescribed impacts of the urban, industrial, infrastructure, agribusiness and transport development on rocky areas is set out in Table 24-7. This assessment takes into account any general mitigation measures under the Plan to manage impacts.

Table 24-7: Assessment of potential prescribed impacts – rocky areas

Relevant species	Assessment of potential prescribed impacts	Residual risk of impacts?
Broad-headed Snake Red-crowned Toadlet	Impacts are unlikely to cause population decline at a local, regional or state scale because no recent records for the species occur in the nominated areas or nearby, reducing the risk that the species relies to a notable extent on habitat in the vicinity of the nominated areas The Plan will apply environmental conservation zoning to all areas avoided for biodiversity purposes as well as riparian corridors to strengthen the protection of avoided lands from the impacts of development. This will reduce the risk of bush rock removal. Furthermore, the removal of bush rock in many reserves is prohibited and management plans for reserves typically include measures to control public access within reserves, which may also reduce the risk of bush rock removal. The new proposed zoning and these existing arrangements are considered adequate for managing the risk of bush rock removal to these species	Unlikely

24.8 ASSESSMENT OF HUMAN-MADE STRUCTURES

24.8.1 LIST OF RELEVANT SPECIES AND TECS

The list of species associated with human-made structures is shown in Table 24-8.

All relevant species associated with this prescribed impact type are microbat species.

Codes within BioNet records ('observation' and 'microhabitat' codes) were interrogated to identify whether there was data on microbats recorded roosting within the nominated areas (Observation Code 'E'), including under bridges (Microhabitat Code 'BR') or in buildings (Microhabitat Code 'BU').

BioNet records suggest no known roost sites occur for any of the species in the nominated areas except for Southern Myotis within GMAC. The records do not indicate whether these roost sites are associated with human made structures.

Table 24-8: Species associated with human-made structures

Relevant species	Use and importance of habitat type
Large Bent-winged Bat	Large Bent-winged Bat mainly roosts in caves with very specific temperature and humidity regimes. The species can also use mines, storm water tunnels, buildings and other human-made structures. The species disperses widely from breeding colonies (within 300 km) (OEH, 2019d). BioNet records suggest no known roost sites occur in the nominated areas
Eastern False Pipistrelle	Roost requirements for Eastern False Pipistrelle are poorly known. The species is thought to mainly roost in tree hollows, but has also been found under loose bark on trees or in buildings. The species may roost in paddock trees. BioNet records suggest no known roost sites occur in the nominated areas
Eastern Freetail-bat	Eastern Freetail-bat mainly roosts in tree hollows. It can also roost inhuman-made structures, including buildings (OEH, 2017c). The species changes breeding sites every few days, making it very difficult to record sites. Occasionally aggregates in large breeding groups (including in buildings). BioNet records suggest no known roost sites occur in the nominated areas
Greater Broad-nosed Bat	Greater Broad-nosed Bat mainly roosts in tree hollows. It can also roost inhuman-made structures, including buildings. Forages along creek and river corridors (OEH, 2017e). BioNet records suggestsno known roost sites occur in the nominated areas
Little Bentwing-bat	Little Bentwing-bat can roost in the following human-made structures: tunnels, abandoned mines, stormwater drains, culverts, bridges and sometimes buildings during the day. It also roosts in caves and tree hollows. Forages in densely vegetated habitats (OEH, 2019f). BioNet records suggest no known roost sites occur in the nominated areas
Southern Myotis	Southern Myotis can roost in the following human-made structures: mine shafts, storm water tunnels, buildings, and under bridges and in culverts. The species also roosts in caves, hollow-bearing trees and dense foliage, and forages over waterbodies within 200 m of roost sites (OEH, 2019j). BioNet records show roost sites have been recorded in GMAC. The records do not indicate whether these roost sites are associated with human-made structures
Yellow-bellied Sheathtail-bat	Yellow-bellied Sheathtail-bat is thought to mainly roost in tree hollows and buildings, and sometimes mammal burrows (OEH, 2017l). BioNet records suggest no known roost sites occur in the nominated areas

24.8.2 OCCURRENCE OF HABITAT OR PRESCRIBED IMPACT TYPE

It was not possible to map the location of human made structures at the scale of the nominated areas.

Human-made structures such as mine shafts, storm water channels, old or derelict buildings, bridges and culverts may provide suitable habitat for several species and are likely to occur thoughout each of the nominated areas.

24.8.3 NATURE, EXTENT AND DURATION IMPACTS

The nature, extent and duration of the impacts of the urban, industrial, infrastructure, agribusiness and transport development on human made structures are set out in Table 24-9.

Table 24-9: Nature, extent and duration of impacts – human-made structures

Species	Nature	Extent	Duration
All relevant micro-bat species	**Direct impacts:** Direct impacts may occur due to removal or upgrade of bridges, culverts, stormwater channels, old buildings and other human-made structures that contain roost sites	Human-made structures within urban capable lands in each nominated area	Long-term
	Indirect impacts: Indirect impacts may occur due to disturbance to individuals using human-made structures though physical disturbance, lighting or noise due to construction activities, or increased presence of human populations	Human-made structures adjacent to urban capable lands in each nominated area	Temporary or long-term

GREEN AND GOLDEN BELL FROG

Note that an area of approximately 5.8 ha mapped as suitable Green and Golden Bell Frog habitat occurs within an existing urban area comprising buildings and roads in GPEC (near Ropes Creek) and will be directly impacted by the urban, industrial and infrastructure development. The area of habitat was mapped on the basis of:

- The locations of known records
- The riparian corridor joining those records
- A buffer of 1,000 m around the riparian corridor and records that could be used by the species for foraging, shelter, breeding and as migratory habitat as individuals disperse between water bodies and riparian corridors(Lemckert, 2019)

This area occurs within the buffer and is very unlikely to provide notable habitat or connectivity for the species as it currently comprises buildings and roads. As such, the impacts on this area are not considered further.

24.8.4 COMMITMENTS AND GENERAL MITIGATION MEASURES TO ADDRESS IMPACTS

The Plan includes a commitment to mitigate indirect and prescribed impacts from development on TECs and species habitat to best practice standards (Commitment 5). This commitment will be delivered through preparation of a Development Control Plan (DCP) for each nominated area. A DCP provides detailed guidelines and environmental standards for new development, which need to be considered when preparing a development application seeking development approval. DCPs for each nominated area will be prepared in accordance with:

- Standard format for DCPs and a set of model provisions prepared by the Department to apply across NSW
- Any processes and guidelines for preparing DCPs specific to each council
- Current best practice standards, guidelines or targets (e.g. water quality standards for urban runoff)

DCPs will include general development controls relevant to managing prescribed impacts on micro-bat species due to the disturbance of human-made structures, including:

- Where noise or light impacts from development may affect wildlife, measures to manage impacts should be implemented, such as managing the timing of activities and/or installing appropriate noise barriers
- High-intensity outdoor lighting should be designed to avoid light spill into adjoining natural areas
- Development within 100 m of known microbat colonies must include street lighting that does not attract insects

A detailed description of the process to implement these development controls in the nominated areas, including Department oversight and assurance mechanisms, is provided in Chapter 15, Section 15.6.1.

24.8.5 ASSESSMENT OF POTENTIAL PRESCRIBED IMPACTS

An assessment of the potential prescribed impacts of the urban, industrial, infrastructure, agribusiness and transport development on species associated with human-made structures is set out in Table 24-10. This assessment takes into account any general mitigation measures under the Plan to manage impacts.

Table 24-10: Assessment of potential prescribed impacts – human-made structures

Relevant species	Assessment of potential prescribed impacts	Residual risk of impact
Southern Myotis	Impacts may cause population decline at a local scale because: • Known roost sites occur in the nominated areas (within GMAC) • Many records for the species occur in the nominated areas suggesting the nominated areas are an important area for these species Impacts are unlikely to cause population decline at a regional or State scale because: • Records are widespread across the Cumberland subregion and Sydney Basin bioregion, suggesting the nominated areas are not a stronghold for the species • The species is widely distributed across a coast band (generally within 100 km of the coast) within NSW both north and south of the Cumberland subregion General mitigation measures are likely to reduce but not completely negate the risk that the development may lead to a population decline at a local scale as there is uncertainty about the location of roosting sites within man-made structures within the nominated areas. The Plan includes a species-specific mitigation measures to address this risk	Yes
Large Bent-winged Bat Eastern Freetail-bat	Impacts are unlikely to cause population decline at a local, regional or State scale because: • BioNet records suggest no known roost sites occur in the nominated areas • Species appears to mainly roost in tree hollows and impacts on human-made structures are therefore unlikely to substantially affect roosting habitat While the risk of population decline is low and the general mitigation measures will reduce the risk to these species further, there is uncertainty about the importance of human made structures for microbat species in the subregion. The Plan includes a species-specific mitigation measures to address this risk	Yes
Little Bentwing-bat Yellow-bellied Sheathtail-bat	Impacts are unlikely to cause population decline at a local, regional or State scale because: • BioNet records suggest no known roost sites occur in the nominated areas • Few records occur for the species in the nominated areas compared to other parts of the Cumberland subregion and Sydney Basin bioregion, which suggests the species is less reliant on these areas for persistence in the subregion or region While the risk of population decline is low and the general mitigation measures will reduce the risk to these species further, there is uncertainty about the importance of human made structures for microbat species in the subregion. The Plan includes a species-specific mitigation measures to address this risk	Yes
Eastern False Pipistrelle Greater Broad-nosed Bat	Impacts are unlikely to cause population decline at a local, regional or State scale because: • BioNet records suggest no known roost sites occur in the nominated areas • Species appears to mainly roost in tree hollows and impacts on human-made structures are therefore unlikely to substantially affect roosting habitat • Few records occur in the nominated areas compared to other parts of the Cumberland subregion and Sydney Basin bioregion, which suggests these species is less reliant on these areas for persistence in the subregion or region While the risk of population decline is low and the general mitigation measures will reduce the risk to these species further, there is uncertainty about the importance of human made structures for microbat species in the subregion. The Plan includes a species-specific mitigation measures to address this risk	Unlikely

24.8.6 ADDITIONAL SPECIFIC MITIGATION TO ADDRESS RESIDUAL RISKS

Table 24-11 identifies additional specific mitigation measures under Appendix E of the Plan to address residual risks to microbat species due to the development. These mitigation measures are considered to adequately address residual risks in the context of the risk and significance of the impacts of the development on microbat species.

Table 24-11: Specific mitigation measures – human-made structures

Relevant species	Specific mitigation measure	Applicable development	Uncertainty or risks of failure
All relevant microbat species	Undertake pre-construction surveys prior to removal or disturbance (seasonally dependent, before torpor) to human made structures to ensure any roosting habitat for microbat species including mine shafts, storm water tunnels, old or derelict buildings, bridges and culverts are retained where possible	Urban and industrial, infrastructure, agribusiness development	There is a low risk that pre-construction surveys may not accurately identify roosting sites for various reasons (e.g. because they are undertaken at the wrong time of year)
	Incorporate artificial breeding and roosting habitat (e.g. bat boxes, structural cavities) in the design of bridges associated with the transport corridors in accordance with relevant guidelines or standards	Transport development	While bat boxes are used widely as a conservation measure for micro-bat species, there is some uncertainty about their effectiveness for some species (Smith, 2002) (Rueegger, Goldingay et al., 2019)

Implementation

Urban, industrial and agribusiness

For the urban, industrial, and agribusiness development, these specific mitigation measures will be implemented through DCPs (see above). A detailed description of this process is provided in Chapter 15, Section 15.6.1.

Infrastructure and transport corridors

The Plan includes commitments to mitigate indirect and prescribed impacts from infrastructure development (Commitment 5.3) and transport development (Commitment 6), as prescribed in Appendix E of the Plan.

These commitments will be delivered through a process of environmental assessment and approval that will be applied to detailed design of each infrastructure and transport project, at the time the project is brought forward for development. These future environmental assessments provide a process through which to implement these specific mitigation measures for microbat species, as prescribed in Appendix E of the Plan.

A detailed description of the assessment and approval process for transport corridors and infrastructure, including Department oversight and assurance mechanisms, is provided in Chapter 15, Section 15.6.2 and 15.6.3.

24.9 ASSESSMENT OF NON-NATIVE VEGETATION

24.9.1 LIST OF RELEVANT SPECIES AND TECS

The list of species associated with the habitat or prescribed impact type is shown in Table 24-12.

Table 24-12: Species/TECs associated with non-native vegetation

Relevant species/TECs	Use and importance of habitat type
Flora	
Acacia bynoeana	These species can occur in areas of non-native vegetation, such as disturbed or partially cleared land, including roadsides or trail margins. However, they mainly rely on native vegetation as habitat All these species were mapped based on expert reports No areas of suitable habitat were mapped outside native vegetation for: • *Acacia bynoeana* • *Grevillea juniperina* • *Persoonia bargoensis* Very small areas of suitable habitat were mapped within areas of non-native vegetation (within areas mapped as 'urban native/exotic'– see Chapter 19) for the following species: • *Pimelea spicata* • *Hibbertia fumana* • *Hibbertia puberula*
Grevillea juniperina subsp. *Juniperina*	
Hibbertia fumana	
Hibbertia puberula	
Persoonia bargoensis	
Pimelea spicata	
Bats	
Grey-headed Flying-fox	The species may roost in non-native vegetation with a dense canopy. While blossom from *Eucalyptus* and related genera form a large part of the species diet (DoEE, 2018), non-native trees can form an important part of the diet in urban areas (DoEE, 2018)
Yellow-bellied Sheathtail-bat	The species primarily use native vegetation or man-made features for roosting. However, some species may occasionally use crevices in non-native trees or dense non-native vegetation for roosting The species prey, such as small insects, may occur within and rely on non-native vegetation to some extent in some areas
Greater broad-nosed Bat	
Little Bentwing-bat	
Large Bent-winged Bat	
Eastern Freetail-bat	
Eastern False Pipistrelle	
Marsupials	
Spotted-tailed Quoll	The species may use non-native vegetation along waterways for dispersal between areas of suitable habitat. Non-native vegetation may benefit the species by increasing protective vegetation cover along the waterways
Frogs	
Green and Golden Bell Frog	The species may occur in disturbed areas, including non-native vegetation. Habitat comprises water bodies and associated terrestrial habitats with grassy areas and low native or non-native vegetation (DEWHA, 2009a) (Lemckert, 2019). The species may use non-native vegetation to disperse between habitat sites Suitable habitat for the Green and Golden Bell Frog that may contain the species has been mapped around St Mary's in GPEC. The area of suitable habitat covers: • The locations of known records • The riparian corridor joining those records • A buffer of 1,000 m around the riparian corridor and records that could be used by the species for foraging, shelter, breeding and as migratory habitat as individuals move between water bodies and riparian corridors (Lemckert, 2019)

Relevant species/TECs	Use and importance of habitat type
Birds	
Dusky Woodswallow	The species occurs primarily in native vegetation (mainly open eucalypt forests and woodland). However, the species may also occur in farmland, usually at the edges of forest or woodland. The species may use deciduous trees for perching
Painted Honeyeater	The species primarily occurs in woodlands and forages on the fruits of mistletoes growing on eucalypts and acacias. The species may forage on planted Silky-Oaks
Little Eagle	The species' prey, such as mammals, may occur within and rely on non-native vegetation to some extent, particularly in the vicinity of urban areas
Square-tailed Kite	
Barking Owl	
Powerful Owl	
Masked Owl	

24.9.2 OCCURRENCE OF HABITAT OR PRESCRIBED IMPACT TYPE

Non-native vegetation was mapped as part of the native vegetation mapping for the nominated areas and is defined as:

> *Vegetation that is not consistent with floristic composition and landscape positions for native plant community types as defined by the NSW BioNet Vegetation Classification system; most common communities comprise of very few native species or consist of an assorted mix of planted native or exotic trees*

Non-native vegetation occurs within urban capable land in all nominated areas. The location of non-native vegetation within the nominated areas is shown in Map 18.

24.9.3 NATURE, EXTENT AND DURATION IMPACTS

The nature, extent and duration of the impacts of the urban, industrial, infrastructure, agribusiness and transport development on non-native vegetation are set out in Table 24-13.

Table 24-13: Nature, extent and duration of impacts – non-native vegetation

Species/TEC	Nature	Extent	Duration
Flora	**Direct impacts:** Direct impacts will occur to suitable habitat within non-native vegetation for the following species: • *Pimelea spicata* • *Hibbertia fumana* • *Hibbertia puberula* Suitable habitat for the other flora species generally occurs within areas of native vegetation and direct impacts for these species are therefore addressed through impacts to native vegetation and habitat (see Chapter 23)	Following impacts in Wilton: • *Pimelea spicata* – 8.6 ha • *Hibbertia fumana* – 0.06 ha • *Hibbertia puberula* – 0.06 ha	Long-term
	Indirect impacts: The development may cause a range of indirect impacts to suitable habitat within non-native vegetation for these flora species. Key risks are weed invasion, rubbish dumping, and increased risk of fire	Non-native vegetation adjacent to urban capable lands in each nominated area	Temporary or long-term

Species/TEC	Nature	Extent	Duration
Bats	**Direct impacts:** The development may directly impact areas of non-native vegetation that provide foraging habitat for Grey-headed Flying-fox and potential roosting habitat for some microbat species. There are no known Grey-headed Flying-fox camps in the urban capable lands	Non-native vegetation within urban capable lands in each nominated area	Temporary or long-term
	Indirect impacts: There may be a decrease in the abundance of prey for some microbat species due to direct impacts on non-native vegetation potentially impacting prey habitat	Non-native vegetation adjacent to urban capable lands in each nominated area	Temporary or long-term
Marsupials	**Direct impacts:** N/A	N/A	N/A
	Indirect impacts: Removal of non-native vegetation along waterways may reduce vegetation cover that facilitates dispersal of the Spotted-tailed Quoll between areas of suitable habitat	Non-native vegetation within riparian corridors	Temporary or long-term
Green and Golden Bell Frog	**Direct impacts:** The development will directly impact a small amount of non-native vegetation within suitable habitat for this species	0.06 ha in the St Mary's area in GPEC	Long-term
	Indirect impacts: The development may cause a range of indirect impacts to suitable habitat within non-native vegetation for Green and Golden Bell Frog. Key risks are weed invasion, rubbish dumping, and increased risk of fire	Adjacent to urban capable land in the St Mary's area in GPEC	Temporary or long-term
Birds	**Direct impacts:** Direct impacts may occur to non-native vegetation used by Dusky Woodswallow and Painted honeyeater for perching or foraging	Within urban capable land in each nominated area	Long-term
	Indirect impacts: There may be a decrease in the abundance of prey for some bird species due to direct impacts on non-native vegetation potentially impacting prey habitat	Within and adjacent to urban capable land in each nominated area	Temporary or long-term

24.9.4 COMMITMENTS AND GENERAL MITIGATION MEASURES TO ADDRESS IMPACTS

The Plan includes a commitment to mitigate indirect and prescribed impacts from development on TECs and species habitat to best practice standards (Commitment 5). This commitment will be delivered through preparation of a DCP for each nominated area. A DCP provides detailed guidelines and environmental standards for new development, which need to be considered when preparing a development application seeking development approval.

DCPs for each nominated area will be prepared in accordance with:

- Standard format for DCPs and a set of model provisions prepared by the Department to apply across NSW
- Any processes and guidelines for preparing DCPs specific to each council
- Current best practice standards, guidelines or targets (e.g. water quality standards for urban runoff)

DCPs will include several general development controls relevant to managing prescribed impacts to species associated with non-native vegetation, including controls to (see Chapter 15, section 15.6.1):

- Manage water cycles and water quality (relevant to Green and Golden Bell Frog)
- Protect riparian corridors (relevant to Spotted-tailed Quoll)
- Control the spread of weeds (relevant to several species above)
- Ensure native trees are planted in open space areas and along major and residential roads as part of the design of new residential areas (relevant to Grey-headed Flying-fox, micro-bat species and birds)

A detailed description of the process to implement these development controls in the nominated areas, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.1.

24.9.5 ASSESSMENT OF POTENTIAL PRESCRIBED IMPACTS

An assessment of the potential prescribed impacts of the urban, industrial, infrastructure, agribusiness and transport development on species associated with non-native vegetation is set out in Table 24-14. This assessment takes into account any general mitigation measures under the Plan to manage impacts.

Table 24-14: Assessment of potential prescribed impacts – non-native vegetation

Relevant species/TECs	Assessment of potential prescribed impacts	Residual risk of impacts?
Flora	Impacts are unlikely to cause population decline at a local, regional or State scale because: • These species mainly rely on native vegetation as habitat • Only very small areas of potential habitat within non-native vegetation will be impacted for *Pimelea spicata*, *Hibbertia fumana* and *Hibbertia puberula* relative to areas of unimpacted habitat within native vegetation. The 8.6 ha of *Pimelea spicata* habitat appears to occur within an area currently heavily infested with African Olive	Unlikely
Bats	Impacts are unlikely to cause population decline for micro-bat species at a local, regional or State scale because: • These species mainly use caves, crevices, human made structures, or tree hollows within native vegetation for roosting • Substantial areas of native and non-native vegetation will be established in open space areas and along major and residential roads, which is likely to negate any low risk of indirect impacts through reduced prey abundance There is a low risk that impacts may cause population decline for Grey-headed Flying-fox at a local scale due to impacts on foraging habitat. Impacts are unlikely to cause population decline for Grey-headed Flying Fox at a regional or State scale because: • There are no known Grey-headed Flying Fox camps in the urban capable lands that rely on non-native vegetation for roosting • Substantial areas of native and non-native vegetation will be established in open space areas and along major and residential roads • The species can travel large distances for foraging and forage primarily on the nectar and pollen of native trees and fruits of rainforest trees and vines (OEH, 2018f) The Plan includes a species-specific mitigation measures to address this risk	Yes for Grey-headed Flying-fox

Relevant species/TECs	Assessment of potential prescribed impacts	Residual risk of impacts?
Marsupials	Impacts are unlikely to cause population decline for Spotted-tail Quoll at a local, regional or State scale because: • Urban capable lands have avoided riparian corridors consistent with the *Water Management Act 2000* along waterways, comprising: o Strahler stream order 2 - buffer 20 m either side o Strahler stream order 3 - buffer 30 m either side o Strahler stream order 4 and above - buffer 40 m either side • Development controls will be put in place to protect riparian corridors	Unlikely
Green and Golden Bell Frog	Impacts are unlikely to cause population decline for Green and Golden Bell Frog at a local, regional or State scale because only very small areas of potential habitat within non-native vegetation will be impacted. Furthermore, this impact occurs towards the edge of suitable habitat and distant from the riparian corridor of Ropes Creek and is therefore unlikely to significantly contribute to further fragmentation of areas of suitable habitat	Unlikely
Birds	Impacts are unlikely to cause population decline for these species at a local, regional or State scale because: • These species mainly rely on native vegetation as habitat • Only small areas of potential habitat within non-native vegetation will be impacted for these species relative to areas of unimpacted habitat within native vegetation • Substantial areas of native and non-native vegetation will be established in open space areas and along major and residential roads,	Unlikely

24.9.6 ADDITIONAL SPECIFIC MITIGATION TO ADDRESS RESIDUAL RISKS

Table 24-15 identifies additional specific mitigation measures under Appendix E of the Plan to address residual risks to Grey-headed Flying-fox due to the development (these measures will also benefit several other species above, including birds and microbats). These mitigation measures are considered to adequately address residual risks in the context of the risk and significance of the impacts of the development on this species.

Table 24-15: Specific mitigation measures – non-native vegetation

Relevant species	Specific mitigation measure	Applicable development	Uncertainty or risks of failure
Grey-headed Flying-fox	Establish minimum setbacks for urban development around flying fox camps	Urban and industrial, infrastructure, agribusiness development	Set-backs are a well-established mitigation measure for camps
	Retain large trees (including dead trees) (≥50cm DBH) during precinct planning where possible and avoid impacts to soil within the dripline of these trees during construction		Large trees generally provide the greatest sources of nectar, which is the primary food for the species

IMPLEMENTATION

Urban, industrial and agribusiness

For the urban, industrial, and agribusiness development, these specific mitigation measures will be implemented through DCPs (see above). A detailed description of this process is provided in Chapter 15, Section 15.6.1.

Infrastructure

The Plan includes a commitment to mitigate indirect and prescribed impacts from infrastructure development (Commitment 5.3), as prescribed in Appendix E of the Plan.

This commitment will be delivered through a process of environmental assessment and approval that will be applied to detailed design of each infrastructure project, at the time the project is brought forward for development. These future environmental assessments provide a process through which to implement these specific mitigation measures for Grey-headed Flying-fox, as prescribed in Appendix E of the Plan.

A detailed description of the assessment and approval process for infrastructure, including Department oversight and assurance mechanisms, is provided in Chapter 15, Section 15.6.2.

24.10 ASSESSMENT OF HABITAT CONNECTIVITY AND MOVEMENT

Habitat connectivity refers to the degree of connectedness of areas of habitat. Habitat connectivity can include:

- Corridors of vegetation linking other areas of habitat
- Isolated patches of habitat that provide 'stepping stones' between other areas of habitat
- Habitat features (such as large trees with hollows) scattered within areas of non-habitat (e.g. urban land) that provide habtiat connectivity between intact areas of habitat

The urban, industrial, infrastructure, agribusiness and transport development have the potential to lead to changes and disruption to habitat connectivity. Potential habitat connectivity impacts could occur in all four nominated areas.

BIO MAP

The Biodiversity Investment Opportunities Map (BIO Map) is a key deliverable of the NSW Government's $40 million Green Corridors program. The BIO Map project aimed to achieve better biodiversity outcomes by directing biodiversity investment funding to the strategic locations of greatest benefit.

The BIO Map for the Cumberland subregion covers an area of 275,693 ha, including the Cumberland Plain. Mapping criteria were used to identify and map priority investment areas. The priority investment areas comprise of a network of 87 core areas and 27 regional biodiversity corridors within the Cumberland subregion. The 87 core areas include all of the priority conservation lands identified by the Cumberland Plain Recovery Plan (DECCW, 2011).

The total area represented within the mapped priority investment areas is 42,124 ha. This represents approximately 15 per cent of the Cumberland subregion or approximately 61 per cent of all mapped vegetation within the subregion.

BIO Map identifies Priority Investment Areas (PIAs) where the protection and management of native vegetation is likely to maximise benefits to biodiversity within the Cumberland subregion. The PIAs comprise:

- BIO Map core areas: large areas of native vegetation and habitat where management will be of greatest benefit to the conservation of biodiversity values. These areas represent the habitat in the subregion most likely to support species persistence and interactions between species and landscape scale ecological processes
- BIO Map regional corridors: linear areas that link core areas and play a crucial role in maintaining connections between species populations that would otherwise be isolated and at greater risk of local extinction

24.10.1 LIST OF RELEVANT SPECIES AND TECS

Habitat connectivity is relevant to all species to some extent for:

- Movement across home ranges/dispersal between areas of suitable habitat
- Breeding or reproduction
- Foraging
- Other important life cycle events

Species reliant on habitat connectivity have been categorised into five groups:

- Fauna more likely to need large habitat corridors and/or large areas of intact native vegetation
- Fauna able to utilise narrower habitat corridors or riparian corridors or waterways
- Fauna able to utilise scattered and/or degraded patches of native vegetation within an urban or agricultural matrix
- Fauna that are relatively immobile and move only short distances
- TECs that rely on habitat connectivity for effective airborne pollination and the movement of pollinators

Table 24-16 shows the groupings for species predicted to occur in the nominated areas.

Table 24-16: Species/TECs associated with areas of habitat connectivity

Group	Relevant species/TECs	Use and importance of habitat type
Large habitat corridors and/or large areas of intact native vegetation	Most gliders and owls and some birds: • Large-eared Pied Bat • Squirrel Glider • Yellow-bellied Glider • Masked Owl • Barking Owl • Powerful Owl • Gang-gang Cockatoo • Glossy Black Cockatoo • Regent Honeyeater • Black-chinned Honeyeater • Brown Treecreeper	May use large habitat corridors for dispersal between larger patches of suitable habitat, including breeding areas, as well as for foraging
	Raptors: • White-bellied Sea-Eagle • Little Eagle • Square-tailed Kite	
Smaller habitat corridors or riparian corridors or waterways	Smaller marsupials: • Eastern Pygmy-possum • Spotted-tailed Quoll	May use smaller habitat corridors for dispersal between larger patches of suitable habitat, including breeding areas, as well as for foraging Spotted-tailed Quoll relies on habitat connectivity to breed as quolls are solitary and come together to breed
	Birds associated with riparian corridors and/or waterways, including: • Australasian Bittern • Freckled Duck • Comb-crested Jacana • Black Bittern • White-fronted Chat • Eastern Osprey • Curlew Sandpiper • Broad-billed Sandpiper • Black-tailed Godwit	Water birds use waterways and riparian corridors and associated vegetation for shelter, foraging, as well as dispersal between other areas of suitable habitat

Group	Relevant species/TECs	Use and importance of habitat type
Scattered and/or degraded native vegetation within a matrix	• Grey-headed Flying-fox Microbats: • Southern Myotis • Little Bentwing-bat • Large Bent-winged Bat • Eastern Freetail-bat • Eastern False Pipistrelle • Yellow-bellied Sheathtail-bat	Microbats and birds may use scattered native vegetation for roosting or resting, to move within areas of foraging habitat, or to access other larger areas of suitable habitat for foraging
	Birds: • Dusky Woodswallow • Spotted Harrier • Little Lorikeet • Diamond Firetail • Swift Parrot • Turquoise Parrot • Varied Sittella • Painted Honeyeater	
	• Green and Golden Bell Frog	While the species appears to generally be associated with a single water body for general activities, it is highly mobile and can move some distance as part of migrations to and from breeding sites (Lemckert, 2019). Movements of up to 5 km may be common and the species may disperse up to 10 km (DoEE, 2018a)
Relatively immobile and moves only short distances	• Cumberland Plain Land Snail • Red-crowned Toadlet	Little is known about Cumberland Plain Land Snail dispersal patterns or over what distances individuals can move (OEH, 2019c) Most populations are small and isolated. The NSW SoS program identifies several actions to ensure connectivity between population, including implementing 'open structure design' when designing structures such as roads which may isolate patches of habitat (EES, 2020) Red-crowned Toadlets are a localised species that are largely restricted to the immediate vicinity of suitable breeding habitat. The species is usually found as small discrete scattered populations along sandstone ridges
TECs	• All TECs	TECs rely on habitat connectivity for effective airborne pollination and the movement of pollinators

24.10.2 OCCURRENCE OF HABITAT OR PRESCRIBED IMPACT TYPE

Key areas of habitat connectivity in the nominated areas are shown in Map 19 and described in Table 24-17.

Habitat connectivity was mapped by:

- Identifying BIO Map regional corridors and core areas. These corridors/core areas are likely to be the most important areas of habitat connectivity in the nominated areas for the majority of species. EES had only identified BIO Map corridors within the boundaries of the Cumberland subregion. To undertake the mapping for the small parts of the nominated areas outside the Cumberland subregion the Priority Conservation Lands layer (DECCW, 2010) (EES used this layer as basis for BIO Map) or the native vegetation map (see Chapter 19) was used to extend the BIO Map corridor mapping
- Identifying local corridors using the native vegetation mapping to identify connected patches of native vegetation. This was done visually in GIS, with only contiguous patches identified as being connected
- Identify any remaining native vegetation not within a regional corridor or local corridor as:
  - Connected – within 100 m of another patch of woody vegetation
  - Isolated – greater than 100 m from another patch of woody vegetation

The categories of habitat connectivity identified in Map 19 are:

- BIO Map corridors, categorised as either
  - BIO Map Regional Corridor / BIO Map Regional Corridor and Core Area
  - BIO Map Regional Corridor - extended to match PCLs
  - BIO Map Regional Corridor - extended to match vegetation
- Local corridor
- Connected vegetation
- Isolated vegetation

Table 24-17: Key areas of habitat connectivity in the nominated areas

Nominated area	BIO Map regional corridors/core areas	Local corridors	Connected and isolated vegetation
Wilton	Occur around the edges of the entire nominated area and across the middle of the northern part of the nominated area associated with the Nepean River and the middle of the southern part of the nominated area	One large corridor occurs on the eastern side of the nominated area between the Hume Motorway and Wilton Road connected to the BIO Map regional corridors/core areas to the east of the nominated area. The corridor is a 'dead end' and does not connect to other native vegetation to the south or west of the nominated area	Connected vegetation occurs in scattered areas mainly towards the edges of the nominated area adjacent to BIO Map regional corridors/core areas Isolated vegetation occurs in only a few very small patches in the middle parts of the nominated area
GMAC	Occur around the edges of the entire southern part of the nominated area and across the middle of the southern part in three locations associated with waterways. The corridors/core areas connect native vegetation associated with the Cataract River to the west of the nominated area with large areas of native vegetation to the east of the nominated area	One corridor occurs across the middle of the southern part of the nominated area associated with a waterway. The corridor connects regional corridors/core areas to the east and north within the nominated area with native vegetation to the west of the nominated area	Connected vegetation occurs in scattered areas across the nominated area mainly in the southern part Isolated vegetation occurs in only a few very small patches in the middle parts of the nominated area
WSA	Occur in the eastern part of the nominated area associated with Wianamatta (South Creek) and Kemps Creek. A regional corridor/core area connects Wianamatta (South Creek) and Kemps Creek in the south-eastern corner of the nominated area in the Kemps Creek area	Two corridors occur in the middle part of the nominated area associated with Badgerys Creek and Cosgrove Creek. The Cosgrove Creek corridor is a 'dead end' and does not connect to other native vegetation. The Badgerys Creek corridor continues outside the nominated area as a narrow strip of native vegetation	Connected vegetation occurs in scattered areas mainly in the middle and north-eastern part of the nominated area Isolated vegetation occurs in only a few very small patches in the middle parts of the nominated area
GPEC	Occur in the northern part of the nominated area around Wianamatta Regional Park and the southern part around Orchid Hills. Two corridors connect Wianamatta Regional Park and Orchid Hills associated with Wianamatta (South Creek) and Ropes Creek. A third corridor connects native vegetation at Orchid Hills to native vegetation to the west of the nominated area near Mulgoa Road along a drainage line	No corridors occur within the nominated area	Connected vegetation occurs in scattered areas across the nominated area Isolated vegetation occurs in a few very small patches across the nominated area

24.10.3 NATURE, EXTENT AND DURATION IMPACTS

The nature, extent and duration of the impacts of the urban, industrial, infrastructure, agribusiness and transport development on habitat connectivity are set out in Table 24-18.

Table 24-18: Nature, extent and duration of impacts – habitat connectivity

Nominated area	Nature	Extent	Duration
Wilton	**Direct impacts:** The vast majority of BIO Map regional corridors/core areas have been avoided and will not be directly impacted. The main direct impact occurs in the southern part of the nominated area where the development will remove part of a corridor/core area that connects native vegetation either side of the nominated area in this location. The impact reduces the width of the corridor/core area by about half. Connectivity is maintained to the south and east of the impacted area. In all other areas, direct impacts occur only to the edges of corridors/core areas in a few locations and connectivity along these areas is maintained There are very minor direct impacts to the local corridor on the eastern side of the nominated area between the Hume Motorway and Wilton Road The majority of impacts to connected vegetation occur to smaller scattered patches in the middle of the nominated area and to the edge of larger areas of connected vegetation where it occurs adjacent to BIO Map regional corridors/core areas around the nominated area	**Direct impacts:** The following approximate amounts of each category of habitat connectivity will be directly impacted by the development: • BIO Map corridors – 79.5 ha (7.6%) • Local corridor – 5.6 ha (2.9%) • Connected vegetation – 141.3 ha (25.8%) • Isolated vegetation – 1 ha (48%)	Long-term
	Indirect impacts: The development may cause a range of indirect impacts to areas of habitat connectivity. Key risks are weed invasion, pest animals, changes to hydrology, increased risk of fire, and human disturbance	**Indirect impacts:** Areas of habitat connectivity adjacent to urban capable lands/transport corridors	Temporary or long-term
GMAC	**Direct impacts:** The vast majority of BIO Map regional corridors/core areas have been avoided and will not be directly impacted. Direct impacts occur only to the edges of corridors/core areas in a few locations. There are no locations were direct impacts completely sever or significantly narrow a core area/corridor and connectivity is maintained for these areas of habitat connectivity across all parts of the nominated area The vast majority of the local corridor in the middle of the southern part of the nominated area has been avoided and is not directly impacted. Impacts occur only to the edges of the corridor and connectivity is maintained in this location across the nominated area The majority of impacts to connected vegetation occur to smaller scattered patches, where patches will be completely cleared. Impacts also occur to the edges of several larger areas of connected	**Direct impacts:** The following approximate amounts of each category of habitat connectivity will be directly impacted by the development: • BIO Map corridors – 468.9 ha (3.3%) • Local corridor – 18.6 ha (12.2%) • Connected vegetation – 219.5 ha (21%) • Isolated vegetation – 1.9 ha (15.7%)	Long-term

Nominated area	Nature	Extent	Duration
	vegetation in the southern part of the nominated area. In these cases, the size of the patches will be reduced, but the impacts will not generally sever connectivity between this connected vegetation and other areas of native vegetation, such as BIO Map corridors/core areas		
	Indirect impacts: The development may cause a range of indirect impacts to areas of habitat connectivity. Key risks are weed invasion, pest animals, changes to hydrology, increased risk of fire, and human disturbance	**Indirect impacts:** Areas of habitat connectivity adjacent to urban capable lands/transport corridors	Temporary or long-term
WSA	**Direct impacts:** The vast majority of BIO Map regional corridors/core areas have been avoided and will not be directly impacted. The main direct impact occurs in the south-eastern part of the nominated area where the development will remove the majority of a corridor/core area that connects Wianamatta (South Creek) and Kemps Creek in the Kemps Creek area. While this area is identified as a regional corridor, connectively has already been completely severed in this location by existing industrial land use. In all other areas, direct impacts occur only to the edges of corridors/core areas in a few locations and connectivity along these areas is maintained The majority of local corridors have been avoided and will not be directly impacted. Direct impacts occur: • At Cosgrove Creek in the middle part of the nominated area where the OSO severs the riparian corridor in two locations • At Badgerys Creek in the middle part of the nominated area where the OSO severs the riparian corridor in one location The majority of impacts to connected vegetation occur to smaller scattered patches, where patches will be completely cleared. Impacts also occur to the edges of several larger areas of connected vegetation in the north-eastern, middle and southern parts of the nominated area. In some cases, the impacts will sever or reduce connectivity between this connected vegetation and other areas of connected vegetation within and outside the nominated area	**Direct impacts:** The following approximate amounts of each category of habitat connectivity will be directly impacted by the development: • BIO Map corridors – 22.3 ha (7.0%) • Local corridor – 34.2 ha (27.4%) • Connected vegetation – 280.5 ha (52.7%) • Isolated vegetation – 9.9 ha (67.1%)	Long-term
	Indirect impacts: The development may cause a range of indirect impacts to areas of habitat connectivity. Key risks are weed invasion, pest animals, changes to hydrology, increased risk of fire, and human disturbance	**Indirect impacts:** Areas of habitat connectivity adjacent to urban capable lands/transport corridors	Temporary or long-term

Nominated area	Nature	Extent	Duration
GPEC	**Direct impacts:** The majority of BIO Map regional corridors/core areas have been avoided and will not be directly impacted. The main direct impacts occur: • Within Wianamatta Regional Park where the OSO severs the eastern part of the regional park that is connected to Ropes Creek with the western part of the park • Along Wianamatta (South Creek) where the OSO directly impacts the Wianamatta (South Creek) riparian corridor and severs the narrow connection along the corridor that links Wianamatta Regional Park and Orchid Hills In all other areas direct impacts have been avoided, except in the western part of the nominated area near Glenmore Park where there is a small direct impact to the edge of a corridor/core area No local corridors occur within the nominated area The majority of impacts to connected vegetation occur to smaller scattered patches, where patches will be completely cleared. Impacts also occur to the edges of several larger areas of connected vegetation in some parts of the nominated area. In these cases, the size of the patches will be reduced, but the impacts will not generally sever connectivity between this connected vegetation and other areas of native vegetation, such as BIO Map corridors/core areas	**Direct impacts:** The following categorises of habitat connectivity will be directly impacted by the development: • BIO Map corridors – 188.4 ha (5.8%) • Local corridor – 0 ha (0%) • Connected vegetation – 190.6 ha (17.2%) • Isolated vegetation – 0.5 ha (5.9%)	Long-term
	Indirect impacts: The development may cause a range of indirect impacts to areas of habitat connectivity. Key risks are weed invasion, pest animals, changes to hydrology, increased risk of fire, and human disturbance	**Indirect impacts:** Areas of habitat connectivity adjacent to urban capable lands/transport corridors	Temporary or long-term

24.10.4 COMMITMENTS AND GENERAL MITIGATION MEASURES TO ADDRESS IMPACTS

The Plan includes a commitment to mitigate indirect and prescribed impacts from development on TECs and species habitat to best practice standards (Commitment 5). This commitment will be delivered through preparation of a DCP for each nominated area. A DCP provides detailed guidelines and environmental standards for new development, which need to be considered when preparing a development application seeking development approval. DCPs for each nominated area will be prepared in accordance with:

- Standard format for DCPs and a set of model provisions prepared by the Department to apply across NSW
- Any processes and guidelines for preparing DCPs specific to each council
- Current best practice standards, guidelines or targets (e.g. water quality standards for urban runoff)

DCPs will include several general development controls relevant to managing prescribed impacts associated with habitat connectivity, including (see Chapter 15, section 15.6.1):

- Maintain waterways of Strahler order 2 or higher in a natural state, including riparian corridors
- Design road crossings of waterways to minimise impacts to vegetated riparian corridors and species movements
- Retain large trees (including dead trees) (≥50cm DBH) during precinct planning where possible
- Retain areas of high density proteaceae shrubs where possible, particularly along riparian corridors
- Plant of native trees in open space areas and along major and residential roads as part of the design of new residential areas (particularly relevant to Grey-headed Flying-fox, micro-bat species and birds)
- A range of controls that would mitigate indirect impacts on habitat that forms part of habitat corridors, including water cycle management and water quality and the spread of weeds

A detailed description of the process to implement these development controls in the nominated areas, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.1.

It is also important to note that the conservation program under the Plan (see Part 2) will result in:

- Protecting a minimum of 5,475 hectares of native vegetation and habitat in the subregion (Commitment 8)
- Securing priority habitat corridors in the subregion (Commitment 12)
- Undertake ecological restoration of up to 25 per cent of the offset target for native vegetation (Commitment 13)
- Managing landscape threats in strategic locations to improve habitat values, including weeds (Commitment 16) and pests (Commitment 17) and fire (Commitment 17)

Importantly, the strategic conservation areas (SCAs) where these commitments will be delivered represent the areas in the Cumberland subregion that are considered most likely to be viable in the long-term and to maximise ecological function and connectivity across the landscape. In determining the location of the SCAs, priority was given to including the largest, best condition and best-connected areas of native vegetation remaining in the subregion (see Part 2).

24.10.5 ASSESSMENT OF POTENTIAL PRESCRIBED IMPACTS

The nominated areas are highly fragmented and key areas of connectivity generally occur along riparian corridors, within steeper land and gully areas, particularly around the edges of Wilton and southern GMAC.

The development will generally reduce habitat connectivity across the nominated areas for species and TECs mainly due to the removal of many smaller connected patches of habitat, which will often generally leave the remaining larger patches along riparian corridors and within steeper land and gully areas more isolated to some extent. This will have a greater impact on the group of species associated with scattered and/or degraded native vegetation within a matrix.

While a reduction in habitat connectivity will occur, the nominated areas are highly fragmented and the majority of key areas of habitat connectivity will be maintained, including the majority of BIO Map core areas and corridors.

An assessment of the potential prescribed impacts of the urban, industrial, infrastructure, agribusiness and transport development on species associated with habitat connectivity is set out in Table 24-19. This assessment takes into account any general mitigation measures under the Plan to manage impacts.

Table 24-19: Assessment of potential prescribed impacts – habitat connectivity

Relevant species	Assessment of potential prescribed impacts	Residual risk of impacts?
Species associated with large habitat corridors and/or large areas of intact native vegetation	Impacts are unlikely to cause population decline at a local, regional or State scale for species associated with large habitat corridors and/or large areas of intact native vegetation (BIO Map corridors/core areas) because: • The vast majority of these areas have been avoided and will not be impacted • Direct impacts generally occur only to the edges of corridors/core areas. There are few locations were direct impacts completely sever or significantly narrow a core area/corridor and connectivity is maintained for these areas The most notable impacts occur: • Within Wianamatta Regional Park • Along Wianamatta (South Creek) where the OSO directly impacts Wianamatta (South Creek) riparian corridor The commitments and general mitigation measures are generally considered adequate to manage the risk of prescribed impacts on these areas of habitat connectivity. The Plan includes a specific mitigation measure to manage the risk from the OSO	Unlikely
Species associated with smaller habitat corridors or riparian corridors or waterways	Impacts are unlikely to cause population decline at a local, regional or State scale for species associated with smaller habitat corridors or riparian corridors (local corridors) because: • The vast majority of these areas have been avoided and will not be impacted • Impacts often occur only to the edges of the local corridors and connectivity is maintained for these areas The most notable impacts occur in WSA: • At Cosgrove Creek in the middle part of the nominated area where the OSO severs the riparian corridor in two locations • At Badgerys Creek in the middle part of the nominated area where the OSO severs the riparian corridor in one location The commitments and general mitigation measures are generally considered adequate to manage the risk of prescribed impacts on these areas of habitat connectivity. The Plan includes a specific mitigation measure to manage the risk from the OSO	Unlikely
Species associated with scattered and/or degraded native vegetation within a matrix	Impacts are unlikely to cause population decline at a local, regional or State scale for species associated with scattered and/or degraded native vegetation (connected vegetation) because impacts generally occur to: • Smaller scattered patches, where patches will be completely cleared • To the edges of larger patches where the size of the patches will be reduced, but the impacts will not generally sever connectivity between this connected vegetation and other areas of native vegetation The most notable impacts occur in WSA, where in some cases, the impacts will sever or reduce connectivity between connected vegetation and other areas of connected vegetation within and outside the nominated area. These impacts may reduce connectivity in this part of the nominated area for microbats and smaller birds The commitments and general mitigation measures are considered adequate to manage the risk of prescribed impacts on these areas of habitat connectivity	Unlikely

Relevant species	Assessment of potential prescribed impacts	Residual risk of impacts?
Species that are relatively immobile and move only short distances	Red-crowned Toadlet: impacts are unlikely to cause population decline at a local, regional or State scale for this species as there are no records within the nominated areas, and mapped suitable habitat occurs in scattered patches within the vicinity of gorges and gullies that occur mainly around the edges of the urban capable land, where habitat connectivity will be maintained Cumberland Plain Land Snail: impacts may potentially cause population decline at a local, regional and State scale for this species. Little is known about Cumberland Plain Land Snail dispersal patterns or over what distances individuals can move (OEH, 2019c). Most populations are small and isolated. Records for the species are scattered across the Cumberland subregion. However, where records occur within the nominated areas, most occur on excluded land and many occur on land avoided for biodiversity, including around the edges of GPEC and along riparian corridors in WSA and GPEC. The development is likely to reduce habitat connectivity for this species, associated particularly with the removal of many smaller connected and more isolated patches of Cumberland Plain Woodland, leaving populations in remaining larger patches more isolated to some extent The commitments and general mitigation measures are generally considered adequate to minimise the risk of prescribed impacts associated with habitat connectivity on Cumberland Plain Land Snail. The Plan includes a specific mitigation measure to manage residual risks to this species	Potentially
TECs/flora species	The development will reduce habitat connectivity across the nominated areas for TECs and flora habitat due to the removal of many smaller connected and more isolated patches of TECs, causing the isolation of more intact, larger patches of TECs. This is due to vegetation removal and associated reduced movement of mobile pollinators such as birds and bats TECs (and associated flora species) within the Plan Area, at a local, regional and State scale, are already highly fragmented with the majority of key areas of habitat connectivity being maintained, including the majority of BIO Map core areas and corridors and riparian corridors The commitments and general mitigation measures are considered adequate to manage the risk of prescribed impacts on these areas of habitat connectivity	Unlikely

24.10.6 ADDITIONAL SPECIFIC MITIGATION TO ADDRESS RESIDUAL RISKS

Table 24-20 identifies additional specific mitigation measures under the Plan to address residual risks.

These mitigation measures are considered to adequately address residual risks in the context of the risk and significance of the impacts of the development on this species.

Table 24-20: Specific mitigation measures – habitat connectivity

Relevant species/TECs	Specific mitigation measure	Applicable development	Uncertainty or risks of failure
• Eastern Pygmy-possum • Spotted-tailed Quoll • Birds associated with riparian corridors	The Plan includes a commitment to ensure transport corridors, including the OSO are designed to avoid and minimise impacts to areas of potential habitat connectivity, particularly vegetation in riparian corridors (Commitment 3)	Transport corridors	Outcome not possible to determine at this stage

Relevant species/TECs	Specific mitigation measure	Applicable development	Uncertainty or risks of failure
• Cumberland Plain Land Snail	The Plan includes a specific mitigation measure to implement 'open structure design' when designing structures such as roads which may isolate patches of habitat, consistent with the critical actions for this species under the Save our Species program (EES, 2020)	Urban, industrial, and agribusiness development	Outcome not possible to determine at this stage. Mitigation measures is consistent with critical actions for this species under the Save our Species program (EES, 2020)

IMPLEMENTATION

Urban, industrial and agribusiness

For the urban, industrial, and agribusiness development, these specific mitigation measures will be implemented through DCPs (see above). A detailed description of this process is provided in Chapter 15, Section 15.6.1.

Transport corridors

The Plan includes a commitment to mitigate indirect and prescribed impacts from transport development (Commitment 6), as prescribed in Appendix E of the Plan.

This commitment will be delivered through a process of environmental assessment and approval that will be applied to detailed design of each transport project, at the time the project is brought forward for development. These future environmental assessments provide a process through which to implement these specific mitigation measures for habitat connectivity, as prescribed in Appendix E of the Plan.

A detailed description of the assessment and approval process for transport corridors and infrastructure, including Department oversight and assurance mechanisms, is provided in Chapter 15, Section 15.6.2 and 15.6.3.

24.11 ASSESSMENT OF WATER BODIES AND HYDROLOGICAL PROCESSES

24.11.1 LIST OF RELEVANT SPECIES AND TECS

WATER BODIES

The list of species or TECs associated with water bodies is shown in Table 24-21.

Table 24-21: Species/TECs associated with water bodies

Relevant species/TECs	Use and importance of habitat type
Green and Golden Bell Frog	The species uses water bodies for breeding and foraging. While it appears to generally be associated with a single water body for general activities, records suggest the species is highly mobile and can move some distance as part of migrations to and from breeding sites (Lemckert, 2019). Movements of up to 5 km may be common and the frog may disperse up to 10 km (DoEE, 2018a). Breeding occurs after heavy rains or storms and spawn is laid among aquatic vegetation (DEWHA, 2009b)
Southern Myotis	The species uses water bodies for foraging. It forages over streams and pools, including dams, on insects and small fish (OEH, 2019j)
White-bellied Sea-eagle	Occurs near large areas of open water including larger rivers, swamps, lakes, and the ocean, or in the vicinity of freshwater swamps, lakes, reservoirs, billabongs and saltmarsh. Uses waterbodies for foraging. Feeds mainly on fish and freshwater turtles, but also waterbirds, reptiles, and mammals. Breeding habitat is constrained to living or dead mature trees within forests or tall woodland within 1 km of rivers, lakes, large dams or creeks, wetlands and coastlines (OEH, 2017k)

Relevant species/TECs	Use and importance of habitat type
Australasian Bittern	The species uses waterbodies for shelter, foraging and breeding. Inhabits permanent freshwater wetlands with tall, dense vegetation. Shelters during the day amongst dense reeds or rushes and feeds on frogs, fish, yabbies, and insects (OEH, 2018b)
Black-necked Stork	The species uses water bodies for foraging and builds large nests high in tall trees close to water. Primary habitat is floodplain wetlands (swamps, billabongs, watercourses and dams) of major coastal rivers. Secondary habitat includes minor floodplains, coastal sandplain wetlands and estuaries. It usually forages in water 5-30 cm deep for vertebrate and invertebrate prey (OEH, 2017b)
Comb-crested Jacana	The species inhabits permanent freshwater wetlands with a good cover of floating vegetation or fringing vegetation and uses water bodies for breeding and foraging. It feeds primarily on insects and other invertebrates (OEH, 2018d)
Black Bittern	The species inhabits terrestrial and estuarine wetlands, generally in areas of permanent water and dense vegetation and uses water bodies for breeding and foraging. It feeds on frogs, reptiles, fish and invertebrates. Nests are built on a branch overhanging water (OEH, 2018c)
Eastern Osprey	Inhabits coastal areas, especially the mouths of large rivers, lagoons and lakes and uses water bodies for foraging. Feeds on fish over open water. Nests are made in dead trees or branches, usually within one kilometre of the sea (OEH, 2018e)
Australian Painted-snipe	Inhabits swamps, dams and nearby marshy areas and uses water bodies or fringing habitat for foraging and breeding. Forages on mud flats and in shallow water. Feeds on worms, molluscs, insects and some vegetation. Nests on the ground in tall vegetation, such as grasses, tussocks or reeds (OEH, 2017a)
Freckled Duck	Inhabits freshwater swamps and creeks with heavy growth of Cumbungi, Lignum or Tea-tree. During drier times, the species inhabits more permanent waters such as lakes, reservoirs, farm dams and sewage ponds. Rests in dense cover, usually in deep water. Nests occur in dense vegetation at or near water level (OEH, 2017d)

HYDROLOGICAL PROCESSES

The list of species or TECs associated with hydrological processes is shown in Table 24-22 and TECs have been grouped based on the potential risk of impacts from changes to hydrological processes associated with the development.

Table 24-22: Species/TECs associated with hydrological processes

Relevant species/TECs	Use and importance of habitat type
Higher Risk TECs	
Castlereagh Scribbly Gum Woodland in the Sydney Basin Bioregion	Higher risk TECs are those that either: • Directly reliant on hydrological processes for the maintenance of their floristic assemblage, or • Are located in landscape positions where processes such as regular flooding and deposition are key to maintaining the edaphic conditions that support the floristic assemblage, or • Are particularly susceptible to erosion, or are considered particularly susceptible to changes in water quality and nutrient load
Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion	
Freshwater Wetlands on Coastal Floodplains of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions	
River-flat Eucalypt Forest on Coastal Floodplains of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions.	
Shale Gravel Transition Forest in the Sydney Basin Bioregion	

Relevant species/TECs	Use and importance of habitat type
Shale Sandstone Transition Forest in the Sydney Basin Bioregion	
Swamp Oak Floodplain Forest of the New South Wales North Coast, Sydney Basin and South East Corner Bioregions	
Lower Risk TECs	
Cumberland Plain Woodland in the Sydney Basin Bioregion	Lower risk TECs are those that occur in landscape positions where hydrological processes have a lower level of influence on species assemblage or edaphic conditions
Moist Shale Woodland in the Sydney Basin Bioregion	
Higher Risk threatened flora species	
Allocasuarina glareicola	Higher risk threatened flora species are those that either: • Grow in waterbodies or swampy areas, or • Require regular inundation and deposition to maintain edaphic conditions, or • Are strongly associated with a higher risk TEC, or • Are higher specialised with regards to requirements for soil moisture content and nutrient levels
Dillwynia tenuifolia	
Eucalyptus benthamii Camden White Gum	
Maundia triglochinoides	
Micromyrtus minutiflora	
Persicaria elatior Tall Knotweed	
Pterostylis saxicola Sydney Plains Greenhood	
Lower Risk threatened flora species	
Acacia bynoeana Bynoe's Wattle	Lower risk threatened flora species are those that occur in landscape positions where hydrological processes have a lower level of influence on edaphic conditions
Acacia pubescens Downy Wattle	
Epacris purpurascens var. *purpurascens*	
Grevillea juniperina subsp. *juniperina* Juniper-leaved Grevillea	
Grevillea parviflora subsp. *parviflora* Small-flower Grevillea	
Hibbertia fumana	
Hibbertia puberula	
Marsdenia viridiflora subsp. *viridiflora* Native Pear	
Melaleuca deanei Deane's Paperbark	
Persoonia bargoensis Bargo Geebung	
Persoonia nutans Nodding Geebung	
Pimelea curviflora var. *curviflora*	
Pimelea spicata Spiked Rice-flower	
Pomaderris brunnea Brown Pomaderris	
Pultenaea parviflora	
Pultenaea pedunculata Matted Bush-pea	

Relevant species/TECs	Use and importance of habitat type
Higher Risk threatened fauna species	
Botaurus poiciloptilus Australasian Bittern	Higher risk threatened fauna species are those that are reliant on wetlands, lower Strahler order watercourses and riparian corridors, or soaks and fringing macrophyte vegetation for key aspects of their lifecycle
Ephippiorhynchus asiaticus Black-necked Stork	
Epthianura albifrons White-fronted Chat	
Heleioporus australiacus Giant Burrowing Frog	
Irediparra gallinacean Comb-crested Jacana	
Ixobrychus flavicollis Black Bittern	
Litoria aurea Green and Golden Bell Frog	
Myotis macropus Southern Myotis	
Pseudophryne australis Red-crowned Toadlet	
Rostratula australis Australian Painted Snipe	
Stictonetta naevosa Freckled Duck	
Lower Risk threatened fauna species	
Remaining candidate species and ecosystem credit fauna species	Lower risk threatened fauna species are those not directly reliant on waterbodies or wetlands, those associated with riparian corridors of higher Strahler watercourses, or those species within limited habitat within the nominated areas (such as waders)

24.11.2 OCCURRENCE OF HABITAT OR PRESCRIBED IMPACT TYPE

WATER BODIES

Water bodies comprise non-vegetated wetlands, ponds, rivers, creeks and other bodies of water, including farm dams, greater than 3 m wide. Water bodies occur in all nominated areas and were identified using the Digital Topographic Database hydro area layer (LPI, 2016).

Direct impacts on Southern Myotis and Green and Golden Bell Frog associated with waterbodies were determined by:

- Intersecting the hydro area layer with the species maps for these three species (see Chapter 11)
- Excluding water bodies that were within native vegetation based on the native vegetation map (see Chapter 11) (direct impacts to these water bodies are assessed through impacts to native vegetation and habitat (see Chapter 23)
- Intersecting water bodies with species habitat that occurs within urban capable lands and transport corridors

The location of water bodies is shown in Map 20.

HYDROLOGICAL PROCESSES

Potential areas of hydrological change were mapped across the nominated areas using topographical features such as watercourses and changes in relief through the landscape to determine catchment areas and floodplains.

A digital elevation model was used to help visualise these catchment areas and floodplains, and highlight those where development is to occur either within the floodplain or near the top of catchments, which were then mapped.

These mapped areas cover the land outside the urban capable land and transport corridors where it is expected that indirect impacts to species and TECs may occur as a result of the development changing the existing hydrological processes that currently support those ecological values.

Table 24-23 provides details of the areas considered to potentially undergo hydrological changes related to development either in the upper reaches of the water catchment area, or development on a floodplain. These mapped areas are shown on Map 20 and are considered to cover the extent of potential hydrological change which may occur as a result of adjacent development within the nominated areas.

Table 24-23: Areas of potential hydrological impacts

Nominated area	Location	Type
Wilton	Allens Creek catchment	Development in catchment area modifying feeder creeks
	Allens Creek tributary catchment	Development in catchment area modifying feeder creeks
	Byrnes Creek catchment	Development in area surrounding catchment
	Nepean River catchment	Development in catchment area modifying feeder creeks
	Stringybark Creek catchment	Development in catchment area modifying feeder creeks
GMAC	Cataract/Elladale/Nepean catchment	Development in upper catchment area modifying feeder creeks
	Cataract/Rocky Ponds catchment	Development in upper catchment area modifying feeder creeks
	Elladale Creek catchment	Development in upper catchment area surrounding watercourses and modifying feeder creeks
	Elladale/Nepean catchment	Development in upper catchment area modifying feeder creeks
	Menangle/Woodhouse/Leafs catchment	Development in upper catchment area modifying feeder creeks
	Nepean River catchment	Development in upper catchment area modifying feeder creeks
	Ousedale Creek catchment	Development in upper catchment area surrounding watercourse and modifying feeder creeks
WSA	Badgerys Creek floodplain	Development on floodplain and within catchment area surrounding watercourse
	Cosgroves Creek floodplain	Development on all sides of floodplain and modification of feeder creeks
	Wianamatta (South Creek) and Kemps Creek floodplains	Development on floodplain and within catchment areas surrounding watercourse
	Wianamatta (South Creek) floodplain	Development on floodplain
GPEC	Wianamatta (South Creek) floodplain	Development on floodplain (major roadway development)
	Surveyors Creek tributary	Development in upper catchment area modifying feeder creeks

24.11.3 NATURE, EXTENT AND DURATION IMPACTS

WATER BODIES

The nature, extent and duration of the impacts of the urban, industrial, infrastructure, agribusiness and transport development on water bodies are set out in Table 24-24.

Table 24-24: Nature, extent and duration of impacts –water bodies

Species/TEC	Nature	Extent	Duration
Green and Golden Bell Frog	**Direct impacts:** The development will directly impact two small waterbodies within the know habitat area, with suitable habitat for this species	0.6 ha of water bodies along Ropes Creek in GPEC	Long-term
	Indirect impacts: The development may cause indirect impacts to water bodies within suitable habitat for the species associated with urban run-off and changes to hydrology	Adjacent to urban capable land along Ropes Creek in GPEC	Temporary or long-term
Southern Myotis	**Direct impacts:** The development will directly impact approximately 1,000 waterbodies within suitable habitat for this species	244 ha of water bodies in all nominated areas	Long-term
	Indirect impacts: The development may cause indirect impacts to water bodies within suitable habitat for the species associated with urban run-off and changes to hydrology	Water bodies adjacent to urban capable lands in each nominated area	Temporary or long-term
White-bellied Sea-eagle	**Direct impacts:** The development will directly impact several waterbodies within suitable habitat for this species	Several water bodies within a total of 10 ha of suitable habitat that occurs in each nominated area. An impact of <1 ha will occur	Long-term
	Indirect impacts: The development may cause indirect impacts to water bodies within suitable habitat for the species associated with urban run-off and changes to hydrology	Water bodies adjacent to urban capable lands in each nominated area	Temporary or long-term
Water birds	**Direct impacts:** The development will directly impact many waterbodies within suitable habitat for these species	Many water bodies scattered across each nominated area	Long-term
	Indirect impacts: The development may cause indirect impacts to water bodies within suitable habitat for the species associated with urban run-off and changes to hydrology	Water bodies adjacent to urban capable lands in each nominated area	Temporary or long-term

HYDROLOGICAL PROCESSES

The nature, extent and duration of the impacts of the urban, industrial, infrastructure, agribusiness and transport development on species on hydrological processes are set out in Table 24-25.

The figures presented in the table for the total extent of habitat has been calculated based on the total area of habitat for each group of ecological values (high/low risk species or TECs) within each nominated area. Where habitat overlaps between species in the same group of ecological value (high/low risk species or TECs) the overlaps are 'dissolved' and the habitat area is calculated only once. The total amount equates to an approximate area of habitat that could be utilised by multiple species or TECs within each group.

For lower risk fauna, which includes ecosystem credit species, all native vegetation mapped in the nominated areas was used as a surrogate for species habitat. This is considered suitable as all mapped native vegetation within the nominated areas is potential habitat for at least one ecosystem credit species.

The potential impact areas are those areas of each ecological value that are potentially subject to hydrological changes. These figures have been estimated and represent a worst case. It is unlikely that impacts would occur across all extents in the table, but rather are likely to be more localised within these larger areas.

The largest impact to a higher risk entity is to higher risk TECs in GPEC, where hydrological changes associated with development on floodplain (major roadway development) potentially impacts up to 744 ha (57.9 per cent) of the mapped higher risk TECs. Potential impacts to higher risk flora include 468 ha (49.1 per cent) in Wilton associated with both development modifying feeder creeks and development in surrounding catchments and 504 ha (48.7 per cent) in GPEC associated with development on floodplain (major roadway development). On average the following impacts estimated:

- Higher risk TECs 1,889 ha (17.7 per cent)
- Lower risk TECs 491 ha (7.0 per cent)
- Higher risk flora 2,670 ha (19.4 per cent)
- Lower risk flora 523 ha (4.6 per cent)
- Higher risk fauna 1,767 ha (13.8 per cent)
- Lower risk fauna 2,908 ha (14.2 per cent)

Table 24-25: Nature, extent and duration of impacts – hydrological processes

Location	Nature	Species/TEC	Total extent in Nominated areas (approx.) (ha)	Potential impact (approx.) (ha & %)	Duration
Wilton	Development in catchment area modifying feeder creeks	• Higher risk TECs • Lower risk TECs • Higher risk flora • Lower risk flora • Higher risk fauna • Lower risk fauna	• 1429 • 451 • 954 • 2231 • 932 • 2350	• 442 (30.9%) • 16 (3.5%) • 468 (49.1%) • 83 (3.7%) • 348 (37.3%) • 699 (29.7%)	Long-term
	Development in area surrounding catchment	• Higher risk TECs • Lower risk TECs • Higher risk flora • Lower risk flora • Higher risk fauna • Lower risk fauna	• 1429 • 451 • 954 • 2231 • 932 • 2350	• 57 (4%) • 10 (2.2%) • 72 (7.5%) • 13 (0.6%) • 63 (6.8%) • 93 (4%)	Long-term
GMAC	Development in catchment area modifying feeder creeks	• Higher risk TECs • Lower risk TECs • Higher risk flora • Lower risk flora • Higher risk fauna • Lower risk fauna	• 2084 • 732 • 1877 • 3102 • 1775 • 3284	• 393 (18.9%) • 44 (6%) • 421 (22.4%) • 25 (0.8%) • 355 (20%) • 658 (20%)	Long-term
	Development in upper catchment area surrounding watercourses and modifying feeder creeks	• Higher risk TECs • Higher risk flora • Higher risk fauna • Lower risk fauna	• 2084 • 1877 • 1775 • 3284	• 125 (6%) • 129 (6.9%) • 75 (4.2%) • 163 (5%)	Long-term

Location	Nature	Species/TEC	Total extent in Nominated areas (approx.) (ha)	Potential impact (approx.) (ha & %)	Duration
WSA	Development on floodplain and within catchment area surrounding watercourse	• Higher risk TECs • Lower risk TECs • Higher risk flora • Higher risk fauna • Lower risk fauna	• 366 • 535 • 291 • 1018 • 901	• 103 (28.1%) • 9 (1.7%) • 55 (18.9%) • 129 (12.7%) • 110 (12.2%)	Long-term
	Development on all sides of floodplain and modification of feeder creeks	• Higher risk TECs • Lower risk TECs • Higher risk flora • Higher risk fauna • Lower risk fauna	• 366 • 535 • 291 • 717 • 901	• 15 (4.1%) • 4 (0.7%) • 7 (2.4%) • 11 (1.5%) • 15 (1.7%)	Long-term
	Development on floodplain - avoided areas potentially impacted	• Higher risk TECs • Lower risk TECs • Higher risk flora • Higher risk fauna • Lower risk fauna	• 366 • 535 • 291 • 717 • 901	• 3 (0.8%) • 20 (3.7%) • 8 (2.7%) • 18 (2.5%) • 24 (2.7%)	Long-term
GPEC	Development on floodplain - major roadway development	• Higher risk TECs • Lower risk TECs • Higher risk flora • Lower risk flora • Higher risk fauna • Lower risk fauna	• 1284 • 1877 • 1034 • 3752 • 2469 • 3255	• 744 (57.9%) • 388 (20.7%) • 504 (48.7%) • 402 (10.7%) • 767 (31.1%) • 1139 (35%)	Long-term
	Development in upper catchment area modifying feeder creeks	• Higher risk TECs • Lower risk TECs • Higher risk flora • Higher risk fauna • Lower risk fauna	• 1284 • 1877 • 1034 • 2469 • 3255	• 7 (0.5%) • 0.1 (0%) • 6 (0.6%) • 0.7 (0%) • 7 (0.2%)	Long-term

24.11.4 COMMITMENTS AND GENERAL MITIGATION MEASURES TO ADDRESS IMPACTS

The Plan includes a commitment to mitigate indirect and prescribed impacts from development on TECs and species habitat to best practice standards (Commitment 5). This commitment will be delivered through preparation of a DCP for each nominated area. A DCP provides detailed guidelines and environmental standards for new development, which need to be considered when preparing a development application seeking development approval. DCPs for each nominated area will be prepared in accordance with:

- Standard format for DCPs and a set of model provisions prepared by the Department to apply across NSW
- Any processes and guidelines for preparing DCPs specific to each council
- Current best practice standards, guidelines or targets (e.g. water quality standards for urban runoff)

DCPs will include several general development controls relevant to managing prescribed impacts associated with hydrological processes and water quality, including (see Chapter 15, section 15.6.1):

- Waterways: Maintain waterways of Strahler order 2 or higher in a natural state, including riparian corridors
- Water cycle management: Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
- Water quality: Stormwater systems must be constructed and maintained to achieve EES water quality targets

- Soil erosion and sedimentation: Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom, 2004) and submitted with each subdivision development application

A detailed description of the process to implement these development controls in the nominated areas, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.1.

24.11.5 ASSESSMENT OF POTENTIAL PRESCRIBED IMPACTS

WATER BODIES

An assessment of the potential prescribed impacts of the urban, industrial, infrastructure, agribusiness and transport development in relation to water bodies is set out in Table 24-26. This assessment takes into account any general mitigation measures under the Plan to manage impacts.

Table 24-26: Assessment of potential prescribed impacts – water bodies

Relevant species/TECs	Assessment of potential prescribed impacts	Residual risk of impacts?
Green and Golden Bell Frog	Development will directly impact a likely population of the Green and Golden Bell Frog associated with Ropes Creek in GPEC. This population comprises 6 BioNet records made between 1998 and 2012. The development will impact an area associated with one of these records made in 1998. It has not been confirmed whether the population at Ropes Creek still exists (Lemckert, 2019). In the absence of targeted surveys, it is considered likely that the population persists in the area The majority of habitat loss within GPEC is associated with the site of the current St Marys Rugby League Club adjacent to the Ropes Creek corridor and includes at least two mapped water bodies. If the population at Ropes Creek is confirmed present, impacts to these areas may be notable at a local level as the aquatic/riparian habitat in that location has the potential to support breeding habitat for the species Impacts are unlikely to cause population decline for this species at a regional or State scale because the majority (greater than 95 %) of records for the species occur in the eastern third of the Cumberland subregion outside the nominated areas (Lemckert, 2019) and the nominated areas are unlikely to be important for species persistence	Likely
Southern Myotis	There is a low risk direct impacts may cause population decline at a local level. The development will remove 246 ha of a total of 785 ha of water bodies within suitable habitat for this species in the nominated areas (approximately 60 % of water bodies within suitable habitat in the nominated areas). However, inspection of aerial photos suggests many of these water bodies are farm dams that are likely to provide more marginal foraging habitat for the species. Urban capable lands have avoided riparian corridors along waterways (see Chapter 14) that are likely to be preferred foraging habitat for the species. Furthermore, riparian corridors across the nominated areas have been avoided (see Chapter 14) and general mitigation measures will be put in place to further protect riparian corridors. It is also likely that urban landform water bodies will be created within developed lands, potentially providing some habitat Impacts are unlikely to cause population decline for this species at a regional or State scale because records for the species are widespread across the bioregion and NSW and the species does not appear to be highly reliant on the Cumberland subregion	Unlikely

Relevant species/TECs	Assessment of potential prescribed impacts	Residual risk of impacts?
White-bellied Sea Eagle	There is a low risk direct impacts may cause population decline at a local, regional or State scale because: • Most water bodies impacted by the development across the nominated areas are farm dams that do not provide suitable foraging habitat for the species • Only very small amounts of potential habitat for the species containing water bodies is being impacted relative to suitable habitat remaining in the subregion Furthermore, riparian corridors across the nominated areas have been avoided (see Chapter 14) and general mitigation measures will be put in place to further protect riparian corridors	Unlikely
Water birds	There is a low risk direct impacts may cause population decline at a local, regional or State scale because most water bodies impacted by the development across the nominated areas are farm dams that are likely to provide more marginal foraging habitat for most of these species, as they are generally associated with vegetated waterbodies Furthermore, riparian corridors across the nominated areas have been avoided (see Chapter 14) and generic mitigation measures will be put in place to further protect riparian corridors	Unlikely

HYDROLOGICAL PROCESSES

The risk and consequences of the impacts of the urban, industrial, infrastructure, agribusiness and transport development in relation to hydrological processes are set out in Table 24-27. This assessment takes into account any general mitigation measures under the Plan to manage impacts.

Table 24-27: Assessment of potential prescribed impacts – hydrological processes

Assessment of potential prescribed impacts	Relevant species/TECs	Residual risk of impacts?
Risks associated with development in upper catchment areas include: • An increase in impermeable areas may result in higher levels of fluctuation in overland flow patterns reaching downstream areas. Following rain events downstream areas are more likely to receive higher volumes of water at higher velocities, over a shorter period of time, leading to higher potential for erosion, changes in deposition and sedimentation patterns and changes to water quality and type and volume of nutrient load. Conversely, as less water is being absorbed by vegetated areas there is less water in the soil during drier times leading to longer periods with lower levels of water availability between rain events • Changes to overland flow patterns through channelisation of stormwater into creeks and stormwater management systems may directly impact upon populations of higher risk flora and fauna species and/or TECs downstream that are reliant on current hydrological patterns for survival • Increases in, or changes to, nutrients and pollutants in stormwater and run-off as a result of anthropogenic inputs such fertilisers, herbicides, soil conditioners, and petrol/oil Risks associated with development on floodplains include: • Changes in flooding regimes and patterns resulting from construction and earthworks may alter the relief of floodplains. This can confine streamlines to channels and reduce the width of those channels, which results in increased water velocities and impacts on groundcover. Increased water velocity may also impact nutrient deposition reducing the nutrient input for floodplain dependent species and TECs • Changes to flooding regimes and patterns may directly impact populations	Higher risk species and TEC	Potentially
	Lower risk species and TECs	Unlikely

Assessment of potential prescribed impacts	Relevant species/TECs	Residual risk of impacts?
of higher risk flora and fauna species and/or TECs downstream that are reliant on current hydrological patterns for survival. Changes may result in periodically wet areas being reduced or lost, or formerly drier areas becoming periodically inundated. This could substantially impact upon the vegetation present within the floodplain The general mitigation measures are considered adequate to manage these risks to lower risk species/TECs. The Plan includes specific mitigation measures to manage this risk for higher risk species and TECs		

24.11.6 ADDITIONAL SPECIFIC MITIGATION TO ADDRESS RESIDUAL RISKS

Table 24-28 identifies additional specific mitigation measures under the Plan to address residual risks to Green and Golden Bell Frog associated with impacts to water bodies. These mitigation measures are considered to adequately address residual risks in the context of the risk and significance of the impacts of the development on this species.

There are no specific mitigation measures under the Plan to address residual risks to Southern Myotis in addition to the measures put in place to avoid riparian corridors and the generic measures to further protect riparian corridors. This is because the risk to this species is considered low and the generic measures are considered adequate in this context.

Table 24-28: Specific mitigation measures – water bodies and hydrological processes

Relevant species	Specific mitigation measure	Applicable development	Uncertainty or risks of failure
Green and Golden Bell Frog	• Actions under Commitment 5 specify the Department will conduct a survey to confirm the presence of the Green and Golden Bell Frog along Ropes Creek. If confirmed present along Ropes Creek, consult with land managers of the riparian corridor to ensure key habitat features are protected and enhanced	Urban, industrial and infrastructure development Transport corridors	Not possible to predict at this stage
Higher risk species and TECs	• An action under Commitment 5 specifies that, in finalising the evaluation program for the Plan, ensure the program monitors impacts of hydrological changes to high risk species and TECs, and evaluations consider feasible adaptive management responses if necessary • The Plan includes an action under commitment to ensure transport corridors are designed to avoid and minimise impacts to vegetation in riparian corridors (Commitment 3). As part of this commitment, the Plan will ensure OSO waterway crossings minimise structures within riparian corridors, waterway re-alignments, and bulk earthworks on adjacent floodplain areas		There is a risk that development in water catchments and on floodplains may result in residual localised impacts to high risk species and TECs. Monitoring and adaptive management in key locations will reduce this risk

IMPLEMENTATION

<u>Transport corridors</u>

The Plan includes a commitment to mitigate indirect and prescribed impacts from transport development (Commitment 5.3), as prescribed in Appendix E of the Plan.

This commitment will be delivered through a process of environmental assessment and approval that will be applied to detailed design of each transport project, at the time the project is brought forward for development. These future environmental assessments provide a process through which to implement these specific mitigation measures for hydrological processes as prescribed in Appendix E of the Plan.

A detailed description of the assessment and approval process for transport, including Department oversight and assurance mechanisms, is provided in Chapter 15, Section 15.6.2.

24.12 ASSESSMENT OF VEHICLE STRIKES

24.12.1 LIST OF RELEVANT SPECIES

Vehicle strikes have been identified as a key threat to several species known or predicted to occur in the nominated areas.

The list of species susceptible to vehicle strikes is shown in Table 24-2.

Note that a detailed assessment of the impacts of vehicle strikes on Koala is provided in Chapter 30.

24.12.2 OCCURRENCE OF HABITAT OR PRESCRIBED IMPACT TYPE

The development will lead to new roads and an increase in the volume of vehicles on existing roads. The main risks areas associated with these impacts occur in areas of suitable habitat of species vulnerable to vehicle strikes where:

- New roads are built within areas of suitable habitat
- Existing roads occur within areas of suitable habitat, assuming that vehicle volumes will increase on these roads

Risk areas area described for each relevant species in Table 24-29.

24.12.3 LIKELIHOOD OF VEHICLE STRIKES WITHIN RISK AREAS

An analysis of the likelihood of vehicle strikes from traffic associated with the urban, industrial, infrastructure, agribusiness and transport development is set out in Table 24-29. The analysis was undertaken on the basis of:

- Likelihood of occurrence of species vulnerable to vehicle strikes, based on records
- Evidence of previous roadkill in the area for those species
- Consideration of relevant life history traits

Observation codes within BioNet records were interrogated to identify whether species records were associated with vehicle strikes (Observation Code R – Roadkill).

Table 24-29: Key risk areas and likelihood of vehicle strikes

Relevant species/TECs	Key risk areas	Likelihood of vehicle strikes in key risk areas
Green and Golden Bell Frog	The key risk area occurs in the northern part of the GPEC, where many existing roads occur across a large patch of suitable habitat associated with a riparian corridor and the OSO intersects the edge of that habitat in Wianamatta Regional Park	The likelihood of vehicle strikes is difficult to predict but is considered to be low to moderate because: • Where the OSO intersects suitable habitat, this only occurs on the edges of suitable habitat and does not disrupt any existing movement corridors. This reduces the likelihood the species needs to cross the OSO to move between areas of suitable habitat • Many existing roads occur within areas of suitable habitat. Despite this, there have been no recorded vehicle strikes on this species. This suggests this species may not be regularly needing to move across existing roads to disperse between areas of suitable habitat, or is able to pass under existing roads where road crossings provide suitable conditions
Eastern Pygmy Possum	The key risk areas occur: • Northern part of Wilton and southern part of GMAC where urban capable lands and associated roads occur adjacent to suitable habitat • Central part of WSA where the OSO impacts small areas of suitable habitat mainly associated with riparian corridors • Northern and central part of GPEC where the OSO intersects suitable habitat in Wianamatta Regional Park and several riparian corridors	The likelihood of vehicle strikes is considered to be low because: • Few records occur within or in the vicinity of the nominated areas, which suggests this species may not occur in the area or occurs only in small numbers • The vast majority of suitable habitat for this species in Wilton and GMAC is restricted to the gorges and gullies mainly on the edges of the nominated areas. The urban capable lands generally occur outside these areas and no major roads directly cross these areas as part of the development
Spotted-tailed Quoll	The key risk areas occur: • Northern part of Wilton and southern part of GMAC where urban capable lands and associated roads occur adjacent to suitable habitat • Central part of WSA where the OSO impacts small areas of suitable habitat mainly associated with riparian corridors • Northern and central part of GPEC	The likelihood of vehicle strikes on the important population of the species near Wilton is difficult to predict but is considered low to moderate as: • The vast majority of suitable habitat for this species is restricted to the gorges and gullies of the edges of Wilton. These areas are outside the urban capable lands and there will be no new roads intersecting these areas as part of the development • Several existing roads occur within areas of suitable habitat. Despite this, there have been no recorded vehicle strikes on this species. This suggests this species may not be regularly needing to move across existing roads to disperse between areas of suitable habitat, or is able to pass under existing roads where road crossings provide suitable conditions The likelihood of vehicle strikes in the other nominated areas is considered to be low because:

Relevant species/TECs	Key risk areas	Likelihood of vehicle strikes in key risk areas
	where the OSO intersects suitable habitat in Wianamatta Regional Park and several riparian corridors	• Few records occur within or in the vicinity of the nominated areas, which suggests this species may not occur in the area or occurs only in small numbers • Many existing roads occur within areas of suitable habitat. Despite this, there have been no recorded vehicle strikes on these species in the nominated areas
Yellow-bellied Glider Squirrel Glider Broad-headed Snake	The key risk areas occur in the northern part of Wilton and southern part of GMAC where urban capable lands and associated roads occur adjacent to suitable habitat	The likelihood of vehicle strikes is considered to be low because: • No records for these species occur in the nominated areas, except for two recent records of Squirrel Glider in the gorge areas in Wilton, which suggests these species may occur only in small numbers • The vast majority of suitable habitat for these species in Wilton and GMAC is restricted to the gorges and gullies mainly on the edges of the nominated areas. The urban capable lands generally occur outside these areas and no major roads directly cross these areas as part of the development
Broad-headed Snake	The key risk areas occur in the northern part of Wilton where urban capable lands and associated roads occur adjacent to suitable habitat	The likelihood of vehicle strikes is considered to be low because: • No records for this species occur in Wilton, which suggests this species may not occur • Suitable habitat for this species in Wilton is likely to be restricted to the gorges and gullies on the edges of the nominated area. The urban capable lands generally occur outside these areas and no major roads directly cross these areas as part of the development
Koala	See Chapter 30	See Chapter 30

24.12.4 COMMITMENTS AND GENERAL MITIGATION MEASURES TO ADDRESS IMPACTS

The Plan includes a commitment to mitigate indirect and prescribed impacts from development on TECs and species habitat to best practice standards (Commitment 5). This commitment will be delivered through preparation of a DCP for each nominated area. A DCP provides detailed guidelines and environmental standards for new development, which need to be considered when preparing a development application seeking development approval. DCPs for each nominated area will be prepared in accordance with:

- Standard format for DCPs and a set of model provisions prepared by the Department to apply across NSW
- Any processes and guidelines for preparing DCPs specific to each council
- Current best practice standards, guidelines or targets (e.g. water quality standards for urban runoff)

DCPs will include several general development controls relevant to managing prescribed impacts to species associated with vehicle strikes, including (see Chapter 15, section 15.6.1):

- Implement traffic calming measures in development areas not subject to Koala exclusion fencing, including speed limit restrictions for areas adjacent to land with biodiversity values, and installation of wildlife signposting and speed humps and audible surfacing in accordance with relevant standards
- Install and maintain fauna-friendly road design structures in appropriate areas adjacent to fauna habitat, such as underpasses, fauna bridges and overpasses

A detailed description of the process to implement these development controls in the nominated areas, including Department oversight and assurance mechanisms, is provided in Chapter 15, section 15.6.1.

The Plan also includes a range of commitments and actions to reduce vehicle strike on Koala, including:

- Install Koala exclusion fencing between important Koala habitat and urban capable land within GMAC and Wilton, except where exclusion fencing is not feasible due to slope, heritage or water courses
- Install Koala exclusion fencing on both sides of Appin Road between Rosemeadow and Appin to mitigate Koala vehicle strikes at roadkill hotspots

Many areas of suitable habitat for Koala overlap with suitable habitat for other species susceptible to vehicle strikes, such as Spotted-tailed Quoll, Eastern Pygmy Possum, and Yellow-bellied Glider, and these mitigation measures for Koala are likely to benefit these other species in many cases.

24.12.5 ASSESSMENT OF POTENTIAL PRESCRIBED IMPACTS

An assessment of the potential prescribed impacts of the urban, industrial, infrastructure, agribusiness and transport development in relation to vehicle strikes is set out in Table 24-30. This assessment takes into account any general mitigation measures under the Plan to manage impacts.

Table 24-30: Risks and consequences of impacts – vehicles strikes

Relevant species/TECs	Assessment of the potential prescribed impacts	Residual risk of impact
Green and Golden Bell Frog	There is a low risk impacts may cause population decline at a local level. The species may occur in GPEC, and while the development will only intersect the edges of suitable habitat and existing roads already occur in the vicinity of suitable habitat, the development will lead to increased traffic levels on existing roads Impacts are unlikely to cause population decline for this species at a regional or State scale because the majority (greater than 95 %) of records for the species occur in the eastern third of the Cumberland subregion outside the nominated areas (Lemckert, 2019) and the nominated areas are unlikely to be important for species persistence The general mitigation measures are considered adequate to reduce this risk The Plan also includes a specific mitigation measure for the transport corridors that may also benefit this species in the northern part of GPEC	Unlikely

Relevant species/TECs	Assessment of the potential prescribed impacts	Residual risk of impact
Eastern Pygmy Possum	Impacts are unlikely to cause population decline for this species at a local, regional or State scale because: • The likelihood of vehicle strikes in key risk areas is considered to be low • Few records occur within or in the vicinity of the nominated areas, which suggests this species may not occur in the area or occurs only in small numbers While risks are considered unlikely, the Plan includes: • General mitigation measures to reduce any actual risk • A specific mitigation measure for the transport corridors that may benefit this species in WSA and GPEC	Unlikely
Spotted-tailed Quoll	There is a low to moderate risk impacts may cause population decline at a local level. An important population of the species occurs immediately to the south of Wilton. While no new major roads will intersect suitable habitat in this area, the development will lead to increased traffic levels on existing roads. Impacts are unlikely to cause population decline for this species at a regional or State scale because: • The vast majority of suitable habitat for this species, including in Wilton and the other nominated areas, are outside the urban capable lands • Few records occur within or in the vicinity of the other nominated areas, which suggests this species may not occur in the area or occurs only in small numbers • There have been no recorded vehicle strikes on this species in the nominated areas suggesting this species may not be regularly needing to move across existing roads to disperse between areas of suitable habitat The general mitigation measures are considered adequate to reduce this risk The Plan also includes a specific mitigation measure for the transport corridors that may also benefit this species in WSA and GPEC	Unlikely
Yellow-bellied Glider Squirrel Glider	Impacts are unlikely to cause population decline for this species at a local, regional or State scale because: • The risk of vehicle strike in key risk areas is considered to be low • Few records occur within or in the vicinity of the nominated areas, which suggests this species may not occur in the area or occurs only in small numbers While risks are considered unlikely, the Plan includes: • General mitigation measures to reduce any actual risk • A specific mitigation measure for the transport corridors that may benefit this species in WSA and GPEC	Unlikely
Broad-headed Snake	Impacts are unlikely to cause population decline for this species at a local, regional or State scale because: • The risk of vehicle strike in key risk areas is considered to be low • No records occur within or in the vicinity of the Wilton (and the other nominated areas), which suggests this species may not occur in the area	Unlikely

24.12.6 ADDITIONAL SPECIFIC MITIGATION TO ADDRESS RESIDUAL RISKS

Table 24-31 identifies additional specific mitigation measures under the Plan to address residual risks to Green and Golden Bell Frog and any actual risks to other species due to the direct and indirect impacts of the development.

These mitigation measures are considered to adequately address residual risks in the context of the risk and significance of the impacts of the development on these species, and the mitigation measures put in place for Koala.

Table 24-31: Specific mitigation measures – vehicle strikes

Relevant species/TECs	Specific mitigation measure	Applicable development	Uncertainty or risks of failure
Green and Golden Bell Frog Yellow-bellied Glider Squirrel Glider Eastern Pygmy Possum Spotted-tailed Quoll	The Plan includes a commitment to ensure transport corridors are designed to avoid and minimise impacts to areas of potential habitat connectivity, particularly vegetation in riparian corridors for these species (Commitment 3)	Transport development	Not possible to predict at this stage

IMPLEMENTATION

Transport corridors

The Plan includes a commitment to mitigate indirect and prescribed impacts from transport development (Commitment 5.3), as prescribed in Appendix E of the Plan.

This commitment will be delivered through a process of environmental assessment and approval that will be applied to detailed design of each transport project, at the time the project is brought forward for development. These future environmental assessments provide a process through which to implement these specific mitigation measures for vehicle strikes as prescribed in Appendix E of the Plan.

A detailed description of the assessment and approval process for transport, including Department oversight and assurance mechanisms, is provided in Chapter 15, Section 15.6.2.

25 Serious and irreversible impacts

25.1 INTRODUCTION

Section 10.2 of the BAM requires the BCAR to assess whether the urban, industrial, infrastructure, agribusiness and transport development in the nominated areas will result in SAII to any NSW listed TECs or species. As outlined in the *Guidance to assist a decision-maker to determine a serious and irreversible impact* (OEH, 2017f), an SAII is one that:

- *Will cause a further decline of the species or ecological community that is currently observed, estimated, inferred or reasonably suspected to be in a rapid rate of decline, or*
- *Will further reduce the population size of the species or ecological community that is currently observed, estimated, inferred or reasonably suspected to have a very small population size, or*
- *Impact on the habitat of a species or ecological community that is currently observed, estimated, inferred or reasonably suspected to have a very limited geographic distribution, or*
- *Impact on a species or ecological community that is unlikely to respond to measures to improve habitat and vegetation integrity and is therefore irreplaceable*

This section:

- Sets out the approach and results for identifying relevant TECs and species that are potentially subject to serious and irreversible impacts due to the development (SAII entities)
- Provides a detailed assessment for each relevant SAII entity

Impacts to SAII entities were assessed in accordance with the requirements of Section 10.2 of the BAM and Appendix 4 of the EES guidelines (OEH, 2017f). The structure of the assessment for each SAII entity in sections 25.3 to 25.11 reflects these requirements.

25.2 IDENTIFYING SAII ENTITIES

25.2.1 APPROACH

The approach to identify SAII entities impacted by the development is described in Chapter 12 and involved:

- Comparing the list of NSW listed TECs and ECS and candidate SCS that occurs within the nominated areas and are potentially impacted by the development with the:
  - List of SAII entities in the *Guidance to assist a decision-maker to determine a serious and irreversible impact* (DPIE, 2019)
  - Threatened Biodiversity Data Collection (TBDC) that indicates whether a TEC or species is an SAII entity
- Determining whether any other NSW listed TECs or ECS and candidate SCS that occur within the nominated areas have the potential to become an SAII in accordance with the requirement of section 10.2.1.4 of the BAM. This section of the BAM requires an assessment against the above EES guidance document (DPIE, 2019) that includes four principles under the BC Regulation (see Table 25-1) that determine whether a species or TEC should be considered an SAII entity. This was undertaken by senior ecologists at Biosis by:
  - Undertaking a literature review to ascertain:
    - Distribution, including geographic extent and area of occupancy
    - Known or inferred reductions in geographic extent or area of occupancy
    - Population sizes and current knowledge of declining populations
    - Susceptibility to known threats, such as invasive weeds and pests, disease or pathogens
    - Life history traits that may make the species particularly vulnerable
  - Investigating existing records and new records found during targeted surveys for this project and the updated native vegetation mapping (see Chapter 11), and using aerial imagery interpretation, to consider likely impacts in areas approved or planned for other future development in the region

- o Considering risk weightings in the TBDC
- o Considering levels of existing protection
- o Consultation with senior Department biodiversity officers

Table 25-1 summarises the principles under the BC Regulation that determine whether a species or TEC should be considered an SAII entity.

Table 25-1: Summary of serious and irreversible impact principles

Principle	Description (DPIE, 2019)
Principle 1	**Species or ecological community currently in a rapid rate of decline** Entities listed as critically endangered under the BC Act • The principle would generally capture entities listed as critically endangered under the BC Act where the reason for that listing is a very large reduction in population size Rapid rate of decline for species considered to be critically endangered by IUCN • The species has an observed, estimated, inferred, suspected or projected population reduction of ≥80% in 10 years or three generations (whichever is longer). Rapid rate of decline for an ecological community considered to be critically endangered by IUCN • To be considered under this principle, the ecological community should have been observed, estimated, inferred, or reasonably suspected to have undergone, or be projected to undergo, a very large reduction in distribution, being: o ≥90% reduction where the reduction is measured since 1750 (historical decline), or o ≥80% reduction where the reduction is over a 50-year period, either in the past, future, or any part of the past, present and future
Principle 2	**Species or ecological communities with a very small population size** Entities listed as critically endangered under the BC Act • The principle would generally capture species or ecological communities listed as critically endangered under the BC Act where the reason for that listing is a very small size or very high environmental degradation and/or a very large disruption of biotic processes or interactions, respectively Very small population size for species considered to be critically endangered by IUCN • Species that have a very small population size are species with a known population size that is either: o fewer than 50 mature individuals independent of whether there are any threats, or o fewer than 250 mature individuals and the species has an observed, estimated or projected continuing decline: ▪ of at least 25% in three years or one generation (whichever is longer) OR ▪ where the number of mature individuals in each subpopulation is <50 OR ▪ the percentage of mature individuals in one subpopulation is 90–100% OR ▪ the population is subject to extreme fluctuations in the number of individuals (IUCN 2017) Very high environmental degradation or disruption of biotic processes or interactions for an ecological community considered to be critically endangered by IUCN • Ecological communities that are considered to have a very large degree of environmental degradation or disruption of biotic processes or interactions are those with: o ≥90% extent and severity where the disruption or impacts are measured since 1970 o ≥80% extent and severity where the disruption or impacts are over a 50-year period, either in the past, future, or any part of the past, present and future (as per Bland et al. 2016).

Principle	Description (DPIE, 2019)
Principle 3	**Species or area of ecological community with very limited geographic distribution** Entities listed as critically endangered under the BC Act • The principle would generally capture entities that are listed as critically endangered under the BC Act where the reason for that listing is their very highly restricted geographic distribution Very limited geographic distribution for species considered to be critically endangered by IUCN • Species that have a very limited geographic distribution are generally known to: o have an area of occupancy (sensu IUCN 2017) of ≤10 km2 o have an extent of occurrence (sensu IUCN 2017) of ≤100 km2 o have at least two of the following three conditions: ▪ are severely fragmented or only known from one location ▪ continuing decline ▪ extreme fluctuations o inhabit less than or equal to three locations in NSW Very limited geographic distribution for an ecological community considered to be critically endangered by IUCN • The geographical distribution of ecological communities is defined by the area of occupancy (sensu Bland et al. 2016). Ecological communities with a very limited geographic distribution have an area of occupancy of less than or equal to two 10 x 10 km grid cells or an extent of occurrence of ≤1000 km2 (sensu Bland et al. 2016) and one of the following: o an observed or inferred continuing decline in: ▪ a measure of spatial extent appropriate to the ecological community ▪ a measure of environmental quality appropriate to characteristic biota of the ecological community ▪ a measure of disruption to biotic interactions appropriate to the characteristic biota of the ecological community o observed or inferred threatening processes that are likely to cause continuing declines in geographic distribution, environmental quality or biotic interactions within the next 20 years o an ecological community exists at one location
Principle 4	**Species or ecological community that is unlikely to respond to management and is therefore irreplaceable** • These are species or ecological communities with: 1. Life history traits and/or ecology which is known, but the ability to control key threats at the site scale is negligible. In general, these are species significantly threatened by uncontrollable disease (e.g. frogs highly threatened by chytrid fungus) 2. Known reproductive characteristics that severely limit their ability to increase the existing population on, or occupy new habitat at, a stewardship site. In general, these are plants that are sterile or largely clonal with no or very limited capacity to increase in number through seed production and recruitment • Irreplaceable o Whether an impact on an entity is considered irreplaceable takes into account two factors. The first factor is the likely success in achieving gain in condition, abundance or habitat area. For potential species that are identified in criteria 1 and 2 above, the likelihood of achieving an offset gain is extremely low or highly uncertain

25.2.2 RESULTS

Table 25-2 and Table 25-3 identify the NSW listed TECs and ECS and candidate SCS species that are SAII entities and that are potentially directly or indirectly impacted by the development (highlighted in blue). These are:

- Cooks River/Castlereagh Ironbark Forest
- Cumberland Plain Woodland
- Shale Sandstone Transition Forest
- *Allocasuarina glareicola*
- *Chalinolobus dwyeri (*Large-eared Pied Bat)
- *Hibbertia fumana*
- *Litoria aurea* (Green and Golden Bell Frog)
- *Micromyrtus minutiflora*
- Three raptor species - *Haliaeetus leucogaster* (White-bellied Sea-Eagle), *Hieraaetus morphnoides* (Little Eagle), and *Lophoictinia isura* (Square-tailed Kite)
- *Pseudophryne australis* (Red-crowned Toadlet)

A TEC or species is an SAII entity either because:

- It is identified in the EES guidelines or TBDC as an SAII entity, or
- It has been assessed as meeting one or more of the four SAII principles in the BC Regulation (section 10.2.1.4 of BAM)

The species assessed as meeting one or more of the four SAII principles in the BC Regulation were:

- Green and Golden Bell Frog and Red-crown Toadlet – these species are likely to meet SAII Principle 4 because of their very high susceptibility to the disease Chytrid fungus
- *Micromyrtus minutiflora –* this species is likely to meet SAII Principle 3 because of its very highly restricted distribution and the development directly impacting potential habitat
- Three raptor species – White-bellied Sea-Eagle, Little Eagle, and Square-tailed Kite – these species are likely to meet SAII Principle 4 because there is potential for the development to impact breeding habitat for the species (hollows of very old trees) that cannot readily be created at a stewardship site

TECs and species were identified as unlikely to trigger SAII principles generally on the basis that the development will not have significant impacts on the TEC or species, and:

- The TEC or species has a relatively broad distribution across the Cumberland subregion or NSW
- Known populations for species are relatively large (> 250 individuals)

In considering the impacts to each TEC and species, both direct impacts on potential habitat for TECs and species (see Chapter 23) and existing and new records based on targeted surveys for this project, were taken into account.

SAII entities that are not mapped as occurring within the nominated areas were not considered to be impacted by the development within the nominated areas and are not considered further. This includes, for example:

- Agnes Banks Woodland
- Elderslie Banksia Scrub Forest
- Western Sydney Dry Rainforest

Each SAII entity impacted by the development is assessed below in accordance with Section 10.2 of the BAM.

Table 25-2: Identification of TEC SAII entities and assessment against SAII principles

TEC name	NSW status	Cth status	Identified by EES as SAII entity	Potential to become SAII entity (Section 10.2.1.4 of BAM)	Is the SAII entity potentially directly or indirectly impacted?	SAII assessment needed
Castlereagh Scribbly Gum Woodland	V	E	No	No – unlikely to trigger SAII principles	N/A	No
Cooks River/Castlereagh Ironbark Forest	E	CE	SAII advice on EES website	N/A	Yes – directly impacted	Yes
Cumberland Plain Woodland	CE	CE	SAII advice on EES website	N/A	Yes – directly impacted	Yes
Freshwater Wetlands on Coastal Floodplains	E	-	No	No – unlikely to trigger SAII principles	N/A	No
Moist Shale Woodland	E	CE	No	No – unlikely to trigger SAII principles	N/A	No
River-flat Eucalypt Forest on Coastal Floodplains	E	-	No	No – unlikely to trigger SAII principles	N/A	No
Shale Gravel Transition Forest	E	CE	No	No – unlikely to trigger SAII principles	N/A	No
Shale Sandstone Transition Forest	CE	CE	SAII advice on EES website	N/A	Yes – directly impacted	Yes
Swamp Oak Floodplain Forest	E	E	No	No – unlikely to trigger SAII principles	N/A	No

Table 25-3: Identification of species SAII entities and assessment against SAII principles

Species name	NSW status	Cth status	Species type	Bio. risk weight.	Identified by EES as SAII entity	Potential to become SAII entity (Section 10.2.1.4 of BAM)	Is the SAII entity potentially directly or indirectly impacted?	SAII assessment needed
Acacia bynoeana	E	V	SCS	2	No	No – unlikely to trigger SAII principles	N/A	No

25.3 COOKS RIVER/CASTLEREAGH IRONBARK FOREST

25.3.1 TEC BACKGROUND

Cooks River Castlereagh Ironbark Forest in the Sydney Basin Bioregion (CRCIF) is a dry sclerophyll open forest to low woodland community with an overstorey dominated by *Eucalyptus fibrosa* and *Melaleuca decora*, with *Eucalyptus longifolia* often present. The midstorey is usually moderate to dense, commonly including *Melaleuca nodosa* and *Lissanthe strigosa*, and to a lesser extent *Melaleuca decora*. The ground layer is generally sparse (OEH, 2019b).

The TEC is equivalent to the ecological community with the same name listed under the EPBC Act (DoE, 2015c).

CRCIF primarily occurs in elevations below 100 m above sea level with mean annual rainfall of approximately 700-1,000 mm. It generally occurs on clay soils derived from Tertiary alluvium and on Wianamatta Shale soils found next to Tertiary alluvium. In the eastern areas of its distribution, the TEC can be found on soils with a sandstone influence (DoE, 2015c). The TEC can intergrade into Shale-Gravel Transition Forest (where the alluvium is shallow), Castlereagh Swamp Woodland (in moist depressions) and Castlereagh Scribbly Gum Woodland (on sandier soils) (OEH, 2019b).

A range of fauna species occur in CRCIF, including reptiles, amphibians, birds, micro-bats, and marsupials. Most of these species also rely on other native vegetation in the Cumberland subregion (DoE, 2015c). Most plant species in the TEC are able to regenerate after fire from lignotubers and buds beneath the bark and seeds stored in the soil (DoE, 2015c).

CRCIF is confined to the Sydney Basin Bioregion and mostly restricted to the Cumberland subregion. The majority of the TEC is found in larger patches in the north-west part of the subregion in the Castlereagh area between Penrith and Richmond. Other significant patches occur in the Kemps Creek and Holsworthy areas. Smaller patches of the ecological community occur in the eastern part of the subregion, such as the upper Cooks River Valley (OEH, 2019b).

25.3.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

CRCIF has been identified as a potential serious and irreversible impacts entity based on advice from EES to accredited assessors in January 2019 as it has a very highly restricted geographic distribution (Principle 3 of the BC Regulation) (OEH, 2017f).

CRCIF is associated with PCT 725 – 'Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion'. The TEC has been mapped within the nominated areas and the Cumberland subregion on the basis of the extent and condition of this PCT (see Chapter 11).

25.3.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of CRCIF in relation to the subject land is shown in Map 21.

The majority of CRCIF within the Cumberland subregion occurs outside the nominated areas within the Londonderry and Castlereagh areas in the northern part of the subregion.

The TEC has been mapped as occurring in the following nominated areas:

- GPEC
- WSA

The main occurrences of the TEC within these nominated areas are located:

- Within Wianamatta Regional Park in the northern part of GPEC
- In the south-eastern part of WSA

25.3.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.2 of the BAM.

10.2.2.1(A) THE ACTION AND MEASURES TAKEN TO AVOID THE DIRECT AND INDIRECT IMPACT ON THE POTENTIAL ENTITY FOR AN SAII

Avoidance and minimisation of impacts to biodiversity values, including CRCIF, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

The baseline mapping for this assessment has mapped 65 ha of CRCIF within the nominated areas (not including excluded lands). Approximately 28 ha (43 per cent) of this was avoided within the nominated areas as part of the design of the urban capable land and transport corridors (not including excluded lands). Almost all of this was avoided for biodiversity purposes.

A breakdown of avoidance across each nominated area is provided in Table 25-4.

The table shows that the majority of the total avoidance that has occurred (71 per cent) has been of CRCIF in intact condition, and that of the 35 ha of intact condition CRCIF (without excluded lands), the majority (19.4 ha or 55 per cent) has been avoided.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-4 shows the amounts of habitat within excluded lands for context only.

Table 25-4: Avoidance outcomes for Cooks River Castlereagh Ironbark Forest (PCT 725)

Condition	Total area in nominated areas (ha)	Area in excluded lands (ha)	Area without excluded lands (ha)	Directly impacted (ha)	Avoided for biodiversity purposes (ha)	Avoided for other purposes (ha)	Total avoidance (ha)
Intact condition	107.4	72.4	35	15.6	19.4	0	19.4
Thinned condition	50.3	24.1	26.3	18.4	0.2	0.1	7.9
Scattered trees	9.6	6.4	3.2	3	7.8	0	0.2
Total	**167.4**	**102.9**	**64.5**	**36.9**	**27.4**	**0.1**	**27.5**

Avoidance of indirect impacts

Potential indirect impacts to CRCIF due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (g).

10.2.2.1(B) THE AREA (HA) AND CONDITION OF THE TEC TO BE IMPACTED DIRECTLY AND INDIRECTLY BY THE DEVELOPMENT

Direct impacts

A total of 37 ha of CRCIF will be directly impacted by the development. This is approximately half of the TEC in the nominated areas (without excluded lands). The direct impacts of the development are mainly associated with the transport corridors.

The main direct impacts occur:

- In the northern part of GPEC within Wianamatta Regional Park associated with the OSO
- In the south-eastern part of WSA associated with urban development

Scattered smaller patches of the TEC will also be directly impacted in the central part of GPEC.

The direct impacts of the development on CRCIF are provided in Table 25-5.

Table 25-5: Direct impacts on Cooks River Castlereagh Ironbark Forest (PCT 725)

PCT	Condition	Direct impacts (ha)						Vegetation integrity score
		Wilton*	GMAC*	WSA*	GPEC*	Transport#	Total	
725	Intact	0	0	0.4	0	15.2	15.6	49.2
725	Thinned	0	0	8.2	6.4	3.7	18.3	43.3
725	Scattered Trees	0	0	3.0	0	0.0	3.00	19.6
Total		**0**	**0**	**11.6**	**6.4**	**18.9**	**36.9**	

* Impacts from urban development only within each nominated area

Impacts from transport corridors across all nominated areas

Indirect impacts

Potential indirect impacts to CRCIF due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (g).

10.2.2.1(C) THE EXTENT TO WHICH THE IMPACT EXCEEDS THE THRESHOLD FOR THE POTENTIAL ENTITY

No threshold has been established for CRCIF.

10.2.2.1(D) THE EXTENT AND OVERALL CONDITION OF THE POTENTIAL TEC WITHIN AN AREA OF 1,000 HA, AND THEN 10,000 HA, SURROUNDING THE URBAN CAPABLE LANDS

The extent and condition of CRCIF surrounding the urban capable lands are provided in Table 25-6. Due to the scale of the development, calculations were also presented based on a 1 km buffer and a 10 km buffer from the outer edge of the urban capable lands, as well as buffers of 1,000 ha or 10,000 ha as per the BAM.

Table 25-6: Extent and condition of Cooks River Castlereagh Ironbark Forest (PCT 725) surrounding the urban capable lands

PCT	Condition	Area in 1,000 ha buffer	Area in 10,000 ha buffer	Area in 1,000 m buffer	Area in 10,000 m buffer
725	Intact	18.5	82.3	162.5	769.3
725	Thinned	20.2	31.2	47.2	117.7
725	Scattered Trees	3.7	6.7	17.7	267.3
Total		**42.4**	**120.2**	**227.4**	**1,154.2**

10.2.2.1(E) AN ESTIMATE OF THE EXTANT AREA AND OVERALL CONDITION OF THE POTENTIAL TEC REMAINING IN THE IBRA SUBREGION BEFORE AND AFTER THE IMPACT OF THE DEVELOPMENT HAS BEEN TAKEN INTO CONSIDERATION

The development will result in a loss of 2.7 per cent of the remaining area of CRCIF in the Cumberland subregion.

The extent and condition of CRCIF remaining in the subregion before and after the impact of the development is provided in Table 25-7. The largest percentage change relates to the TEC in thinned condition. Only very small changes occur to the TEC in intact condition (-1.8 per cent change).

Table 25-7: Extent and condition of Cooks River Castlereagh Ironbark Forest (PCT 725) before and after development

PCT	Condition	Current area in Cumberland subregion (ha)	Area in Cumberland subregion after the direct impacts of the development (ha)	Per cent loss of current area in Cumberland subregion (%)
725	Intact	851.4	835.9	-1.8
725	Thinned	189.5	171.2	-9.7
725	Scattered Trees	327.5	324.5	-0.9
Total		**1,368.5**	**1,331.6**	**-2.7**

10.2.2.1(F) AN ESTIMATE OF THE AREA OF THE POTENTIAL TEC THAT IS IN THE RESERVE SYSTEM WITHIN THE IBRA REGION AND THE IBRA SUBREGION

The area of CRCIF occurring within protected lands (land reserved under NPW Act) within the Cumberland subregion is 412 ha. This represents 30 per cent of the total area of the remaining TEC in the subregion.

The extent and condition of CRCIF within protected lands is provided in Table 25-8.

Table 25-8: Extent and condition of Cooks River Castlereagh Ironbark Forest (PCT 725) in protected lands

PCT	Condition	Area in protected lands within the Cumberland subregion (ha)
725	Intact	402.4
725	Thinned	5.9
725	Scattered Trees	4.0
	Total	**412.3**

10.2.2.1(G) THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION PROPOSAL'S IMPACT ON:

(I) ABIOTIC FACTORS CRITICAL TO THE LONG-TERM SURVIVAL OF THE POTENTIAL TEC

(II) CHARACTERISTIC AND FUNCTIONALLY IMPORTANT SPECIES

(III) THE QUALITY AND INTEGRITY OF AN OCCURRENCE OF THE POTENTIAL TEC THROUGH THREATS AND INDIRECT IMPACTS

The Final Determination (NSW Scientific Committee, 2011) and BioNet profile (OEH, 2019b) for CRCIF identifies a range of threats to the TEC. Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Inappropriate habitat disturbance
- Changes to hydrology
- Diseases, pathogens and dieback
- Invasive fauna

These threats and indirect impacts have the potential to degrade the condition of the TEC and reduce the long-term viability of the patches of the TEC, particularly in the following locations:

- Northern part of GPEC where the OSO corridor fragments TEC patches
- South-eastern part of WSA where urban development occurs immediately adjacent to several TEC patches

To help address these potential indirect impacts, the Plan includes a requirement to undertake mitigation in accordance with the *Best Practice Guidelines: Cooks River/Castlereagh Ironbark Forest* (DECC, 2008) within and adjacent to the TEC. These are discussed further below in relation to specific indirect impacts.

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes can affect the structure and species composition of the TEC by altering the mid and ground layers (NSW Scientific Committee, 2011). This can be caused by:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

The diversity and composition of species will change with time since fire, and may also change in response to changes in fire frequency (NSW Scientific Committee, 2011). This is despite most plant species in the TEC being able to regenerate after fire from lignotubers and buds beneath the bark, as well as seeds stored in the soil (OEH, 2019b).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact the TEC. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development. For the TEC this includes areas in the north of GPEC, and the south east of WSA.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant to the outcome for the TEC being:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the Strategic Conservation Areas that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from the TEC. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes
- A specific requirement in relation to two commitments (Commitments 5 and 6) to apply the best practice guidelines for managing the TEC (DECC, 2008). This includes specifics around fire management for the TEC.

The package of measures in the Plan is expected to adequately manage the risk to the TEC from altered fire regimes as a result of development. This is because:

- Avoided lands in WSA where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting the TEC
- Fire management authorities will be engaged to ensure they understand the requirements of the TEC and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas

- The fire management requirements for the TEC specified in the best practice guidelines will be applied

WEED INVASION

The TEC is threatened with invasion and competition by weeds. It typically occurs on soils that are richer in nutrients compared to other soil types in the Sydney Basin bioregion, which means it is particularly susceptible to threats from weeds (DECC, 2008). The most serious threats are African Lovegrass, scramblers and vines, and urban weeds such as Mother of Millions (OEH, 2019b).

These weeds are already present within the nominated areas and pose a threat to the TEC. However, urban and transport development in the vicinity of the TEC has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or changing conditions to favour weeds. The TEC is most susceptible to the threat of weeds from development under the Plan where new urban development or transport corridors occur adjacent to the TEC and/or fragments patches of the TEC into smaller patches and introduces edge effects. Key risk areas include the northern part of GPEC and south-eastern part of WSA.

The Plan incorporates a range of measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Areas. This includes a number of actions, of which the following are the most relevant to the outcome for the TEC:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas
- A specific requirement in relation to two commitments (Commitments 5 and 6) to apply the best practice guidelines for managing the TEC (DECC, 2008). This includes specifics around weed management

Importantly for the TEC, weeds will be actively managed within the 110 ha to be added to conservation as part of the conservation program under the Plan.

The package of measures in the Plan is expected to adequately manage the risk posed to the TEC from weed invasion. This is because:

- Avoided lands where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management

- The Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy. This includes the land to be protected under the conservation program for the TEC
- There will be a range of planning controls to minimise the potential spread of weeds during and after construction
- The weed management requirements for the TEC specified in the best practice guidelines will be applied

INAPPROPRIATE HABITAT DISTURBANCE

Damage caused by human disturbance, such as motorbikes, bicycles, 4WD vehicles, rubbish dumping, trampling, and erosion is identified in the BioNet profile as a threat to the TEC (OEH, 2019b).

These activities have the potential to alter the structure and floristic composition of the TEC.

Inappropriate habitat disturbance within the nominated areas may increase due to the urban development. Occurrences of the TEC considered most at risk are those in the northern part of GPEC and the south-eastern part of WSA.

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for the TEC. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations (including the 110 ha offset for the TEC)
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan is expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development. This is because:

- Avoided lands where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

CHANGES TO HYDROLOGY

The main threat to the TEC is associated with altered hydrology is increased runoff into patches of the TEC carrying high nutrient and sediment loads, as well as weed seeds or propagules. This can both encourage weed invasion and cause siltation and erosion (OEH, 2019b).

The TEC is most susceptible to the threat of increased runoff from development under the Plan where new urban or transport development occurs adjacent (and upstream or upslope) to the TEC. Key risk areas are those in the northern part of GPEC and the south-eastern part of WSA.

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for the TEC. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5) and transport (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through:

- Development controls in the nominated areas in relation to:
  - Water cycle management. For example:
    - Water management measures must comply with council's requirements for detention, drainage and water sensitive urban design principles
    - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
  - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
  - Soil erosion and sedimentation. For example:
    - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
    - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom, 2004) and submitted with each subdivision development application
- The implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the TfNSW Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the TEC from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts to the TEC
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to the TEC

DISEASES, PATHOGENS AND DIEBACK

The TEC is potentially susceptible to dieback caused by the root-rot fungus *Phytophthora cinnamomi* (OEH, 2019b).

Development under the Plan may increase the risk of the spread of infection/disease. This is primarily related to:

- Soil transportation on contaminated footwear, vehicles and machinery, and in residential garden establishment
- Increased site visitation rates
- Earthworks and activities conducted during construction
- Increased surface water runoff

The Plan incorporates a range of measures to manage the risks associated with diseases, pathogens and dieback. In summary, these include:

- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
  - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
  - Entering into written agreements with delivery partners to implement priority disease control programs
- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures methods to protect the environment during construction, including best practice site hygiene protocols to minimise spread of *Phytophthora*

The package of measures in the Plan is expected to adequately manage the risk to the TEC from diseases, pathogens and dieback because:

- It supports a landscape scale approach to the issue across the Cumberland subregion

- It will ensure appropriate controls during construction

INVASIVE FAUNA

TECs can be threatened by introduced animals and aggressive native species, including CRCIF (DECC, 2008). These species include:

- Domestic species such as cats and dogs which are related to urban development
- Pest species such as foxes, rats, house mice and rabbits which are primarily related to agricultural development
- Aggressive bird species which compete for resources including the introduced Indian Myna, and native species such as the Sulphur-crested Cockatoo

Collectively, these animals can lead to declines in biodiversity through:

- Predation
- Damage to vegetation and soils
- Competition for resources

Existing land use within the nominated areas and surrounding region (which includes residential and rural residential areas, and farming) means that these issues are already present in the nominated areas and are unlikely to pose a novel threat to the TEC.

However, the extent of proposed new urban development under the Plan means that the threats associated with cats and dogs are likely to be exacerbated. It is likely that there will be an increase in the number of domestic cats and dogs in the local area, which, in turn, may lead to an increase in feral cat and wild dog numbers.

In relation to the residual risks associated with invasive fauna, the Plan incorporates a range of measures to manage the risks. In summary, these include:

- A commitment (Commitment 17) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the Strategic Conservation Areas. This includes a number of actions with the most relevant to the outcome for the TEC being:
  - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
  - Preparation of a Pest Animal Control Implementation Strategy
  - A process to enter into written agreements with delivery partners to implement the pest animal control program
  - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Development controls that will:
  - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
  - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
  - Require appropriate management and control of pest animals relevant to development sites
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing pests, consistent with the pest animal implementation strategy outlined in Commitment 16

10.2.2.1(H) DIRECT OR INDIRECT FRAGMENTATION AND ISOLATION OF AN IMPORTANT AREA OF THE POTENTIAL TEC

Direct loss of CRCIF may cause fragmentation and isolation of remaining patches of the TEC, which may increase the susceptibility of the TEC to weed invasion and other edge effects and reduce its long-term viability.

Fragmentation and isolation of CRCIF will mainly occur in the following areas:

- In the northern part of GPEC within Wianamatta Regional Park associated with the OSO

- In the south-eastern part of WSA associated with urban development

The small area of scattered patches of the TEC in the central part of GPEC will be completed removed.

The most notable impact to CRCIF occurs within Wianamatta Regional Park. The patches of the TEC in this location form part of a larger, well-connected patch of native vegetation, and large parts of the patch are in intact condition. These impacts will lead to fragmentation of the TEC in this location, reducing the size and increasing the isolation of the areas that remain. This will increase the susceptibility of CRCIF in this location to weed invasion and other edge effects and reduce its long-term viability. The patch that is directly impacted is only marginally connected to the second occurrence of the TEC within Wianamatta Regional Park (to the east of Ropes Crossing) and as such, the development is not expected to increase the level of fragmentation to the TEC in this locality more broadly.

The patches of the TEC in the south-eastern part of WSA are already relatively fragmented and isolated as a result of existing industrial land use and farming. The urban development in this location is not considered to greatly increase the level of fragmentation and isolation in this location.

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE POTENTIAL TEC IN THE IBRA SUBREGION

The Plan includes a range of commitments that will contribute to the recovery of CRCIF in the Cumberland subregion. Several commitments are described in more detail the sections above.

Key commitments relevant to the TEC are:

- TEC-specific commitments or mitigation measures to:
  - Secure an offset target of 110 ha of CRCIF (Commitment 8.1) in conservation lands within Strategic Conservation Areas (SCAs). This would increase the area of TEC protected within the Cumberland subregion by approximately 27 per cent
  - Undertake management of fire, weeds and pest animals and disease control consistent with the *Best Practice Guidelines: Cooks River/Castlereagh Ironbark Forest* (DECC, 2008) (as part of Commitment 5.1)
- As part of securing a minimum of 5,475 ha of native vegetation in SCAs:
  - Undertake ecological restoration of priority areas secured for conservation within the Cumberland subregion (Commitment 13). This includes restoring up to 1,365 ha of native vegetation, including targeting CRCIF
  - Secure priority habitat corridors within the Cumberland subregion to support habitat connectivity (Commitment 12)
- Manage weeds (Commitment 16) and pest animals(Commitment 17) in strategic locations in the Cumberland subregion to reduce threats to conservation lands secured within SCAs. This includes preparing:
  - A Weed Control Implementation Strategy to guide and co-ordinate delivery of a weed control program
  - A Pest Animal Control Implementation Strategy to guide and co-ordinate delivery of a pest control program
- Manage fire in strategic locations in the Cumberland subregion (Commitment 18) to support the maintenance of biodiversity values on land secured within SCAs. This includes:
  - Consulting with Rural Fire Service, NSW NPWS, and EES to identify fire management priorities, including fire sensitive species and ecological communities
  - Preparing a Fire Management Strategy to guide and co-ordinate fire management

25.4 CUMBERLAND PLAIN WOODLAND

25.4.1 TEC BACKGROUND

Cumberland Plain Woodland in the Sydney Basin Bioregion (CPW) is a woodland or forest with an overstorey dominated by Grey Box (*Eucalyptus moluccana*) and Forest Red Gum (*E. tereticornis*), with Narrow-leaved Ironbark (*E. crebra*), Spotted Gum (*Corymbia maculata*) and Thin-leaved Stringybark (*E. eugenioides*) occurring less frequently. The TEC typically comprises an open tree canopy, a near-continuous groundcover dominated by grasses and herbs, sometimes with layers of shrubs and/or small trees (NSW Scientific Committee, 2009).

The TEC is listed under the EPBC Act as part of *Cumberland Plain Shale Woodlands and Shale Gravel Transition Forest in the Sydney Basin Bioregion* (DEWHA, 2009a).

CPW generally occurs on flat to undulating or hilly terrain up to about 350 m elevation but may also occur on locally steep sites and at slightly higher elevations, and on clay soils derived from Wianamatta Group geology, or more rarely alluvial substrates, on the Cumberland Plain (NSW Scientific Committee, 2009).

Several other TECs may intergrade with CPW, including CRCIF, *Shale Gravel Transition Forest in the Sydney Basin Bioregion (SGTF)* and *Moist Shale Woodland and Shale Sandstone Transition Forest* (SSTF) (NSW Scientific Committee, 2009).

CPW is restricted to the Sydney Basin Bioregion. It is known to occur in the Auburn, Bankstown, Baulkham Hills, Blacktown, Camden, Campbelltown, Fairfield, Hawkesbury, Holroyd, Liverpool, Parramatta, Penrith and Wollondilly LGAs (NSW Scientific Committee, 2009). The remaining area of the TEC is severely fragmented, with more than half of the remaining area occurring in patches of less than 80 ha in 2009 (NSW Scientific Committee, 2009).

25.4.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

CPW has been identified as a potential serious and irreversible impacts entity under the EES guidelines because it is currently in a rapid rate of decline (Principle 1 of the BC Regulation) and is subject to high levels of degradation or disruption of biotic processes (Principle 2 of the BC Regulation) (EES, 2019).

CPW is associated with the following PCTs:

- PCT 849 – Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain
- PCT 850 – Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain

The TEC has been mapped within the nominated areas and the Cumberland subregion on the basis of the extent and condition of these PCTs (see Chapter 11).

25.4.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of CPW in relation to the subject land is shown in Map 22.

CPW is relatively evenly distributed in scattered patches across the Cumberland subregion generally west of Parramatta and Liverpool, with the majority of large patches occurring in the centre and northern parts of the subregion.

The TEC has been mapped as occurring in all nominated areas.

25.4.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.2 of the BAM.

10.2.2.1(A) THE ACTION AND MEASURES TAKEN TO AVOID THE DIRECT AND INDIRECT IMPACT ON THE POTENTIAL ENTITY FOR AN SAII

Avoidance and minimisation of impacts to biodiversity values, including CPW, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

The baseline mapping for this assessment has mapped 1,488 ha of CPW within the nominated areas (not including excluded lands). Approximately 473 ha (32 per cent) of this was avoided within the nominated areas as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 393 ha was avoided for biodiversity purposes
- 80 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-9.

The table shows that of the 147 ha of intact condition CPW (without excluded lands), the majority (109 ha or 74 per cent) has been avoided.

It is important to note that the avoidance calculations in the table including for ‘avoidance for biodiversity purposes’, ‘avoidance for other reasons’, and ‘total avoidance’, have been calculated without including excluded lands. Table 25-9 shows the amounts of habitat within excluded lands for context only.

Table 25-9: Avoidance outcomes for Cumberland Plain Woodland (PCT 849 and 850)

Condition	Total area in nominated areas (ha)	Area in excluded lands (ha)	Area without excluded lands (ha)	Directly impacted (ha)	Avoided for biodiversity purposes (ha)	Avoided for other purposes (ha)	Total avoidance (ha)
Intact condition	646	499	147	38	92	17	109
Thinned condition	1,979	1,276	703	402	249	53	302
Scattered trees	356	192	164	148	12	4	17
DNG	592	117	474	428	41	6	47
Total	**3,573**	**2,084**	**1,488**	**1,015**	**394**	**80**	**474**

<u>Avoidance of indirect impacts</u>

Potential indirect impacts to CPW due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (g).

10.2.2.1(B) THE AREA (HA) AND CONDITION OF THE TEC TO BE IMPACTED DIRECTLY AND INDIRECTLY BY THE DEVELOPMENT. THE CONDITION OF THE TEC IS TO BE REPRESENTED BY THE VEGETATION INTEGRITY SCORE FOR EACH VEGETATION ZONE

<u>Direct impacts</u>

A total of 1,015 ha of CPW will be directly impacted by the development. This is approximately 68 per cent of the TEC in the nominated areas (without excluded lands). The direct impacts of the development are mainly associated with urban development. The direct impacts mainly occur:

- Wilton: to most remaining patches of the TEC, including several large patches. These patches are mainly low condition (DNG or scattered trees) and occur primarily in the northern and central parts of the nominated area. Many of these patches are relatively isolated, although some occur adjacent to other native vegetation associated with the gorges and gullies along the edges of the nominated area
- GMAC: to many small to moderate scattered patches of mainly low to moderate condition (DNG, scattered trees or thinned) throughout the nominated area. Most of these patches are isolated, particularly in the northern section of the nominated area, although some occur adjacent to other native vegetation associated with the gorges and gullies along the edges of the southern part of the nominated area. Development will impact some intact patches in the southern part of the nominated area. These patches are generally small and narrow
- WSA: to several moderate to large patches of mainly low to moderate condition TEC (DNG, scattered trees or thinned) in two main areas – the southern arm of the nominated area, and the northern part of the nominated area near Luddenham Road, which will be impacted by the transport corridors (Outer Sydney Orbital (OSO)). Most patches are relatively isolated and surrounded by either farmland or existing urban development
- GPEC: to many scattered mostly small patches in moderate condition that are generally isolated from larger patches of native vegetation and surrounded by farmland or existing urban development. Two large areas of CPW occur in this nominated area around Jordan Springs west of Wianamatta Regional Park, and at Orchard Hills.

The direct impacts of the development on CPW are provided in Table 25-10.

Table 25-10: Direct impacts on Cumberland Plain Woodland (PCT 849 and 850)

PCT	Condition	Direct impacts (ha)						Vegetation integrity score
		Wilton*	GMAC*	WSA*	GPEC*	Transport#	Total	
849	Intact	1.6	13.5	5.6	0.1	9.0	29.7	53.9
849	Thinned	22.4	31.7	149.3	68.2	64.1	335.6	42.3
849	Scattered trees	24.1	31.4	56.3	3.6	9.8	125.3	18.3
849	DNG	139.5	32.3	33.0	8.8	25.6	239.2	24.1
850	Intact	0.0	8.1	0.0	0.0	0.0	8.1	58.1
850	Thinned	0.0	44.5	5.7	15.9	0.0	66.1	41.9
850	Scattered trees	0.9	17.2	2.1	2.1	0.0	22.2	38.1
850	DNG	151.1	14.2	0.2	23.0	0.0	188.5	25.7
Total		**339.6**	**192.8**	**252.1**	**121.5**	**108.6**	**1,014.5**	

* Impacts from urban development only within each nominated area
# Impacts from transport corridors across all nominated areas

Indirect impacts

Potential indirect impacts to CPW due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (g).

10.2.2.1(C) A DESCRIPTION OF THE EXTENT TO WHICH THE IMPACT EXCEEDS THE THRESHOLD FOR THE POTENTIAL ENTITY

No threshold has been established for CPW.

10.2.2.1(D) THE EXTENT AND OVERALL CONDITION OF THE POTENTIAL TEC WITHIN AN AREA OF 1,000 HA, AND THEN 10,000 HA, SURROUNDING THE URBAN CAPABLE LANDS

The extent and condition of CPW surrounding the urban capable lands are provided in Table 25-11. Due to the scale of the development, calculations were also presented based on a 1 km buffer and a 10 km buffer from the outer edge of the urban capable lands, as well as buffers of 1,000 ha or 10,000 ha as per the BAM.

Table 25-11: Extent and condition of Cumberland Plain Woodland (PCT 849 and 850) surrounding the urban capable lands

PCT	Condition	Area in 1,000 ha buffer	Area in 10,000 ha buffer	Area in 1,000 m buffer	Area in 10,000 m buffer
849	Intact	37.3	203.1	656.8	3,039.6
849	Thinned	384.8	776.6	1,315.2	3,358.3
849	Scattered trees	137.1	237.2	671.2	4,196.0
849	DNG	251.0	329.9	344.8	380.7
850	Intact	13.6	98.1	277.5	1,883.2
850	Thinned	78.1	157.7	268.0	1,031.0
850	Scattered trees	25.2	100.9	410.8	4,067.8
850	DNG	198.5	210.1	210.8	211.4
Total		**1,125.5**	**2,113.7**	**4,155.1**	**18,168.0**

10.2.2.1(E) AN ESTIMATE OF THE EXTANT AREA AND OVERALL CONDITION OF THE POTENTIAL TEC REMAINING IN THE IBRA SUBREGION BEFORE AND AFTER THE IMPACT OF THE DEVELOPMENT HAS BEEN TAKEN INTO CONSIDERATION

The development will result in a loss of 4.4 per cent of the remaining area of CPW in the Cumberland subregion.

The extent and condition of CPW remaining in the subregion before and after the impact of the development is provided in Table 25-12. The largest percentage changes relate to the TEC in very low condition (DNG). Only very small changes occur to the TEC in intact condition (-0.7 per cent change for PCT 849, and -0.3 per cent change for PCT 850).

Table 25-12: Extent and condition of Cumberland Plain Woodland (PCT 849 and 850) before and after the development

PCT	Condition	Current area in Cumberland subregion (ha)	Area in Cumberland subregion after the direct impacts of the development (ha)	Per cent loss of current area in Cumberland subregion (%)
849	Intact	4,309.6	4,280.0	-0.7
849	Thinned	3,659.0	3,323.4	-9.2
849	Scattered trees	5,949.0	5,823.7	-2.1
849	DNG	380.7	141.5	-62.8
850	Intact	2,668.6	2,660.5	-0.3
850	Thinned	1,137.1	1,071.0	-5.8
850	Scattered trees	4,900.3	4,878.1	-0.5
850	DNG	211.4	23.0	-89.1
Total		**23,221.9**	**22,201.1**	**-4.4**

Trend analysis for PCT 849

As part of the EPBC Act strategic assessment process for the nominated areas and transport corridors, a trend analysis looking at the extent and condition of PCT 849 over the life of the Plan was undertaken by RMIT University (Gordon & Peterson, 2019) (see Supporting Document D). The project (while only looking at one of the two PCTs that make up CPW) has direct relevance to the assessment of CPW as an SAII entity.

The trend analysis examined the potential impacts of development and offsetting under various scenarios on PCT 849 in the Cumberland subregion. It considered a summed score across the landscape for the PCT of extent and ecological condition (the latter being based on an approximation of the BAM vegetation integrity score).

The project involved two major components:

- A formal expert elicitation to gather quantitative knowledge regarding how the condition of PCT 849 will change over time under:
  - High or low intensity management
  - The case where the PCT is exposed to typical ongoing private land activities
- Quantitative modelling to simulate the urban development within the designated nominated areas and compensation via managing areas as biodiversity offsets in a strategically defined offset region and the ecological response of the PCT. The modelling included eight scenarios exploring different options for implementing biodiversity offsets which varied:
  - The timing of when offsets are implemented
  - The total area of offsets implemented
  - The type of management implemented for the offsets (low or high intensity)

The analysis found that:

- Existing landscape scale threats (e.g. weed invasion, grazing, rubbish dumping, disturbance from recreational activities) across the Cumberland subregion are significant and will result in an approximate 5.8% decline in the extent and condition of the PCT over the life of the Plan unless additional areas are managed
- The proposed impacts of development under the Plan will lead to approximately the same magnitude of losses (~5.8%) to the PCT that will result due to existing landscape threats
- High intensity management and early offsetting will provide the greatest benefits to the outcomes of the PCT over the life of the Plan
- Securing approximately 1,600 ha of offsets for the PCT:
  - Will compensate for the impacts of development where earlier offsetting and higher intensity management is preferential by improving the extent and condition of the PCT over the life of the Plan
  - Has the potential to also contribute significantly to addressing the declines across the subregion due to existing landscape scale threats

Subsection (i) below sets out the actual offsets that are proposed under the Plan for CPW. These include a commitment to protect 2,803 ha of PCT 849 which is significantly greater than the modelled amount of 1,600 ha used in the trend analysis. The results of the trend analysis when considered in the context of the actual commitments of the Plan strongly indicate that PCT 849 will be substantially better off due to implementation of the Plan.

10.2.2.1(F) AN ESTIMATE OF THE AREA OF THE POTENTIAL TEC THAT IS IN THE RESERVE SYSTEM WITHIN THE IBRA REGION AND THE IBRA SUBREGION

The area of CPW occurring within protected lands (land reserved under NPW Act) within the Cumberland subregion is 1,289 ha. This represents 6 per cent of the total area of the remaining TEC in the subregion.

The extent and condition of CPW within protected lands is provided in Table 25-13.

Table 25-13: Extent and condition of Cumberland Plain Woodland (PCT 849 and 850) in protected lands

PCT	Condition	Area in protected lands within the Cumberland subregion (ha)
849	Intact	920.7
849	Thinned	71.9
849	Scattered trees	110.7
849	DNG*	N/A
850	Intact	152.1
850	Thinned	8.2
850	Scattered trees	25.3
850	DNG*	N/A
Total		**1,288.9**

* DNG mapping is not available outside of the nominated areas

10.2.2.1(G) THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION PROPOSAL'S IMPACT ON:

(I) ABIOTIC FACTORS CRITICAL TO THE LONG-TERM SURVIVAL OF THE POTENTIAL TEC

(II) CHARACTERISTIC AND FUNCTIONALLY IMPORTANT SPECIES THROUGH IMPACTS

(III) THE QUALITY AND INTEGRITY OF AN OCCURRENCE OF THE POTENTIAL TEC THROUGH THREATS AND INDIRECT IMPACTS

The Final Determination (NSW Scientific Committee, 2009) and BioNet profile (OEH, 2009) for CPW identifies a range of threats to the TEC. Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15

(Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Inappropriate habitat disturbance
- Changes to hydrology
- Diseases, pathogens and dieback
- Invasive fauna

The greatest risk areas within GPEC and WSA for these relevant threats are:

- Wilton: along the edges of the urban capable lands mainly around the outer edges of the nominated area, particularly in the northern part of the area
- GMAC: along the edges of the urban capable lands within the southern part of the nominated area
- WSA: along the edges of the urban capable lands
- GPEC: along the edges of the urban capable lands, in particular in the west and north of the nominated area

Impacts from inappropriate livestock grazing regimes were also identified in the Conservation Advice as a key threat. However, this is not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate this risk across the nominated areas.

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes can affect the structure and species composition of the TEC (OEH, 2009). This can be caused by:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

Fire regimes influence the plant species composition and vegetation structure of the TEC and are also likely to influence other components of the community (NSW Scientific Committee, 2009). Fire intervals of 4 to 12 years are likely to maintain most understorey species within the TEC. Fire intervals which are too short are associated with reduced native plant diversity (NSW Scientific Committee, 2009). Disruption of ecological processes associated with altered fire regimes contributes to a very large reduction in the ecological function of the TEC (NSW Scientific Committee, 2009).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact the TEC. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development. For the TEC, this includes areas in and around GPEC, WSA and GMAC, and to a lesser degree in Wilton, where the TEC is much less extensive.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Plan Area. This includes a number of actions with the most relevant to the outcome for the TEC being:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy for the Strategic Conservation Areas that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are

permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas

- o Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from the TEC. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the TEC from altered fire regimes as a result of development. This is because:

- Avoided lands where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting the TEC
- Fire management authorities will be engaged to ensure they understand the requirements of the TEC and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas

WEED INVASION

Weed invasion also poses a major threat to the TEC ((NSW Scientific Committee, 2009). Weeds can displace native plants and reduce the diversity and regenerative capacity of the TEC. The Final Determination lists a wide range of weed species that threaten the TEC, including African Olive (O*lea europa* subsp. *cuspidata*), Bridal Creeper (*Asparagus asparagoides*) and a range of exotic grasses (NSW Scientific Committee, 2009).

These weeds are already present within the nominated areas and pose a threat to the TEC. However, urban development and transport have the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or changing conditions to favour weeds.

The TEC is most susceptible to the threat of weeds from development under the Plan where new urban development occurs adjacent to the TEC and introduces edge effects. Key risk areas include in and around GPEC, WSA and GMAC, and to a lesser degree in Wilton where the TEC is much less extensive.

The Plan incorporates a range of measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Areas. This includes a number of actions, of which the following are the most relevant to the outcome for the TEC:
  - o Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - o Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - o Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - o Require proponents to undertake the following when applying for/undertaking development:
    - ▪ Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction

    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

Importantly for the TEC, weeds will be actively managed within the 3,170 ha to be added to conservation as part of the conservation program.

The package of measures in the Plan is expected to adequately manage the risk posed to the TEC from weed invasion. This is because:

- Avoided lands where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- The Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy. This includes the land to be protected under the conservation program for the TEC
- There will be a range of planning controls to minimise the potential spread of weeds during and after construction

INAPPROPRIATE HABITAT DISTURBANCE

Inappropriate habitat disturbance is identified as a threat to the TEC (OEH, 2009). This relates to a wide range of different mechanisms for disturbance including:

- Dumping of rubbish and garden waste which can directly impact areas of the TEC as well as cause weed invasion
- Inappropriate recreational activities such as 4WD and trail bike use which can directly impact areas of the TEC and facilitate processes such as erosion
- Removal of woody debris and firewood collection which changes the structure and habitat features of the TEC

Each of these mechanisms have the potential to alter the structure and floristic composition of the TEC.

Inappropriate habitat disturbance within the nominated areas may increase due to the urban development. Occurrences of the TEC considered most at risk are those in and around GPEC, WSA and GMAC, and to a lesser degree in Wilton where the TEC is much less extensive.

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for the TEC. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations (including the 3,170 ha for the TEC)
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand

and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan is expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development. This is because:

- Avoided lands where areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

CHANGES TO HYDROLOGY

The creation of hard surfaces associated with urban development and transport results in changes to the hydrology of surrounding areas. The main threat to the TEC associated with altered hydrology is increased runoff into patches of the TEC carrying high nutrient and sediment loads, as well as weed seeds or propagules (OEH, 2009). This can both encourage weed invasion and cause erosion and sedimentation.

The TEC is most susceptible to the threat of increased runoff from development under the Plan where new urban or transport development occurs adjacent (and upstream or upslope) to the TEC. Key risk areas include in and around GPEC, WSA and GMAC, and to a lesser degree in Wilton where the TEC is much less extensive.

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for the TEC. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5) and transport (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through:

- Development controls in the nominated areas in relation to:
  - Water cycle management. For example:
    - Water management measures must comply with council's requirements for detention, drainage and water sensitive urban design principles
    - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
  - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
  - Soil erosion and sedimentation. For example:
    - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
    - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom, 2004) and submitted with each subdivision development application
- The implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the TfNSW Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the TEC from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts to the TEC
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to the TEC

DISEASES, PATHOGENS AND DIEBACK

TECs are potentially susceptible to a range of diseases, pathogens and dieback which can substantially affect their long term viability. CPW at a Commonwealth level is recognised as being susceptible to dieback caused by the root-rot fungus *Phytophthora cinnamomi* (DoEE, 2018b).

Development under the Plan may increase the risk of the spread of infection/disease. This is primarily related to:

- Soil transportation on contaminated footwear, vehicles and machinery, and in residential garden establishment
- Increased site visitation rates
- Earthworks and activities conducted during construction
- Increased surface water runoff

The Plan incorporates a range of measures to manage the risks associated with diseases, pathogens and dieback. In summary, these include:

- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
    - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
    - Entering into written agreements with delivery partners to implement priority disease control programs
- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures methods to protect the environment during construction, including best practice site hygiene protocols to minimise spread of *Phytophthora*

The package of measures in the Plan is expected to adequately manage the risk to the TEC from diseases, pathogens and dieback because:

- It supports a landscape scale approach to the issue across the Cumberland subregion
- It will ensure appropriate controls during construction

INVASIVE FAUNA

TECs can be threatened by introduced animals and aggressive native species. Predation of native fauna by cats and foxes is specifically identified as a threat to the TEC (OEH, 2009). Pest animals can lead to declines in biodiversity through:

- Predation on native fauna
- Damage to vegetation and soils
- Competition for resources

Existing land use within the nominated areas and surrounding region (which includes residential and rural residential areas, and farming) means that these issues are already present in the nominated areas and are unlikely to pose a novel threat to the TEC.

However, the extent of proposed new urban development under the Plan means that the threats associated with cats and foxes are likely to be exacerbated. It is likely that there will be an increase in the number of domestic cats in the local area, which, in turn, may lead to an increase in feral cat numbers.

The Plan incorporates a range of measures to manage these risks. In summary, these include:

- A commitment (Commitment 17) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the Strategic Conservation Areas. This includes a number of actions with the most relevant to the outcome for the TEC being:
    - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
    - Preparation of a Pest Animal Control Implementation Strategy
    - A process to enter into written agreements with delivery partners to implement the pest animal control program

    - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Development controls that will:
    - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
    - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
    - Require appropriate management and control of pest animals relevant to development sites
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing pests, consistent with the pest animal implementation strategy outlined in Commitment 16

10.2.2.1(H) DIRECT OR INDIRECT FRAGMENTATION AND ISOLATION OF AN IMPORTANT AREA OF THE POTENTIAL TEC

Direct loss of CPW may cause fragmentation and isolation of remaining patches of the TEC, which may increase the susceptibility of the TEC to weed invasion and other edge effects and reduce its long-term viability.

Fragmentation and isolation of patches of CPW will mainly occur in the following areas:

- Wilton: Development will remove most remaining patches of the TEC. Three larger patches of mostly moderate condition TEC will be reduced in size. These patches will not be isolated by the development and will remain contiguous with larger areas of native vegetation associated with the gorges and gullies on the edges of the nominated area, which will reduce the effects of fragmentation
- GMAC: Development will mostly remove scattered patches of mainly low to moderate condition TEC. Patches of the TEC that will remain are already generally isolated and surrounded by farm land or existing urban development, particularly in the southern part of the nominated area and the development will not generally result in further isolation of remaining patches. In some areas, remaining patches will remain contiguous with larger areas of native vegetation associated with the gorges and gullies on the edges and middle of the southern part of the nominated area, which will reduce the effects of fragmentation
- WSA: In the northern part of the nominated area near Luddenham Road, the OSO will fragment a large patch of mainly low to moderate condition TEC. In the southern part of the nominated area, an area of relatively well-connected patches of the TEC will be mostly removed and the TEC will only remain along a narrow riparian corridor. In both these cases, the development will reduce the size of the patch and increase the susceptibility of the TEC to weed invasion and other edge effects, which may reduce its long-term viability
- GPEC: In the northern part of the nominated area, a relatively narrow patch of the TEC that occurs within Wianamatta Regional Park will be fragmented by the OSO. This will reduce the size of the patch and increase the susceptibility of the TEC within the Regional Park to weed invasion and other edge effects. This is not expected to reduce the long-term viability of the TEC in this locality as the remaining patches will be managed for conservation in the Regional Park. In other parts of the nominated area, the development usually removes entire patches of the TEC and will not generally result in increased fragmentation or increased isolation of patches

10.2.2.1(I) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE POTENTIAL TEC IN THE IBRA SUBREGION

The Plan includes a range of commitments and actions that will contribute to the recovery of CPW in the Cumberland subregion. Several commitments are described in more detail the sections above.

The key commitments relevant to the TEC are:

- TEC-specific commitments to secure an offset target of 3,170 ha of CPW (Commitment 8.1) in conservation lands within SCAs. This includes a target of 2,325 ha of PCT 849 and a target of 845 ha of PCT 850. This would increase the area of TEC protected within the Cumberland subregion by approximately 245 per cent
- As part of securing a minimum of 5,475 ha of native vegetation in SCAs:
    - Undertake ecological restoration of priority areas secured for conservation within the Cumberland subregion (Commitment 13). This includes restoring up to 1,365 ha of native vegetation, including targeting CPW
    - Secure priority habitat corridors within the Cumberland subregion to support habitat connectivity (Commitment 12)

- Manage weeds (Commitment 16) and pest animals (Commitment 17) in strategic locations in the Cumberland subregion to reduce threats to conservation lands secured within SCAs. This includes preparing:
  - A Weed Control Implementation Strategy to guide and co-ordinate delivery of a weed control program
  - A Pest Animal Control Implementation Strategy to guide and co-ordinate delivery of a pest control program
- Manage fire in strategic locations in the Cumberland subregion (Commitment 18) to support the maintenance of biodiversity values on land secured within SCAs. This includes:
  - Consulting with Rural Fire Service, NSW NPWS, and EES to identify fire management priorities, including fire sensitive species and ecological communities
  - Preparing a Fire Management Strategy to guide and co-ordinate fire management

As outlined previously in subsection (e), the trend analysis (Gordon & Peterson, 2019) when considered in the context of the commitments of the Plan, strongly indicates that PCT 849 will be substantially better off due to implementation of the Plan under scenarios of high intensity management and early offsetting. While care needs to be taken in extrapolating the results of the analysis to PCT 850, it is considered highly likely that the commitments in the Plan will also provide substantial benefits to that PCT over the life of the Plan.

25.5 SHALE SANDSTONE TRANSITION FOREST

25.5.1 TEC BACKGROUND

Shale Sandstone Transition Forest in the Sydney Basin Bioregion (SSTF) is a forest or woodland with an overstorey that may include *Eucalyptus punctata*, *Eucalyptus resinifera*, one of the stringybarks (*Eucalyptus globoidea, Eucalyptus eugenioides, Eucalyptus sparsifolia, Eucalyptus agglomerata*). One or more ironbark species may be locally important. The understorey may be either grassy and herbaceous or shrubby with a notable amount of grass cover (although the presence of some shrubs, such as *Banksia* and *Persoonia* species, indicate the site may not be SSTF). In areas that have not been burnt for long periods the understorey may be dense. Species composition varies between sites depending on geographical location and local conditions (e.g. topography, relative influence of sandstone or shale) (NSW Scientific Committee, 1995).

The TEC is equivalent to the ecological community with the same name listed under the EPBC Act, although it is important to note that condition thresholds apply to the EPBC listed community (DoE, 2014b).

SSTF generally occurs on soils derived from a shallow shale or clay material overlying sandstone, or where shale-derived materials have washed down over sandstone-derived substrate. Such sites are generally close to the geological boundary between the Wianamatta Shale and the Hawkesbury Sandstone (NSW Scientific Committee, 1995). The contributing shale has to come from the Wianamatta group. Shale lenses that occur in the Hawkesbury Sandstone provide a different chemistry and may relate to a different TEC (O'Hares Creek Shale Forest).

The TEC is confined to the Sydney Basin Bioregion and mostly restricted to areas transitional between clay soils derived from Wianamatta Shale and sandy soils derived from Hawkesbury Sandstone on the margins of the Cumberland Plain (NSW Scientific Committee, 1995). The main occurrences of the TEC are in the Hawkesbury, The Hills, Liverpool, Parramatta, Penrith, Campbelltown and Wollondilly LGAs (OEH, 2019i) and it extends west into the lower Blue Mountains. Many occurrences are linear s, which may be as narrow as 20 m wide (NSW Scientific Committee, 1995).

25.5.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

SSTF has been identified as a potential SAII entity under the OEH guidelines because it is it subject to high levels of degradation or disruption of biotic processes (Principle 2 of the BC Regulation) and a very highly restricted geographic distribution (Principle 3 of the BC Regulation) (OEH, 2017f).

SSTF is associated with PCT 1395 – 'Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion'. The TEC has been mapped within the nominated areas and the Cumberland subregion on the basis of the extent and condition of this PCT (see Chapter 11)

25.5.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of SSTF in relation to the subject land is shown in Map 23.

The majority of SSTF within the Cumberland subregion occurs on the edges of the subregion outside the nominated areas north-west of Richmond, west of the Nepean River around Gulguer Nature Reserve, and in the southern part of the subregion around Tahmoor, Wilton and Appin.

The TEC has been mapped as occurring in the following nominated areas:

- Wilton
- GMAC, mainly in the southern part of the nominated area
- A small area in far western GPEC

25.5.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.2 of the BAM.

10.2.3.1(A) THE ACTION AND MEASURES TAKEN TO AVOID THE DIRECT AND INDIRECT IMPACT ON THE POTENTIAL ENTITY FOR AN SAII

Avoidance and minimisation of impacts to biodiversity values, including SSTF, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

The baseline mapping for this assessment has mapped 2,623 ha of SSTF within the nominated areas (not including excluded lands). Approximately 2,135 ha (82 per cent) of this was avoided within the nominated areas as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 1,865 ha was avoided for biodiversity purposes
- 270 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-14.

The table shows that the majority of the total avoidance that has occurred (69 per cent) has been of SSTF in intact condition, and that of the 1,511 ha of intact condition SSTF (without excluded lands), the vast majority (1,466 ha or 97 per cent) has been avoided.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-14 shows the amounts of habitat within excluded lands for context only.

Table 25-14: Avoidance outcomes for Shale Sandstone Transition Forest (PCT 1395)

Condition	Total area in nominated areas (ha)	Area in excluded lands (ha)	Area without excluded lands (ha)	Directly impacted (ha)	Avoided for biodiversity purposes (ha)	Avoided for other purposes (ha)	Total avoidance (ha)
Intact condition	1,836	325	1,511	45	1,231	235	1,466
Thinned condition	972	262	711	155	523	32	556
Scattered trees	140	52	88	51	36	2	38
DNG	377	64	314	237	75	2	76
Total	**3,326**	**703**	**2,623**	**488**	**1865**	**270**	**2,135**

Avoidance of indirect impacts

Potential indirect impacts to SSTF due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (g).

10.2.2.1(B) THE AREA (HA) AND CONDITION OF THE TEC TO BE IMPACTED DIRECTLY AND INDIRECTLY BY THE DEVELOPMENT. THE CONDITION OF THE TEC IS TO BE REPRESENTED BY THE VEGETATION INTEGRITY SCORE FOR EACH VEGETATION ZONE

Direct impacts

A total of 488 ha of SSTF will be directly impacted by the development. This is approximately 19 per cent of the TEC in the nominated areas (without excluded lands). The direct impacts of the development are mainly associated with urban development. The direct impacts mainly occur:

- Wilton: along the edges of the urban capable lands mainly around the outer edges of the nominated area, particularly in the northern part of the area
- GMAC: along the edges of the urban capable lands within the southern part of the nominated area

The direct impacts of the development on SSTF are provided in Table 25-15.

Table 25-15: Direct impacts on Shale Sandstone Transition Forest (PCT 1395)

PCT	Condition	Direct impacts (ha)						Vegetation integrity score
		Wilton*	GMAC*	WSA*	GPEC*	Transport#	Total	
1395	Intact	13.3	31.6	0	0	0	44.9	72.9
1395	Thinned	84.7	70.3	0	0	0	155.1	64
1395	Scattered trees	20.2	30.4	0	0	0	50.5	30
1395	DNG	205.8	31.5	0	0	0	237.3	28.4
Total		**324.0**	**163.8**	**0**	**0**	**0**	**488**	

* Impacts from urban development only within each nominated area

\# Impacts from transport corridors across all nominated areas

Indirect impacts

Potential indirect impacts to SSTF due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (g).

10.2.2.1(C) A DESCRIPTION OF THE EXTENT TO WHICH THE IMPACT EXCEEDS THE THRESHOLD FOR THE POTENTIAL ENTITY THAT IS SPECIFIED IN THE GUIDANCE TO ASSIST A DECISION-MAKER TO DETERMINE A SERIOUS AND IRREVERSIBLE IMPACT

No threshold has been established for SSTF.

10.2.2.1(D) THE EXTENT AND OVERALL CONDITION OF THE POTENTIAL TEC WITHIN AN AREA OF 1000HA, AND THEN 10,000HA, SURROUNDING THE URBAN CAPABLE LANDS

The extent and condition of SSTF surrounding the urban capable lands are provided in Table 25-16. Due to the scale of the development, calculations were also presented based on a 1 km buffer and a 10 km buffer from the outer edge of the urban capable lands, as well as buffers of 1,000 ha or 10,000 ha as per the BAM.

Table 25-16: Extent and condition of Shale Sandstone Transition Forest (PCT 1395) surrounding the urban capable lands

PCT	Condition	Area in 1,000 ha buffer	Area in 10,000 ha buffer	Area in 1,000 m buffer	Area in 10,000 m buffer
1395	Intact	76.6	1,107.9	2,367.6	5,404.4
1395	Thinned	200.2	637.5	928.5	1,635.4
1395	Scattered trees	55.6	113.5	453.6	2,691.5
1395	DNG	255.9	346.2	358.1	377.4
Total		**588.3**	**2,205.1**	**4,086.9**	**6,005.3**

10.2.2.1(E) AN ESTIMATE OF THE EXTANT AREA AND OVERALL CONDITION OF THE POTENTIAL TEC REMAINING IN THE IBRA SUBREGION BEFORE AND AFTER THE IMPACT OF THE DEVELOPMENT HAS BEEN TAKEN INTO CONSIDERATION

The development will result in a loss of 3.9 per cent of the remaining area of SSTF in the Cumberland subregion.

The extent and condition of SSTF remaining in the subregion before and after the impact of the development is provided in Table 25-17. The largest percentage change relates to the TEC in very low condition (DNG). Only very small changes occur to the TEC in intact condition (-0.7 per cent change).

Table 25-17: Extent and condition of Shale Sandstone Transition Forest (PCT 1395) before and after the development

PCT	Condition	Current area in Cumberland subregion (ha)	Area in Cumberland subregion after the direct impacts of the development (ha)	Per cent loss of current area in Cumberland subregion (%)
1395	Intact	6,618.6	6,573.7	-0.7
1395	Thinned	1,759.7	1,604.7	-8.8
1395	Scattered trees	4,186.6	4,136.1	-1.2
1395	DNG	377.4	140.1	-62.9
Total		**12,501.9**	**12,014.1**	**-3.9**

10.2.2.1(F) AN ESTIMATE OF THE AREA OF THE POTENTIAL TEC THAT IS IN THE RESERVE SYSTEM WITHIN THE IBRA REGION AND THE IBRA SUBREGION

The area of SSTF occurring within protected lands (land reserved under NPW Act) within the Cumberland subregion is 509 ha. This represents 4 per cent of the total area of the remaining TEC in the subregion.

The extent and condition of SSTF within protected lands is provided in Table 25-18.

Table 25-18: Extent and condition of Shale Sandstone Transition Forest (PCT 1395) in protected lands

PCT	Condition	Area in protected lands within the Cumberland subregion (ha)
1395	Intact	422.6
1395	Thinned	27.6
1395	Scattered trees	58.8
1395	DNG*	N/A
Total		**509.1**

* DNG mapping is not available outside of the nominated areas

10.2.2.1(G) THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION PROPOSAL'S IMPACT ON:

(I) ABIOTIC FACTORS CRITICAL TO THE LONG-TERM SURVIVAL OF THE POTENTIAL TEC

(II) CHARACTERISTIC AND FUNCTIONALLY IMPORTANT SPECIES THROUGH IMPACTS

(III) THE QUALITY AND INTEGRITY OF AN OCCURRENCE OF THE POTENTIAL TEC THROUGH THREATS AND INDIRECT IMPACTS

The Final Determination (NSW Scientific Committee, 1995) and BioNet profile (OEH, 2019i) for SSTF identify a range of threats to the TEC. Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Inappropriate habitat disturbance
- Changes to hydrology

The greatest risk areas within Wilton and GMAC for these relevant threats are:

- Wilton: along the edges of the urban capable land mainly around the outer edges of the nominated area, particularly in the northern part of the area
- GMAC: along the edges of the urban capable land within the southern part of the nominated area

Inappropriate fire regimes

Inappropriate fire regimes can affect the structure and species composition of the TEC (OEH, 2019i). This can be caused by:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact the TEC. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development. For the TEC this includes areas in and around Wilton and the southern part of GMAC where significant areas of the TEC are present.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Plan Area. This includes a number of actions with the most relevant to the outcome for the TEC being:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the Strategic Conservation Areas that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from the TEC. While these APZs are

designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes.

Also relevant for the TEC is the fact that it largely overlaps with Koala habitat which is a key focus of the Plan in terms of protection and management. Significant areas of Koala habitat will be managed which will include the application of the fire management strategy and a set of measures to control access to bushland which will help minimise risks around arson and accidental fires.

The package of measures in the Plan is expected to adequately manage the risk to the TEC from altered fire regimes as a result of development. This is because:

- Avoided lands where large areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting the TEC
- Fire management authorities will be engaged to ensure they understand the requirements of the TEC and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas
- The measures in the Plan for Koalas in terms of protecting and managing habitat, and constraining access to bushland will help protect the TEC

Weed invasion

The TEC is threatened with invasion of weeds. Weeds can displace native plants and reduce the diversity and regenerative capacity of the TEC. Weeds that are a particular threat are invasive exotic grasses like African love grass (*Eragrostis curvula*) and Chilean needle grass (*Nassella neesiana*), as well as Lantana (*Lantana camara*), Broad-leafed and Small-leaf Privet (*Ligustrum lucidum* and *L. Sinense*), African olive (*Olea europaea* subsp. *cuspidate*), and Bridal Creeper (*Myrsiphyllum asparagoides*), and environmental weeds such as Sweet Pittosporum (*Pittosporum undulatum*) (OEH, 2019i).

These weeds are already present within the nominated areas and pose a threat to the TEC. However, development within the nominated areas has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or changing conditions to favour weeds.

The TEC is most susceptible to the threat of weeds from development under the Plan where new urban development occurs adjacent to the TEC and introduces edge effects. Key risk areas include:

- In north and north west of Wilton, where the urban capable land impacts the edges of patches of the TEC connected to gorges and gullies on the edge of the nominated area
- In the southern part of GMAC, where the urban capable land impacts the edges of patches of the TEC connected to gorges and gullies on the edge and middle of the nominated area

The Plan incorporates a range of measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Areas. This includes a number of actions, of which the following are the most relevant to the outcome for the TEC:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to

provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16

- The introduction of planning controls that will:
    - Require proponents to undertake the following when applying for/undertaking development:
        - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
        - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
        - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

Importantly for the TEC, weeds will be actively managed within the 1,540 ha to be added to conservation as part of the conservation program.

The package of measures in the Plan is expected to adequately manage the risk posed to the TEC from weed invasion. This is because:

- Avoided lands where large areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- The Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy. This includes the land to be protected under the conservation program for the TEC
- There will be a range of planning controls to minimise the potential spread of weeds during and after construction

Inappropriate habitat disturbance

Inappropriate habitat disturbance is identified in the Final Determination and BioNet profile as a threat to the TEC. Disturbance can relate to a wide range of different mechanisms for disturbance including:

- Inappropriate mowing, slashing or scrubbing of the understorey for reasons such as bushfire fuel reduction, grazing and perceived aesthetics
- Dumping of rubbish and garden waste which can directly impact areas of the TEC as well as facilitate increases in weeds (see above) and pollutants
- Inappropriate recreational activities such as mountain bike use and 4WDs which can directly impact areas of the TEC and facilitate processes such as erosion

Each of these mechanisms have the potential to alter the structure and floristic composition of the TEC.

Inappropriate habitat disturbance may increase due to development within the nominated areas. Occurrences of the TEC considered most at risk are those that occur in close proximity to development within Wilton and GMAC.

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for the TEC. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values

- A commitment (Commitment 7) to mitigate indirect and prescribed impacts from urban, infrastructure and major infrastructure (transport) development on Koalas. This is relevant to the TEC because large areas of the TEC are identified as important Koala habitat. Of particular relevance to habitat disturbance are associated actions around the use of exclusion fencing which will assist in controlling access to Koala habitat. These measures will help minimise inappropriate habitat disturbance to the TEC within both Wilton and GMAC
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations (including the 1,540 ha for the TEC)
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas.

The package of measures in the Plan is expected to adequately manage the risk to the TEC from inappropriate habitat disturbance as a result of development. This is because:

- Avoided lands where large areas of the TEC occur will be zoned appropriately to enable an adequate framework for management
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- The measures in the Plan for Koalas in terms of protecting and managing habitat, and constraining access to bushland will help protect the TEC
- A program of education for the community will be run to help them understand the biodiversity values they live near

Changes to hydrology

The creation of hard surfaces associated with urban development and transport results in changes to the hydrology of surrounding areas. The main threat to the TEC associated with altered hydrology is increased runoff into patches of the TEC carrying high nutrient and sediment loads, as well as weed seeds or propagules (OEH, 2019i). This can both encourage weed invasion and cause erosion.

The TEC is most susceptible to the threat of increased runoff from development under the Plan where new urban development occurs adjacent (and upstream or upslope) to the TEC. Key risk areas are:

- In north and north west of Wilton
- In the southern part of GMAC

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for the TEC. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5) and transport (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through:

- Development controls in the nominated areas in relation to:
  - Water cycle management. For example:
    - Water management measures must comply with council's requirements for detention, drainage and water sensitive urban design principles
    - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
  - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets

    - Soil erosion and sedimentation. For example:
        - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
        - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom, 2004) and submitted with each subdivision development application
- The implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the TfNSW Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the TEC from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts to the TEC
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to the TEC

10.2.2.1(H) DIRECT OR INDIRECT FRAGMENTATION AND ISOLATION OF AN IMPORTANT AREA OF THE POTENTIAL TEC

Direct loss of SSTF may cause fragmentation and isolation of remaining patches of the TEC, which may increase the susceptibility of the TEC to weed invasion and other edge effects and reduce its long-term viability.

Fragmentation and isolation of patches of SSTF will mainly occur in the following areas:

- Wilton: along the edges of the urban capable lands mainly around the outer edges of the nominated area, particularly in the northern part of the area
- GMAC: along the edges of the urban capable lands within the southern part of the nominated area

Within both nominated areas, patches of the TEC are relatively well connected around the edges of the urban capable lands. In Wilton, this occurs mainly around the outer edges of the nominated area, particularly in the northern part. In GMAC, this occurs around the outer edges as well as through the middle of the southern part of the nominated area.

Urban development in these nominated areas mainly directly impacts the edges of the TEC and does not generally impact this connectivity. While direct impacts will reduce the size and width of some patches around the edges of the urban capable lands, it does not generally result in isolation of these patches.

Where direct impacts will impact connectivity between patches of the TEC, these areas are generally already only marginally connected as a result of existing urban development or farming, and as such, the development is not expected to increase the level of fragmentation to the TEC in the locality more broadly.

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE POTENTIAL TEC IN THE IBRA SUBREGION

The Plan includes a range of commitments that will contribute to the recovery of SSTF in the Cumberland subregion. Several commitments are described in more detail the sections above.

The key commitments relevant to the TEC are:

- TEC-specific commitments to secure an offset target of 1,540 ha of SSTF (Commitment 8.1) in conservation lands within SCAs. This would increase the area of TEC protected within the Cumberland subregion by approximately 300 per cent
- As part of securing a minimum of 5,475 ha of native vegetation in SCAs:
    - Undertake ecological restoration of priority areas secured for conservation within the Cumberland subregion (Commitment 13). This includes restoring up to 1, 365 ha of native vegetation, including targeting SSTF
    - Secure priority habitat corridors within the Cumberland subregion to support habitat connectivity (Commitment 12)
- Manage weeds (Commitment 16) and pest animals (Commitment 17) in strategic locations in the Cumberland subregion to reduce threats to conservation lands secured within SCAs. This includes preparing:
    - A Weed Control Implementation Strategy to guide and co-ordinate delivery of a weed control program

- A Pest Animal Control Implementation Strategy to guide and co-ordinate delivery of a pest control program
- Manage fire in strategic locations in the Cumberland subregion (Commitment 18) to support the maintenance of biodiversity values on land secured within SCAs. This includes:
  - Consulting with Rural Fire Service, NSW NPWS, and EES to identify fire management priorities, including fire sensitive species and ecological communities
  - Preparing a Fire Management Strategy to guide and co-ordinate fire management

25.6 ALLOCASUARINA GLAREICOLA

25.6.1 SPECIES BACKGROUND

Allocasuarina glareicola is an erect, smooth-barked shrub with cones that grows to approximately 2 m tall (DoEE, 2018a; OEH, 2018a). The species is monoecious or dioecious and flowers around October each year. The time taken for the plants to flower and set seed is not known. Regeneration is commonly by suckers. Root suckers can appear up to 3 m from the parent plant, where clumps of hundreds of stems may be a single individual. Seedling recruitment has only been observed at one site. The species is wind pollinated which means the distance between individuals may be a critical factor in enabling pollination and seed set (DoEE, 2018a; OEH, 2018a).

A. glareicola inhabits Castlereagh woodland and open woodland (with *Eucalyptus parramattensis, Eucalyptus fibrosa, Angophora bakeri, Eucalyptus sclerophylla and Melaleuca decora*). It occurs on strongly acidic soils with low fertility (DoEE, 2018a; OEH, 2018a).

Records are primarily restricted to the Castlereagh and Londonderry areas of the Cumberland Plain where there are 36 known occurrences of the species, with an outlier population found in Liverpool (Holsworthy Military Area). The total range of the species is approximately 36 km^2.

25.6.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

A. glareicola is being assessed as a candidate species credit species for GPEC. The species has been also identified as a potential SAII entity under the EES guidelines (Principle 3 of the BC Regulation) (OEH, 2017f), as it has a very highly restricted geographic distribution.

25.6.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of *A. glareicola* in relation to the subject land is shown in Map 24.

GPEC occurs within the southern extent of *A. glareicola's* stronghold in the Castlereagh and Londonderry areas.

There is one known population of *A. glareicola* within the nominated areas. This occurs in GPEC, located within a rail corridor along Hobart St in St Marys. This population is disjunct from the majority of known records which occur approximately 8 km to the north and are generally associated with larger, more intact remnants of native vegetation. The population in St Marys is located approximately 1.2 km from the nearest urban capable land.

Approximately 186 ha of potential habitat for the species has been identified in the nominated areas. This occurs in GPEC. The majority of potential habitat occurs within the Wianamatta Regional Park in the northern part of GPEC. A smaller patch of potential habitat has been mapped in Orchard Hills towards the middle of GPEC. The remaining habitat areas exist as scattered and isolated remnants across the eastern half of GPEC.

25.6.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.3 of the BAM.

10.2.3.1(A) THE ACTION AND MEASURES TAKEN TO AVOID DIRECT AND INDIRECT IMPACTS

Avoidance and minimisation of impacts to biodiversity values, including *A. glareicola*, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

The population of *A. glareicola* within GPEC occurs outside the urban capable land and has been avoided.

The baseline mapping for this assessment has mapped 22 ha of potential habitat for *A. glareicola* within GPEC (not including excluded lands). Approximately 10 ha (46 per cent) of this was avoided within GPEC as part of the design of the urban capable land and transport corridors (not including excluded lands). All of this was avoided for biodiversity purposes.

A breakdown of avoidance across each nominated area is provided in Table 25-19.

Table 25-19: Avoidance outcomes for *A. glareicola*

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential habitat (ha)	186	164	22	11.9	10	0	10

Avoidance of indirect impacts

Potential indirect impacts to *A. glareicola* due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(B) THE SIZE OF THE LOCAL POPULATION DIRECTLY AND INDIRECTLY IMPACTED BY THE DEVELOPMENT

Development within the nominated areas will not directly impact on any records or known populations of *A. glareicola.*

Potential indirect impacts to *A. glareicola* due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(C) THE EXTENT TO WHICH THE IMPACT EXCEEDS ANY THRESHOLD FOR THE POTENTIAL ENTITY

No threshold has been established for *A. glareicola.*

10.2.3.1(D) THE LIKELY IMPACT (INCLUDING DIRECT AND INDIRECT) THAT THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION WILL HAVE ON THE HABITAT OF THE LOCAL POPULATION

Direct impacts

A total of 11.9 ha of potential habitat will be directly impacted by the development. This is 54.1 per cent of the potential habitat in the nominated areas (not including excluded lands). The direct impacts of the development are associated with urban development and a transport corridor (the M7/Ropes Crossing Link Road). The main direct impacts occur:

- Along the northern boundary of GPEC within the alignment of the M7/Ropes Crossing Link Road
- Two scattered patches of potential habitat at Orchard Hills, which will be impacted by urban development

Although survey confirmed the species is absent from the OSO, the OSO alignment does bisect two areas of mapped potential habitat to the east of west of the OSO alignment.

The direct impacts of the development on *A. glareicola* are provided in Table 25-20.

Table 25-20: Direct impacts on *A. glareicola*

Impacts to:	Wilton*	GMAC*	WSA*	GPEC*	Transport corridors#	Total
Potential habitat (ha)	0	0	0	7.4	4.5	11.9

Impacts to habitat within northern GPEC

The M7/Ropes Crossing Link Road impacts on 4.5 ha of potential habitat along the northern boundary of GPEC. The habitat impacted is contiguous with mapped habitat in Shanes Park.

Although not directly impacting on mapped habitat, the OSO corridor will lead to fragmentation of potential habitat within Wianamatta Regional Park, leading to a number of smaller, isolated patches of vegetation. This fragmentation may increase impacts associated with edge effects (primarily weeds) and this has the potential to compromise the suitability of remaining habitat areas directly adjacent to development.

The species was confirmed absent within the OSO corridor during project surveys, and the likelihood that the species actually occurs within lands adjacent to the corridor is considered low given:

- The area forms part of a Regional Park which is managed by the NSW NPWS and would be well traversed
- The species is a conspicuous shrub which can be surveyed for throughout the year

This low likelihood of occurrence considerably reduces the risk of impacts to *A. glareicola* on key life-cycle processes. Furthermore, the species primarily regenerates through suckers and occasionally via wind pollination and neither of these processes are likely to be affected by fragmentation of potential habitat in this location.

Impacts to habitat at Orchard Hills

The loss of potential habitat for *A. glareicola* at Orchard Hills is associated with small remnants of scattered vegetation surrounded by houses and farmland. The extent of cleared land in the area means that impacts are unlikely to increase edge effects to retained habitat areas or further reduce their viability.

A section of potential habitat within the urban capable land which could be accessed as part of this biodiversity certification process was surveyed and the species was not observed. It is generally considered unlikely that potential habitat in this area contributes to the ongoing survival or viability of the species more broadly.

Indirect impacts

Potential indirect impacts to *A. glareicola* due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(E) THE LIKELY IMPACT ON THE ECOLOGY OF THE LOCAL POPULATION

As discussed in response to subsection (d) above, the loss of potential habitat areas within GPEC is unlikely to affect the ecology of *A. glareicola* in the locality because:

- There is a low likelihood the species occurs within this habitat
- The loss and extent of fragmentation of potential habitat will not affect the key life-cycle processes of the species, which primarily regenerates through suckers and occasional seed production via wind pollination

10.2.3.1(F) A DESCRIPTION OF THE EXTENT TO WHICH THE LOCAL POPULATION WILL BECOME FRAGMENTED OR ISOLATED

As discussed in response to subsection (d) above, the loss of potential habitat areas within GPEC is unlikely to fragment or isolate any local populations of *A. glareicola.* There will be fragmentation of potential habitat from impacts caused by the M7/Ropes Crossing Link Road. Further fragmentation may occur within Wianamatta Regional Park as a result of the OSO corridor bisecting two areas of potential habitat. However, this is considered to have limited implications for the species in the region given the low likelihood of occurrence within this habitat.

10.2.3.1(G) THE RELATIONSHIP OF THE LOCAL POPULATION TO OTHER POPULATION/POPULATIONS OF THE SPECIES

Potential habitat within GPEC occurs within the southern extent of the *A. glareicola* stronghold in the Castlereagh and Londonderry areas, and is within the geographic extent of the species.

There is one known population within the nominated area in St Marys. This population is disjunct from the majority of known records which occur approximately 8 km to the north and are generally associated with larger, more intact remnants of native vegetation and will not be directly or indirectly impacted by development.

10.2.3.1(H) THE EXTENT TO WHICH THE DEVELOPMENT WILL LEAD TO AN INCREASE IN THREATS AND INDIRECT IMPACTS, INCLUDING IMPACTS FROM INVASIVE FLORA AND FAUNA, THAT MAY IN TURN LEAD TO A DECREASE IN THE VIABILITY OF THE LOCAL POPULATION

The BioNet profile and additional available information for *A. glareicola* identifies a range of threats to the species (DoEE, 2018a; OEH, 2018a). Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Habitat degradation from rubbish dumping and unrestricted access
- Weed invasion
- Inappropriate fire regimes

The greatest risk areas within GPEC for these relevant threats are:

- The southern end of Shanes Park where M7/Ropes Crossing Link Road occurs adjacent to potential habitat areas
- The north-eastern section of Wianamatta Regional Park, where the OSO corridor bisects two areas of potential habitat

HABITAT DEGRADATION

Habitat degradation through unrestricted public access and rubbish dumping have been identified as a key threat to *A. glareicola* (OEH, 2018a). Development within GPEC may lead to an increase in human activity within the species' known and potential habitat areas, and this may exacerbate the threat.

The Plan incorporates a range of broader measures that are considered adequate to mitigating the risks associated with inappropriate habitat disturbance. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in locations where species habitat occurs in protected areas
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

WEED INVASION

A. glareicola is threatened with invasion and competition by weeds, with African lovegrass *(Eragrostis curvula)*, Whisky grass (*Andropogon virginicus*), *Pennisetum clandestinum*, *Ricinus communis* and Asparagus fern considered to be the main competitors (OEH, 2018a). These weeds are already present within the Strategic Assessment Area. However, urban and transport development within GPEC has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity that are expected to adequately manage the risk to the species. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Area (SCA). This includes a number of actions, of which the following are the most relevant to the outcome the species:
    - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program

  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes:
  - Partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

INAPPROPRIATE FIRE REGIMES

A. glareicola can regenerate following fire. However, plants may be damaged and fruit production and seed set prevented by too frequent fires (OEH, 2018a). Increased human activity within GPEC increases the risk of fire to habitat areas supporting the species.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity that are expected to adequately manage the risk to the species. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for the species being:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for the species. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes.

10.3.2.1(I) AN ESTIMATE OF THE AREA, OR NUMBER OF POPULATIONS AND SIZE OF POPULATIONS THAT IS IN THE RESERVE SYSTEM IN NSW, THE IBRA REGION AND THE IBRA SUBREGION

There is currently approximately 1,160 ha of potential habitat mapped within protected areas. This includes potential habitat within:

- Wianamatta Regional Park
- Wianamatta Nature Reserve
- Castlereagh Nature Reserve
- Agnes Banks Nature Reserve
- Windsor Downs Nature Reserve

Eleven records (likely to comprise a single biological population) occur within the Castlereagh Nature Reserve. No other occurrences of the species are currently protected.

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE SPECIES IN THE IBRA SUBREGION

The Plan includes a range of commitments that will contribute to the recovery of *A. glareicola* in the Cumberland subregion. Several commitments are described in more detail the sections above.

Key commitments relevant to the species are:

- Secure a minimum of 5,475 ha of native vegetation in conservation lands within SCAs (Commitment 8). Offset targets to secure PCTs (see Chapter 8) are likely to result in securing of additional potential habitat for *A. glareicola* in the SCAs, as there is approximately 572 ha of mapped potential habitat in the SCAs for this species
- Manage weeds (Commitment 16) in strategic locations in the Cumberland subregion to reduce threats to conservation lands secured within SCAs. This includes preparing a Weed Control Implementation Strategy to guide and co-ordinate delivery of a weed control program
- Manage fire in strategic locations in the Cumberland subregion (Commitment 18) to support the maintenance of biodiversity values on land secured within SCAs. This includes:
    - Consulting with Rural Fire Service, NSW NPWS, and EES to identify fire management priorities, including fire sensitive species and ecological communities
    - Preparing a Fire Management Strategy to guide and co-ordinate fire management

25.7 CHALINOLOBUS DWYERI

25.7.1 SPECIES BACKGROUND

Large-eared Pied Bat (*Chalinolobus Dwyeri*) is a small to medium insectivorous bat with shiny, black fur (DoEE, 2018).

The species appears to roost predominantly in caves and crevices in sandstone cliffs and forage in nearby high-fertility forest or woodland near watercourses and in gullies (DERM, 2011). Roosting areas can also include old mines and disused mud nests. The species is generally constrained to 'areas within two kilometres of rocky areas containing caves, overhangs, escarpments, outcrops, or crevices, or within two kilometres of old mines or tunnels' (OEH, 2019a).

Large-eared Pied Bat has specific requirements in relation to the structure of breeding roosts. Caves need to be high and deep enough to allow juvenile bats to learn to fly and have indentations in the roof to allow the capture of heat. These physical characteristics are very uncommon in the landscape (OEH, 2018). The species is not known to roost in tree hollows (DERM, 2011). The species breeds in early winter and young are born in early summer. The species uses the same maternity roosting sites over many years (OEH, 2018).

Almost all records of the Large-eared Pied Bat are within several kilometres of cliff lines or rocky terrain. Evidence suggests the species does not usually forage in sandstone habitat and prefers fertile valleys and plains, as well as areas with moderately-tall to taller trees along waterways (DERM, 2011).

Habitat critical to the survival of the species comprises:

- Breeding sites
- Sandstone cliffs and fertile wooded valley habitat within close proximity of each other (DERM, 2011)

Large-eared Pied Bat occurs from Shoalwater Bay in central Queensland to Ulladulla in south-eastern NSW. In NSW, the species is generally rare with a very patchy distribution. It is found in the north east at Coolah Tops, Mt Kaputar and Warrumbungle National Park and in sandstone areas of the Sydney Basin and the western slopes and plains including Pilliga Nature Reserve (DERM, 2011). The area of occupancy is estimated to be 9,120 km^2 (DoEE, 2018a).

The species is known to breed in very few locations across NSW and the distance bats move from the maternity roost to over-wintering roosts has not been established, but is likely to be less than 100 km (DoEE, 2018a). As such all records within the Cumberland subregion are considered likely to be from the same breeding population.

Records for the Large-eared Pied Bat are widespread surrounding the Cumberland subregion and some records occur within the subregion. Records occur within Wilton and GMAC and adjacent to GPEC.

25.7.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

The Large-eared Pied Bat is being assessed as a candidate Species Credit Species for all four nominated areas.

The species has been identified as a potential SAII entity under the TBDC because it has a very highly restricted geographic distribution (Principle 3 of the BC Regulation) (EES, 2019). The species is also likely to be a potential entity because of Principle 4 of the BC Regulation as breeding habitat is likely to be irreplaceable.

The species has been identified as a potential SAII entity in relation to potential breeding habitat and the presence of breeding individuals. Potential breeding habitat comprises:

> *PCTs associated with the species within 100 m of rocky areas containing caves, or overhangs or crevices, cliffs or escarpments, or old mines, tunnels, culverts, derelict concrete buildings*

For the purposes of this BCAR, potential breeding habitat was mapped on the basis of:

- Associated PCTs as defined in TBDC in 'intact', 'thinned' and 'scattered trees' condition, and that are:
  - Within areas of Hawkesbury Sandstone and Minchinbury Sandstone geology, and
  - Within 200 m of locations where caves, crevices and cliffs are more likely to occur

Locations where caves, crevices and cliffs are more likely to occur were mapped by:

- Manipulation of a bare earth Digital Elevation Model to produce a layer that showed the mean elevation within a 30 m x 30 m grid surrounding each 1 m elevation grid cell
- Creation of a Topographic Position Index to identify the height of each 1 m cell above/below local mean elevation
- Reclassification of the Topographic Position Index to identify only areas that were high enough above the local mean elevation to create a topographic brake that might support cliffs
- Overlay the cliffs layer with a sandstone geology layer to exclude areas outside sandstone geology

The cliffs layer was validated through inspection of aerial photos and knowledge of the topography and landscape of the nominated areas, as well as site observations during surveys.

The potential breeding habitat was not able to be confirmed as actual breeding habitat. While Anabat surveys were undertaken for the species within a part of the northern section of Wilton, the surveys did not confirm the presence of breeding habitat or breeding individuals. The species was not detected during surveys.

25.7.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of Large-eared Pied Bat in relation to the subject land is shown in Map 25.

Records for the Large-eared Pied Bat are widespread surrounding the Cumberland subregion and some records occur within the subregion. A population of Large-eared Pied Bat occurs within Wilton and the southern part of GMAC associated with several records. Within Wilton, a cluster of recent records (as recent as 2016) occur in the vicinity of existing development in the central-eastern section of the nominated area. Within GMAC, a few recent records (as recent as 2014) occur in the Gilead area around the centre of the southern section of the nominated area.

Interrogation of the observation codes of records for the species indicate there are no known roost or breeding sites for the species within the nominated areas (OEH, 2019a).

Approximately 1,105 ha of potential breeding habitat for the Large-eared Pied Bat has been identified in the nominated areas. This occurs within Wilton and the southern section of GMAC.

25.7.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.3 of the BAM.

10.2.3.1(A) THE ACTION AND MEASURES TAKEN TO AVOID DIRECT AND INDIRECT IMPACTS

Avoidance and minimisation of impacts to biodiversity values, including Large-eared Pied Bat, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

Records associated with a population of Large-eared Pied Bat have been avoided within the nominated areas, although one record in GMAC occurs on the very edge of the urban capable land.

The baseline mapping for this assessment has mapped 888 ha of potential breeding habitat for Large-eared Pied Bat within Wilton and GPEC (not including excluded lands). Approximately 882 ha (99 per cent) of this was avoided as part of the design of the urban capable land and transport corridors (not including excluded lands). Of this:

- 452 ha was avoided for biodiversity purposes
- 429 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-21.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-21 shows the amounts of habitat within excluded lands for context only.

Table 25-21: Avoidance outcomes for Large-eared Pied Bat

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential breeding habitat (ha)	1,105	216	889	7.5	452	429	882

Avoidance of indirect impacts

Potential indirect impacts to Large-eared Pied Bat due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(B) THE SIZE OF THE LOCAL POPULATION DIRECTLY AND INDIRECTLY IMPACTED BY THE DEVELOPMENT

Development in the nominated areas will not directly impact on records or known populations of Large-eared Pied Bat.

Potential indirect impacts to Large-eared Pied Bat potential breeding habitat due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(C) THE EXTENT TO WHICH THE IMPACT EXCEEDS ANY THRESHOLD FOR THE POTENTIAL ENTITY

Breeding habitat has been identified as an impact threshold for Large-eared Pied Bat.

While Anabat surveys were undertaken for the species within a part of the northern section of Wilton, the surveys did not confirm the presence of breeding habitat or breeding individuals.

10.2.3.1(D) THE LIKELY IMPACT (INCLUDING DIRECT AND INDIRECT) THAT THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION WILL HAVE ON THE HABITAT OF THE LOCAL POPULATION

Direct impacts

A total of 7.5 ha of potential breeding habitat will be directly impacted by the development. This is 0.8 per cent of the potential habitat in the nominated areas (without excluded lands). The direct impacts of the development are associated with urban development. The main direct impacts occur at the edges of Wilton and the southern part of GMAC.

The direct impacts of the development on Large-eared Pied Bat are provided in Table 25-22.

Table 25-22: Direct impacts on Large-eared Pied Bat

Impacts to:	Wilton*	GMAC*	WSA*	GPEC*	Transport corridors#	Total
Potential breeding habitat (ha)	4.6	2.9	0	0	0	7.5

* Impacts from urban development only within each nominated area

Impacts from transport corridors across all nominated areas

The impacts to potential breeding habitat within Wilton and GMAC are unlikely to affect life cycle processes or impact the viability of any local population of Large-eared Pied Bat because:

- While roosting or breeding sites may occur, there are no known roosting or breeding sites for the species in the area
- Only a very small proportion of potential breeding habitat is directly impacted. The vast majority of potential breeding habitat has been avoided for biodiversity or other purposes
- The impacts are unlikely to cause fragmentation or isolation of potential breeding habitat because only the fringes of potential breeding habitat that occurs on the edges of gorges and gullies are impacted
- The corridors of potential breeding habitat that exist along the gorges and gullies are maintained
- Potential breeding habitat in the nominated areas forms a relatively small part of much broader and intact areas of habitat to the north and west of the Plan Area and to the south of Sydney

10.2.3.1(E) THE LIKELY IMPACT ON THE ECOLOGY OF THE LOCAL POPULATION

As discussed in response to subsection (d) above, the loss of potential breeding habitat within the Wilton and GMAC is unlikely to affect the ecology of any local population of Large-eared Pied Bat in the area, including because:

- Only a very small proportion of potential breeding habitat is directly impacted
- The impacts are unlikely to cause fragmentation or isolation of potential breeding habitat and the corridors of potential breeding habitat that exist along the gorges and gullies are maintained

10.2.3.1(F) A DESCRIPTION OF THE EXTENT TO WHICH THE LOCAL POPULATION WILL BECOME FRAGMENTED OR ISOLATED

As discussed in response to subsection (d) above, the loss of potential breeding habitat within Wilton and GMAC is unlikely to cause fragmentation or isolation of habitat because only the edges of potential breeding habitat are impacted and the corridors of habitat that exist along the gorges and gullies are maintained.

10.2.3.1(G) THE RELATIONSHIP OF THE LOCAL POPULATION TO OTHER POPULATION/POPULATIONS OF THE SPECIES

All records within the Cumberland subregion are considered likely to be from the same breeding population.

While roosting or breeding sites may occur, development within Wilton and GMAC will not directly impact any known roosting or breeding sites for Large-eared Pied Bat, and will only impact a very small proportion of potential breeding habitat for the species in the nominated areas around the edges of this habitat.

The development is therefore not considered likely to affect the broader population in the Cumberland subregion.

Potential breeding habitat within Wilton and GMAC is not at the limit of the species range. Records for the species are widespread surrounding the Cumberland subregion.

10.2.3.1(H) THE EXTENT TO WHICH THE DEVELOPMENT WILL LEAD TO AN INCREASE IN THREATS AND INDIRECT IMPACTS, INCLUDING IMPACTS FROM INVASIVE FLORA AND FAUNA, THAT MAY IN TURN LEAD TO A DECREASE IN THE VIABILITY OF THE LOCAL POPULATION

The BioNet profile (OEH, 2017g) and Recovery Plan (DERM, 2011) for the Large-eared Pied Bat identifies a range of threats to the species Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Use of pesticides
- Disturbance of roosts from human recreational activities
- Fire in the proximity of roosts

The greatest risk areas within Wilton and GMAC for these relevant threats are around the edges of the nominated areas along gorges and gullies associated with waterways, including the Nepean River.

USE OF PESTICIDES

Use of pesticides has been identified as a threat to the Large-eared Pied Bat. Poisoning of pest animals may occur during implementation of the Plan as part of the Pest Animal Control Implementation Strategy (Commitment 17, Action 1).

The Plan includes Action 4 under Commitment 17.1, as follows: "*Ensure that the Pest Animal Control Implementation Strategy specifies the use of pest control techniques that will reduce the risk of secondary poisoning from Pindone or second-generation rodenticides*"

This measure is considered to be sufficient to address the threat posed to the Large-eared Pied Bat.

DISTURBANCE OF ROOSTS FROM HUMAN RECREATIONAL ACTIVITIES

Disturbance of roosts from recreational activities such as bushwalking, caving and abseiling is identified as a threat to the Large-eared Pied Bat. Regular disturbance can lead to bats abandoning roosts or depleting essential fat reserves (DERM, 2011).

Areas considered most at risk from increased disturbance due to recreational activities are those that occur in close proximity to development within Wilton and GMAC. Roosting and maternity caves are most likely to be located within the sandstone areas adjacent to and surrounding the Strategic Assessment Area. Much of this land is protected for conservation or as part of Sydney's drinking water catchment and should have existing management frameworks to prevent inappropriate access and use.

The Plan incorporates a range of measures to mitigate the risks associated with recreational disturbance within the Strategic Assessment Area, including:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- A commitment (Commitment 7) to mitigate indirect and prescribed impacts from urban, infrastructure and major infrastructure (transport) development on Koalas. This is relevant to the species because a lot of the mapped habitat for the Large-eared Pied Bat is identified as important Koala habitat. Of particular relevance to habitat disturbance are associated actions around the use of exclusion fencing which will assist in controlling access to Koala habitat. These measures will help minimise inappropriate habitat disturbance to potential habitat within both Wilton and GMAC
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate access and use

- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor issues such as illegal access and use
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan, combined with existing management of protected areas adjacent to the Plan Area is expected to adequately manage the risk to the species from inappropriate recreational use.

FIRE IN THE PROXIMITY OF ROOSTS

Bushfires and prescribed burning are identified as a key threat to the Large-eared Pied Bat as they are potentially susceptible to direct mortality from heat and smoke if the fire is close to their relatively shallow cave roosts (DERM, 2011). Changes in foraging resources and prey species as a result of altered fire regimes may also impact the species (DERM, 2011).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact habitat for the species. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant including:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the Strategic Conservation Areas that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from potential foraging habitat. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the species from increased fire frequency as a result of development. This is because:

- Avoided lands supporting potential habitat will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat
- Fire management authorities will be engaged to ensure they understand the values relevant to the species and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

10.3.2.1(I) AN ESTIMATE OF THE AREA, OR NUMBER OF POPULATIONS AND SIZE OF POPULATIONS THAT IS IN THE RESERVE SYSTEM IN NSW, THE IBRA REGION AND THE IBRA SUBREGION

There is currently approximately 25 ha of potential breeding habitat for the Large-eared Pied Bat mapped within protected areas in the nominated areas. The number of known breeding sites in NSW is very limited. However, other protected areas in NSW where the species is known to occur include (DERM, 2011):

- Bouddi National Park
- Big Scrub Flora Reserve
- Blue Mountains National Park
- Bungonia Nature Reserve
- Coolah Tops National Park
- Goulburn River National Park
- Mt Kaputar National Park
- Morton National Park
- Munghorn Gap Nature Reserve
- Pilliga Scrub Nature Reserve
- Richmond Range National Park
- Royal National Park
- Warrumbungle National Park
- Wollemi National Park
- Yengo National Park

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE SPECIES IN THE IBRA SUBREGION

The Plan includes a range of commitments that will contribute to the recovery of Large-eared Pied Bat in the Cumberland subregion. Several commitments are described in more detail the sections above.

The key commitments relevant to the species are:

- Manage pest animals in strategic locations in the Cumberland subregion (Commitment 17) to reduce threats to conservation lands secured within SCAs. This includes preparing a Pest Animal Control Implementation Strategy to guide and co-ordinate delivery of a pest control program
- Manage fire in strategic locations in the Cumberland subregion (Commitment 18) to support the maintenance of biodiversity values on land secured within SCAs. This includes:
  - Consulting with Rural Fire Service, NSW NPWS, and EES to identify fire management priorities, including fire sensitive species and ecological communities
  - Preparing a Fire Management Strategy to guide and co-ordinate fire management

Due to the low risk of direct impacts on Large-eared Pied Bat potential breeding habitat, the Plan does not include any specific commitment to secure any known or potential breeding habitat in conservation lands.

However, the Plan includes a commitment to secure a minimum of 5,475 ha of native vegetation in conservation lands within SCAs. Given that several records of Large-eared Pied Bat occur within and immediately adjacent to SCAs, some of this land may contain potential breeding habitat for this species.

25.8 HIBBERTIA FUMANA

25.8.1 SPECIES BACKGROUND

Hibbertia fumana is a small low shrub or sub-shrub (OEH, 2020).

Little is known about the life history and ecology of the species. Regeneration can occur through suckers, suggesting it may be able to resprout from rootstock following fire (TSSC, 2016). Peak flowering times are spring to early summer, although the species appears to be capable of minor sporadic flowering at other times of the year as a response to suitable climatic conditions (Miller, 2018b).

H. fumana inhabits areas of woodland generally with an open understorey. Within the nominated areas, the species is associated with the following PCTs and transition zones between these (Miller, 2018a):

- PCT 724 - Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain
- PCT 725 Broad-leaved Ironbark - *Melaleuca decora* shrubby open forest on clay soils of the Cumberland Plain
- PCT 808 – Derived shrubland on Tertiary Gravels of the Cumberland Plain
- PCT 883 Hard-leaved Scribbly Gum – Parramatta Red Gum heathy woodland of the Cumberland Plain
- PCT 1067 - Parramatta Red Gum woodland on moist alluvium of the Cumberland Plain

The species has a highly restricted range and until very recently was only known from only two populations:

- Moorebank (population size of approximately 370 individuals)
- Bankstown Airport (population size unknown) (Miller, 2018b)

However, it appears that as a result of recent surveys "populations of this species have been detected over a wider range within greater Sydney stretching from Richmond to Mittagong" (OEH, 2020). These records are not available to inform the assessment at this stage. If available, they will be integrated into the assessment after public comment.

At Moorebank, the population mainly occurs within a transition zone between Castlereagh Scribbly Gum Woodland and Castlereagh Ironbark Forest, and in soils of fine sandy clay loam. It has the potential to occur in similar intergrade alluvial habitats rich in sands and laterite in other parts of Western Sydney (OEH, 2020).

The population at Moorebank is surrounded by existing development, including urban development, particularly to the north, east and west of the site. A rail line occurs along the boundary of southern end of the site. Habitat at the site is disturbed, and the population is traversed by a disused railway line. Proposed infrastructure in the area will result in further habitat loss and disturbance (TSSC, 2016). Habitat at the site at Bankstown Airport is heavily disturbed – the site is managed and is routinely slashed to a height of about 10 cm (Miller, 2018b).

It should be noted that *H. fumana* is difficult to survey and may have been overlooked in past surveys as it:

- Has only recently been described
- Is extremely cryptic
- Is easily misidentified and/or overlooked as a depauperate version of other species

25.8.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

Hibbertia fumana is being assessed as a candidate species credit species in all four nominated areas.

The species has been identified as a potential SAII entity under the EES guidelines because it has a very highly restricted geographic distribution (Principle 3 of the BC Regulation) (OEH, 2017f).

Two expert reports have been prepared for *H. fumana* by Cumberland Flora & Fauna Interpretive Services. One for GPEC and WSA (Miller, 2018a) and one for Wilton and GMAC (Miller, 2018b).

25.8.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of *H. fumana* in relation to the subject land is shown in Map 26.

There are no records of *H. fumana* in the nominated areas.

Targeted surveys for the species were undertaken as part of the expert report for *H. fumana* within some areas of habitat similar to the sites that support the populations of the species. Areas targeted for survey are shown in the expert report (see Supporting Document C). Targeted surveys were also undertaken in small areas of the nominated areas by ecological consultants as part of the biodiversity certification process. The species was not recorded during any of these surveys.

The two known populations of *H. fumana* occur outside the nominated areas. The population at Moorebank occurs 1.2 km to the north-east of GMAC, and the population at Bankstown Airport occurs about 9 km from GMAC.

Approximately 1,650 ha of potential habitat for *H. fumana* has been identified within the nominated areas.

25.8.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.3 of the BAM.

10.2.3.1(A) THE ACTION AND MEASURES TAKEN TO AVOID DIRECT AND INDIRECT IMPACTS

Avoidance and minimisation of impacts to biodiversity values, including *H. fumana*, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

The only known populations of *H. fumana* occur outside the nominated areas. Avoidance of impacts to these populations were therefore not a relevant consideration.

The baseline mapping for this assessment has mapped 1,245 ha of potential habitat for *H. fumana* within the nominated areas (not including excluded lands). Approximately 1,207 ha (97 per cent) of this was avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 1,064 ha was avoided for biodiversity purposes
- 143 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-23.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-23 shows the amounts of habitat within excluded lands for context only.

Table 25-23: Avoidance outcomes for *H. fumana*

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential habitat (ha)	1,650	405	1,245	37.5	1,064	143	1,207

Avoidance of indirect impacts

Potential indirect impacts to *H. fumana* due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(B) THE SIZE OF THE LOCAL POPULATION DIRECTLY AND INDIRECTLY IMPACTED BY THE DEVELOPMENT

Development within the nominated areas will not directly impact on any records or known populations of *H. fumana*.

Potential indirect impacts to *H. fumana* due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(C) THE EXTENT TO WHICH THE IMPACT EXCEEDS ANY THRESHOLD FOR THE POTENTIAL ENTITY

There are currently no impact thresholds for *H. fumana*.

10.2.3.1(D) THE LIKELY IMPACT (INCLUDING DIRECT AND INDIRECT) THAT THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION WILL HAVE ON THE HABITAT OF THE LOCAL POPULATION

Direct impacts

A total of 37.5 ha of potential habitat will be directly impacted by the development. This is 3.0 per cent of the potential habitat in the nominated areas (without excluded lands). The direct impacts of the development are associated with urban development. The direct impacts mainly occur:

- WSA: habitat mapped in the south-east corner of WSA
- GMAC: within the areas mapped as 'likely habitat' by the expert in the south west corner of GMAC (see Supporting Document C)
- Wilton: along the edges of the urban capable land in the northern part of the nominated area

Surveys confirmed *H. fumana* as absent within the OSO corridor, however mapped potential habitat remains present within the Wianamatta Regional Park in the northern part of GPEC. The OSO alignment bisects two areas of 'low probability' habitat for the species.

The direct impacts of the development on *H. fumana* are provided in Table 25-24.

Table 25-24: Direct impacts on *H. fumana*

Impacts to:	Wilton*	GMAC*	WSA*	GPEC*	Transport corridors#	Total
Potential habitat (ha)	25.9	8.4	3.1	0	0	37.5

* Impacts from urban development only within each nominated area

Impacts from transport corridors across all nominated areas

Impacts to potential habitat within GPEC

Surveys for the species confirmed that the species was not present within the OSO alignment, however the OSO does bisect potential habitat for *H. fumana* within the north-eastern part of Wianamatta Regional Park. This will lead to loss and fragmentation of potential habitat at this location, leading to a number of smaller, isolated patches of habitat. This fragmentation may increase impacts associated with edge effects and weed invasion and this has the potential to compromise the suitability of remaining habitat areas directly adjacent to the development.

Surveys for *H. fumana* were undertaken within Wianamatta Regional Park (see Supporting Document C). The species was not recorded during surveys and the expert report concluded that the potential for the species to occur was low. This reduces the risk of impacts to life-cycle processes and viability of any local population.

Impacts to potential habitat within WSA

Urban capable land impacts on potential habitat for *H. fumana* in the south-east corner of WSA. The impacts are generally around the edges of larger potential habitat polygons, with a total impact of 3.1 ha recorded across WSA. The likelihood that the species occurs within the urban capable footprint is low as:

- The likelihood the species occurred within the potential habitat mapped in the Kemps Creek area was assessed as moderate to low potential
- The species was not recorded during surveys of the area undertaken as part of the strategic biodiversity certification by either the expert (see Supporting Document C) or the ecological consultants

Impacts to potential habitat within GMAC

The urban capable land directly impacts potential habitat for *H. fumana* along the edges of a corridor of habitat that occurs along the outer perimeter of the southern part of GMAC.

This potential habitat currently occurs adjacent to farmland, which means that the impacts of urban development are unlikely to greatly increase edge effects to retained habitat areas or further reduce their viability. Furthermore, the likelihood that the species occurs within the urban capable land is considered low for the following reasons:

- The expert report for *H. fumana* concluded that the species has low potential to occur in GMAC because areas of potential habitat with similar attributes to known sites are highly modified and of limited extent (Miller, 2018b)
- The species was not recorded during surveys of the area undertaken as part of the strategic biodiversity certification by either the expert (see Supporting Document C) or the ecological consultants

The expert identified mostly small areas of 'likely habitat' for the species in the centre and north of GMAC, including at Menangle Park, Milton Part, Kayess Park and Bunbury Curran Creek. These areas are not directly impacted by the urban capable lands. The indirect impacts of the development are considered unlikely to further reduce the viability these areas because these areas are distant from the urban capable lands.

Impacts to potential habitat within Wilton

The urban capable land directly impacts potential habitat for *H. fumana* along the edges of a corridor of habitat that occurs along the outer edge of the northern section of Wilton.

This potential habitat currently occurs adjacent to farmland, which means that the impacts of urban development are unlikely to greatly increase edge effects to retained habitat areas or further reduce their viability. Furthermore, the likelihood that the species occurs within the urban capable land is considered low for the following reasons:

- The expert report concluded that while the species could possibly occur within Wilton, the species is unlikely to occur within the urban capable land because the majority of this area is confined to the Wianamatta Shale-derived soils which, based on current knowledge, is not potential habitat for the species
- The species was not recorded during surveys of the area undertaken as part of the strategic biodiversity certification by either the expert (see Supporting Document C) or the ecological consultants

10.2.3.1(E) THE LIKELY IMPACT ON THE ECOLOGY OF THE LOCAL POPULATION

As discussed in response to subsection (d) above, the loss of potential habitat within the nominated areas is unlikely to affect the ecology of any local population of *H. fumana* because the potential for the species to occur is low.

10.2.3.1(F) A DESCRIPTION OF THE EXTENT TO WHICH THE LOCAL POPULATION WILL BECOME FRAGMENTED OR ISOLATED

As discussed in response to subsection (d) above, the loss of potential habitat within the nominated areas is unlikely to fragment or isolate any local population of *H. fumana* because the potential for the species to occur is low.

Two areas of potential habitat will be fragmented within Wianamatta Regional Park as a result of the OSO corridor. The low likelihood of occurrence of *H. fumana* in the area considerably reduces the risk of these impacts.

10.2.3.1(G) THE RELATIONSHIP OF THE LOCAL POPULATION TO OTHER POPULATION/POPULATIONS OF THE SPECIES

H. fumana is currently only known from two populations at Moorebank and Bankstown outside the nominated areas. The distance between the populations suggest they are unlikely to interact.

10.2.3.1(H) THE EXTENT TO WHICH THE DEVELOPMENT WILL LEAD TO AN INCREASE IN THREATS AND INDIRECT IMPACTS, INCLUDING IMPACTS FROM INVASIVE FLORA AND FAUNA, THAT MAY IN TURN LEAD TO A DECREASE IN THE VIABILITY OF THE LOCAL POPULATION

The Final Determination and BioNet profile for *H. fumana* identify a range of threats to the species. Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Habitat disturbance

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes are recognised as a threat to the species (OEH, 2020). This can relate to fire that is either:

- Too frequent which has the potential to limit recruitment, or
- Too rare which may allow the midstorey to thicken

Inappropriate fire regimes can be caused by:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact the species. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity that are expected to adequately manage the risk to the species. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for the species being:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for the species. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

WEED INVASION

Weeds are recognised as a threat to the species. In particular low shrubs, dense shrubs and smothering grasses (OEH, 2020). Weeds are present in the Strategic Assessment Area and are unlikely to pose a novel threat to *H. fumana*. However, development within the nominated has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity that are expected to adequately manage the risk to the species. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Area (SCA). This includes a number of actions, of which the following are the most relevant to the outcome of the species:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program

  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

HABITAT DISTURBANCE

Habitat disturbance is a recognised as a threat to the species (OEH, 2020). This relates to mechanisms such as land management practices (e.g. mowing) and uncontrolled vehicle movements.

The Plan incorporates a range of measures that are considered adequate to mitigating the risks associated with inappropriate habitat disturbance. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in locations where species habitat occurs in protected areas
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

10.3.2.1(I) AN ESTIMATE OF THE AREA, OR NUMBER OF POPULATIONS AND SIZE OF POPULATIONS THAT IS IN THE RESERVE SYSTEM IN NSW, THE IBRA REGION AND THE IBRA SUBREGION

The two known populations of *H. fumana* are not within reserves, but are managed for conservation – the site at Moorebank is a BioBank/stewardship site, and the site at Bankstown is managed within the airport complex.

There is currently approximately 92 ha of potential habitat for the species mapped within protected areas in the Plan Area. This comprises potential habitat within Wianamatta Regional Park.

Potential habitat also occurs within several Council reserves.

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE SPECIES IN THE IBRA SUBREGION

The Plan includes a range of commitments and actions that will contribute to the recovery of *H. fumana* in the Cumberland subregion. The key commitments and actions relevant to the species are:

- A species-specific commitment to secure 1 offset location of *H. fumana* in conservation lands within the SCAs (Commitment 9.1)
- Secure a minimum of 5,475 ha of native vegetation in conservation lands within SCAs (Commitment 8). Offset targets to secure PCTs (see Chapter 8) are likely to result in securing of additional potential habitat for *H. fumana* in the SCAs, as there is approximately 1,779 ha of mapped potential habitat in the SCAs for this species
- Manage weeds in strategic locations in the Cumberland subregion (Commitment 16) to reduce threats to conservation lands secured within SCAs. This includes preparing a Weed Control Implementation Strategy to guide and co-ordinate delivery of a weed control program
- Manage fire in strategic locations in the Cumberland subregion (Commitment 18) to support the maintenance of biodiversity values on land secured within SCAs. This includes:
    - Consulting with Rural Fire Service, NSW NPWS, and EES to identify fire management priorities, including fire sensitive species and ecological communities
    - Preparing a Fire Management Strategy to guide and co-ordinate fire management

25.9 LITORIA AUREA

25.9.1 SPECIES BACKGROUND

Green and Golden Bell Frog (*Litoria aurea*) is a relatively large, dull, olive to bright emerald-green frog.

The species requires different habitats for foraging, breeding, over-wintering and dispersal. The species also uses certain habitats on a periodic or seasonal basis (DEWHA, 2009b). Habitat comprises one or more water bodies, and associated terrestrial habitats with grassy areas and low vegetation, although the species tends not to disperse far from waterbodies into more terrestrial non-breeding habitats (DEWHA, 2009; Lemckert, 2019). The species has been found in a wide range of water bodies except those that are fast flowing and the species can occur in disturbed habitats (DEWHA, 2009b).

Breeding habitat includes water bodies that are still, shallow, temporary, unshaded, with aquatic plants and free of mosquito fish. Ephemeral water bodies are important habitat for the species as they can provide habitat stepping stones between otherwise disconnected areas and they are less likely to contain mosquito fish (DEWHA, 2009b).

Records suggest that Green and Golden Bell Frog is highly mobile and moves between breeding sites. Movements of up to 5 km may be common and the frog may disperse up to 10 km (DoEE, 2018c). Connectivity between habitat sites is vital as the species exhibits a 'metapopulation structure', which relies on dispersal between 'local' populations within a larger 'metapopulation'. The species is more likely to be present, and habitat more likely to be important, where:

- Multiple suitable breeding sites are within a close enough proximity for individuals to migrate between them
- Multiple non-breeding water bodies are present in an area and within close enough proximity to allow migration between them (and breeding sites) with relative ease
- The connectivity of breeding and non- breeding habitat contains vegetation and shelter that facilitates migration
- There are other individuals occupying waterbodies in close proximity (Lemckert, 2019)

Breeding of the Green and Golden Bell Frog occurs generally between September and February after heavy rains or storms, and spawn is laid among aquatic vegetation (DEWHA, 2009a). The species has high fecundity and clutch sizes have been known to contain between over 2000 to 11,000 eggs (DEWHA, 2009a).

Records of the species in NSW are widely separated and isolated (OEH, 2019e). Approximately 30 populations are known. The largest populations of the species are located in Sydney and the Shoalhaven and mid north coast areas (OEH, 2019e). Most populations have fewer than 20 adults. Over 1,000 individuals have been recorded at Homebush, Kooragang Island and Broughton Island (DoEE, 2018c).

Nearly all known populations of Green and Golden Bell Frog are located with 10 km of the coast or saline waterways. This is likely due to the species being susceptible to the amphibian chytrid fungus, as the fungus is intolerant of salt. These locations therefore provide some refuge from the impacts of chytrid (Lemckert, 2019).

25.9.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

Green and Golden Bell Frog is being assessed as a candidate species credit species for all four nominated areas.

The species has been identified as a potential SAII entity in accordance with the requirement of section 10.2.1.4 of the BAM because of its very high susceptibility to the disease Chytrid fungus (Principle 4 of the BC Regulation).

An expert report has been prepared for the Green and Golden Bell Frog (Lemckert, 2019).

The expert report involved:

- Targeted surveys within the most likely areas of potential habitat for this species
- Identification of potential habitat within the nominated areas

25.9.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of Green and Golden Bell Frog in relation to the subject land is shown in Map 27.

A total of 13,146 records for the Green and Golden Bell Frog occur within the Cumberland subregion. The majority (greater than 95 per cent) occur in the eastern third of the subregion outside the nominated areas (Lemckert, 2019).

In relation to the records in the subregion, the expert report concluded that:

- Few records occur in the Cumberland subregion and it appears the species has never been common in this area, reflecting the fact that the region is over 10 km from the coast where chytrid fungus is more likely to be present
- The majority of records are from prior to 1990, indicating that most populations are likely to now be extinct. This is consistent with the pattern of declines noted for the species by Mahony et al (2013), who noted that populations rarely persist more than 10 kilometres from the coast (i.e. east of the nominated areas)

Records of the species within the nominated areas are limited. There are 12 records within GPEC and two records within GMAC. The records primarily occur around St Marys and Ropes Creek in GPEC and Blair Athol in GMAC. There are no records in Wilton and WSA and the expert report concluded that the species is unlikely to be present in those nominated areas (Lemckert, 2019). The expert report concluded that the population around St Marys and Ropes Creek is likely to be present. However, the records at Blair Athol are likely to be from individuals that escaped a captive colony and the population is no longer likely to persist in that location (Lemckert, 2019).

As part of the EPBC assessment for the development, two important populations of Green and Golden Bell Frog were identified in proximity to the nominated areas:

- A population at Gow Park in Mulgoa, approximately 2.4 km south of the nearest urban capable land within GPEC. This population was recorded in 1999 in a non-permanent creek
- A population along the eastern boundary of the Strategic Assessment Area, approximately 17 km east of WSA

The population around St Marys and Ropes Creek occurs within the urban capable land.

Approximately 1,655 ha of potential habitat for Green and Golden Bell Frog has been identified within the nominated areas. This occurs GPEC and GMAC. The majority of potential habitat occurs around St Marys between Ropes Crossing in the north and Minchinbury in the south. A smaller area occurs around Blair Athol.

25.9.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.3 of the BAM:

10.2.3.1(A) THE ACTION AND MEASURES TAKEN TO AVOID DIRECT AND INDIRECT IMPACTS

Avoidance and minimisation of impacts to biodiversity values, including Green and Golden Bell Frog, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

A likely population of Green and Golden Bell Frog occurs within the urban capable land in GPEC around St. Marys. No other known populations of the species occur within urban capable lands.

The baseline mapping for this assessment has mapped 25 ha of potential habitat for Green and Golden Bell Frog within GPEC and GMAC (not including excluded lands). Approximately 11 ha (46 per cent) of this was avoided as part of the design of the urban capable land and transport corridors (not including excluded lands). All of this was avoided for biodiversity purposes.

A breakdown of avoidance across each nominated area is provided in Table 25-25.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-25 shows the amounts of habitat within excluded lands for context only.

Table 25-25: Avoidance outcomes for Green and Golden Bell Frog

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential habitat (ha)	1,655	1,630	25	13.3	11	0	11

Avoidance of indirect impacts

Potential indirect impacts to Green and Golden Bell Frog due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(B) THE SIZE OF THE LOCAL POPULATION DIRECTLY AND INDIRECTLY IMPACTED BY THE DEVELOPMENT

Direct impacts

Development within GPEC will directly impact a likely population of the Green and Golden Bell Frog associated with Ropes Creek. This population comprises 6 BioNet records made between 1998 and 2012. The development will impact an area associated with one of these records made in 1998. The impact is associated with urban development.

It has not been confirmed whether the population at Ropes Creek still exists. However, there are a series of other records for this population from nearby habitat associated with Ropes Creek and areas of potential habitat remain along the corridor in the form of a high density of water bodies within undeveloped lands (Lemckert, 2019). In the absence of targeted surveys, it is considered likely that the population persists in the area.

If the population at Ropes Creek is confirmed present, the population would be important. Nearly all populations in Australia occur within 10 km of the coast or saline waterways. This population is located almost 60 km from the coast, placing it on the edge of the western range for the species and outside of the area of refuge potentially provided by elevated salinity levels (Lemckert, 2019).

A smaller area of potential habitat occurs around Blair Athol between the Hume Motorway and Campbelltown in GMAC. The species is unlikely to occur in GMAC and the records at Blair Athol are likely to be from individuals that escaped a captive colony and the population no longer appears to persist in that location (Lemckert, 2019)

Indirect impacts

Potential indirect impacts to Green and Golden Bell Frog due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(C) THE EXTENT TO WHICH THE IMPACT EXCEEDS ANY THRESHOLD FOR THE POTENTIAL ENTITY

There are currently no impact thresholds for Green and Golden Bell Frog.

10.2.3.1(D) THE LIKELY IMPACT (INCLUDING DIRECT AND INDIRECT) THAT THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION WILL HAVE ON THE HABITAT OF THE LOCAL POPULATION

Direct impacts

The area of potential habitat within and around the Ropes Creek corridor at St Marys in GPEC covers:

- The locations of known records
- The riparian corridor joining those records
- A buffer of 1,000 m around the riparian corridor and records that could be used by the species for foraging, shelter, breeding and as migratory habitat as individuals move between water bodies and riparian corridors (Lemckert, 2019)

Approximately 13.4 ha of potential habitat will be directly impacted by the development within GPEC along Ropes Creek. This is about half of the potential habitat in the nominated areas (without excluded lands). This includes:

- 1.9 ha of aquatic/riparian habitat
- 7.1 ha of terrestrial habitat less than 200 m from aquatic habitat
- 4.4 ha of terrestrial habitat greater than 200 m from aquatic habitat

The direct impacts of the development on Green and Golden Bell Frog are provided in Table 25-26.

Table 25-26: Direct impacts on Green and Golden Bell Frog^

Impacts to:	Wilton*	GMAC*	WSA*	GPEC*	Transport corridors#	Total
Potential habitat (ha)	0	0	0	11	2.3	13.3

* Impacts from urban development only within each nominated area

Impacts from transport corridors across all nominated areas

^ Note that this total impact of 13.3 ha is comprised of:

- 7.58 ha of impact on native vegetation
- 0.06 ha of impact on non-native vegetation (see Chapter 24)
- 0.6 ha of impact on a non-vegetated waterbodies (see Chapter 24)
- Approximately 5 ha of impact on within an existing urban area comprising buildings and roads (see Chapter 24)

The majority of habitat loss within GPEC is associated with the site of the current St Marys Rugby League Club adjacent to the Ropes Creek corridor and includes at least two mapped water bodies. A smaller impact occurs to the north-west of St Marys Rugby League Club associated with the OSO.

If the population at Ropes Creek is confirmed present, impacts to these areas may be notable as the aquatic/riparian habitat in that location has the potential to support breeding habitat for the species.

The development is unlikely to cause fragmentation or isolation of potential habitat at Ropes Creek because the area impacted occurs at the edge of the area of potential habitat (excluding areas that are already developed) and distant from the riparian corridor of Ropes Creek, as well as being adjacent to existing urban development, including two major roads. The corridor of habitat along the riparian corridor at Ropes Creek will therefore be maintained.

Indirect impacts

Potential indirect impacts to Green and Golden Bell Frog due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(E) THE LIKELY IMPACT ON THE ECOLOGY OF THE LOCAL POPULATION

As discussed in response to subsection (d) above, if the population at Ropes Creek is confirmed present, the aquatic/riparian habitat in that location may support breeding habitat and impacts to these areas may be notable.

10.2.3.1(F) A DESCRIPTION OF THE EXTENT TO WHICH THE LOCAL POPULATION WILL BECOME FRAGMENTED OR ISOLATED

As discussed in response to subsection (d) above, the development is unlikely to cause fragmentation or isolation of any local population because impacts occur at the edge of the area of potential habitat and distant from the riparian corridor of Ropes Creek. The corridor of habitat along the riparian corridor at Ropes Creek will be maintained.

10.2.3.1(G) THE RELATIONSHIP OF THE LOCAL POPULATION TO OTHER POPULATION/POPULATIONS OF THE SPECIES

Potential habitat for the Green and Golden Bell Frog within GPEC and GMAC occurs towards the western edge of the distribution of the species in the Cumberland subregion. The potential population at Ropes Creek is disjunct from the majority of known records which generally occur over 20 km to the east.

If the population at Ropes Creek is confirmed present, the population would be important. Despite nearly all populations occurring within 10 km of the coast, this population is located almost 60 km from the coast, placing it on the edge of the western range for the species and outside of the area of refuge potentially provided by elevated salinity levels.

10.2.3.1(H) THE EXTENT TO WHICH THE DEVELOPMENT WILL LEAD TO AN INCREASE IN THREATS AND INDIRECT IMPACTS, INCLUDING IMPACTS FROM INVASIVE FLORA AND FAUNA, THAT MAY IN TURN LEAD TO A DECREASE IN THE VIABILITY OF THE LOCAL POPULATION

The BioNet profile and Conservation Advice for the Green and Golden Bell Frog identifies a range of threats to the species. Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Changes to the structure and diversity of aquatic vegetation
- Changes to hydrology and water quality
- Intensification of public access to habitat
- Predation by foxes, cats, dogs and rats
- Inappropriate fire regimes
- Infection with amphibian chytrid fungus
- Road mortality

Predation of eggs and tadpoles, predation by exotic fish, interaction with cane toads and grazing are also identified as potential threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the risk across the Strategic Assessment Area.

The greatest risk areas for these relevant threats are at Ropes Creek near St Marys, in GPEC.

CHANGES TO THE STRUCTURE AND DIVERSITY OF AQUATIC VEGETATION

Changes to the structure and diversity of aquatic vegetation from weed invasion is a key threat to the Green and Golden Bell Frog. Weeds are already present within the Strategic Assessment Area. However, urban and transport development has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

The species is most susceptible to the threat of weeds from development under the Plan where new urban growth or transport occurs adjacent to known populations or habitat, in particular adjacent to the OSO and close to North St Marys along Ropes Creek in GPEC.

The Plan incorporates a range of measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Areas. This includes a number of key actions:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

The package of measures in the Plan is expected to adequately manage the risk posed to the Green and Golden Bell Frog from invasive weeds. This is because:

- Avoided lands will be zoned appropriately to enable an adequate framework for management
- The Plan provides for a landscape scale approach to managing weeds through the development and implementation of a weed management strategy
- There will be a range of planning controls to minimise the potential spread of weeds during and after construction

CHANGES TO HYDROLOGY AND WATER QUALITY

A reduction in water quality and changes to hydrology are recognised as a principal threat to the species (DEWHA, 2009c). Key issues relate to changes to drainage patterns and stormwater runoff, soil erosion and sedimentation and increased pollutants.

Development under the Plan has the potential to alter water quality and hydrology in areas of known and potential habitat for the Green and Golden Bell Frog. The areas at risk include the population associated with Ropes Creek where development of the Western Sydney Freight Line (transport corridor to the east of WSA) intersects an upstream section of the creek.

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for the species. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5) and transport (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through:

- Development controls in the nominated areas in relation to:
  - Water cycle management. For example:

        - Water management measures must comply with council's requirements for detention, drainage and water sensitive urban design principles
        - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
    - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
    - Soil erosion and sedimentation. For example:
        - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
        - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom, 2004) and submitted with each subdivision development application
- The implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the TfNSW Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the species from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts to habitat for the species
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to habitat for the species

INTENSIFICATION OF PUBLIC ACCESS TO HABITAT

Intensification of public access to habitat is identified as a threat to the species. However, populations of the Green and Golden Bell Frog adjacent to or within proximity of proposed development are already subject to this threat as they are located within highly urbanised areas. Implementation of the Plan is unlikely to change the current level of disturbance.

The Plan also incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for the species. In summary, these include:

- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate access and use by the public
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal activities
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas.
- A specific measure in relation to Commitment 5 to ensure key habitat features are protected and enhanced if the Green and Golden Bell Frog is confirmed present along Ropes Creek following targeted surveys

The package of measures in the Plan is expected to adequately manage the risk to the species from increased public access to habitat areas as a result of development. This is because:

- The Ropes Creek corridor will be protected and managed if the species is confirmed to occur there
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

PREDATION BY CATS AND OTHER PEST ANIMALS

Predation by cats and other pest animals is recognised as a threat to the Green and Golden Bell Frog. New urban development under the Plan is likely to increase the number of domestic cats in the local area. However, areas of habitat within proximity of proposed development already occur within highly urbanised areas. Any increase in the risk of predation from cats on populations of the Green and Golden Bell Frog as a result of the Plan is expected to be minimal.

The Plan also incorporates a range of measures to manage this issue across throughout the nominated areas. In summary, these include:

- A commitment (Commitment 17) to manage priority pest animals in strategic locations in the Cumberland subregion to reduce threats to land protected in the strategic conservation areas. This includes a number of actions with the most relevant to the outcome for the species being:
  - The establishment of a pest animal working group to guide the implementation of pest animal control activities under the Plan
  - Preparation of a Pest Animal Control Implementation Strategy
  - A process to enter into written agreements with delivery partners to implement the pest animal control program
  - Integration of pest control actions for conservation lands into biodiversity stewardship agreements and reserve management plans
- Development controls that will:
  - Ensure that domestic animals are appropriately contained at urban/bushland interfaces
  - Require property boundaries to have appropriate fencing to contain domestic animals within the landholders' property
  - Require appropriate management and control of pest animals relevant to development sites
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land. This includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing pests, consistent with the pest animal implementation strategy outlined in Commitment 16

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes are identified as a potential threat to the Green and Golden Bell Frog (DoE, 2014a).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact habitat for the species. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity across the Strategic Assessment Area. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant including:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the Strategic Conservation Areas that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are

permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas

- Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from potential foraging habitat. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the species from increased fire frequency as a result of development. This is because:

- Avoided lands supporting potential habitat will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat
- Fire management authorities will be engaged to ensure they understand the values relevant to the species and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

INFECTION WITH AMPHIBIAN CHYTRID FUNGUS

Amphibian chytrid fungus, which causes the infection known as chytridiomycosis, is likely to impact on populations of the Green and Golden Bell Frog. The threat to the species from chytrid fungus is not well understood, with the risk of extinction from the disease categorised as low to moderate (DEWHA, 2009b; DoEE, 2016). However, the suitability of habitat is influenced by the presence of chytrid fungus.

Chytrid fungus is already present in the Cumberland subregion, although there may be pockets of disease free areas that are inhospitable to the growth of the disease (for example, due to salinity levels or elevated concentrations of trace metals). The potential for dispersing chytridiomycosis in wild frog populations increases with urbanisation around streams. This comes from growing potential for human interaction, more water flow (urban run-off) and reduced optimal habitat. Increased risks associated with development under the Plan are minimal, however, as habitat areas are already highly urbanised.

The Plan also incorporates a range of measures to manage the risks associated with this issue. In summary, these include:

- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
  - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion (this measure specifically relates to chytrid fungus)
  - Entering into written agreements with delivery partners to implement priority disease control programs
- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures to protect the environment during construction, including best practice site hygiene protocols to minimise the spread of disease
- A specific measure in relation to Commitments 5 and 6 to incorporate best practice site hygiene protocols to manage the potential spread of chytrid fungus within construction environmental management plans, if the Green and Golden Bell Frog is confirmed present along Ropes Creek. This measure is consistent with the following priority action in the Conservation Advice (DoE, 2014a): “develop and implement suitable hygiene protocols to protect known sites from further outbreaks of chytrid fungus”

The package of measures in the Plan is expected to adequately manage the risk associated with chytrid fungus because:

- It supports a landscape scale approach to the issue across the Cumberland subregion
- It will ensure appropriate controls during construction, including a species specific measure for the Ropes Creek corridor

ROAD MORTALITY

Road mortality is identified as a potential threat to the Green and Golden Bell Frog (DoE, 2014d). This is not a novel threat to the species within the Strategic Assessment Area as roads have already been developed in proximity to habitat areas. However, implementation of the Plan will lead to new roads and an increase in the volume of cars on existing roads within nominated areas. The main area of concern is the development of the Outer Sydney Orbital downstream of habitat associated with the Ropes Creek corridor

The Plan incorporates a range of measures to manage the increased threat from road mortality. In summary, these include:

- Development controls that will require fauna-friendly road design structures to be installed and maintained in appropriate areas adjacent to fauna habitat, such as underpasses, fauna bridges and overpasses
- A commitment (Commitment 6) to mitigate indirect and prescribed impacts on threatened species from major infrastructure (transport) development on threatened species and their habitat. This includes an action to identify potential design options for major watercourse crossings to reduce disruption to connectivity and the risk of vehicle strikes, with specific reference to the Green and Golden Bell Frog

These measures are considered to adequately address any potential increased threat from road mortality due to implementation of the Plan.

10.3.2.1(I) AN ESTIMATE OF THE AREA, OR NUMBER OF POPULATIONS AND SIZE OF POPULATIONS THAT IS IN THE RESERVE SYSTEM IN NSW, THE IBRA REGION AND THE IBRA SUBREGION

There is currently approximately 340 ha of potential habitat mapped within protected areas within the area covered by the Plan. This includes potential habitat within:

- Wianamatta Regional Park
- Agnes Banks Nature Reserve

Populations are known to occur in several conservation reserves outside the Cumberland subregion.

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE SPECIES IN THE IBRA SUBREGION

The Plan includes a range of commitments that will contribute to the recovery of Green and Golden Bell Frog in the Cumberland subregion. Several commitments are described in more detail the sections above.

The key commitments and actions relevant to the species are:

- A species-specific commitment (under Commitment 5) to:
  - Undertake targeted surveys along the Ropes Creek corridor to determine the presence of the species
  - If confirmed present:
    - Consult with land managers of the riparian corridor to ensure key habitat features are protected from development impacts and enhanced
    - Incorporate site hygiene protocols to manage the potential spread of chytrid fungus
- Secure a minimum of 5,475 ha of native vegetation in conservation lands within SCAs (Commitment 8). Offset targets to secure PCTs (see Chapter 8) are likely to result in securing of additional potential habitat for Green and Golden Bell Frog in the SCAs, as there is approximately 660 ha of mapped potential habitat in the SCAs for this species
- Manage pest animals in strategic locations in the Cumberland subregion (Commitment 17) to reduce threats to conservation lands secured within SCAs. This includes preparing a Pest Animal Control Implementation Strategy to guide and co-ordinate delivery of a pest control program
- Support new or existing programs to control key diseases affecting TECs and species in the Cumberland subregion (Commitment 19)

25.10 MICROMYRTUS MINUTIFLORA

25.10.1 SPECIES BACKGROUND

Micromyrtus minutiflora is a slender spreading shrub that grows to 2 m high with solitary flowers and white petals (DEWHA, 2008).

The species flowers sporadically from June to March. Response to disturbance (such as fire or mechanical) is uncertain. Regeneration may occur as a result of re-sprouting, or germination of seeds stored within the soil (OEH, 2019g).

M. minutiflora inhabits Scribbly Gum Woodland, Cooks River/Castlereagh Ironbark Forest, Shale/Gravel Transition Forest, open forest on tertiary alluvium and consolidated river sediments (DEWHA, 2008; OEH, 2019g).

The species is endemic to the western parts of the Cumberland subregion in the Richmond-Castlereagh area and has a highly restricted distribution. The distribution overlaps with CRCIF and Castlereagh Scribbly Gum Woodland.

In 2002 there were 11 known populations with approximately 1,800 individuals across the Blacktown, Hawkesbury and Penrith Local Government Areas. In 1997, there were over 1,160 individuals in the Australian Defence Industries site and 500 individuals at Marsden Park site. Populations range from fewer than 50 plants to over 1,000 (DEWHA, 2008).

25.10.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

Micromyrtus minutiflora is being assessed as a candidate species credit species for GPEC and WSA nominated areas.

The species has been identified as a SAII entity in accordance with the requirement of section 10.2.1.4 of the BAM because it has a very highly restricted geographic distribution, which triggers Principle 3 of the BC Regulation.

25.10.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of *M. minutiflora* in relation to the subject land is shown in Map 28.

The majority of records and potential habitat for *M. minutiflora* occur to the north of the nominated areas. GPEC and WSA occur within the southern extent of the species stronghold in the Castlereagh and Londonderry areas.

There are several records of the species within GPEC located in the vicinity of Wianamatta Regional Park in the Ropes Crossing area, including one important population identified as part of the strategic assessment process under the EPBC Act. There are no records of the species within WSA.

There are no records of *M. minutiflora* within the urban capable lands of GPEC and WSA. The important population on the edge of Wianamatta Regional Park in the Ropes Crossing area occurs approximately 1.5 km from the nearest urban capable land.

The species was targeted during surveys within the nominated areas, but was not recorded.

Approximately 232 ha of potential habitat for *M. minutiflora* has been identified within GPEC and WSA. The majority of potential habitat occurs within the Wianamatta Regional Park in the northern part of GPEC, however surveys confirmed the species was not present within the OSO alignment. A smaller patch of potential habitat has been mapped in Orchard Hills in the middle part of GPEC and around Kemps Creek in WSA. The remaining habitat areas exists mainly as scattered and isolated habitat patches across the eastern half of GPEC.

25.10.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.3 of the BAM.

10.2.3.1(A) THE ACTION AND MEASURES TAKEN TO AVOID DIRECT AND INDIRECT IMPACTS

Avoidance and minimisation of impacts to biodiversity values, including *M. minutiflora*, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

The population of *M. minutiflora* within GPEC occurs outside the urban capable land and has been avoided.

The baseline mapping for this assessment has mapped 50 ha of potential habitat for *M. minutiflora* within the nominated areas (not including excluded lands). Approximately 28 ha (56 per cent) of this was avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 28 ha was avoided for biodiversity purposes
- <1 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-27.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-27 shows the amounts of habitat within excluded lands for context only.

Table 25-27: Avoidance outcomes for *M. minutiflora*

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential habitat (ha)	231	181	50	22	28	< 1	28

Avoidance of indirect impacts

Potential indirect impacts to *M. minutiflora* due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(B) THE SIZE OF THE LOCAL POPULATION DIRECTLY AND INDIRECTLY IMPACTED BY THE DEVELOPMENT

Development within GPEC and WSA will not directly impact on any records or known populations of *M. minutiflora.*

Potential indirect impacts to *M. minutiflora* potential habitat due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(C) THE EXTENT TO WHICH THE IMPACT EXCEEDS ANY THRESHOLD FOR THE POTENTIAL ENTITY

There are currently no impact thresholds for *M. minutiflora.*

10.2.3.1(D) THE LIKELY IMPACT (INCLUDING DIRECT AND INDIRECT) THAT THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION WILL HAVE ON THE HABITAT OF THE LOCAL POPULATION

Direct impacts

A total of 22 ha of potential habitat for *M. minutiflora* will be directly impacted by the development. This is 42 per cent of the potential habitat in the nominated areas (without excluded lands). The direct impacts of the development are associated with urban development. The direct impacts mainly occur:

- To scattered patches of potential habitat at Orchard Hills in the central part of GPEC, which will be impacted by urban development
- To potential habitat within the alignment of the M7/Ropes Crossing Link Road in northern GPEC
- To potential habitat within the Kemps Creek area in WSA associated with urban development

An area of potential habitat within the Wianamatta Regional Park in the northern part of GPEC is bisected by the corridor for the Outer Sydney Orbital (OSO). Survey confirmed the species was absent with the road corridor, however potential habitat is mapped either side of the OSO and would be fragmented by the proposed development.

The direct impacts of the development on *M. minutiflora* are provided in Table 25-28.

Table 25-28: Direct impacts on *M. minutiflora*

Impacts to:	Wilton*	GMAC*	WSA*	GPEC*	Transport corridors#	Total
Potential habitat (ha)	0	0	10.9	6.6	4.5	22

* Impacts from urban development only within each nominated area

Impacts from transport corridors across all nominated areas

Impacts to habitat in northern GPEC

The M7/Ropes Crossing Link Road impacts on 4.5 ha of potential habitat along the northern boundary of GPEC. Although not directly impacting on mapped habitat, the OSO corridor will lead to fragmentation of potential habitat within Wianamatta Regional Park, leading to a number of smaller, isolated patches of vegetation. This fragmentation may increase impacts associated with edge effects (primarily weeds) and this has the potential to compromise the suitability of remaining habitat areas directly adjacent to development.

The species was confirmed absent within the OSO corridor during project surveys, and the likelihood that the species occurs within lands adjacent to the corridor is considered low given:

- The area forms part of a Regional Park which is managed by the NSW NPWS and would be well traversed
- The species is relatively easy to identify when it is in flower

This low likelihood of occurrence considerably reduces the risk of impacts to *M. minutiflora* on key life-cycle processes.

Impacts to habitat at Orchard Hills

The loss of potential habitat at Orchard Hills is associated with small scattered patches of habitat that are currently surrounded by houses and farmland. The extent of cleared land in the area means that impacts are unlikely to increase edge effects to retained habitat areas or further reduce their viability. It is generally considered unlikely that potential habitat in this area contributes to the ongoing survival or viability of the species more broadly.

Impacts to habitat in WSA

Impacts to potential habitat within WSA are restricted to the Kemps Creek area and are associated with urban capable development. The impacts generally occur on the edges of larger potential habitat polygons, with the habitat surrounded by rural residential development and farmland. The extent of cleared land in the area means that impacts are unlikely to increase edge effects to retained habitat areas or further reduce their viability. It is generally considered unlikely that potential habitat in this area contributes to the ongoing survival or viability of the species more broadly.

Indirect impacts

Potential indirect impacts to *M. minutiflora* due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(E) THE LIKELY IMPACT ON THE ECOLOGY OF THE LOCAL POPULATION

As discussed in response to subsection (d) above, the loss of potential habitat within GPEC and WSA is unlikely to affect the ecology of any local population of *M. minutiflora* because the potential for the species to occur is low.

10.2.3.1(F) A DESCRIPTION OF THE EXTENT TO WHICH THE LOCAL POPULATION WILL BECOME FRAGMENTED OR ISOLATED

As discussed in response to subsection (d) above, the loss of potential habitat within the nominated areas is unlikely to fragment or isolate any local population of *M. minutiflora* because the potential for the species to occur is low.

Surveys of the OSO did not detect *M. minutiflora*, but potential habitat remains either side of the OSO corridor in Wianamatta Regional Park. This mapped potential habitat will be fragmented by the OSO. However, the low likelihood of occurrence of *M. minutiflora* in the area considerably reduces the risk of these impacts.

10.2.3.1(G) THE RELATIONSHIP OF THE LOCAL POPULATION TO OTHER POPULATION/POPULATIONS OF THE SPECIES

Potential habitat for *M. minutiflora* within GPEC and WSA occurs within the southern extent of the species stronghold in the Castlereagh and Londonderry areas.

There is one known population within GPEC on the edge of Wianamatta Regional Park near Ropes Crossing. This population is disjunct from the majority of known records which occur approximately 7 km to the north-west and are generally associated with larger, more intact remnants of native vegetation and will not be directly or indirectly impacted by development. This population is generally within the southern geographic extent of the species range, although there are two relatively recent (2014) records of the species further south near Mulgoa.

10.2.3.1(H) THE EXTENT TO WHICH THE DEVELOPMENT WILL LEAD TO AN INCREASE IN THREATS AND INDIRECT IMPACTS, INCLUDING IMPACTS FROM INVASIVE FLORA AND FAUNA, THAT MAY IN TURN LEAD TO A DECREASE IN THE VIABILITY OF THE LOCAL POPULATION

The BioNet profile for *M. minutiflora* (OEH, 2019g) identifies a range of threats to the species. Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Habitat degradation

The greatest risk areas for these relevant threats are

- Within the alignment of the M7/Ropes Crossing Link Road in northern GPEC
- Within Wianamatta Regional Park, where the OSO corridor fragments potential habitat
- At Orchard Hills, where urban development fragments potential habitat

INAPPROPRIATE FIRE REGIMES

The response of *M. minutiflora* to fire is unknown. However, altered fire regimes are an identified threat (OEH, 2019g) and a 2016 fire in the Wianamatta Nature Reserve (outside of the nominated areas to the north of GPEC) may have substantially affected the species. Increased human activity within the nominated areas increases the risk of fire to habitat areas supporting the species.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity that are expected to adequately manage the risk to the species. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for the species being:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for the species. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the

sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

WEED INVASION

M. minutiflora is threatened with invasion and competition by weeds. Weeds are already present within the Strategic Assessment Area. However, urban and transport development within GPEC has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

M. minutiflora is most susceptible to the threat of weeds from development under the Plan where new urban growth or transport occur adjacent to known populations or habitat. Key risk areas include population 108 that occurs within GPEC.

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity that are expected to adequately manage the risk to the species. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Area (SCA). This includes a number of actions, of which the following are the most relevant to the outcome of the species:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

HABITAT DEGRADATION

Habitat degradation through unrestricted public access and rubbish dumping have been identified as a key threat to *M. minutiflora* (OEH, 2019g). Development within GPEC may lead to an increase in human activity within the species' known and potential habitat areas, and this may exacerbate the threat.

The Plan incorporates a range of measures that are considered adequate to mitigating the risks associated with inappropriate habitat disturbance. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance

- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in locations where species habitat occurs in protected areas
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

10.3.2.1(I) AN ESTIMATE OF THE AREA, OR NUMBER OF POPULATIONS AND SIZE OF POPULATIONS THAT IS IN THE RESERVE SYSTEM IN NSW, THE IBRA REGION AND THE IBRA SUBREGION

There is currently approximately 2,036 ha of potential habitat mapped within protected areas within the area covered by the Plan. This includes potential habitat within:

- Castlereagh Nature Reserve
- Wianamatta Regional Park
- Wianamatta Nature Reserve
- Agnes Banks Nature Reserve
- Windsor Downs Nature Reserve

Four populations occur on public land managed for conservation. They are:

- Castlereagh Nature Reserve – two populations
- Wianamatta Regional Park – one population
- Wianamatta Nature Reserve – one population
- Agnes Banks Nature Reserve – one population

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE SPECIES IN THE IBRA SUBREGION

The Plan includes a range of commitments and actions that will contribute to the recovery of *M. minutiflora* in the Cumberland subregion. The key commitments and actions relevant to the species are:

- Secure a minimum of 5,475 ha of native vegetation in conservation lands within SCAs (Commitment 8). Offset targets to secure PCTs (see Chapter 8) are likely to result in securing of additional potential habitat for *M. minutiflora* in the SCAs, as there is approximately 3,818 ha of mapped potential habitat in the SCAs for this species
- Manage weeds in strategic locations in the Cumberland subregion (Commitment 16) to reduce threats to conservation lands secured within SCAs. This includes preparing a Weed Control Implementation Strategy to guide and co-ordinate delivery of a weed control program
- Manage fire in strategic locations in the Cumberland subregion (Commitment 18) to support the maintenance of biodiversity values on land secured within SCAs. This includes:
    - Consulting with Rural Fire Service, NSW NPWS, and EES to identify fire management priorities, including fire sensitive species and ecological communities
    - Preparing a Fire Management Strategy to guide and co-ordinate fire management

25.11 RAPTORS

This assessment addresses three raptor species together – White-bellied Sea-Eagle (*Haliaeetus leucogaster*), Little Eagle (*Hieraaetus morphnoides*) and Square-tailed Kite (*Lophoictinia isura*).

25.11.1 SPECIES BACKGROUND

LITTLE EAGLE

Little Eagle is a medium-sized bird of prey that occurs throughout the Australian mainland except the most densely forested parts of the Dividing Range escarpment (OEH, 2017h). The species is found throughout NSW, but is more common in the western two-thirds of the state (Saunders and Debus, 2018a).

The species inhabits open eucalypt forest, woodland or open woodland. It also occurs in Sheoak or Acacia woodlands and riparian woodlands of interior NSW (OEH, 2017h).

Little Eagle generally nests in tall living eucalypts (between 5 and 30 m) in open forest, woodland, and remnant woodland within farmland. Nests are generally between 13 and 20 m above ground. They prefer to nest in dense woodland adjacent to open habitat (e.g. grassy woodland) for foraging. Nests are typically:

- In an emergent eucalypt, the tallest in the stand and often with the largest girth
- In woodland patches at least 4.8 ha in size (average 85 ha)
- Mostly within 200 m of the edge of habitat
- More distant from sealed roads (average 838 m) than gravel roads (average 546 m) than tracks (average 304 m)
- At least 38 m from the nearest dwelling (average 457 m)
- At least 1 km from urban development (Saunders and Debus, 2018a)

Little Eagle will forage up to 3 km from the nest, which gives a maximum breeding/foraging territory of 2,800 hectares. Banding data suggest that birds occupy a home range for at least 6-10 years (Saunders and Debus, 2018a).

The species occurs as a single population throughout NSW (OEH, 2017h).

SQUARE-TAILED KITE

Square-tailed Kite is a reddish, medium-sized raptor that occurs along coastal and subcoastal areas from south-western to northern Australia, NSW, Queensland, and Victoria. There are scattered records across NSW (OEH, 2017j).

The species inhabits a variety of forests, including dry woodlands and open forests (OEH, 2017j). Square-tailed Kite prefers timbered watercourses through open or cleared land and the margins between open and timbered country, and can tolerant human disturbance and urban bushland (Saunders and Debus, 2018b).

Nests are generally located along or near watercourses and on the edge of habitat areas, in a fork or on horizontal limbs of a large living trees, and mostly between 15 and 28 m above ground (Saunders and Debus, 2018b).

The species appears to be monogamous as breeding pairs, as they are intolerant of other adults within their breeding territory, and they occupy the same nest site for many years (Saunders and Debus, 2018b).

The species migrates in the summer to south-east NSW to breed, arriving in September and leaving by March (OEH, 2017j). In the Cumberland subregion, breeding has been recorded from July to February (Saunders and Debus, 2018b).

The species occupies large hunting ranges of more than 100 km^2.

WHITE-BELLIED SEA-EAGLE

The White-bellied Sea-Eagle is a large eagle that has long, broad wings and a short, wedge-shaped tail that occurs around the Australian coastline and inland along rivers and wetlands of the Murray Darling Basin. In NSW, it is widespread along the east coast, and along all major inland rivers and waterways (OEH, 2017k).

The species occurs in a variety of habitats, including coastal dunes, tidal flats, grassland, heathland, woodland, and forest close to large bodies of open water including larger rivers, swamps, lakes, and the ocean (OEH, 2017k).

Breeding habitat is constrained to living or dead mature trees within forests or tall woodland within 1 km of rivers, lakes, large dams or creeks, wetlands and coastlines. Nest are generally located in large emergent eucalypts, often with emergent dead branches or large dead trees nearby, which are used as 'guard roosts' (OEH, 2017k).

25.11.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

The raptors are being assessed as candidate species credit species in terms of breeding habitat for all nominated areas.

The raptors have been identified as potential SAII entities in accordance with the requirement of section 10.2.1.4 of the BAM because of the potential for the development to impact breeding habitat that cannot readily be created at a stewardship site. This SAII assessment addresses direct and indirect impacts on breeding habitat only.

An expert report was prepared for Little Eagle and Square-tailed Kite. Potential breeding habitat for the raptors was mapped on the basis of the expert reports, as well as a KBM, as follows:

- Little Eagle:
    - An expert report for Wilton and GMAC (Saunders and Debus, 2018a) and addendum letter (Saunders, 2020)
    - A KBM for WSA and GPEC
- Square-tailed Kite:
    - An expert report for Wilton and GMAC (Saunders and Debus, 2018b) and addendum letter (Saunders, 2020)
    - A KBM for WSA and GPEC
- White-bellied Sea-Eagle: A KBM for all four nominated areas

The expert reports involved:

- Targeted surveys within the most likely areas of potential breeding and foraging habitat for these species
- Identification of potential breeding and foraging habitat within the nominated areas
- Targeted surveys in potential habitat by the expert as part of preparing the expert report as well as Biosis as part of other targeted surveys for this project (the Biosis surveys were taken into account in preparing the expert report)

The addendum refined the mapping of potential breeding and foraging habitat and clarified the location of such habitat.

25.11.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of the raptors in relation to the subject land is shown in Map 29.

Records

Little Eagle

The majority of records of the Little Eagle within the Cumberland subregion are recorded on the Cumberland Plain. This includes 35 records within the nominated areas, or within 5 km of the nominated area boundaries.

Most records are associated with large patches of open woodland that occur within open grassland areas. Some records are found close to the edges of forests along watercourses. A few records were from woodlands associated with wetlands. The records support the conclusion that a mosaic of open woodland and open grassland with scattered trees provides important foraging habitat for the Little Eagle (Saunders and Debus, 2018a).

The expert report concluded that there is a very high likelihood that Little Eagle occurs in the nominated areas at any time of the year and that the nominated areas provide good foraging habitat for the species. There are likely to be 4 to 6 resident pairs resident in Wilton and GMAC, including (Saunders and Debus, 2018a):

- 1 pair in the northern part of GMAC
- 2 pairs in the middle part of GMAC
- 1 pair in the southern part of GMAC
- 1 pair in Wilton

Square-tailed Kite

Square-tailed Kite was seldom recorded in the Cumberland subregion prior to 1990, but the number of records has increased over the last two decades. All records for the Liverpool, Campbelltown and Wollondilly Local Government Areas are more recent than 2000. There are breeding records within the subregion, from near Asquith in 2012, Lane Cove National Park in 2015, and more recently near Penrith, Asquith and South Turramurra (Saunders and Debus, 2018b).

There are 32 records in the nominated areas, including 12 within Wilton and the southern part of GMAC. Another 15 records occur within 5 km of the nominated areas, with 11 occurring just outside the northern part of GMAC. The majority of records are from January to April, which represents the post-breeding dispersal phase (Saunders and Debus, 2018b).

The expert report concluded that there is a very high likelihood that Square-tailed Kite occurs in the nominated areas during the breeding season, and that the nominated areas provide good foraging habitat for the species. There are likely to be 2 to 3 breeding pairs of Square-tailed Kite resident in Wilton and GMAC, including:

- 1 pair centred along the Georges River along the eastern edge of the northern part of GMAC
- 1 pair in the Appin Road area that extends into contiguous forest to the east of the southern part of GMAC
- Possibly 1 pair in the southern part of Wilton

White-bellied Sea-Eagle

There are many records of the White-bellied Sea-Eagle in the Cumberland subregion, although the majority in the Sydney Basin bioregion occur to the east of the subregion along the coast, to the north and south of Sydney.

There are several records of the species in the nominated areas. There is one old record in GPEC and two records in the central part of WSA, including a recent (2017) record. There is a cluster of relatively recent records (2013) within or just outside the central part of GPEC, and several other records in the southern part of GPEC. There are several recent (2018) records just outside the northern part of the GPEC to the east. There are no records in Wilton.

POTENTIAL BREEDING HABITAT

Potential breeding habitat for the raptors has been mapped in all nominated areas.

Potential breeding habitat for Little Eagle and Square-tailed Kite occurs in the urban capable lands of GPEC, GMAC and WSA, and for White-bellied Sea-Eagle, occurs in the urban capable lands of all nominated areas.

Little Eagle

No nests have been recorded in the nominated areas and no evidence of breeding was observed during surveys by ecological consultants or by the authors of the expert report. As the Little Eagle is considered to be resident for at least several consecutive years while nesting, it is likely that if nesting has occurred within the nominated areas it would have been detected. However, suitable nesting habitat is still considered to occur within the nominated areas (Saunders and Debus 2018a). This view is supported by the occurrence of species records within and around the nominated areas in the breeding season (e.g. a mating pair was observed by Starr et al. (2004) near Camden (Saunders and Debus 2018a)).

Square-tailed Kite

There is a very high likelihood that Square-tailed Kite occurs within the nominated areas during the breeding season. However, no nests have been recorded in the nominated areas. Breeding was not observed during surveys by the ecological consultants or by the authors of the expert report. As other bird species build similar stick nests it is difficult to identify a Square-tailed Kite nest without the bird being in attendance, which would be required to confirm breeding habitat. The breeding habitat areas indicated in the expert reports (Saunders and Debus 2018b) are based on the minimum criteria presented in Tables 1 and 2 of the report.

Note that the conclusions in the expert reports are supported by mapping showing 'Breeding and foraging habitat' for Little Eagle and Square-tailed Kite. This habitat is generally restricted to areas outside urban capable lands. Further clarification was sought from the experts and additional refinement of the mapping was completed in June 2020 (Saunders, 2020). The refined mapping was used to define breeding habitat for the species in GMAC and Wilton and calculate impacts consistent with the BAM. KBM mapping was used to identify potential breeding habitat in GPEC and WSA

25.11.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.3 of the BAM.

10.2.3.1(A) THE ACTION AND MEASURES TAKEN TO AVOID DIRECT AND INDIRECT IMPACTS

Avoidance and minimisation of impacts to biodiversity values, including the raptors, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

Little Eagle

The baseline mapping for this assessment has mapped 4,163 ha of potential breeding habitat for Little Eagle within the nominated areas (not including excluded lands). Approximately 3,006 ha (99 per cent) of this was avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 2,311 ha was avoided for biodiversity purposes
- 696 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-29.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-29 shows the amounts of habitat within excluded lands for context only.

Table 25-29: Avoidance outcomes for Little Eagle

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential breeding habitat (ha)	4,163	1,137	3,026	18.9	2,311	696	3,006

Square-tailed Kite

The baseline mapping for this assessment has mapped 4,246 ha of potential breeding habitat for White-bellied Sea-Eagle within the nominated areas (not including excluded lands). Approximately 2,955 ha (99 per cent) of this was avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 2,279 ha was avoided for biodiversity purposes
- 676 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-30.

Table 25-30: Avoidance outcomes for Square-tailed Kite

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential breeding habitat (ha)	4,246	1,264	2,983	27.8	2,279	676	2,955

White-bellied Sea-Eagle

The baseline mapping for this assessment has mapped 2,485 ha of potential breeding habitat for White-bellied Sea-Eagle within the nominated areas (not including excluded lands). Approximately 1,661 ha (99 per cent) of this was avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 1,066 ha was avoided for biodiversity purposes
- 596 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-31.

Table 25-31: Avoidance outcomes for White-bellied Sea-Eagle in all four nominated areas

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential breeding habitat (ha)	2,485	806	1,679	16.6	1,066	596	1,661

Avoidance of indirect impacts

Potential indirect impacts to the raptors due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(B) THE SIZE OF THE LOCAL POPULATION DIRECTLY AND INDIRECTLY IMPACTED BY THE DEVELOPMENT

Little Eagle and Square-tailed Kite

There are likely to be 4 to 6 resident pairs of Little Eagle, and 2 to 3 breeding pairs of Square-tailed Kite (that will use the areas for foraging during the breeding season), in Wilton and GMAC.

The expert report found no evidence of breeding of Little Eagle of Square-tailed Kite, as defined by the presence of a bird on a nest, or the presence of pairs of birds in potential habitat, in Wilton or GMAC. Refined mapping completed in June 2020 did map areas of potential breeding habitat in both Wilton and GMAC (Saunders, 2020).

It is uncertain whether Little Eagle or Square-Tailed Kite resides in GPEC or WSA, or the number of resident individuals. Potential breeding habitat occurs in these nominated areas, and relatively recent records occur within or in close proximity to the nominated areas. It is considered likely that the species uses the nominated areas at least for foraging.

White-bellied Sea-Eagle

It is uncertain whether White-bellied Sea-Eagle resides in any of the nominated areas, and if it does occur, the number of potential resident individuals. Potential breeding habitat occurs in each of the nominated areas, particularly Wilton and GMAC, and recent records occur in WSA and particularly within or just outside the central part of GPEC. It is considered likely that the species uses the nominated areas at least for foraging.

10.2.3.1(C) THE EXTENT TO WHICH THE IMPACT EXCEEDS ANY THRESHOLD FOR THE POTENTIAL ENTITY

There are currently no impact thresholds for the raptors.

10.2.3.1(D) THE LIKELY IMPACT (INCLUDING DIRECT AND INDIRECT) THAT THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION WILL HAVE ON THE HABITAT OF THE LOCAL POPULATION

Direct impacts

The direct impacts of the development on the raptors are provided in Table 25-32. The direct impacts are mainly associated with the transport corridors. For all raptors, the impacts mainly occur:

- In Wianamatta Regional Park where the OSO intersects an area of habitat, which will fragment this habitat into two patches and lead to the isolation of one of the patches from the remainder of habitat in the regional park
- In the central part of the nominated area where the OSO mostly removes habitat associated with riparian corridors
- To the edges of smaller scattered patches of habitat in WSA that are mainly associated with riparian corridors

For Little Eagle and Square-tailed Kite potential breeding habitat is impacted in the central southern area of GMAC by urban development.

It is important to note that potential foraging habitat was also mapped within GMAC and Wilton for Little Eagle and Square-tailed Kite (Saunders, 2020). The potential foraging habitat is generally represented by grassed paddocks adjacent to mapped potential breeding habitat and are not considered to be impacts to breeding habitat requiring credit calculations under the BAM. In total 2,838 ha of Little Eagle potential foraging habitat is mapped across GMAC and Wilton, with 1,323 ha impacted. For Square-tailed Kite 1,623 ha of potential foraging habitat is mapped across GMAC and Wilton, with 511 ha impacted.

For White-bellied Sea-Eagle in Wilton and GMAC, impacts also occur to the edges of potential breeding habitat that is associated with gullies and gorges that run down to the Nepean River.

Table 25-32: Direct impacts on potential breeding habitat (ha) for raptors

Impacts to:	Wilton*	GMAC*	WSA*	GPEC*	Transport corridors#	Total
Little Eagle	0	14.7	0.5	0.5	3.2	18.9
Square-tailed Kite	0	14.7	0.2	0.3	12.6	27.8
White-bellied Sea-Eagle	2	8.5	0.2	0.3	5.5	16.6

* Impacts from urban development only within each nominated area

Impacts from transport corridors across all nominated areas

Direct impacts to potential breeding habitat for the raptors are unlikely to affect life cycle processes or impact the viability of any local populations of raptors because:

- While there are likely to be resident pairs of Little Eagle and Square-tailed Kite in Wilton and GMAC, there are no direct impacts on potential breeding habitat for these species in Wilton and only relatively minor impacts on potential breeding habitat in GMAC
- In GPEC and WSA, and in relation to White-bellied Sea-Eagle, in Wilton and GMAC, direct impacts to potential breeding habitat for raptors are very small relative to the amount of potential breeding habitat remaining
- Impacts generally occur to the edges of potential breeding habitat that in most cases remains connected to larger patches of habitat associated with gullies and gorges that run down to the Nepean River or along riparian corridors. This reduces the risk that potential breeding habitat becomes isolated from foraging habitat

The development will lead to some fragmentation of potential breeding habitat. This mainly occurs:

- GPEC:
  - In Wianamatta Regional Park where the OSO will fragment habitat into two patches
  - In the central part of the nominated area where the OSO will reduce the size of some habitat patches
- WSA: Along some riparian corridors where the development will reduce the size of patches to some extent
- GMAC and Wilton: Along the edges of habitat associated with waterways, gullies and gorges and, for Little Eagle and Square-tailed Kite, some fragmentation of habitat within the southern area of GMAC

In most cases, this fragmentation will lead to a small reduction in the size of some potential breeding habitat patches as impacts mainly occur only to the edges of patches. Particularly in Wilton and the southern part of GMAC, potential breeding habitat usually remains connected to large areas of habitat associated with waterways, gullies and gorges in the nominated areas, as well as large patches of habitat outside the nominated areas. In WSA, impacts mainly occur to the edges of riparian corridors which generally remain connected along their length.

It is also important to note that in Wilton, the development will not impact potential breeding habitat for Little Eagle and Square-tailed Kite and therefore no fragmentation or isolation of habitat will occur.

As a result, it is not considered that the development is likely to significantly fragment or isolate the likely resident pairs of Little Eagle and Square-tailed Kite and any population of White-bellied Sea-Eagle in Wilton and GMAC, or fragment or isolate any populations of these species in the WSA or GPEC.

Indirect impacts

Potential indirect impacts to the raptors due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(E) THE LIKELY IMPACT ON THE ECOLOGY OF THE LOCAL POPULATION

As discussed in response to subsection (d) above, the loss of potential breeding habitat is unlikely to affect the ecology of any local populations of raptors because:

- While there are likely to be resident pairs of Little Eagle and Square-tailed Kite in Wilton and GMAC, there are no direct impacts on potential breeding habitat for these species in Wilton and only relatively minor impacts on potential breeding habitat in GMAC
- Direct impacts to potential breeding habitat for raptors are very small relative to the amount of habitat remaining

10.2.3.1(F) A DESCRIPTION OF THE EXTENT TO WHICH THE LOCAL POPULATION WILL BECOME FRAGMENTED OR ISOLATED

As discussed in response to subsection (d) above, the loss of potential breeding habitat is unlikely to fragment or isolate any local populations of raptors because in most cases, impacts mainly occur only to the edges of patches and potential breeding habitat usually remains connected to large areas of habitat or along riparian corridors. Furthermore, in Wilton, the development will not impact potential breeding habitat for Little Eagle and Square-tailed Kite and therefore no fragmentation or isolation of habitat for these species will occur.

10.2.3.1(G) THE RELATIONSHIP OF THE LOCAL POPULATION TO OTHER POPULATION/POPULATIONS OF THE SPECIES

There are likely to be 4 to 6 resident pairs of Little Eagle, and 2 to 3 breeding pairs of Square-tailed Kite (that will use the areas for foraging during the breeding season), in Wilton and GMAC. It is uncertain whether White-bellied Sea-Eagle resides in any of the nominated areas, and if it does occur, the number of potential resident individuals.

The importance of these resident pairs to other populations outside the nominated areas is uncertain.

Little Eagle occurs as a single population throughout NSW (OEH, 2017h), while Square-tailed Kite appears to be monogamous as breeding pairs, as they are intolerant of other adults within their breeding territory, and they occupy the same nest site for many years (Saunders and Debus, 2018b).

The expert report found no evidence of breeding of Little Eagle or Square-tailed Kite, as defined by the presence of a bird on a nest, or the presence of pairs of birds in potential habitat, in Wilton or GMAC. If breeding does not occur within the nominated areas, it is likely that these species breed outside the nominated areas and use the nominated areas for foraging.

10.2.3.1(H) THE EXTENT TO WHICH THE DEVELOPMENT WILL LEAD TO AN INCREASE IN THREATS AND INDIRECT IMPACTS, INCLUDING IMPACTS FROM INVASIVE FLORA AND FAUNA, THAT MAY IN TURN LEAD TO A DECREASE IN THE VIABILITY OF THE LOCAL POPULATION

The BioNet profiles for the three species identify a range of threats. Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Non-target poisoning during pest animal control
- Habitat disturbance

Non-target poisoning during pest animal control

Accidental poisoning during pest animal control is recognised as a threat to the species. Poisoning of pest animals may occur during implementation of the Plan as part of the Pest Animal Control Implementation Strategy (Commitment 17, Action 1).

To mitigate the risk to the three raptor species, the Plan includes a specific commitment and a specific action to address the threat. These are:

- Commitment 17.1 – "*Reduce the risk of secondary poisoning from pesticides for the following threatened raptor species:*
  - *Little Eagle*
  - *Spotted Harrier*
  - *Square-tailed Kite*
  - *White-bellied Sea-Eagle"*
- Commitment 17.1, Action 4 – "*Ensure that the Pest Animal Control Implementation Strategy specifies the use of pest control techniques that will reduce the risk of secondary poisoning from Pindone or second-generation rodenticides"*

These measures are considered adequate to address the threat to the species.

Habitat disturbance

Habitat disturbance (particularly to nest sites) is recognised as a threat to the species. Habitat disturbance can occur due to a range of mechanisms including:

- Uncontrolled access to areas of high biodiversity
- Inappropriate land management practices

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance which are considered adequate for protecting the species. In summary, these include:

- Retaining large trees (including dead trees) (≥50cm DBH) during precinct planning where possible and avoid impacts to soil within the dripline of these trees during construction (under Commitment 5)
- Establishing ecological setbacks for raptor nests to provide a buffer to adjacent development
- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas. This commitment is consistent with a number of actions in the Conservation Advice around educating the community about the TEC

10.3.2.1(I) AN ESTIMATE OF THE AREA, OR NUMBER OF POPULATIONS AND SIZE OF POPULATIONS THAT IS IN THE RESERVE SYSTEM IN NSW, THE IBRA REGION AND THE IBRA SUBREGION

An estimate of the potential breeding habitat for raptors in protected lands in the area covered by the Plan is:

- Little Eagle: 197 ha
- Square-tailed Kite: 232 ha
- White-bellied Sea-Eagle: 249 ha

Each of the raptors has been recorded within several of the following protected lands within and outside the Cumberland subregion, including:

- Wianamatta Nature Reserve
- Dharawal National Park
- Dharug National Park
- Scheyville National Park
- Cattai National Park
- Yengo National Park
- Blue Mountains National Park
- Dharawal National Park
- Royal National Park
- Castlereagh Nature Reserve
- Windsor Downs Nature Reserve

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE SPECIES IN THE IBRA SUBREGION

The Plan includes a range of commitments that will contribute to the recovery of the raptors in the Cumberland subregion. Several commitments are described in more detail the sections above.

The key commitments and actions relevant to the species are:

- Species-specific commitments under Commitment 5 to retain large trees (including dead trees) (≥50cm DBH) during precinct planning where possible and establish ecological setbacks for raptor nests to provide a buffer to adjacent development
- Ensuring that the Pest Animal Control Implementation Strategy specifies the use of pest control techniques that will reduce the risk of secondary poisoning from Pindone or second-generation rodenticides (Commitment 17.1)
- Secure a minimum of 5,475 ha of native vegetation in conservation lands within SCAs (Commitment 8). Offset targets to secure PCTs (see Chapter 8) are likely to result in securing of additional potential breeding habitat for raptors in the SCAs, as there is approximately 15,000 ha of mapped potential breeding habitat in the SCAs for these species

25.12 PSEUDOPHRYNE AUSTRALIS

25.12.1 SPECIES BACKGROUND

Red-crowned Toadlet (*Pseudophryne australis*) is a small frog that is dark brown to black, with distinctive reddish-orange patches. It is a relatively long-lived species (up to 8 to 10 years) (OEH, 2019h).

The species inhabits periodically wet drainage lines below sandstone ridges within open forests, mostly at the interface of Hawkesbury sandstone and Wianamatta and Narrabeen shale (OEH, 2019h).

The Red-crowned Toadlet appears to be largely restricted to the immediate vicinity of suitable breeding habitat. Breeding habitat comprises dense vegetation and debris beside ephemeral creeks and gutters (OEH, 2019h). The species deposits eggs in terrestrial nests beneath rocks and logs or in leaf litter, and relies on rainfall to wash the partially developed tadpoles into ephemeral creeks for completion of the reproductive cycle (NSW Scientific Committee, 2002).

Outside the breeding period, the species disperses to refuge areas close to breeding sites, under rocks and amongst masses of dense vegetation or thick piles of leaf litter generally on sandstone ridges (OEH, 2019h).

The Red-crowned Toadlet has a restricted distribution. It is confined to the Sydney Basin, from Pokolbin in the north, the Nowra area to the south, and west to Mt Victoria in the Blue Mountains (OEH, 2019h).

Records for the species are widespread surrounding the Cumberland subregion, but few records occur in the subregion.

25.12.2 ASSESSMENT UNDER THE STRATEGIC BIODIVERSITY CERTIFICATION

The Red-crowned Toadlet is being assessed as a candidate species credit species for GPEC, GMAC and Wilton.

The species has been identified as a potential SAII entity in accordance with the requirement of section 10.2.1.4 of the BAM because of its very high susceptibility to the disease chytrid fungus, which triggers Principle 4 of the BC Regulation.

25.12.3 OCCURRENCE IN RELATION TO THE SUBJECT LAND

The occurrence of Red-crowned Toadlet in relation to the subject land is shown in Map 30.

There are no records for the Red-crowned Toadlet within the nominated areas. The closest records occur within a few kilometres of GPEC, GMAC and Wilton.

Approximately 1,090 hectares of potential habitat for Red-crowned Toadlet has been identified within the nominated areas. This occurs in Wilton and GMAC. No potential habitat was mapped within GPEC.

Potential habitat in Wilton and GMAC generally occurs in scattered patches within the vicinity of gorges and gullies that occur mainly around the edges of the nominated areas. The vast majority of potential habitat in GMAC is restricted to the southern part of the nominated area, with only one small patch of habitat occurring in the northern part.

25.12.4 IMPACT ASSESSMENT

The following assessment addresses the provisions set out in section 10.2.3 of the BAM.

10.2.3.1(A) THE ACTION AND MEASURES TAKEN TO AVOID DIRECT AND INDIRECT IMPACTS

Avoidance and minimisation of impacts to biodiversity values, including Red-crowned Toadlet, was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

Avoidance of direct impacts

No known populations of Red-crowned Toadlet occur within GMAC and Wilton. Avoidance of impacts to populations was therefore not a relevant consideration for this species.

The baseline mapping for this assessment has mapped 884 ha of potential habitat for Red-crowned Toadlet within the nominated areas (not including excluded lands). Approximately 875 ha (99 per cent) of this was avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 652 ha was avoided for biodiversity purposes
- 223 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 25-33.

It is important to note that the avoidance calculations in the table including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands. Table 25-33 shows the amounts of habitat within excluded lands for context only.

Table 25-33: Avoidance outcomes for Red-crowned Toadlet

Avoidance of:	Total in nominated areas	Total in excluded lands	Total without excluded lands	Directly impacted	Avoided for biodiversity purposes	Avoided for other purposes	Total avoidance
Potential habitat (ha)	1,090	206	884	9.0	652	223	875

Avoidance of indirect impacts

Potential indirect impacts to Red-crowned Toadlet due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(B) THE SIZE OF THE LOCAL POPULATION DIRECTLY AND INDIRECTLY IMPACTED BY THE DEVELOPMENT

Development within GMAC and Wilton will not directly impact any known populations of Red-crowned Toadlet.

10.2.3.1(C) THE EXTENT TO WHICH THE IMPACT EXCEEDS ANY THRESHOLD FOR THE POTENTIAL ENTITY

There are currently no impact thresholds for Red-crowned Toadlet.

10.2.3.1(D) THE LIKELY IMPACT (INCLUDING DIRECT AND INDIRECT) THAT THE DEVELOPMENT, CLEARING OR BIODIVERSITY CERTIFICATION WILL HAVE ON THE HABITAT OF THE LOCAL POPULATION

Direct impacts

A total of 9 ha of potential habitat for Red-crowned Toadlet will be directly impacted by the development. This is 1.0 per cent of the potential habitat in the nominated areas (without excluded lands). The direct impacts of the development are associated with urban development. The direct impacts mainly occur at the very edges of potential habitat associated with gorges and gullies that run down to the Nepean River, in the following locations:

- Scattered areas of Wilton
- Southern part of GMAC

The direct impacts of the development on Red-crowned Toadlet are provided in Table 25-34.

Table 25-34: Direct impacts on Red-crowned Toadlet

Impacts to:	Wilton*	GMAC*	WSA*	GPEC*	Transport corridors#	Total
Potential habitat (ha)	3.3	5.8	0	0	0	9.0

* Impacts from urban development only within each nominated area

Impacts from transport corridors across all nominated areas

The impacts to the areas of potential habitat within Wilton and GMAC are unlikely to impact the ongoing survival or viability of the Red-crowned Toadlet in the local area because:

- Only a very small proportion (1.0 per cent) of this potential habitat is directly impacted. The vast majority of potential habitat has been avoided for biodiversity or other purposes
- There are no records or known populations of the species in the area. While many records of the species occur surrounding the Cumberland subregion, the species is generally not known from the subregion
- The impacts are unlikely to cause fragmentation or isolation of habitat because, where impacts occur, only the edges of potential habitat at the tops of gorges and gullies are impacted
- The corridors of potential habitat that exist along gorges and gullies are maintained

Indirect impacts

Potential indirect impacts to Red-crowned Toadlet due to the development, including mitigation measures under the Plan to avoid and manage these impacts, are assessed in subsection (h).

10.2.3.1(E) THE LIKELY IMPACT ON THE ECOLOGY OF THE LOCAL POPULATION

As discussed in response to subsection (d) above, the loss of potential habitat within Wilton and GMAC is unlikely to affect the ecology of any local population of Red-crowned Toadlet because:

- Only a very small proportion (1.0 per cent) of this potential habitat is directly impacted
- There are no records or known populations of the species in the locality and the species is generally not known from the subregion, reducing the risk that breeding habitat occurs in the locality

10.2.3.1(F) A DESCRIPTION OF THE EXTENT TO WHICH THE LOCAL POPULATION WILL BECOME FRAGMENTED OR ISOLATED

As discussed in response to subsection (d) above, the loss of potential habitat within Wilton and GMAC is unlikely to fragment and isolate any local population because impacts occur only to the very edges of potential habitat and the corridors of potential habitat that exist along gorges and gullies are maintained.

10.2.3.1(G) THE RELATIONSHIP OF THE LOCAL POPULATION TO OTHER POPULATION/POPULATIONS OF THE SPECIES

Development within Wilton and GMAC will not directly impact any records or known populations of Red-crowned Toadlet. No populations are known from these nominated areas.

Potential habitat within Wilton and GMAC is not at the limit of the species range. Records for the species are widespread surrounding the Cumberland subregion.

10.2.3.1(H) THE EXTENT TO WHICH THE DEVELOPMENT WILL LEAD TO AN INCREASE IN THREATS AND INDIRECT IMPACTS, INCLUDING IMPACTS FROM INVASIVE FLORA AND FAUNA, THAT MAY IN TURN LEAD TO A DECREASE IN THE VIABILITY OF THE LOCAL POPULATION

The BioNet profile for the Red-crowned Toadlet identifies a range of threats to the species (OEH, 2019h). Where these threats are present in the nominated areas and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. As outlined in Chapter 15 (Section 15.5 and Attachment A), the following potential threats or indirect impacts are considered relevant to implementation of the Plan:

- Reduction in water quality
- Inappropriate fire regimes
- Habitat disturbance including collection of bush rock and recreational activities
- Infection with amphibian chytrid fungus

The greatest risk areas for these relevant threats are at the edges of potential habitat associated with gorges and gullies that run down to the Nepean River in the northern part of Wilton, and the western part of GMAC.

REDUCTION IN WATER QUALITY

A reduction in water quality and changes to hydrology are recognised as a principal threat to the species (OEH, 2019h). Key issues relate to increased pollutants in runoff from developed areas.

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for the species. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5) and transport (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through:

- Development controls in the nominated areas in relation to:
  - Water cycle management. For example:
    - Water management measures must comply with council’s requirements for detention, drainage and water sensitive urban design principles
    - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
  - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
  - Soil erosion and sedimentation. For example:
    - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
    - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom, 2004) and submitted with each subdivision development application
- The implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the TfNSW Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to the species from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts to habitat for the species
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to habitat for the species

INAPPROPRIATE FIRE REGIMES

High frequency fire is identified as a potential threat to the Red-crowned Toadlet (OEH, 2019h).

Increased human activity within the nominated areas increases the risk of arson or accidental fires and may lead to further increases in fire frequency that could impact habitat for the species. Key risk areas are those that are easily accessible to the public and in close proximity to urban development. Bushfire management by authorities is also likely in areas close to new urban development.

The Plan incorporates a range of measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant including:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy for the Strategic Conservation Areas that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
    - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from potential foraging habitat. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes

The package of measures in the Plan is expected to adequately manage the risk to the species from increased fire frequency as a result of development. This is because:

- Avoided lands supporting potential habitat will be zoned appropriately to enable an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting habitat
- Fire management authorities will be engaged to ensure they understand the values relevant to the species and incorporate these values into their fire management practices. This will include specific fire management approaches for conservation areas

HABITAT DISTURBANCE INCLUDING COLLECTION OF BUSH ROCK AND RECREATIONAL ACTIVITIES

Inappropriate habitat disturbance has been identified as a threat to the Red-crowned Toadlet (OEH, 2019h).

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for the Red-crowned Toadlet. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas. This commitment is consistent with a number of actions in the Conservation Advice around educating the community about the Red-crowned Toadlet

The package of measures in the Plan is expected to adequately manage the risk to the Red-crowned Toadlet from inappropriate habitat disturbance as a result of development. This is because:

- Avoided lands where areas of mapped habitat for Red-crowned Toadlet occur will be zoned appropriately to enable an adequate framework for management
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

INFECTION WITH AMPHIBIAN CHYTRID FUNGUS

Amphibian chytrid fungus, which causes the infection known as chytridiomycosis, is recognised as a threat to the Red-crowned Toadlet (OEH, 2019h).

Chytrid fungus is already present in the Cumberland subregion, although there may be pockets of disease free areas that are inhospitable to the growth of the disease (for example, due to salinity levels or elevated concentrations of trace metals).

The Plan incorporates a range of measures to manage the risks associated with diseases, pathogens and dieback. In summary, these include:

- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
  - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
  - Entering into written agreements with delivery partners to implement priority disease control programs
- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures methods to protect the environment during construction, including best practice site hygiene protocols to minimise the spread of disease

The package of measures in the Plan is expected to adequately manage the risk to potential habitat from diseases, pathogens and dieback because:

- It supports a landscape scale approach to the issue across the Cumberland subregion
- It will ensure appropriate controls during construction

10.3.2.1(I) AN ESTIMATE OF THE AREA, OR NUMBER OF POPULATIONS AND SIZE OF POPULATIONS THAT IS IN THE RESERVE SYSTEM IN NSW, THE IBRA REGION AND THE IBRA SUBREGION

There is currently approximately 27 ha of potential habitat for the Red-crowned Toadlet mapped within protected areas in the area covered by the Plan. This comprises potential habitat within the Upper Nepean State Conservation Area.

Populations are known from many reserves managed for conservation outside the Cumberland subregion, including:

- Nattai National Park
- Blue Mountains National Park
- Wollemi National Park
- Dharawal National Park
- Royal National Park
- Berowra Valley National Park

10.3.2.1(J) THE MEASURES PROPOSED TO CONTRIBUTE TO THE RECOVERY OF THE SPECIES IN THE IBRA SUBREGION

The Plan includes a range of commitments that will contribute to the recovery of Red-crowned Toadlet in the Cumberland subregion. Several commitments are described in more detail the sections above.

The key commitments and actions relevant to the species are:

- Secure a minimum of 5,475 ha of native vegetation in conservation lands within SCAs (Commitment 8). Offset targets to secure PCTs (see Chapter 8) are likely to result in securing of additional potential habitat for Red-crowned Toadlet in the SCAs, as there is approximately 8,593 ha of mapped potential habitat in the SCAs for this species
- Support new or existing programs to control key diseases affecting TECs and species in the Cumberland subregion (Commitment 19)
- Manage fire in strategic locations in the Cumberland subregion (Commitment 18) to support the maintenance of biodiversity values on land secured within SCAs. This includes:
  - Consulting with Rural Fire Service, NSW NPWS, and EES to identify fire management priorities, including fire sensitive species and ecological communities
  - Preparing a Fire Management Strategy to guide and co-ordinate fire management

26 Impact summary

The BCAR must include the number and classes of biodiversity credits that would be required to be retired if the offset rules under the BC Act applied (clause 6.9(c) BC Regulation).

This Chapter identifies:

- Impacts on native vegetation (PCTs) and species requiring offsets and the native vegetation not requiring offsets
- Areas not requiring assessment in accordance with section 10 of the BAM
- Biodiversity credits that would be required to be retired if the offset rules under the BC Act applied

It is important to note that the number and classes of biodiversity credits needed to offset the impacts of the development are not required to be retired under a strategic biodiversity certification (see Part 1). However, the NSW Environment Minister must be satisfied that the 'approved conservation measures' under the Plan adequately address the likely impacts on biodiversity values. The Minister will have regard to the BCAR in making this decision.

The Plan has had regard to the credit output of the BAM in determining the commitments under the conservation program. The adequacy of the commitments in offsetting the impacts of the development are evaluated in Part 7.

26.1 IMPACTS REQUIRING OFFSET

Table 26-1 and Table 26-3 identify the impacts on native vegetation and species that require offsets.

Map 31 and Map 32 provide maps of impacts on native vegetation and species that require offsets and impacts on native vegetation and species that do not require offsets.

26.1.1 NATIVE VEGETATION REQUIRING OFFSETS

Section 10.3.1 of the BAM specifies that an offset is required for impacts on native vegetation where the vegetation integrity score is:

- ≥15 where the PCT is representative of an endangered or critically endangered ecological community
- ≥17 where the PCT is associated with threatened species habitat (as represented by ecosystem credits), or is representative of a vulnerable ecological community
- ≥20 where the PCT is not representative of a TEC or associated with threatened species habitat

The PCTs/vegetation zones requiring offsets are provided in Table 26-1.

The PCT/vegetation zones not requiring offsets are provided in Table 26-2.

Table 26-1: PCTs/vegetation zones requiring offsets

PCT	Condition
724 - Broad-leaved Ironbark - Grey Box - Melaleuca decora grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion	Intact
	Thinned
	Scattered Trees
725 - Broad-leaved Ironbark - Melaleuca decora shrubby open forest on clay soils of the Cumberland Plain, Sydney Basin Bioregion	Intact
	Thinned
	Scattered Trees
781 - Coastal freshwater lagoons of the Sydney Basin Bioregion and South East Corner Bioregion	Thinned

PCT	Condition
830 - Forest Red Gum - Grey Box shrubby woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Thinned
835 - Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	Intact
	Thinned
	Scattered Trees
849 - Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	Intact
	Thinned
	Scattered Trees
	DNG
850 - Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Intact
	Thinned
	Scattered Trees
	DNG
1395 - Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion	Intact
	Thinned
	Scattered Trees
	DNG
1800 - Swamp Oak open forest on riverflats of the Cumberland Plain and Hunter valley	Intact
	Thinned
	Scattered Trees

Table 26-2: PCTs/vegetation zones not requiring offsets

PCT	Condition
835 - Forest Red Gum - Rough-barked Apple grassy woodland on alluvial flats of the Cumberland Plain, Sydney Basin Bioregion	Non-offsettable grassland
849 - Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion	Non-offsettable grassland
850 - Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion	Non-offsettable grassland
1395 - Narrow-leaved Ironbark - Broad-leaved Ironbark - Grey Gum open forest of the edges of the Cumberland Plain, Sydney Basin Bioregion	Non-offsettable grassland

26.1.2 SPECIES REQUIRING OFFSETS

The species credit species requiring offsets are provided in Table 26-3.

Table 26-3: Species credit species requiring offsets

Species	Common Name
Acacia bynoeana	Bynoe's Wattle
Acacia pubescens	Downy Wattle
Allocasuarina glareicola	-
Callocephalon fimbriatum	Gang-gang Cockatoo
Calyptorhynchus lathami	Glossy Black Cockatoo
Cercartetus nanus	Eastern Pygmy-possum
Chalinolobus dwyeri	Large-eared Pied Bat
Dillwynia tenuifolia	-
Epacris purpurascens var. *purpurascens*	-
Grevillea juniperina subsp. *juniperina*	-
Grevillea parviflora subsp. *parviflora*	Small-flower Grevillea
Haliaeetus leucogaster	White-bellied Sea-Eagle
Heleioporus australiacus	Giant Burrowing Frog
Hibbertia fumana	-
Hibbertia puberula	-
Hieraaetus morphnoides	Little Eagle
Litoria aurea	Green and Golden Bell Frog
Lophoictinia isura	Square-tailed Kite
Marsdenia viridiflora subsp. *viridiflora* - endangered population	*Marsdenia viridiflora* R. Br. subsp. *viridiflora* population in the Bankstown, Blacktown, Camden, Campbelltown, Fairfield, Holroyd, Liverpool and Penrith local government areas
Maundia triglochinoides	-
Melaleuca deanei	Deane's Paperbark
Meridolum corneovirens	Cumberland Plain Land Snail
Micromyrtus minutiflora	*Micromyrtus minutiflora*
Myotis macropus	Southern Myotis
Ninox strenua	Powerful Owl
Persicaria elatior	Tall Knotweed
Persoonia bargoensis	Bargo Geebung
Persoonia nutans	Nodding Geebung
Petaurus norfolcensis	Squirrel Glider
Phascolarctos cinereus	Koala

Species	Common Name
Pimelea curviflora var. *curviflora*	-
Pimelea spicata	Spiked Rice-flower
Pomaderris brunnea	Brown Pomaderris
Pseudophryne australis	Red-crowned Toadlet
Pterostylis saxicola	Sydney Plains Greenhood
Pultenaea parviflora	-
Pultenaea pedunculata	Matted Bush-pea
Tyto novaehollandiae	Masked Owl

26.2 IMPACTS NOT REQUIRING FURTHER ASSESSMENT

Areas that do not require assessment in accordance with section 10. 4 of the BAM include:

- Urban native/exotic vegetation
- Non-offsettable grassland
- Cleared land and existing building

26.3 BIODIVERSITY CREDIT CALCULATIONS

The biodiversity credit reports are provided at Supporting Document E.

26.3.1 ECOSYSTEM CREDITS

Table 26-4 to Table 26-7 identify the area of impact and associated number of biodiversity credits for each impacted PCT within each nominated area that would be required to be retired if the offset rules applied under the BC Act.

The total number of ecosystem credits that would be required to be retired to offset the impact of the proposed development on PCTs is 41,347 credits.

As noted, the number and classes of biodiversity credits needed to offset the impacts of the development are not required to be retired under a strategic biodiversity certification (see Part 1). The adequacy of the commitments in offsetting the impacts of the development are evaluated in Part 7.

26.3.2 SPECIES CREDITS

As noted, the number and classes of biodiversity credits needed to offset the impacts of the development are not required to be retired under a strategic biodiversity certification (see Part 1). The adequacy of the commitments in offsetting the impacts of the development are evaluated in Part 7.

Table 26-8 to Table 26-11 identifies the area of impact and associated number of biodiversity credits for each impacted species credit species within each nominated area that would be required to be retired if the offset rules applied under the BC Act.

The total number of species credits that would be required to be retired to offset the impact of the proposed development on species credit species is 145,014 credits.

As noted, the number and classes of biodiversity credits needed to offset the impacts of the development are not required to be retired under a strategic biodiversity certification (see Part 1). The adequacy of the commitments in offsetting the impacts of the development are evaluated in Part 7.

Part 6A Contents

Part 6A List of Figures

Part 6A List of Tables

27 Introduction

Parts 6a and 6b of the Cumberland Plain Assessment Report present the impact assessment for relevant matters protected under the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act).

27.1 SCOPE OF THE EPBC ACT ASSESSMENT

As outlined in Chapter 1, the scope of the EPBC Act assessment includes:

- Urban and industrial development within urban capable land in nominated areas
- Infrastructure within urban capable land in nominated areas, as well as 'essential' infrastructure in limited cases within avoided lands in the nominated areas
- Agribusiness within agribusiness lands in the Western Sydney Aerotropolis (WSA)
- Western Sydney Major Infrastructure Corridors (transport corridors) within and outside nominated areas

Chapter 7 in Part 2 of the report provides details about these development types and locations.

27.2 STRUCTURE AND APPROACH TO PARTS 6A AND 6B

Part 6a (this document) includes:

- Chapter 27: Introduction (this chapter)
- Chapter 28: Description of the protected matters affected by the Plan
- Chapter 29: Listed threatened flora species
- Chapter 30: Listed threatened fauna species
- Chapter 31: Listed threatened ecological communities

Part 6b includes:

- Chapter 32: Listed migratory species
- Chapter 33: Ramsar wetlands
- Chapter 34: World and National Heritage
- Chapter 35: Areas of Commonwealth land
- Chapter 36: Analysis of the transport program
- Chapter 37: Analysis of the urban and industrial program
- Chapter 38: Cumulative impact assessment

Chapters in these Parts address the Terms of Reference for the assessment as they relate to specific protected matters. Parts 1, 2, 3, 4 and 7 of the report also address components of the Terms of Reference and must be read in conjunction with Parts 6a and 6b for a complete understanding of the project. Section 4.2.2 (in Chapter 4 of Part 1) sets out the Terms of Reference in full and identifies where they have been addressed throughout the report.

Given the size and complexity of the assessment report, each chapter in Parts 6a and 6b attempts to provide a stand-alone analysis of the relevant issues. However, to avoid excessive repetition each chapter includes cross references to other relevant sections of the report and supporting documents where it is appropriate to do so. For example, details about the baseline data used in the assessment are provided in Part 3 of the report.

Each chapter provides:

- An introduction that sets out the assessment approach for those protected matters
- Descriptions of the relevant protected matters
- Analysis of:
    - How impacts have been avoided

  - Any direct impacts and offsets
  - Potential indirect impacts and mitigation measures
  - An evaluation of the outcomes for each protected matter against the relevant requirements of the EPBC Act and Terms of Reference
- Where appropriate, detailed attachments for any specific technical information that is best presented separately and out of the main text
- Maps of the protected matters (e.g. habitat and records for threatened species). In some cases these are presented within chapters and in others are presented as separate files which can be viewed as layered PDFs. Layered PDFs enable more information to be presented on maps and allow viewers to turn layers on and off as they interrogate the information

Reference lists are provided at the end of both Part 6a and 6b.

28 Description of the protected matters affected by the Plan

This Chapter describes the protected matters likely to be affected by the Plan by:

- Providing a high-level description of the existing environment within the Strategic Assessment Area
- Identifying the relevant matters for assessment under the EPBC Act

28.1 EXISTING ENVIRONMENT

As required by Clause 3.1 of the Terms of Reference:

> *The Report must describe the nature of the environment within the Strategic Assessment Area, and other areas outside the Strategic Assessment Area that may be impacted by actions taken under the Plan. This must include (at a minimum):*
>
> 1. *A description of historical and current land use*
> 2. *The extent and quality of native vegetation present including detailed mapping of ecological communities and habitat for threatened species listed under the EPBC Act*
> 3. *The nature of the environment, including ecosystem processes and threatening processes*
> 4. *A description of the landscape context for key environmental matters, including connectivity, habitat fragmentation and ecological processes*
> 5. *A spatial map of areas that are already protected for environmental purposes, including Bio-banking and Biodiversity Stewardship sites*

This section broadly addresses these requirements. For the Strategic Assessment Area, it provides:

- A discussion of historical and existing land uses
- An overview of native vegetation
- A description of ecological processes
- A description of threatening processes
- Information about currently protected areas

Detailed information about threatened ecological communities (TECs) and species (e.g. mapping of individual species habitat) as well as relevant protected matters that sit outside the Strategic Assessment Area is provided elsewhere in this report.

28.1.1 HISTORICAL AND EXISTING LAND USES

The Strategic Assessment Area occurs primarily within the Cumberland IBRA subregion of Western Sydney (Cumberland subregion). The Cumberland subregion is a broad geographic basin that is bounded by the Hornsby Plateau in the north, the base of the Blue Mountains in the west, the Woronora plateau in the south, and the centre of Sydney to the east. It has an area of approximately 275,000 hectares, rising gradually from the flat low-lying areas at sea level in the east to an altitude of around 350 metres on the margins to the north and south.

The Strategic Assessment Area has been greatly affected by historical and ongoing land use pressures. Its gentle undulating plains and fertile soils mean it has been a focus of agriculture and occupation both before and after European settlement (DECCW, 2011).

Before European settlement it had extensive grassy woodlands and abundant fauna. Hundreds of records of Aboriginal sites have been found across the subregion, suggesting it was an important area for Aboriginal people. Records indicate Aboriginal occupation of the Sydney region for at least 20,000 years, and possibly 40,000 years (Nanson, Young et al., 1987; Stockton, 2009; Stockton & Holland, 1974). There also is evidence of Aborigines using fire to manage the landscape to establish mosaics of forest and grassland in a way that facilitated hunting of kangaroos (Gammage, 2011).

Since European settlement the Strategic Assessment Area has been used for agriculture and more recently for urban development. Agriculture was established by European settlers in 1792, and since the mid-1900s most of the area has been subject to grazing or cultivation (Tozer, 2003). Fire and clearing have been used extensively to support this.

In the second half of 1900s, Sydney's growth accelerated and residential, commercial and industrial areas expanded further into the Cumberland subregion (Benson & Howell, 1990). At 2019, the Cumberland subregion is expected to support 44 per cent of Sydney's population (DECCW, 2011). The need to accommodate and provide services for the increasing urban population has put pressure on existing agriculture. The Sydney Metropolitan Area is predicted to reach 6 million by 2036. (DECCW, 2011). One recent study projected that on the current trajectory, by 2031 total food production in the Basin may reduce by 60 per cent, including 90 per cent of fresh vegetable production (Institute for Sustainable Futures, 2016).

28.1.2 NATIVE VEGETATION

The native vegetation in the Cumberland subregion is diverse and very different to the surrounding areas. It supports a variety of flora and fauna, including a range of migratory and threatened species. As a result of historical and ongoing patterns of use, the Cumberland subregion and its biodiversity have suffered significant disturbance and it is thought to be one of the most threatened regions in NSW (DEC, 2005b). Many of the ecological communities and the fauna and flora they support are listed as threatened under both NSW and Commonwealth environmental legislation. Approximately 8 per cent of the remaining bushland is protected in reserves (DECCW, 2011).

Areas of remaining native vegetation (see Figure 28-1) are often of high conservation value as they may contain the only remaining habitat for ecological communities and species that rely on the Cumberland subregion for survival.

Native vegetation remaining in the Strategic Assessment Area comprises 39 different PCTs which represent 19 vegetation classes within 10 vegetation formations.

In 2010 only 13 per cent of the pre-1750 extent of the region's vegetation remained as intact, with an additional 12 per cent occurring as scattered trees in disturbed areas (DECCW, 2011). What remains is often highly fragmented. An estimated 2,446 individual native vegetation remnants remain, and the 81 largest patches (containing >50ha) represent 51 per cent of the remaining native vegetation across the Cumberland subregion (DECCW, 2011).

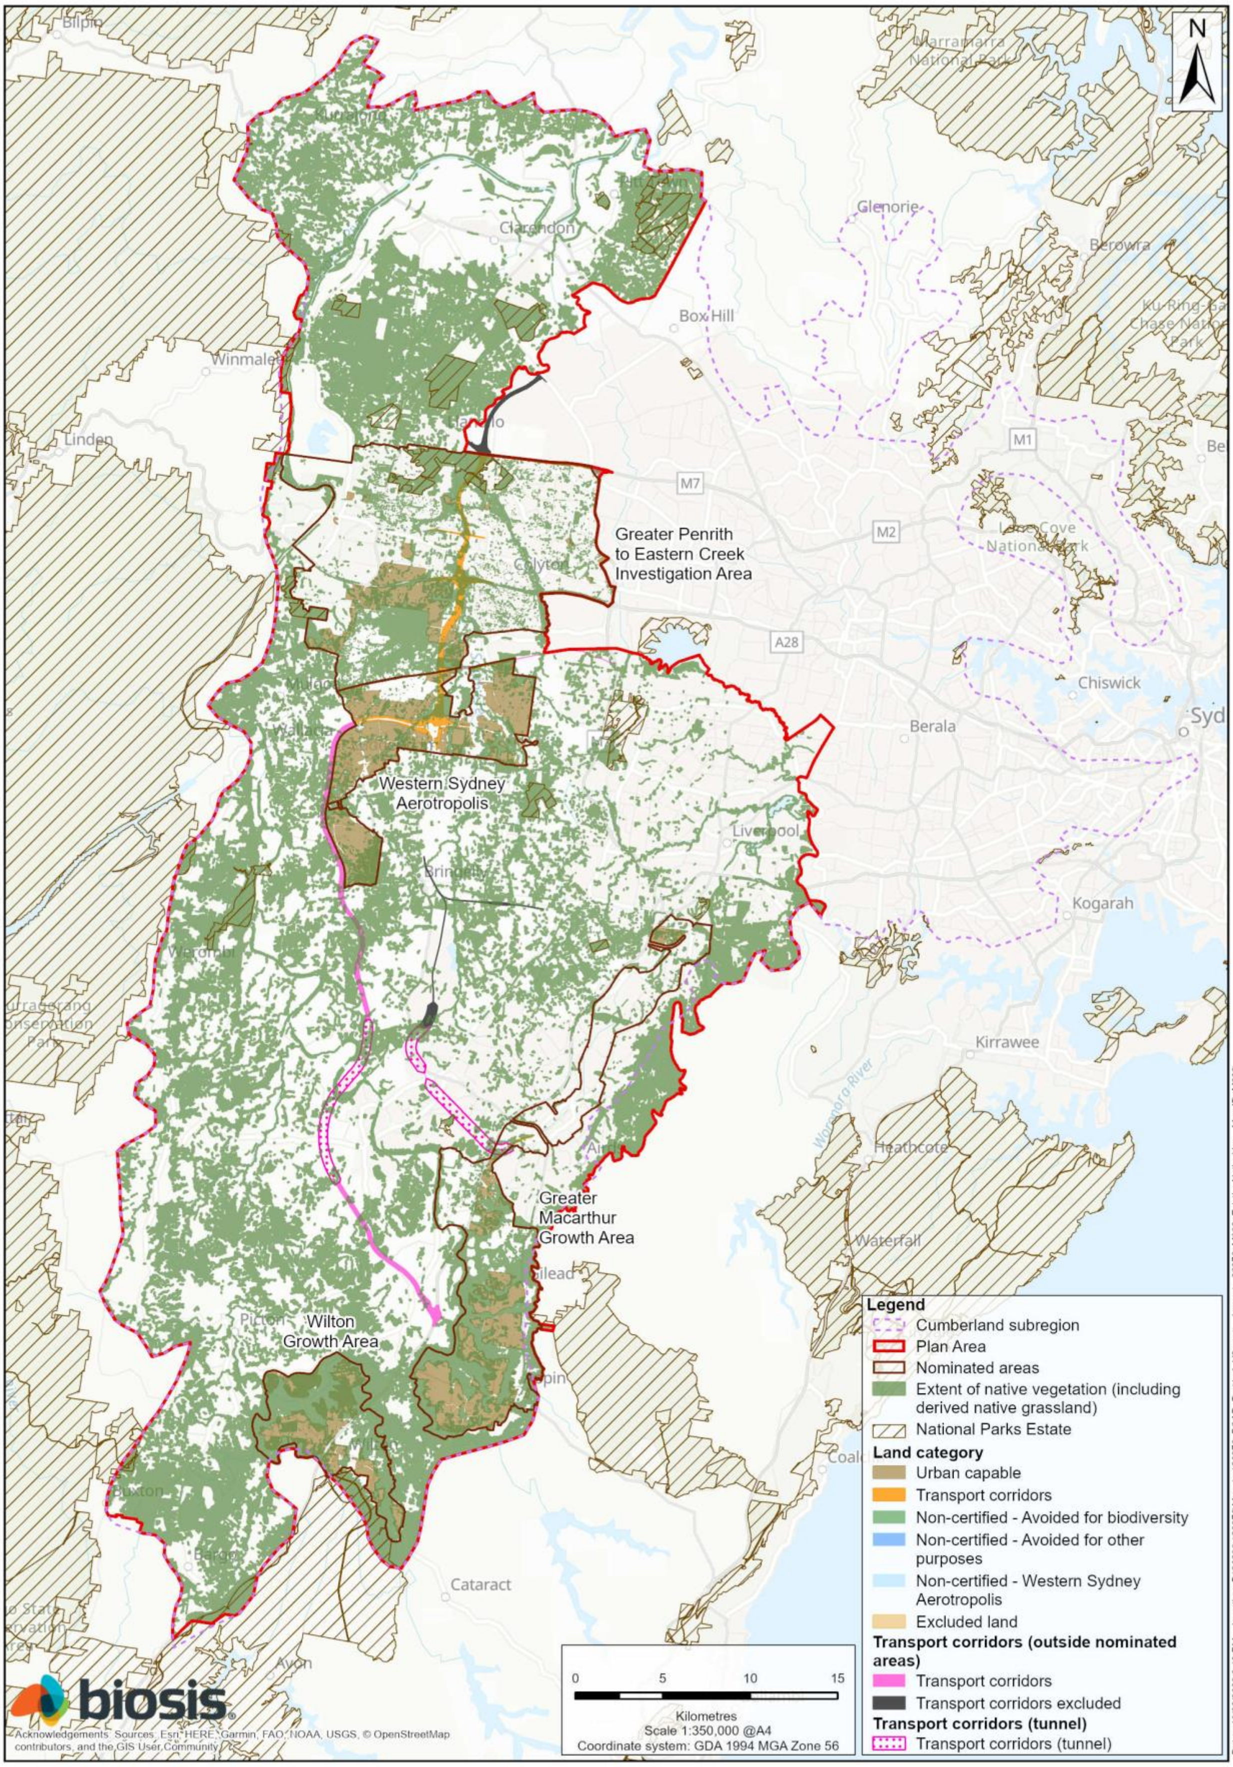

Figure 28-1: Extent of native vegetation in the Strategic Assessment Area

28.1.3 ECOLOGICAL PROCESSES

The ecological processes in an area determine the species composition, habitat structure, and ecological health of sites and landscapes. They include biological, physical, and chemical processes such as natural disturbance, hydrology, nutrient cycling, flora and fauna interactions, population dynamics, and evolution (US EPA, 1999).

There are several ecological processes that are particularly relevant to consideration of the Plan and its contribution to the Cumberland subregion. They are:

- Landscape connectivity and fragmentation
- Fire regimes
- Soil nutrient cycling
- Hydrology

LANDSCAPE CONNECTIVITY AND FRAGMENTATION

Landscape connectivity is important for biodiversity as it allows the linkage of habitats, species, communities and ecological processes. In undisturbed areas connectivity is high, and as development increases, fragmentation occurs.

Larger patches of vegetation are often more diverse and less susceptible to 'edge effects'. Edge effects are an indirect impact of habitat fragmentation. New environmental conditions at edges can promote growth of invasive species and weeds which can compete with native flora and fauna. Altered conditions can also reduce the health of important habitat features such as hollow-bearing trees. Changes in connectivity can allow invasion of pest fauna specialising in edge habitats which may alter the behaviour of resident animals and make them at risk of higher levels of predation.

The Cumberland subregion is highly fragmented, and connectivity is already compromised to the point that many of the species that previously occurred there are no longer present (DECCW, 2011). However, it is still very important for species such as Koalas, woodland birds, and a range of flora. Once clearing levels exceed 70 per cent of the landscape, biodiversity loss from fragmentation increases (DECCW, 2011). This threshold has been passed already in the Cumberland subregion (DECCW, 2011).

Significant conservation planning has occurred in the Cumberland subregion over the last decade which has examined landscape connectivity. Following the Cumberland Plain Recovery Plan (DECCW, 2011), EES prepared the Biodiversity Investment Opportunities Map (BIO Map) (OEH, 2015), to ensure that conservation funding within the subregion is targeted towards areas of greatest strategic benefit.

BIO Map identifies Priority Investment Areas (PIAs) where the protection and management of native vegetation is likely to maximise benefits to biodiversity within the subregion. The PIAs comprise:

- Core areas: large areas of native vegetation and habitat where management will be of greatest benefit to the conservation of biodiversity values. These areas represent the habitat in the Cumberland subregion most likely to support species persistence and interactions between species and landscape-scale ecological processes
- Regional biodiversity corridors: linear areas that link core areas and play a crucial role in maintaining connections between species populations that would otherwise be isolated and at greater risk of local extinction

BIO Map identifies a total of 87 core areas and 27 regional biodiversity corridors within the Cumberland subregion. The core areas comprise a total of 20,175 ha of native vegetation and the corridors a total of 11,672 ha of native vegetation.

The combination of core and corridor areas is considered suitable for use as a surrogate measure of habitat connectivity. See Figure 28-2 for the Cumberland subregion BIO Map.

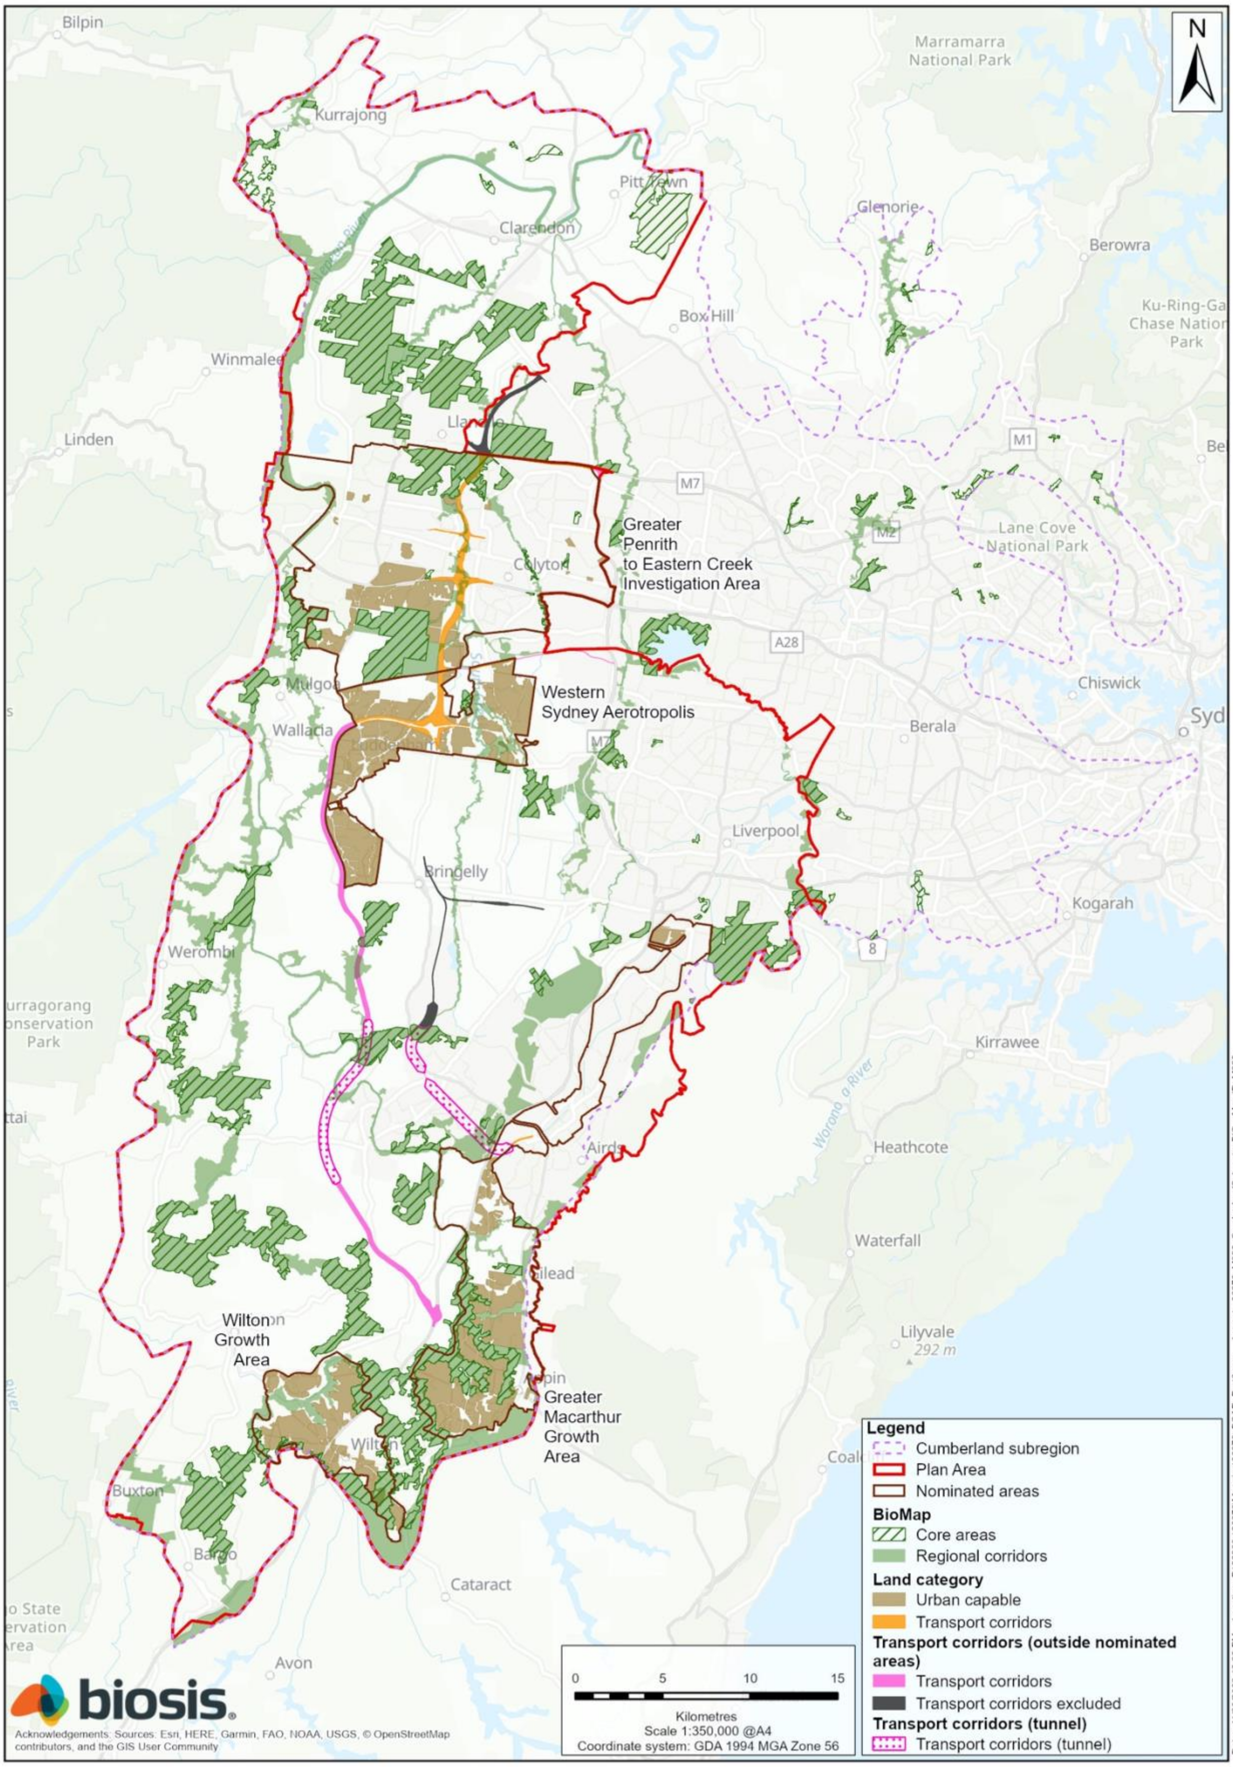

Figure 28-2: Cumberland subregion BIO Map

FIRE

Fire has been shown to be important in maintaining native species richness in remnant grasslands in south-eastern Australia (Lunt & Morgan, 2002; Lunt, Prober et al., 2012).

Fire regimes in the Cumberland subregion were established over hundreds of years and fire plays an important role in shaping the landscape and vegetation. The fire regimes of the subregion have been significantly altered over time due to urbanisation. In and around urban areas, fire is primarily used to manage fire risk to property from surrounding vegetation. This results in either more frequent fires than would occur naturally (through hazard reduction burns), or alternatively the total exclusion of fire. Both of these situations represent a deviation from natural fire patterns and this impacts fire-dependent vegetation communities.

Fire regimes are characterised by their frequency, seasonality, and intensity. Different ecological communities have different recommended fire intervals. For example, the suggested minimum fire interval for Cumberland Plain Woodland is five years and the maximum fire interval is 12 years (DECCW, 2011). For other communities, including Moist Shale Woodland and Western Sydney Dry Rainforest, burning is not recommended at all (DECCW, 2011). In general, grassy woodlands require a higher fire frequency than shrubby woodlands (DECCW, 2011).

Particularly relevant to restoration efforts, fire can be used to increase the native species richness in previously cleared Cumberland Plain Woodland derived grasslands (Morris, de Barse et al., 2016).

SOIL NUTRIENT CYCLING

Soil nutrient cycling is another important ecological process that contributes to the healthy functioning of vegetation communities and species habitats on the Cumberland subregion. It does this through storing water and carbon and transforming waste and nutrients.

Natural soil nutrient cycling processes have been negatively affected in several ways through urbanisation and agricultural practices. Grazing has led to soil compaction, which hinders the re-establishment of a diverse native understorey, and makes soil more susceptible to erosion.

The soils of Cumberland Plain woodland communities have been shown to be subject to nutrient loading from fertilisers from previous agricultural use, deposition of livestock dung, rubbish dumping and stormwater runoff from urban areas (NSW Scientific Committee, 2009). The soils of other vegetation communities within the Cumberland subregion would have likely also been subject to similar nutrient loading.

The effects of agriculture and urbanisation on soils of the Cumberland subregion have promoted invasion by exotic species, displacing native species (Hill, Tung et al., 2005). Areas that have been cleared and grazed are now dominated by exotics (mainly perennial grasses), which make up two thirds of the canopy cover and up to half of species richness (Hill, Tung et al., 2005). This is partly due to elevated levels of soil nitrogen (which is found in fertilisers) that creates conditions which favour that exotic species over native species.

Understanding soil nutrient cycling is relevant for restoration efforts. A study examining barriers to restoring Cumberland Plain Woodland on previously cleared areas found that adding carbon to the soil and/or fire, when combined with native seed addition, increased the abundance and species richness of native species relative to exotic species (Morris & de Barse, 2013). Adding carbon to the soil reduces the nitrate levels in the soil and increases soil microbes, creating conditions that allow natives to be more competitive with exotic species.

HYDROLOGY

The Strategic Assessment Area occurs within two catchments and is traversed by a number of major rivers and a wide range of smaller waterways (see Figure 28-3). The two catchments are:

- Botany Bay
- Hawkesbury-Nepean

Development and agricultural practices over the years have reduced riparian vegetation and impacted the hydrology of the catchments. During heavy rain water moves more quickly off surfaces which leads to flooding, erosion, and sedimentation and can contribute to reduced water quality (DEC, 2005b). For plants and animals dependent on flood flows to trigger critical life cycle events, changes to hydrology could impact their viability.

Botany Bay catchment

Parts of Greater Macarthur Growth Area (GMAC) occur within the Georges River sub-catchment of the Botany Bay catchment. The Georges River ultimately flows directly into Botany Bay and the waters surrounding Towra Point Ramsar site (outside the Strategic Assessment Area).

The water quality of the Georges River varies depending upon the degree of development within each sub-catchment of the river. The water quality in the vicinity of GMAC ranges from poor (within the Bunbury-Curran Creek sub-catchment) to good (the Mid Georges River sub-catchment) (GRCCC, 2016). Large areas of the upper reaches of the catchment are vegetated, which provides protection from activities that reduce water quality.

Hawkesbury-Nepean catchment

The majority of the Strategic Assessment Area occurs within the Hawkesbury-Nepean catchment. The catchment is one of the longest coastal catchments in NSW, stretching from Broken Bay in the north to Goulburn in the south with the Hawkesbury-Nepean river flowing for 470 km and draining more than 22,000 km^2 of land (Western Sydney University, 2016).

The Nepean River flows south to north through the Strategic Assessment Area to near the point that it becomes the Hawkesbury River where it junctions to the Grose River. Wianamatta (South Creek) is another major waterway running through Western Sydney Aerotropolis (WSA) and Greater Penrith to Eastern Creek Investigation Area (GPEC). Many of the waterways in the Strategic Assessment Area have extensive floodplains (GES, 2018).

Water quality is variable throughout the area. The majority of the upper reaches of streams and rivers are healthy, while downstream reaches are affected by the negative effects of historical land uses (e.g. clearing, urbanisation) (GES, 2018).

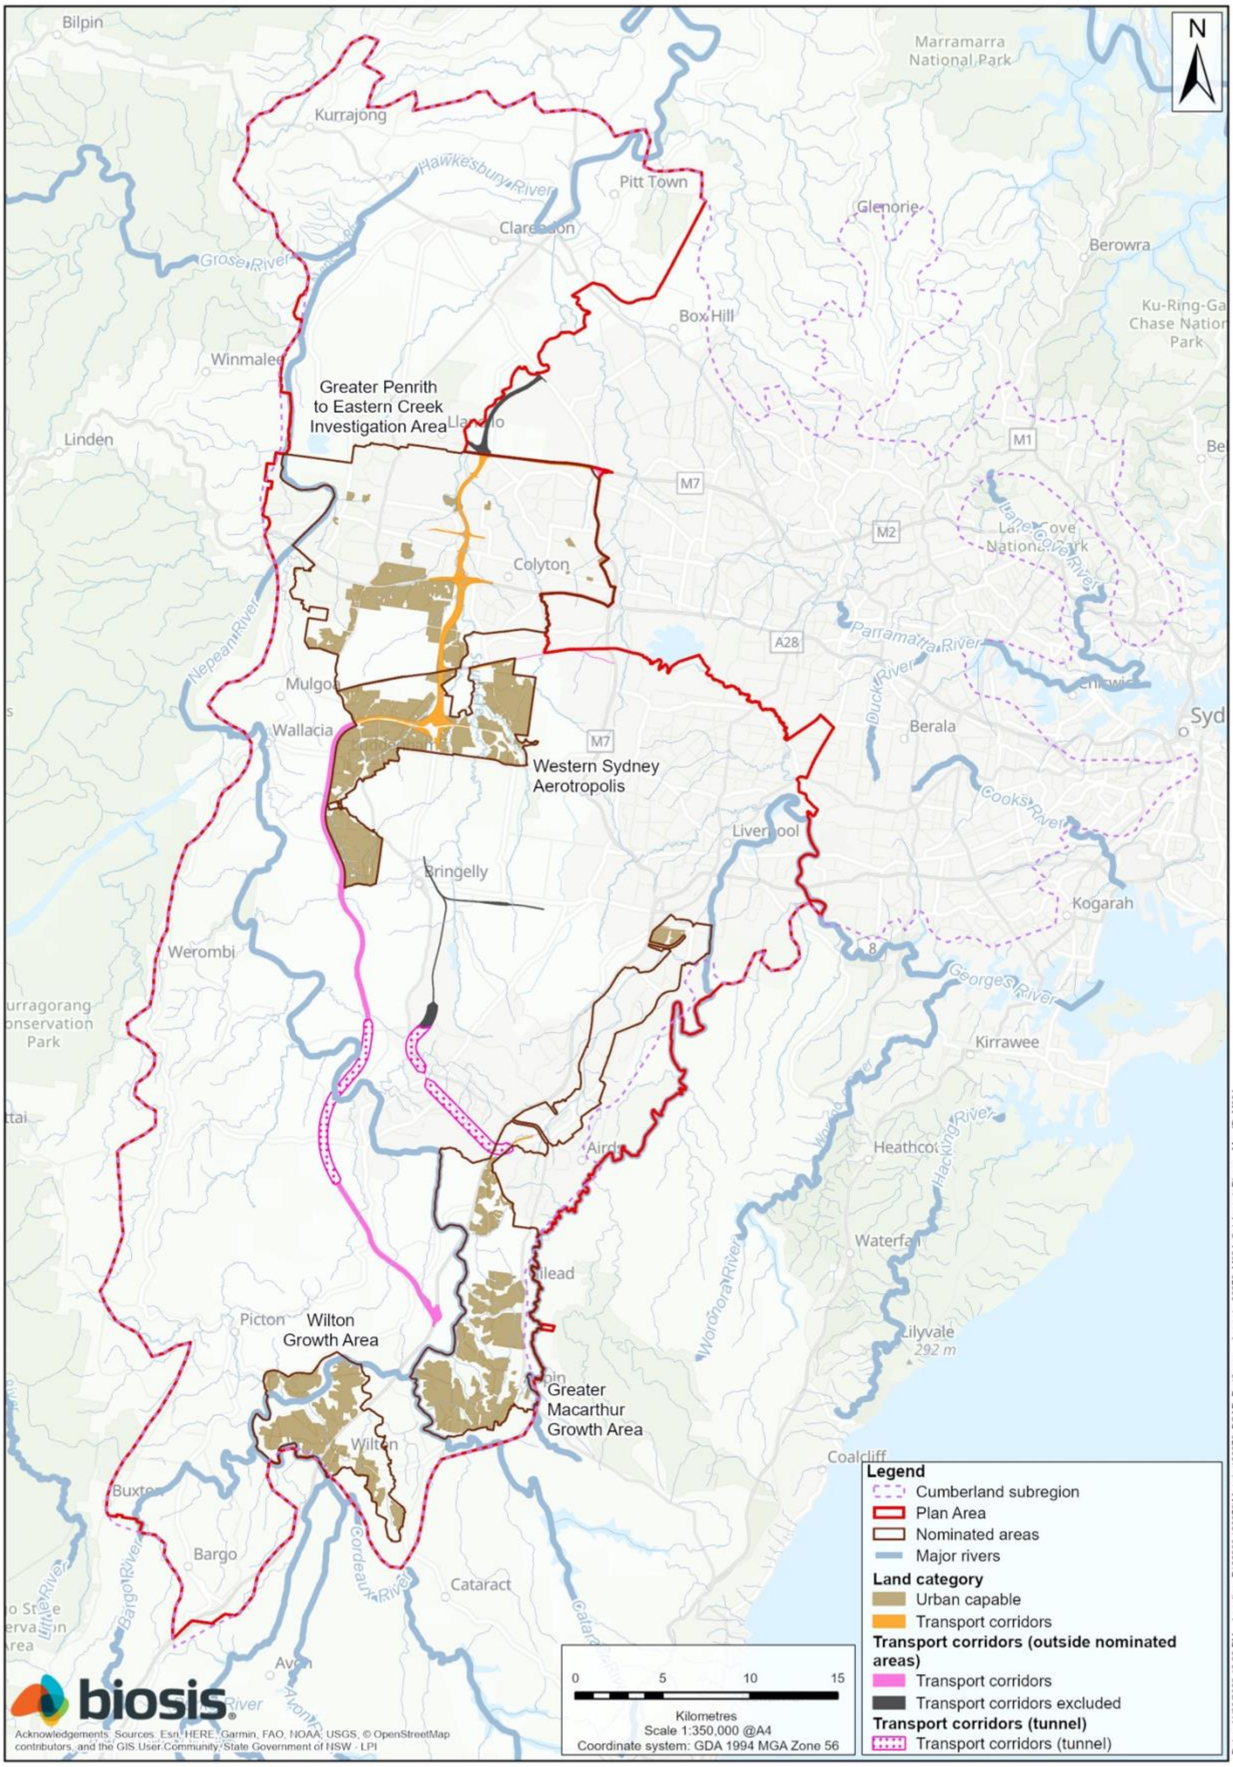

Figure 28-3: Major rivers of the Strategic Assessment Area

28.1.4 THREATENING PROCESSES

A process is defined as a threatening process under the EPBC Act if it threatens or may threaten the survival, abundance or evolutionary development of a native species or ecological community.

The EPBC Act enables the listing of key threatening processes. A threatening process may be added to the list of key threatening processes in several circumstances, including where it could cause a native species or an ecological community to become eligible for listing under the EPBC Act as threatened.

The key threatening processes in the Cumberland subregion fall into the following categories:

- Habitat loss
- Climate change
- Weeds
- Pest animals
- Fire
- Disease

HABITAT LOSS

Habitat loss is one of the key threats to the biodiversity of the Cumberland subregion (DECCW, 2011). Further clearing of native vegetation places more pressure on already over-cleared landscapes and leads to increasingly isolated and small remnants that are more susceptible to degradation, provide less habitat and support fewer species (DECCW, 2011).

The EPBC Act lists 'Land clearance' under this category.

CLIMATE CHANGE

Climate change is a key threat to the biodiversity of the Cumberland subregion (DECCW, 2011). The nature and extent of the threat is difficult to quantify, but may include (DECCW, 2010):

- Reductions in the geographic range of species
- Changes to the timing of species' lifecycle events
- Changes in population dynamics and survival
- Changes in the location of species' habitats
- Increases in the risk of extinction for species that are already vulnerable
- Increased opportunity for range expansion of invasive species
- Changes in the structure and composition of ecosystems and communities
- Increased likelihood of extreme weather events and fire
- Changes in coastal and estuarine habitat due to rising sea levels

The EPBC Act lists 'Loss of climatic habitat caused by anthropogenic emissions of greenhouse gases' under this category.

WEED INVASION

Weed invasion is an ongoing threat to the remaining vegetation in the Cumberland subregion. In particular, African Olive, African Lovegrass and Bridal Creeper have established themselves widely, are very competitive and can dominate native understory species (DECCW, 2011; Tozer, 2003).

Key threatening processes listed under the EPBC Act in this category include:

- Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants
- Novel biota and their impact on biodiversity

Several threatening processes relevant to the subregion are also listed under the *Biodiversity Conservation Act 2016* (BC Act) in this category, including:

- Invasion of native plant communities by African Olive
- Invasion, establishment and spread of Lantana
- Invasion of native plant communities by exotic perennial grasses

PEST ANIMALS

Pest animals are a key threat to native fauna species and native vegetation in the Cumberland subregion, including threatened ecological communities such as Cumberland Plain Woodland (DIPNR, 2003). Grazing by pest animals has prevented the recovery and regeneration of native species (DIPNR, 2003).

KTPs listed under the EPBC Act in this category include:

- Aggressive exclusion of birds from potential woodland and forest habitat by over-abundant noisy miners (*Manorina melanocephala*)
- Competition and land degradation by rabbits
- Competition and land degradation by unmanaged goats
- Predation by European red fox
- Predation by feral cats
- Predation, habitat degradation, competition and disease transmission by feral pigs
- The biological effects, including lethal toxic ingestion, caused by Cane Toads (*Bufo marinus*)

FIRE

Inappropriate fire regimes are a key issue for biodiversity, particularly ecological communities, in the Cumberland subregion. Frequent fire from arson is a major problem and has resulted in a significant change to ecological communities in the subregion, which have evolved and been selected by pre-European practices to be dependent on a certain fire regime (DECCW, 2011).

High frequency fire and inappropriate fire regimes have been identified as threats to a number of species and ecological communities in the Cumberland subregion, including Cumberland Plain Woodland (NSW Scientific Committee, 2000).

No key threatening processes listed under the EPBC Act are included in this category.

The BC Act lists 'High frequency fire resulting in the disruption of life cycle processes in plants and animals and loss of vegetation structure and composition' as a threatening process under this category.

DISEASE

KTPs listed under the EPBC Act in this category include:

- Dieback caused by the root-rot fungus *Phytophthora cinnamomi*
- Infection of amphibians with chytrid fungus resulting in chytridiomycosis
- Novel biota and their impact on biodiversity
- Psittacine Circoviral (beak and feather) Disease affecting endangered psittacine species

Phytophthora has the potential to affect several ecological communities in the Cumberland subregion, including Castlereagh Scribbly Gum and Agnes Banks Woodland, Cumberland Plain Woodland and Shale Sandstone Transition Forest (DoEE, 2018d).

Several frog species are under threat from the impacts of chytrid fungus in the subregion, including Green and Golden Bell Frog and Giant Burrowing Frog (DoEE, 2016b).

Although not listed under the EBPC Act, psyllid-induced dieback of grey box in the Cumberland subregion has been observed. Specifically a native lace lerp species, or psyllid (*Cardiaspina* sp.) has been found to cause defoliation, canopy dieback and tree mortality on *E. moluccana* (NSW Environmental Trust & NSW Environmental Trust, 2016). The canopy loss removes patches from being within the EPBC-listed state as it is dependent on the presence of a minimum foliage density.

28.1.5 CURRENTLY PROTECTED AREAS

There are a range of currently protected lands within the Strategic Assessment Area (see Figure 28-4). These comprise:

- Land within the National Parks estate
- Land that is in the process of being incorporated into the National Parks estate
- Existing offset sites
- Existing Biobank and Biodiversity Stewardship sites

The total area of protected lands within the Strategic Assessment Area is 9,063 hectares.

Existing offset sites, BioBank and Biodiversity Stewardship sites have not been shown in Figure 28-4 due to privacy reasons.

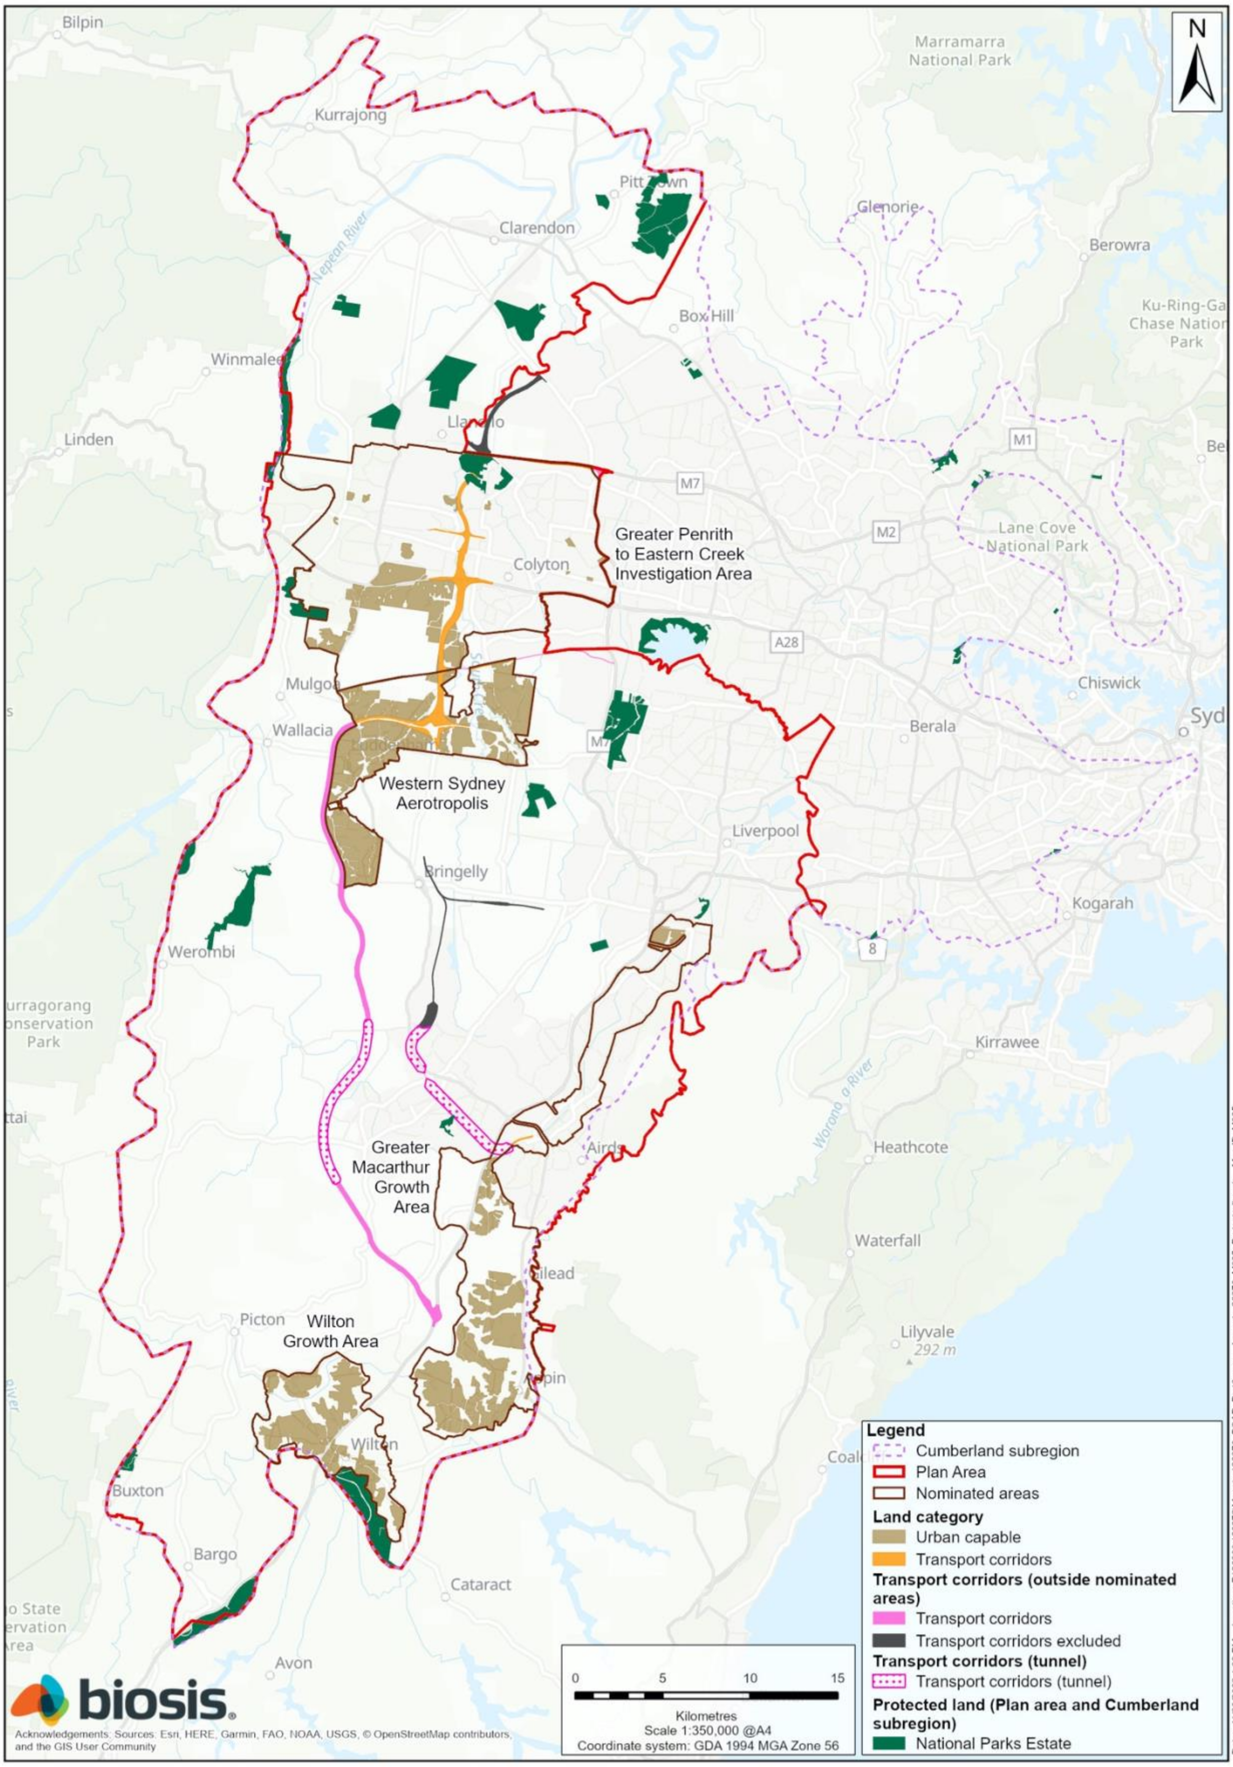

Figure 28-4: Currently protected lands within the Strategic Assessment Area

28.2 RELEVANT PROTECTED MATTERS

As required by Clause 3.2 of the Terms of Reference:

> *The Report must identify and describe each protected matter that may be impacted directly, indirectly and cumulatively by actions taken under the Plan…*

A method to identify these matters was applied (see Section 11.1.2 in Part 3 of the report). This was based on applying a set of criteria and using expert input to assign the full list of potential matters for the Strategic Assessment Area into one of two categories:

- Category 1: matter needs detailed assessment. These matters are reliant on the Cumberland subregion, have some potential to be impacted (directly, indirectly or cumulatively), and are addressed in detail in the SAR
- Category 2: assessment of the matter is completed and no further analysis is required. These matters are not reliant on the Cumberland subregion, are subject to no or very low risk of impacts (directly, indirectly or cumulatively), and are not addressed further in the SAR

This work identified the following groups of protected matters as being relevant to the assessment:

- Listed threatened species (see Section 28.2.1)
- Listed threatened ecological communities (see Section 28.2.2)
- Listed migratory species (see Section 28.2.3)
- Finalised Priority Assessment List (FPAL) (see Section 28.2.4)
- Wetlands of international importance (Ramsar wetlands) (see Section 28.2.5)
- World and National Heritage (see Section 28.2.6)
- Commonwealth land (see Section 28.2.7)

Detailed impact assessments have been undertaken for Category 1 protected matters which are highlighted in blue in the following tables.

28.2.1 THREATENED SPECIES

The following threatened species were assigned to Category 1 for detailed assessment in the report:

- 20 threatened fauna species (see Table 28-1)
- 23 threatened flora species (see Table 28-2)

Detailed impact assessments for Category 1 threatened species are presented in Chapter 29 (flora species), Chapter 30 (threatened species) and Chapter 32 (migratory species).

Table 28-1: Threatened fauna

Scientific name	Common name	Commonwealth status (EPBC Act)	NSW status	No. of important populations, Post 1990 Cumberland records as % of NSW records, % of total C'wealth distribution	Category	Comment
BIRDS						
Anthochaera phrygia	Regent Honeyeater	Critically Endangered	Critically Endangered	1, 1.36%, 0.63%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30
Botaurus poiciloptilus	Australasian Bittern	Endangered	Endangered	1, 3.97%, 0.42%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30
Calidris canutus	Red Knot, Knot	Endangered; Migratory	Not Listed	1, 0.34%, 0	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30 in relation to its listing as a threatened species, and Chapter 32 in relation to its listing as a migratory species
Calidris ferruginea	Curlew Sandpiper	Critically Endangered; Migratory	Not Listed	1, 0.08%, 0.03%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30 in relation to its listing as a threatened species, and Chapter 32 in relation to its listing as a migratory species
Calidris tenuirostris	Great Knot	Critically Endangered; Migratory;	Vulnerable	0, 0, 0.08%	Category 2	The species has a broad Australian distribution and NSW does not contain any important sites for the species. It is unlikely to occur in the Strategic Assessment Area

Scientific name	Common name	Commonwealth status (EPBC Act)	NSW status	No. of important populations, Post 1990 Cumberland records as % of NSW records, % of total C'wealth distribution	Category	Comment
Charadrius leschenaultii	Greater Sand Plover, Large Sand Plover	Vulnerable; Migratory	Vulnerable	1, 0.63%, 0.11%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30 in relation to its listing as a threatened species, and Chapter 32 in relation to its listing as a migratory species
Charadrius mongolus	Lesser Sand Plover, Mongolian Plover	Endangered; Migratory	Not Listed	0, 0, 0.06%	Category 2	The species has a widespread Australian distribution and no records occur in the Strategic Assessment Area. It is unlikely to occur in the Strategic Assessment Area
Dasyornis brachypterus	Eastern Bristlebird	Endangered	Endangered	0, 0, 1.3%	Category 2	The species does not occur on the Cumberland subregion. It is unlikely to occur in the Strategic Assessment Area
Diomedea antipodensis	Antipodean Albatross	Vulnerable	Vulnerable	0, 0, 0	Category 2	The species is endemic to New Zealand and forages in open water off the coast of NSW. It is unlikely to occur in the Strategic Assessment Area
Diomedea antipodensis gibsoni	Gibson's Albatross	Vulnerable	Vulnerable	0, 0, 0	Category 2	The species is a non-breeding visitor to Australian waters. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Diomedea epomophora	Southern Royal Albatross	Vulnerable; Migratory	Not Listed	0, 0, 0	Category 2	The species forages in open water off the east, west and south Australian coast. It is unlikely to occur in the Strategic Assessment Area
Diomedea exulans	Wandering Albatross	Vulnerable; Migratory	Endangered	0, 0, 0	Category 2	The species forages in open water from Fremantle in WA around southern Australia to the Whitsunday Islands in Queensland. It is unlikely to occur in the Strategic Assessment Area

Scientific name	Common name	Commonwealth status (EPBC Act)	NSW status	No. of important populations, Post 1990 Cumberland records as % of NSW records, % of total C'wealth distribution	Category	Comment
Diomedea sanfordi	Northern Royal Albatross	Endangered	Not Listed	0, 0, 0	Category 2	The species has a broad distribution across the Southern Ocean. It forages in waters off Tasmania and South Australia, and less frequently in NSW waters. It is unlikely to occur in the Strategic Assessment Area
Grantiella picta	Painted Honeyeater	Vulnerable	Vulnerable	0, 0.18%, 0.16%	Category 2	The species has a broad but sparse distribution from south-east Australia to the Northern Territory that is associated with the fruiting of mistletoe. It is unlikely to be reliant on the Strategic Assessment Area
Hirundapus caudacutus	White-throated Needletail	Vulnerable; Migratory	Not Listed	0, 2.43%, 0.38	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30 in relation to its listing as a threatened species, and Chapter 32 in relation to its listing as a migratory species
Lathamus discolor	Swift Parrot	Critically Endangered	Endangered	1, 9.49%, 0.41%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30
Limosa lapponica baueri	Bar-tailed Godwit (baueri), Western Alaskan Bar-tailed Godwit	Vulnerable; Migratory	Not Listed	1, 0, 0.06%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30 in relation to its listing as a threatened species, and Chapter 32 in relation to its listing as a migratory species
Limosa lapponica menzbieri	Northern Siberian Bar-tailed Godwit, Bar-tailed Godwit (menzbieri)	Critically Endangered; Migratory	Not Listed	0, 0, 0.06%	Category 2	The species occurs predominately in Western Australia and is not considered likely to occur in the Strategic Assessment Area
Macronectes giganteus	Southern Giant-Petrel, Southern Giant Petrel	Endangered; Migratory	Endangered	0, 0, 0	Category 2	The species is a pelagic bird with a range as far as northern Queensland. It does not occur in the Strategic Assessment Area and is unlikely to be reliant on the area

Scientific name	Common name	Commonwealth status (EPBC Act)	NSW status	No. of important populations, Post 1990 Cumberland records as % of NSW records, % of total C'wealth distribution	Category	Comment
Macronectes halli	Northern Giant Petrel	Vulnerable; Migratory	Vulnerable	0, 0, 0	Category 2	The species is a pelagic bird with an Australian distribution from Freemantle in WA to Sydney in NSW. No records occur in the Strategic Assessment Area and it is unlikely to be reliant on the area
Neophema chrysogaster	Orange-bellied Parrot	Critically Endangered	Critically Endangered	0, 0, 0.09%	Category 2	The species is associated with saltmarsh and foredune vegetation communities either on coastlines or coastal lagoons. No records occur in the Strategic Assessment Area and it is unlikely to be reliant on the area
Numenius madagascariensis	Eastern Curlew, Far Eastern Curlew	Critically Endangered; Migratory	Not Listed	1, 0, 0.05%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30 in relation to its listing as a threatened species, and Chapter 32 in relation to its listing as a migratory species
Pachyptila turtur	Fairy Prion	Vulnerable	Not Listed	0, 0, 0	Category 2	The species has a circumpolar distribution and is known from areas in the vicinity to Macquarie Island, and Bishop and Clerk Island. No records occur in the Cumberland subregion and it is unlikely to occur in the Strategic Assessment Area due to the lack of suitable habitat
Pachyptila turtur subantarctica	Fairy Prion (southern)	Vulnerable	Not Listed	0, 0, 0	Category 2	The species has a circumpolar distribution and is known from areas in the vicinity to Macquarie Island, and Bishop and Clerk Island. No records occur in the Cumberland subregion and it is unlikely to occur in the Strategic Assessment Area due to the lack of suitable habitat
Rostratula australis	Australian Painted Snipe	Endangered	Endangered	1, 6.38%, 0.07%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30

Scientific name	Common name	Commonwealth status (EPBC Act)	NSW status	No. of important populations, Post 1990 Cumberland records as % of NSW records, % of total C'wealth distribution	Category	Comment
Rostratula benghalensis (sensu lato)	Painted Snipe	Endangered	Not Listed	0, 0, 0.07%	Category 2	The species is generally accepted as *Rostratula australis*. The Australian painted snipe is now accepted as a full species rather than a sub species of *Rostratula benghalensis*, based on morphological differences (listing advice). This does not need assessment because *Rostratula australis* is being assessed
Sternula nereis nereis	Australian Fairy Tern	Vulnerable	Not Listed	0, 0, 0	Category 2	The species' extent occurs along the coast from NSW to Western Australia, including Tasmania. It is associated with offshore estuarine or lake islands, wetlands, beaches and spits. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Thalassarche bulleri	Buller's Albatross, Pacific Albatross	Vulnerable; Migratory	Not Listed	0, 0, 0	Category 2	The species is a non-breeding visitor to Australian waters with a broad distribution. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Thalassarche bulleri platei	Northern Buller's Albatross, Pacific Albatross	Vulnerable	Not Listed	0, 0, 0	Category 2	The species is a non-breeding visitor to Australian waters with a broad distribution. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Thalassarche cauta	Tasmanian Shy Albatross	Vulnerable; Migratory	Vulnerable	0, 0, 0	Category 2	The species is accepted as being the same as *Thalassarche cauta cauta*. It is a non-breeding visitor to Australian waters and does not occur on the Cumberland subregion. It is unlikely to occur in the Strategic Assessment Area
Thalassarche cauta cauta	Shy Albatross, Tasmanian Shy Albatross	Vulnerable	Not Listed	0, 0, 0	Category 2	The species is a non-breeding visitor to Australian waters with a broad distribution. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area

Scientific name	Common name	Commonwealth status (EPBC Act)	NSW status	No. of important populations, Post 1990 Cumberland records as % of NSW records, % of total C'wealth distribution	Category	Comment
Thalassarche cauta steadi	White-capped Albatross	Vulnerable	Not Listed	0, 0, 0	Category 2	The species is a non-breeding visitor to Australian waters, particularly off the coast of south-east Australia. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Thalassarche eremita	Chatham Albatross	Endangered	Not Listed	0, 0, 0	Category 2	The species' principle foraging range occurs in waters off the coast off eastern and southern New Zealand, and Tasmania. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Thalassarche impavida	Campbell Albatross, Campbell Black-browed Albatross	Vulnerable	Not Listed	0, 0, 0	Category 2	The species is a non-breeding visitor to Australian waters. Its Australian distribution occurs over the oceanic continental slope off the coast of Tasmania, Victoria and NSW. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Thalassarche melanophris	Black-browed Albatross	Vulnerable; Migratory	Vulnerable	0, 0, 0	Category 2	The species breeds on Heard Island, Macquarie Island, McDonald Islands, and Bishop and Clerk Islets and has a broad Australian oceanic distribution. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Thalassarche salvini	Salvin's Albatross	Vulnerable	Not Listed	0, 0, 0	Category 2	The species is a non-breeding visitor to Australian waters, with a broad distribution. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
MAMMALS						
Chalinolobus dwyeri	Large-eared Pied Bat, Large Pied Bat	Vulnerable	Vulnerable	0, 3.19%, 0.61%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30

Scientific name	Common name	Commonwealth status (EPBC Act)	NSW status	No. of important populations, Post 1990 Cumberland records as % of NSW records, % of total C'wealth distribution	Category	Comment
Dasyurus maculatus maculatus (SE mainland population)	Spot-tailed Quoll, Spotted-tail Quoll, Tiger Quoll (south eastern mainland population)	Endangered	Vulnerable	1, 0.4%, 0.98%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30
Isoodon obesulus obesulus	Southern Brown Bandicoot (eastern), Southern Brown Bandicoot (south-eastern)	Endangered	Endangered	0, 0, 0.59%	Category 2	The species distribution extends from the Hawkesbury River in NSW to Kangaroo Island in South Australia. In NSW it occurs in two populations located in Ku-ring-gai Chase and Garigal National Parks, and far south east NSW around Ben Boyd National Park. It is unlikely to occur in the Strategic Assessment Area
Megaptera novaeangliae	Humpback Whale	Vulnerable	Vulnerable	0, 0, 0	Category 2	The species occurs in marine areas. It is unlikely to occur in the Strategic Assessment Area
Petauroides volans	Greater Glider	Vulnerable	Not Listed	3, 0.15%, 0.37%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30
Petrogale penicillata	Brush-tailed Rock-wallaby	Vulnerable	Endangered	0, 0, 0.87%	Category 2	The species' distribution occurs along the Great Dividing Range from Queensland to Victoria. No records occur in the Strategic Assessment Area and it is unlikely to be reliant on the area
Phascolarctos cinereus	Koala (combined populations of Queensland, New South Wales and the Australian Capital Territory)	Vulnerable	Vulnerable	1, 0.89%, 0.22%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30

Scientific name	Common name	Commonwealth status (EPBC Act)	NSW status	No. of important populations, Post 1990 Cumberland records as % of NSW records, % of total C'wealth distribution	Category	Comment
Potorous longipes	Long-footed potoroo	Endangered	Critically Endangered	0, 0, 0	Category 2	The species occurs in Victoria and south eastern NSW. No records occur in the Cumberland subregion and it is unlikely to occur in the Strategic Assessment Area
Potorous tridactylus tridactylus	Long-nosed Potoroo (SE mainland)	Vulnerable	Vulnerable	0, 0, 0	Category 2	The species' distribution occurs from Queensland to eastern Victoria and Tasmania. No records occur on the Cumberland subregion and it is unlikely to occur in the Strategic Assessment Area
Pseudomys fumeus	Smoky mouse	Endangered	Critically Endangered	0, 0, 0	Category 2	The species occurs in south-east NSW in the vicinity of Kosciuszko National Park. No records occur on the Cumberland subregion and it is unlikely to occur in the Strategic Assessment Area
Pseudomys novaehollandiae	New Holland Mouse, Pookila	Vulnerable	Not Listed	0, 0, 2.09%	Category 2	The species has a fragmented distribution from Queensland down to Tasmania. No records occur in the Strategic Assessment Area and it is unlikely to occur in the area
Pseudomys oralis	Hastings River mouse	Endangered	Endangered	0, 0, 0	Category 2	The species' range extends from Mount Royal National Park in NSW to Main Range National Park in Queensland. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Pteropus poliocephalus	Grey-headed Flying-fox	Vulnerable	Vulnerable	4, N/A, 0.42%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30
REPTILES						
Caretta caretta	Loggerhead Turtle	Endangered; Migratory	Endangered	0, 0, 0	Category 2	The species is a marine animal. It is unlikely to occur in the Strategic Assessment Area

Scientific name	Common name	Commonwealth status (EPBC Act)	NSW status	No. of important populations, Post 1990 Cumberland records as % of NSW records, % of total C'wealth distribution	Category	Comment
Chelonia mydas	Green Turtle	Vulnerable; Migratory	Vulnerable	0, 0, 0	Category 2	The species is a marine animal. It is unlikely to occur in the Strategic Assessment Area
Dermochelys coriacea	Leatherback Turtle, Leathery Turtle, Luth	Endangered; Migratory	Endangered	0, 0, 0	Category 2	The species is a marine animal. It is unlikely to occur in the Strategic Assessment Area
Eretmochelys imbricata	Hawksbill Turtle	Vulnerable; Migratory	Not Listed	0, 0, 0	Category 2	The species is a marine animal. It is unlikely to occur in the Strategic Assessment Area
Hoplocephalus bungaroides	Broad-headed Snake	Vulnerable	Endangered	0, 0.87%, 4.34%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30
Natator depressus	Flatback Turtle	Vulnerable; Migratory	Not Listed	0, 0, 0	Category 2	The species is a marine animal. It is unlikely to occur in the Strategic Assessment Area
AMPHIBIANS						
Heleioporus australiacus	Giant Burrowing Frog	Vulnerable	Vulnerable	0, 0.84%, 1.54%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30
Litoria aurea	Green and Golden Bell Frog	Vulnerable	Endangered	6, 63.09%, 5.48%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30
Litoria castanea	Yellow-spotted tree frog	Endangered	Critically Endangered	0, 0, 0	Category 2	The species' distribution occurs within the New England Tablelands and the South Eastern Highlands Bioregions. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Litoria littlejohni	Littlejohn's Tree Frog, Heath Frog	Vulnerable	Vulnerable	0, 0, 0.74%	Category 2	The species does not occur on the Cumberland subregion. It is unlikely to occur in the Strategic Assessment Area

Scientific name	Common name	Commonwealth status (EPBC Act)	NSW status	No. of important populations, Post 1990 Cumberland records as % of NSW records, % of total C'wealth distribution	Category	Comment
Litoria raniformis	Growling Grass Frog, Southern Bell Frog, Green and Golden Frog, Warty Swamp Frog	Vulnerable	Endangered	0, 0, 0.15%	Category 2	The species occurs along the Murray and Murrumbidgee Rivers. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Mixophyes balbus	Stuttering Frog, Southern Barred Frog (in Victoria)	Vulnerable	Endangered	0, 0, 0.87%	Category 2	The species occurs along the east coast from southern Queensland to north-eastern Victoria. No records occur in the Strategic Assessment Area and it is unlikely to be reliant on the area
INVERTEBRATES						
Pommerhelix duralensis	Dural Land Snail	Endangered	Endangered	4, 16.36%, 55.37%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30
FISH						
Epinephelus daemelii	Black Rockcod, Black Cod, Saddled Rockcod	Vulnerable	Not Listed	0, 0, 0.13%	Category 2	The species occurs in marine areas. It is unlikely to occur in the Strategic Assessment Area
Macquaria australasica	Macquarie Perch	Endangered	Not Listed	1, 3.45%, 0.97%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30
Prototroctes maraena	Australian Grayling	Vulnerable	Not Listed	0, 0, 0.55%	Category 2	There are no records of the species in the Strategic Assessment Area. It is unlikely to be reliant on the area
Thunnus maccoyii	Southern Bluefin Tuna	Conservation Dependent	Not Listed	0, 0, 0	Category 2	The species is associated with marine areas. It is unlikely to occur in the Strategic Assessment Area

Table 28-2: Threatened flora

Scientific name	Common name	Commonwealth status (EPBC Act)	NSW status	No. of important populations, Post 1990 Cumberland records as % of NSW records, % of total C'wealth distribution	Category	Comment
Acacia bynoeana	Bynoe's Wattle, Tiny Wattle	Vulnerable	Endangered	25, 10.12%, 9.54%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Acacia gordonii	Gordon's Wattle	Endangered	Endangered	0, 2.5%, 4.83%	Category 2	The species only occurs in the lower Blue Mountains and Glenorie areas, and is associated with sandstone. It is unlikely to occur in Strategic Assessment Area
Acacia meiantha		Endangered; FPAL	Endangered	0, 0, 0	Category 2	The species is endemic to NSW and occurs in the Central Tablelands, west of the Great Dividing Range. It is unlikely to occur in the Strategic Assessment Area
Acacia pubescens	Downy Wattle, Hairy-stemmed Wattle	Vulnerable	Vulnerable	90, 96.05%, 61.16%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Acacia terminalis subsp. *terminalis MS*	Sunshine Wattle (Sydney region)	Endangered	Endangered	0, 0, 8.61%	Category 2	The species is associated with sandstone and is restricted to Sydney's eastern suburbs, northern suburbs and northern beaches. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Allocasuarina glareicola		Endangered	Endangered	10, 88.89%, 30.69%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Asterolasia elegans		Endangered	Endangered	0, 0, 3.53%	Category 2	The species occurs in Baulkham Hills, Hawkesbury and Hornsby LGAs. It is unlikely to occur in the Strategic Assessment Area
Bossiaea fragrans		Critically Endangered	Critically Endangered	0, 0, 0	Category 2	The species occurs only in Abercrombie Karst reserve in NSW. It is unlikely to occur in the Strategic Assessment Area
Caladenia attenuata	Duramana fingers	Critically Endangered	Critically Endangered	0, 0, 0	Category 2	The species occurs only in the Duramana area, north of Bathurst. It is unlikely to occur in the Strategic Assessment Area

Scientific name	Common name	Commonwealth status (EPBC Act)	NSW status	No. of important populations, Post 1990 Cumberland records as % of NSW records, % of total C'wealth distribution	Category	Comment
Caladenia tessellata	Thick-lipped Spider-orchid, Daddy Long-legs	Vulnerable	Endangered	0, 10%, 3.28%	Category 2	The species is primarily associated with sandstone derived communities in coastal areas. It is unlikely to occur in the Strategic Assessment Area
Callistemon purpurascens		Critically Endangered	Not Listed	0, 0, 0	Category 2	The species occurs only in the far west of the Blue Mountains. It is unlikely to occur in the Strategic Assessment Area
Commersonia prostrata	Dwarf Kerrawang	Endangered	Endangered	1, 0.96%, 13.45%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Cryptostylis hunteriana	Leafless Tongue-orchid	Vulnerable	Vulnerable	0, 0, 1.4%	Category 2	The species does not occur on the Cumberland subregion. It is unlikely to occur in the Strategic Assessment Area
Cynanchum elegans	White-flowered Wax Plant	Endangered	Endangered	9, 4.87%, 4.7%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Darwinia biflora		Vulnerable	Vulnerable	0, 1.46%, 30.61%	Category 2	This species met the criteria for a Category 1 species. However, in preparing the Assessment Report it was found that no records or potential habitat occurs for the species in the Strategic Assessment Area. As a result, the species was changed to Category 2 and was not assessed further
Deyeuxia appressa		Endangered	Endangered	0, 81.63%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Diuris eborensis		Endangered	Endangered	0, 0, 0	Category 2	The species is not known or predicted on the Cumberland subregion. Its distribution is contained within the New England Plateau. It is unlikely to occur in the Strategic Assessment Area
Eucalyptus aggregata	Black Gum	Vulnerable	Vulnerable	0, 0, 0.35%	Category 2	The species does not occur on the Cumberland subregion. It is unlikely to occur in the Strategic Assessment Area

Scientific name	Common name	Commonwealth status (EPBC Act)	NSW status	No. of important populations, Post 1990 Cumberland records as % of NSW records, % of total C'wealth distribution	Category	Comment
Eucalyptus benthamii	Camden White Gum, Nepean River Gum	Vulnerable	Vulnerable	8, 84.19%, 54.41%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Eucalyptus camfieldii	Camfield's Stringybark	Vulnerable	Vulnerable	0, 0.08%, 6.49%	Category 2	The species is restricted to sandstone and shale-capped ridges to the north-east of the Cumberland subregion. It is unlikely to occur in the Strategic Assessment Area
Eucalyptus largeana	Craven Grey Box	Endangered	Endangered	0, 0, 0	Category 2	The species occurs between Dungog and Taree; and does not occur on the Cumberland subregion. It is unlikely to occur in the Strategic Assessment Area
Eucalyptus sp. Cattai (NSW 318983)	Cattai Stringybark	Critically Endangered	Critically Endangered	0, 0, 0	Category 2	The species is found on sandstone ridges in the north-east of the Cumberland subregion. It is unlikely to occur in the Strategic Assessment Area
Genoplesium baueri	Yellow Gnat-orchid	Endangered	Endangered	1, 3.13%, 16.1%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Grevillea caleyi	Caley's Grevillea	Critically Endangered	Critically Endangered	0, 0, 0.6%	Category 2	The species is highly restricted to the Ingleside area of north-east Sydney. It is unlikely to occur in the Strategic Assessment Area
Grevillea parviflora subsp. *parviflora*	Small-flower Grevillea	Vulnerable	Vulnerable	10, 4.66%, 13.98%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Haloragis exalata subsp. *exalata*	Wingless Raspwort, Square Raspwort	Vulnerable	Vulnerable	0, 0, 8.13%	Category 2	The species favours sandstone gullies. It is unlikely to occur on the Cumberland subregion or be reliant on the Strategic Assessment Area
Haloragodendron lucasii	Hal	Endangered	Endangered	0, 3.45%, 2.12%	Category 2	The species occurs on Hawkesbury Sandstone and is restricted to Turramurra and Pymble in northern Sydney. It is unlikely to occur in the Strategic Assessment Area

Scientific name	Common name	Commonwealth status (EPBC Act)	NSW status	No. of important populations, Post 1990 Cumberland records as % of NSW records, % of total C'wealth distribution	Category	Comment
Hibbertia puberula subsp. *glabrescens*		Critically Endangered	Not Listed	1, 3.77%, 100%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Hibbertia spanantha	Julian's Hibbertia	Critically Endangered	Critically Endangered	0, 0, 0	Category 2	The species occurs mainly in Turramurra and Pymble. It is unlikely to occur in the Strategic Assessment Area
Lasiopetalum joyceae		Vulnerable	Vulnerable	0, 1.52%, 2.21%	Category 2	The species is found in the sandstone country to the north-east and north of the Cumberland subregion. It is unlikely to occur in the Strategic Assessment Area
Leptospermum deanei	Deane's Tea-tree	Vulnerable	Vulnerable	0, 25%, 14.42%	Category 2	The species is known only from the Lane Cove Valley area. It is unlikely to occur in the Strategic Assessment Area
Leucopogon exolasius	Woronora Beard-heath	Vulnerable	Vulnerable	2, 8.2%, 16.18%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Melaleuca biconvexa	Biconvex Paperbark	Vulnerable	Vulnerable	0, 0, 1.29%	Category 2	The species distribution is limited to coastal districts and adjacent tablelands in NSW, from Jervis Bay to Port Macquarie. There are no records in the Strategic Assessment Area and it is considered unlikely to occur
Melaleuca deanei	Deane's Melaleuca	Vulnerable	Vulnerable	2, 16.35%, 10.35%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Micromyrtus minutiflora		Vulnerable	Endangered	14, 98.41%, 94.62%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Olearia cordata		Vulnerable	Vulnerable	0, 0, 0.3%	Category 2	The species is associated with woodland on exposed Hawkesbury Sandstone ridges. No records occur in the Strategic Assessment Area it is unlikely to be reliant on the area

Pelargonium sp. *striatellum (G.W.Carr 10345)*	Omeo Stork's-bill	Endangered	Endangered	0, 0, 1.77%	Category 2	The species occurs in the South Eastern Highlands and South East Corner IBRA bioregions as well as the Hawkesbury-Nepean, Murrumbidgee, Southern Rivers and North East Natural Resource Management Regions. No records occur in the Cumberland subregion and it is unlikely to occur in the Strategic Assessment Area
Persicaria elatior	Tall Knotweed	Vulnerable	Vulnerable	N/A	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Persoonia acerosa	Needle Geebung	Vulnerable	Vulnerable	0, 0, 3.26%	Category 2	The species' distribution is restricted to the central coast and Blue Mountains. No records occur on the Cumberland subregion and it is unlikely to occur in the Strategic Assessment Area
Persoonia bargoensis	Bargo Geebung	Vulnerable	Endangered	1, 69.7%, 62.77%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Persoonia glaucescens	Mittagong Geebung	Vulnerable	Endangered	10, 8.02%, 8.92%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Persoonia hirsuta	Hairy Geebung, Hairy Persoonia	Endangered	Endangered	6, 6.27%, 12.51%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Persoonia mollis subsp. *maxima*		Endangered	Endangered	0, 2.68%, 25.72%	Category 2	The species occurs in the sandstone surrounding northern Sydney and beyond the Cumberland subregion. It is unlikely to occur in the Strategic Assessment Area
Persoonia nutans	Nodding Geebung	Endangered	Endangered	9, 96.66%, 88.45%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29

Scientific name	Common name	Commonwealth status (EPBC Act)	NSW status	No. of important populations, Post 1990 Cumberland records as % of NSW records, % of total C'wealth distribution	Category	Comment
Pimelea curviflora var. *curviflora*		Vulnerable	Vulnerable	3, 6.79%, 26.75%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Pimelea spicata	Spiked Rice-flower	Endangered	Endangered	26, 98.06%, 74.42%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Pomaderris brunnea	Rufous Pomaderris	Vulnerable	Endangered	3, 67.12%, 16.02%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Pomaderris cocoparrana		Endangered	Endangered	0, 0, 0	Category 2	The species is endemic to NSW and mainly occurs in and around the Cocoparra Range, northeast of Griffith. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Pomaderris delicata		Critically Endangered	Critically Endangered	0, 0, 0	Category 2	The species occurs between Goulburn and Bungonia. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Prostanthera marifolia	Seaforth Mintbush	Critically Endangered	Critically Endangered	0, 0.61%, 4.29%	Category 2	The species is endemic to NSW. It only occurs in the Manly area in northern Sydney, in the Duffy's Forest ecological community. It is unlikely to occur in the Strategic Assessment Area
Pterostylis gibbosa	Illawarra Greenhood, Rufa Greenhood, Pouched Greenhood	Endangered	Endangered	0, 0, 7.1%	Category 2	The species only occurs in the Illawarra and middle Hunter Valley. It is closely related to *Pterostylis saxicola*. It does not occur in the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Pterostylis pulchella	Pretty Greenhood	Vulnerable	Vulnerable	0, 0, 4.78%	Category 2	The species is restricted to the Illawarra escarpment and Southern Highlands of NSW. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area

Scientific name	Common name	Commonwealth status (EPBC Act)	NSW status	No. of important populations, Post 1990 Cumberland records as % of NSW records, % of total C'wealth distribution	Category	Comment
Pterostylis saxicola	Sydney Plains Greenhood	Endangered	Endangered	8, 88%, 59.69%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Pultenaea aristata		Vulnerable	Vulnerable	0, 0, 2.23%	Category 2	The species occurs from Heathcote to Port Kembla in NSW and is associated with low nutrient sandstone soils. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Pultenaea glabra	Smooth Bush-pea, Swamp Bush-pea	Vulnerable	Vulnerable	0, 0, 2.46%	Category 2	The species occurs in disjunct populations in Queensland, NSW, and Victoria. In NSW it is restricted to the higher Blue Mountains. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Pultenaea parviflora		Vulnerable	Endangered	15, 98.96%, 92.95%	Category 1	A detailed impact analysis has been carried out for this species in Chapter 29
Rhizanthella slateri	Eastern Underground Orchid	Endangered	Vulnerable	0, 0, 4.4%	Category 2	The species is endemic to NSW and occurs from the mid-north coast to the south coast. It does not occur in the Strategic Assessment Area and is unlikely to be reliant on the area
Syzygium paniculatum	Magenta Lilly Pilly, Magenta Cherry, Daguba, Scrub Cherry, Creek Lilly Pilly, Brush Cherry	Vulnerable	Endangered	0, 7.28%, 5.7%	Category 2	The species is only found in NSW and occurs from Upper Lansdowne on the north coast to Conjola National Park on the south coast. Six records occur in the Strategic Assessment Area, but it is unlikely to be reliant on the area and likely results from records of planted individuals as the species is popular in cultivation
Thelymitra kangaloonica	Kangaloon Sun Orchid	Critically Endangered	Critically Endangered	0, 0, 11.77%	Category 2	The species only occurs in Wingecarribee, NSW. It does not occur in the Cumberland subregion or the Strategic Assessment Area

Scientific name	Common name	Commonwealth status (EPBC Act)	NSW status	No. of important populations, Post 1990 Cumberland records as % of NSW records, % of total C'wealth distribution	Category	Comment
Thesium australe	Austral Toadflax, Toadflax	Vulnerable	Vulnerable	0, 0, 0.84%	Category 2	The species is considered to be extinct on the Cumberland as no records have been recorded since the original specimen was collected. It is unlikely to rely on the Cumberland subregion as it is distributed across NSW, ACT and parts of Queensland and Victoria
Wollemia nobilis	Wollemi pine	Critically Endangered	Critically Endangered	N/A	Category 2	The species is found naturally only in western Wollemi National Park. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Zieria involucrata		Vulnerable	Endangered	0, 0, 1.54%	Category 2	The species has a restricted distribution between Yengo National Park and Marramarra National Park adjacent to the Blue Mountains National Park. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area
Zieria parrisiae		Critically Endangered	Critically Endangered	N/A	Category 2	The species is highly restricted to one site on a private property west of Pambula, NSW. It does not occur on the Cumberland subregion and is unlikely to occur in the Strategic Assessment Area

28.2.2 THREATENED ECOLOGICAL COMMUNITIES

All TECs identified as potentially occurring in the Strategic Assessment Area were assigned to Category 1 (see Table 28-1).

There are eight Category 1 TECs in total. The assessments of each TEC are contained in Chapter 31.

Table 28-3: Threatened ecological communities

Commonwealth-listed TEC	Commonwealth status
Castlereagh Scribbly Gum and Agnes Banks Woodlands of the Sydney Basin Bioregion	Endangered
Coastal Swamp Oak (Casuarina glauca) Forest of New South Wales and South East Queensland ecological community	Endangered
Cooks River/Castlereagh Ironbark Forest of the Sydney Basin Bioregion	Critically Endangered
Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest	Critically Endangered
Elderslie Banksia Scrub Forest in the Sydney Basin Bioregion	Critically Endangered
Shale Sandstone Transition Forest of the Sydney Basin Bioregion	Critically Endangered
Turpentine-Ironbark Forest of the Sydney Basin Bioregion	Critically Endangered
Western Sydney Dry Rainforest and Moist Woodland on Shale	Critically Endangered

28.2.3 MIGRATORY SPECIES

The following listed migratory species were assigned to Category 1:

- 21 species of migratory shorebirds (see Table 28-4)
- 8 other migratory birds (see Table 28-5)

Table 28-4: Migratory shorebirds

Scientific name	Common name	Commonwealth status (EPBC Act)	Species recorded in the Cumberland subregion	Category	Comment
Actitis hypoleucos	Common Sandpiper	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Arenaria interpres	Ruddy Turnstone	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Calidris acuminata	Sharp-tailed Sandpiper	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Calidris canutus	Red Knot	Migratory; Endangered	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30 in relation to its listing as a threatened species, and Chapter 32 in relation to its listing as a migratory species
Calidris ferruginea	Curlew Sandpiper	Migratory; Critically Endangered	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30 in relation to its listing as a threatened species, and Chapter 32 in relation to its listing as a migratory species
Calidris melanotos	Pectoral Sandpiper	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Calidris ruficollis	Red-necked Stint	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Calidris subminuta	Long-toed Stint	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Charadrius bicinctus	Double-banded Plover	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Charadrius leschenaultii	Greater Sand-plover	Migratory; Vulnerable	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30 in relation to its listing as a threatened species, and Chapter 32 in relation to its listing as a migratory species
Gallinago hardwickii	Latham's Snipe	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32

Scientific name	Common name	Commonwealth status (EPBC Act)	Species recorded in the Cumberland subregion	Category	Comment
Limosa lapponica	Bar-tailed Godwit	Migratory; Vulnerable	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30 in relation to its listing as a threatened species, and Chapter 32 in relation to its listing as a migratory species
Limosa limosa	Black-tailed Godwit	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Numenius madagascariensis	Eastern Curlew	Migratory; Critically Endangered	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 30 in relation to its listing as a threatened species, and Chapter 32 in relation to its listing as a migratory species
Numenius minutus	Little Curlew	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Philomachus pugnax	Ruff	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Pluvialis fulva	Pacific Golden Plover	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Pluvialis squatarola	Grey Plover	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Tringa glareola	Wood Sandpiper	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Tringa nebularia	Common Greenshank	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Tringa stagnatilis	Marsh Sandpiper	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32

Table 28-5: Other migratory species*

Scientific name	Common name	Commonwealth status (EPBC Act)	Species recorded in the Strategic Assessment Area	Category	Comment
BIRDS					
Anous stolidus	Common Noddy	Migratory	No	Category 2	The species has a broad distribution and mainly occurs in the ocean off the coast of Queensland. It is unlikely to occur in the Strategic Assessment Area
Apus pacificus	Fork-tailed Swift	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Calonectris leucomelas	Streaked Shearwater	Migratory	No	Category 2	The species is migratory and occurs in waters off the coast of northern and eastern Australia. It is unlikely to occur in the Strategic Assessment Area
Cuculus optatus	Oriental Cuckoo, Horsfield's Cuckoo	Migratory	No	Category 2	The species is the same as *Cuculus saturates* (IUCN, 2018)
Cuculus saturatus	Oriental Cuckoo, Himalayan Cuckoo	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Fregata ariel	Lesser Frigatebird, Least Frigatebird	Migratory	No	Category 2	The species has a broad oceanic distribution in Australia with no records on the Cumberland subregion. It is unlikely to occur in the Strategic Assessment Area
Fregata minor	Great Frigatebird, Greater Frigatebird	Migratory	No	Category 2	The species is a pelagic bird with a broad Australian oceanic distribution. No records occur on the Cumberland subregion and it is unlikely to occur in the Strategic Assessment Area
Monarcha melanopsis	Black-faced Monarch	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Motacilla flava	Yellow Wagtail	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Myiagra cyanoleuca	Satin Flycatcher	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Pandion haliaetus	Osprey	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Rhipidura rufifrons	Rufous Fantail	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32
Symposiachrus trivirgatus	Spectacled Monarch	Migratory	Yes	Category 1	A detailed impact analysis has been carried out for this species in Chapter 32

Scientific name	Common name	Commonwealth status (EPBC Act)	Species recorded in the Strategic Assessment Area	Category	Comment
FISH					
Lamna nasus	Porbeagle, Mackerel Shark	Migratory	No	Category 2	The species occurs in marine areas. It is unlikely to occur in the Strategic Assessment Area
Manta alfredi	Reef Manta Ray, Coastal Manta Ray, Inshore Manta Ray, Prince Alfred's Ray, Resident Manta Ray	Migratory	No	Category 2	The species occurs in marine areas. It is unlikely to occur in the Strategic Assessment Area
Manta birostris	Giant Manta Ray, Chevron Manta Ray, Pacific Manta Ray, Pelagic Manta Ray, Oceanic Manta Ray	Migratory	No	Category 2	The species occurs in marine areas. It is unlikely to occur in the Strategic Assessment Area.

* This table does not include migratory species that are also listed as threatened under the EPBC Act. These species are dealt with in Section 28.2.1

28.2.4 FINALISED PRIORITY ASSESSMENT LIST (FPAL)

All relevant species, ecological communities or key threatening processes on FPAL lists up to and including the assessment period commencing 1 October 2019 were assigned to Category 1 (see Table 28-6). There is one ecological community which has been assessed in Chapter 31.

Table 28-6: Matters on the FPAL list

Species, ecological community or key threatening process	Assessment completion date	Category	Comment
Coastal floodplain eucalypt forest of eastern Australia (previously referred to as river-flat eucalypt forest on coastal floodplains of New South Wales)	31/07/2020	Category 1	A detailed impact analysis has been carried out for this ecological community in Chapter 31

28.2.5 RAMSAR

Towra Point Nature Reserve is the only wetland of international importance (Ramsar Wetland) that was identified as being relevant to the strategic assessment. It occurs outside and downstream of the Strategic Assessment Area. It has been assigned to Category 1 and a detailed impact assessment is presented in Chapter 33.

28.2.6 WORLD AND NATIONAL HERITAGE

Four World and/or National Heritage Places were identified as being present within, or within 10 km of the Strategic Assessment Area (see Chapter 34). These include:

- The Greater Blue Mountains World Heritage Area which is listed as both a World and National Heritage Place
- Parramatta Female Factory and Institutions Precinct which is listed as a National Heritage Place
- Old Government House and Government Domain which is listed as both a World and National Heritage Place
- Ku-ring-gai Chase National Park which is listed as a National Heritage Place

A detailed impact assessment for each place is presented in Chapter 34.

28.2.7 COMMONWEALTH LAND

Commonwealth land is a protected matter under the EPBC Act. It has been assigned to Category 1 and an impact assessment is provided in Chapter 35.

29 Threatened flora impact assessment

29.1 INTRODUCTION

There are 23 Category 1 threatened flora species that are assessed in this Chapter. These species were identified as needing detailed assessment (see Part 3 for the approach, and Chapter 28 for the results) as they are reliant on the Cumberland subregion and have some potential to be impacted (directly, indirectly or cumulatively).

The Chapter is structured around the level of risk of residual adverse direct impacts (prior to the application of offsets) occurring to each species (see Table 29-1). Species most at risk from development under the Plan are discussed first, with species at lower levels of risk discussed subsequently.

The overall assessment approach for threatened flora is presented below in Section 29.2, and the methodology for the risk assessment is set out in Section 29.3.

The analysis in this Chapter concludes that the avoidance, mitigation and offset measures in the Plan will ensure that the long-term viability of all 23 threatened flora species will not be adversely influenced.

Table 29-1: Species assessed in the threatened flora chapter categorised according to the risk of residual adverse direct impacts

Level of risk of residual adverse direct impacts to species	Number of species	Species names
High risk	2	• *Pimelea spicata* • *Pultenaea parviflora*
Medium risk	2	• *Cynanchum elegans* • *Persoonia nutans*
Low risk	4	• *Eucalyptus benthamii* • *Grevillea parviflora* subsp. *parviflora* • *Persoonia bargoensis* • *Pomaderris brunnea*
Very low risk	9	• *Acacia bynoeana* • *Acacia pubescens* • *Allocasuarina glareicola* • *Melaleuca deanei* • *Micromyrtus minutiflora* • *Persicaria elatior* • *Persoonia hirsuta* • *Pimelea curviflora* var. *curviflora* • *Pterostylis saxicola*
No risk	6	• *Commersonia prostrata* • *Deyeuxia appressa* • *Genoplesium baueri* • *Hibbertia puberula* subsp. *glabrescens* • *Leucopogon exolasius* • *Persoonia glaucescens*

29.2 THREATENED FLORA ASSESSMENT APPROACH

The assessments for threatened flora follow a standard format. However, the content is tailored for the specific context of each species.

There are eight sections to the assessments. They are described below and include:

- Species background
- Approach to baseline data
- Occurrence in the Strategic Assessment Area
- Avoidance of impacts
- Direct impacts and offsets
- Potential indirect impacts and mitigation
- Potential additional impacts from essential infrastructure and tunnels
- Likely effects of implementation of the Plan on the long-term viability of the species
- Data tables

To assist the reader, standard explanatory text about the purpose and content of each section is provided throughout the assessments in *blue italics text*. The text is repeated for each species. It enables the reader to quickly understand the content of each section and where in the broader report more detailed information is available about a particular issue.

29.2.1 SPECIES BACKGROUND

Sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

29.2.2 APPROACH TO BASELINE DATA

Provides a summary of the baseline information used in the assessment. It sets out:

- If the species is a candidate species under the Biodiversity Certification Assessment Report (BCAR) process. A candidate species is a species that has been determined through the BCAR assessment as needing to be assessed because suitable habitat occurs in the nominated areas. A candidate species can be either an ecosystem credit species (ECS) (one that can be reasonably predicted to occur within a nominated area based on the habitat that occurs there - surveys are not required to determine the presence of these species); or a species credit species (SCS) (one that cannot be reasonably predicted to occur within a nominated areas based on habitat – species in these areas may either be assumed present, or their presence needs to be determined through surveys or a report prepared by an expert on that species). Understanding whether a species has been categorised as a candidate species is useful to know for the EPBC Act assessments as it is based on the application of a systematic method under the BCAR process and provides an initial indication of how development in the nominated areas might interact with the species. This helps to shape the assessment narrative
- If an expert report was prepared for the species under the BCAR process. Expert reports were prepared as part of the BCAR process for a subset of species that: could not be sufficiently surveyed for within the nominated areas due to either access restrictions, seasonality or their cryptic nature; or had highly specific habitat requirements and restrictions for which expert advice was required. It is relevant to note that the expert reports were prepared as a requirement of the BCAR process and were not specifically prepared to support the EPBC assessments. As a result, the expert reports are not relied on heavily in these assessments and instead, information (particularly relating to species ecology and distribution) has been identified and drawn on as relevant
- An overview of the habitat mapping for the species within and outside the nominated areas. Habitat maps were generated using either species distribution models (SDMs), knowledge-based maps (KBMs) reflecting broad habitat associations (for instance, with mapped PCTs) and expert polygons defined through the expert reports under the BCAR process
- An overview of the population mapping for the species. This includes:
  - Any filters applied to the use of species (BioNet) records
  - Assumptions made in identifying biological populations from the species records. It is relevant to note that the method used to define populations for this assessment was tailored to the available data and purpose of the

baseline mapping. While the definition used is based on the theoretical definition of a biological population used elsewhere in the literature, it is confounding to try to match or relabel these populations to corresponding populations in other publications, such as recovery plans or species profiles, which will be based on a different dataset, often with a different purpose, set of criteria and level of resolution. The population mapping presented in this report therefore needs to be considered as standalone and fit for purpose

    - Any criteria met in determining the importance of populations

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

29.2.3 OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

Describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file (layered PDF). The map provides critical context for the assessment and should be viewed in conjunction with the text presented in the assessments. This section also provides a qualitative description of where records and habitat occur.

29.2.4 AVOIDANCE OF IMPACTS

Provides an overview of the area of potential habitat that was avoided for each species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan.

The definition of what constitutes avoidance has been adopted from the BCAR process. Under the BAM, avoidance refers to land that is suitable for development and included in the area proposed for development or biodiversity certification, but has been avoided because of its biodiversity value. This is referred to as avoided for 'biodiversity purposes' in this assessment.

Land not impacted because it is not suitable for development or biodiversity certification, or land that has been excluded from the area proposed for development is not considered to have been avoided under the BAM. This land is referred to as avoided for 'other purposes' and includes:

- Riparian corridors consistent with the *Water Management Act 2000*:
    - Strahler stream order 2 - buffer 20 m either side
    - Strahler stream order 3 - buffer 30 m either side
    - Strahler stream order 4 and above - buffer 40 m either side
- State protected land (>18 degrees slope, considered too steep for urban development)

Some land within the nominated areas was not considered for inclusion in the area proposed for development and has therefore been identified as 'excluded' land. These lands include:

- Existing protected land, including reserves and established offset sites
- Council owned land which is zoned for environmental conservation, environmental management or recreation
- Commonwealth land, such as Defence Establishment Orchard Hills
- Lands within the nominated areas already assessed as part of another development approval (Bingara Gorge), or lands progressing through an alternate assessment (Mount Gilead, Menangle Park, Sydney Metro Stage 1)
- Lands already developed (existing urban areas, urban land zones and roads)

A further, detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.2.5 DIRECT IMPACTS AND OFFSETS

Provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts. Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat.

Direct impacts were determined based on an intersect of the urban capable lands and transport corridors with the baseline mapping generated for each threatened flora species. It has been assumed that total permanent clearing will occur within the urban capable lands and transport corridors for the purposes of the assessment. However, it is important to note that in reality:

- Further avoidance will be undertaken within the transport corridors (see Chapter 7)
- Direct impacts will occur progressively over the life of the Plan, which reduces the severity of impacts

The extent or scale of loss is presented in terms of:

- Number and size of populations/important populations
- Hectares of potential habitat

The analysis also considers the likelihood of direct impacts leading to fragmentation of populations and areas of potential habitat.

To provide a sense of the magnitude and importance of direct impacts, the risk of residual adverse impacts to each species occurring as a result of any direct impacts was characterised as per the methodology set out in Section 29.3 below.

The Plan provides offsets for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.2.6 POTENTIAL INDIRECT IMPACTS AND MITIGATION

Identifies the potential indirect impacts to each species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to a species if:

- The indirect impact is identified as a threat in a relevant profile, conservation advice or recovery plan, *and*
- The threat is present in the Cumberland subregion, *and*
- The Plan has the potential to exacerbate the threat

Relevant indirect impacts were identified by drawing on ecological and life history information in species profiles, conservation advices and recovery plans, and species records and habitat maps prepared for this Assessment Report.

The indirect impacts section then goes on to determine if the generic management strategies in the Plan will be adequate for addressing indirect impacts, or if species-specific commitments are necessary. Species-specific commitments were generally considered necessary where a species was found to have a particular vulnerability or susceptibility to a potential indirect impact in a discrete location.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

31.1.1 POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

Considers the potential additional impacts to species due to essential infrastructure projects that are needed to support development within the nominated areas. These might include projects such as water and electricity utilities, communications facilities, stormwater management systems, and waste or resource management systems. The assessment covers projects that may need to be located outside urban capable lands and on areas that are identified as avoided lands within the nominated areas.

This section also assesses the likelihood of potential additional impacts to species due to the tunnel sections of the transport corridors. The impacts of tunnels were assessed separately to the rest of the transport corridors as only small areas of the footprints will be disturbed and it is not possible to determine at this stage the nature and extent of those impacts.

Please refer to the following chapters for details about these development types:

- Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels

- Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)

29.2.7 LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

Considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.2.8 DATA TABLES

Sets out the data tables for occurrence, avoidance and direct impacts for each species.

29.3 RISK ASSESSMENT APPROACH FOR THREATENED FLORA

This section sets out:

- The purpose of the risk assessment approach
- The risk assessment framework
- A description of the risk ratings
- The likelihood and consequence definitions for direct impacts to populations and/or potential habitat
- The likelihood and consequence definitions for direct impacts leading to fragmentation

29.3.1 PURPOSE

The purpose of the risk assessment for threatened flora was to determine the level of risk of residual adverse impacts occurring to a species as a result of direct impacts. Indirect impacts were assessed differently (see Chapter 15) and were not subject to the same risk assessment process.

The term "residual adverse impacts" was used as it forms part of the EPBC Act Environmental Offsets Policy (DSEWPC, 2012c). Offsets are typically required under the EPBC Act when residual adverse impacts remain after avoidance and mitigation measures have been applied. In this case, the Plan provides offsets for species which are considered to be at high or medium risk of residual adverse impacts. Offsets are not provided for species which are considered to be at low or very low risk. As outlined above, the rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

A risk based approach to considering residual adverse impacts is appropriate for the strategic assessment. The Terms of Reference (Clause 4.2) identify the need for the impact assessment to consider the "level of likely risk to each protected matter". The spatial and temporal scale of the Plan means that there is an inherent level of uncertainty in the baseline data (both for habitat and records). In particular, the potential habitat mapping for the majority of species is highly precautionary and does not necessarily indicate with great certainty if a species will occur in an impact area. It is critical therefore to understand the level of risk to each species rather than take a simplistic view of direct impacts as presented in the impact numbers.

29.3.2 RISK ASSESSMENT FRAMEWORK

Risk is generally considered to be the combination of the likelihood and consequence of an event occurring. The methodology used in the assessment is based on an adapted version of the Australian Standard on Risk Management (Standards Australia, 2018).

The assessment for threatened flora was based on:

- The risk ratings table shown in Table 29-2

- Understanding the risk of residual adverse impacts due to direct impacts to populations and/or potential habitat based on:
  - The likelihood definitions in Table 29-3
  - The consequence definitions in Table 29-4, Table 29-5, Table 29-6, and Table 29-7
- Understanding the risk of residual adverse impacts due to fragmentation based on:
  - The likelihood definitions in Table 29-8
  - The consequence definitions in Table 29-11

The final level of risk for a species was determined on a precautionary basis. The highest level of risk based on the consideration of impacts to populations, potential habitat, or due to fragmentation was taken.

29.3.3 RISK RATINGS

Four levels of risk were defined through the process (see Table 29-2). They were:

- Very low risk = very low risk that residual adverse impacts to a species will occur. Offsets for residual impacts were not considered necessary
- Low risk = low risk that residual adverse impacts to a species will occur. Offsets for residual impacts were not considered necessary
- Medium risk = medium risk that residual adverse impacts to a species will occur. Offsets were considered necessary
- High risk = high risk that residual adverse impacts to a species will occur. Offsets were considered necessary

Where there were no direct impacts to a species, there was considered to be no risk of residual adverse impacts.

Table 29-2: Risk ratings table

	CONSEQUENCE				
LIKELIHOOD	**Negligible**	**Minor**	**Moderate**	**Major**	**Extreme**
Almost certain	Low	Medium	Medium	High	High
Likely	Low	Low	Medium	Medium	High
Possible	Very low	Low	Low	Medium	Medium
Unlikely	Very low	Very low	Low	Low	Medium

29.3.4 LIKELIHOOD AND CONSEQUENCE DEFINITIONS FOR DIRECT IMPACTS TO POPULATIONS AND/OR POTENTIAL HABITAT

LIKELIHOOD

Table 29-3 sets out the definitions for the likelihood that a threatened flora species will be directly impacted due to impacts to populations and/or potential habitat. These definitions:

- Draw on the baseline data for the species in terms of records and potential habitat mapping
- Consider the level of confidence in the records and potential habitat mapping. Strict definitions of “high”, “moderate” and “low” confidence are not provided as they are species specific in relation to the baseline data. Judgements about the level of confidence in the data were instead determined based on the expert judgement of the assessment team who created the baseline data

Table 29-3: Likelihood definitions for direct impacts to populations and/or potential habitat

Likelihood	Definition
Almost certain	• Direct impacts to a known population with high confidence in the accuracy of the records
Likely	• Direct impacts to a known population with some uncertainty in the accuracy of the records OR • Direct impacts to potential habitat with high confidence that the species occurs in the impact area
Possible	• No direct impacts to a known population • Direct impacts to potential habitat with moderate confidence that the species occurs in the impact area
Unlikely	• No direct impacts to a known population • Direct impacts to potential habitat with low confidence that the species occurs in the impact area

CONSEQUENCES

Consequence was determined by separately considering impacts to potential habitat as well as any impacts to known populations. The highest ranking of consequence was then taken for a species.

The criteria for determining consequence were based on a range of factors including:

- Conservation status. Impact thresholds for consequence were smaller for critically endangered species than for endangered species, and smaller for endangered species than for vulnerable species
- If the species is considered to be an SAII entity under the BCAR process or is endemic (>90 per cent of records in the subregion) to the Cumberland subregion. Species that met either of these criteria were treated under the consequence thresholds for critically endangered species even if they had a lower conservation status
- The application of both population impact thresholds and potential habitat impact thresholds. It should be noted that like all threshold approaches the numbers are arbitrary to a degree. However, the thresholds are considered to be appropriate because they:
  - Reflect the nature of the baseline data. In particular the potential habitat mapping which has been generated across the Strategic Assessment Area is precautionary in many cases and over-maps habitat
  - Are structured around conservation status
  - Reflect the expert view of the assessment team about the level of risk to species

The consequence definitions for direct impacts due to impacts to populations and/or potential habitat are set out in:

- Table 29-4 – habitat for vulnerable species
- Table 29-5 – habitat for endangered species
- Table 29-6 – habitat for critically endangered, SAII, and/or endemic species
- Table 29-7 - populations

Table 29-4: Consequence definitions for direct impacts to potential habitat for vulnerable species

Potential habitat thresholds	Confidence that species occurs in impact area		
	High	Moderate	Low
Loss of >15% of mapped potential habitat	Extreme	Extreme	Minor
Loss of 10-15% of mapped potential habitat	Extreme	Major	Minor
Loss of 6-10% of mapped potential habitat	Major	Moderate	Negligible
Loss of 2-6% of mapped potential habitat	Moderate	Minor	Negligible
Loss of <2% of mapped potential habitat	Minor	Negligible	Negligible

Table 29-5: Consequence definitions for direct impacts to potential habitat for endangered species

Potential habitat thresholds	Confidence that species occurs in impact area		
	High	Moderate	Low
Loss of >10% of mapped potential habitat	Extreme	Extreme	Minor
Loss of 7-10% of mapped potential habitat	Extreme	Major	Minor
Loss of 3-7% of mapped potential habitat	Major	Moderate	Negligible
Loss of 1-3% of mapped potential habitat	Moderate	Minor	Negligible
Loss of <1% of mapped potential habitat	Minor	Negligible	Negligible

Table 29-6: Consequence definitions for direct impacts to potential habitat for critically endangered, SAII* and/or endemic species**

Potential habitat thresholds	Confidence that species occurs in impact area		
	High	Moderate	Low
Loss of >5% of mapped potential habitat	Extreme	Extreme	Minor
Loss of 2-5% of mapped potential habitat	Extreme	Major	Minor
Loss of 1-2% of mapped potential habitat	Major	Moderate	Negligible
Loss of 0.5-1% of mapped potential habitat	Moderate	Minor	Negligible
Loss of <0.5% of mapped potential habitat	Minor	Negligible	Negligible

* SAII = species that are potentially subject to Serious and Irreversible Impacts as identified through the BCAR process

** Endemic = species that are considered endemic to Cumberland subregion because more than 90 per cent of records of the species occur within the subregion

Table 29-7: Consequence definitions for direct impacts to populations

Consequence	TYPE OF IMPACT	MEASURE BY CONSERVATION STATUS		
		Vulnerable	Endangered	Critically endangered or SAII* or endemic**
Extreme	• Impacts to known population, OR	• Loss of 2 or more important populations	• Loss of 2 or more populations	• Loss of 1 or more populations
	• Impacts to population at edge of occurrence, OR	• Loss of 1 important population at edge of occurrence	• Loss of 1 population at edge of occurrence	• Loss of records within a population at the edge of occurrence
Major	• Impacts to known population, OR	• Loss of 1 important population	• Loss of 1 population	• Loss of records within a population
	• Impacts to population at edge of occurrence	• Loss of records within an important population at the edge of occurrence	• Loss of records within a population at the edge of occurrence	• N/A
Moderate	• Impacts to known population, OR	• Loss of records within an important population, or the loss of a non-important population	• Loss of records within a population	• N/A
	• Impacts to population at edge of occurrence	• N/A	• N/A	• N/A
Minor	• Impacts to known population, OR	• Loss of records within a non-important population	• N/A	• N/A
	• Impacts to population at edge of occurrence	• N/A	• N/A	• N/A
Negligible	• Impacts to known population, OR	• N/A	• N/A	• N/A
	• Impacts to population at edge of occurrence	• N/A	• N/A	• N/A

* SAII = species that are potentially subject to Serious and Irreversible Impacts as identified through the BCAR process

** Endemic = species that are considered endemic to Cumberland subregion because more than 90 per cent of records of the species occur within the subregion

29.3.5 LIKELIHOOD AND CONSEQUENCE DEFINITIONS FOR FRAGMENTATION IMPACTS

Likelihood

Table 29-8 sets out a matrix for determining the likelihood that a threatened flora species will be impacted by fragmentation. The two axes of the matrix are:

- Barrier likelihood which represents a judgement about how likely a particular development will disrupt connectivity for a species. Table 29-9 provides examples of different barrier likelihoods
- Fragmentation type which sets out how a species may be impacted. Table 29-10 provides criteria for fragmentation types

Table 29-8: Likelihood definitions for fragmentation

	FRAGMENTATION TYPE (see Table 29-10**)**			
BARRIER LIKELIHOOD (see Table 29-9**)**	**Certain impact within population**	**Likely impact within population OR certain impact between populations**	**Possible impact between populations OR likely impact to habitat connected to a population**	**Impact to mapped habitat only**
Certain barrier	Almost certain	Almost certain	Likely	Possible
Likely barrier	Almost certain	Likely	Possible	Possible
Possible barrier	Likely	Likely	Possible	Unlikely
Unlikely barrier	Possible	Possible	Unlikely	Unlikely

Table 29-9: Examples of barrier likelihood

Barrier likelihood	**Examples**
Certain barrier	• If a species is thought to be unable to cross barriers >100 m, a barrier of 120 m or more is inconsistent with dispersal requirements • If a species requires continuous or semi-continuous vegetated areas for dispersal (e.g. to provide shelter for fauna or to support pollinator populations), areas with little to no vegetation (such as high density urban and/or commercial areas) are inconsistent with dispersal requirements • If a species is highly susceptible to being impacted by major roads with high traffic density (either through high roadkill rates, through aversion to noise and light, or through aversion to crossing open spaces) a major road is inconsistent with dispersal requirements
Likely barrier	• If a species is thought to be unable to cross barriers >100 m, a 100-120 m barrier is likely to be inconsistent with dispersal requirements • If a species requires continuous or semi-continuous vegetated areas for dispersal (e.g. to provide shelter for fauna or to support pollinator populations), areas with sparse vegetation (such as low to moderate density urban areas with gardens) are likely to be inconsistent with dispersal requirements • If a species is thought to be susceptible to being impacted by major roads with high traffic density (either through moderate roadkill rates, through moderate aversion to noise and light, or through moderate aversion to crossing open spaces) a major road is likely to be inconsistent with dispersal requirements
Possible barrier	• If a species is thought to be unable to cross barriers >100 m, an 80-100 m barrier may be inconsistent with dispersal requirements

Barrier likelihood	Examples
	• If a species requires continuous or semi-continuous vegetated areas for dispersal (e.g. to provide shelter for fauna or to support pollinator populations), areas with sparse vegetation (such as rural residential areas and agricultural areas) may be inconsistent with dispersal requirements • If a species is thought to have potential to be impacted by major roads with high traffic density (either through possible roadkill occurrences, possible aversion to noise and light, or through possible aversion to crossing open spaces), a major road may be inconsistent with dispersal requirements
Unlikely barrier	• If a species is thought to be unable to cross barriers >100 m, barrier of <80 m is unlikely to be inconsistent with dispersal requirements • If a species requires continuous or semi-continuous vegetated areas for dispersal (e.g. to provide shelter for fauna or to support pollinator populations), areas with moderate vegetation density (such as parks, nature reserves and vegetated areas) are unlikely to be inconsistent with dispersal requirements • If a species is not known to be impacted by major roads with high traffic density (the species is not known to be susceptible to roadkill, noise or light aversion, or aversion to open spaces), then a major road is unlikely to be inconsistent with dispersal requirements

Table 29-10: Criteria for fragmentation types

Fragmentation type	Criteria
Certain impact within population	• Barrier is placed between records of a single population, with high confidence in the accuracy of the records
Likely impact within population **OR** **Certain impact between populations**	• Barrier is placed between records of a single population, with some uncertainty in the accuracy of the records OR • Barrier is placed in mapped potential habitat between records of two or more different populations, with high confidence in the accuracy of the records
Possible impact between populations **OR** **Likely impact to habitat connected to a population**	• Barrier is placed in mapped potential habitat between records of two or more different populations, with some uncertainty in the accuracy of the records OR • Barrier is placed in mapped potential habitat, where the mapped habitat is in the vicinity of, or connected to, only one known population of the species
Impact to mapped habitat only	• Barrier is placed in mapped potential habitat, where the mapped habitat is not connected to any known populations of the species

CONSEQUENCES

Consequence was determined by considering fragmentation type and applying different criteria depending on the conservation status of the species.

Table 29-11: Consequence definitions for fragmentation

Consequence	FRAGMENTATION TYPE	MEASURE BY CONSERVATION STATUS		
		Vulnerable	Endangered	Critically endangered or SAII* or endemic**
Extreme	Internal fragmentation	• Internal fragmentation of two or more important populations, OR • Internal fragmentation of an important population at edge of occurrence	• Internal fragmentation of two or more populations, OR • Internal fragmentation of a population at edge of occurrence	• Internal fragmentation of one population
	Fragmentation between populations	• Fragmentation between populations, which impacts an important population at the edge of occurrence	• Fragmentation between populations, which impacts a population at the edge of occurrence	• Fragmentation between populations, which impacts a population at the edge of occurrence, OR • Fragmentation between populations, which impacts two or more populations which are not at the edge of occurrence
	Fragmentation between a population and potential habitat	• N/A	• N/A	• N/A
	Fragmentation of potential habitat	• N/A	• N/A	• N/A
Major	Internal fragmentation	• Internal fragmentation of one important population	• Internal fragmentation of one population	• N/A
	Fragmentation between populations	• Fragmentation between populations, which impacts two or more important populations which are not at the edge of occurrence	• Fragmentation between populations, which impacts two or more populations which are not at the edge of occurrence	• N/A

Consequence	FRAGMENTATION TYPE	MEASURE BY CONSERVATION STATUS		
		Vulnerable	Endangered	Critically endangered or SAII* or endemic**
	Fragmentation between a population and potential habitat	• Fragmentation of one important population, where the population is separated from a large area of connected mapped potential habitat	• Fragmentation of one population, where the population is separated from a large area of connected mapped potential habitat, OR • Fragmentation of two or more populations, where each population is connected to either a moderate or small area of connected mapped potential habitat	• Fragmentation of one population, where the population is separated from a large area of connected mapped potential habitat, OR • Fragmentation of two or more populations, where each population is connected to either a moderate or small area of connected mapped potential habitat
	Fragmentation of potential habitat	• N/A	• N/A	• Fragmentation of a large area of potential habitat with no associated records
Moderate	Internal fragmentation	• Internal fragmentation of two or more non-important populations	• N/A	• N/A
	Fragmentation between populations	• Fragmentation between populations, which impacts one important population and one or more non-important populations not at the edge of occurrence	• N/A	• N/A
	Fragmentation between a population and potential habitat	• Fragmentation of one important population, where the population is separated from a moderate area of connected mapped potential habitat	• Fragmentation of one population, where the population is separated from a moderate area of connected mapped potential habitat	• Fragmentation of one population, where the population is separated from a moderate area of connected mapped potential habitat
	Fragmentation of potential habitat	• Fragmentation of a large area of potential habitat with no associated records	• Fragmentation of a large area of potential habitat with no associated records	• Fragmentation of a moderate area of potential habitat with no associated records
Minor	Internal fragmentation	• Internal fragmentation of one non-important populations	• N/A	• N/A
	Fragmentation between populations	• Fragmentation between populations, which impacts two or more non-	• N/A	• N/A

Consequence	FRAGMENTATION TYPE	MEASURE BY CONSERVATION STATUS		
		Vulnerable	Endangered	Critically endangered or SAII* or endemic**
		important populations not at the edge of occurrence		
	Fragmentation between a population and potential habitat	• Fragmentation of one important population, where the population is separated from a small area of connected mapped potential habitat, OR • Fragmentation of one or more non-important population, where the population is separated from a large area of connected mapped potential habitat	• Fragmentation of one or more populations, where the population is separated from a small area of connected mapped potential habitat	• Fragmentation of one population, where the population is separated from a small area of connected mapped potential habitat
	Fragmentation of potential habitat	• Fragmentation of a moderate area of potential habitat with no associated records	• Fragmentation of a moderate area of potential habitat with no associated records	• Fragmentation of a small area of potential habitat with no associated records
Negligible	Internal fragmentation	• N/A	• N/A	• N/A
	Fragmentation between populations	• N/A	• N/A	• N/A
	Fragmentation between a population and potential habitat	• Fragmentation of one or more non-important populations, where the population is separated from a moderate or small area of connected mapped potential habitat	• N/A	• N/A
	Fragmentation of potential habitat	• Fragmentation of a small area of potential habitat with no associated records, OR • Fragmentation of mapped habitat, where impacted habitat occurs outside of the known range of the species	• Fragmentation of a small area of potential habitat with no associated records, OR • Fragmentation of mapped habitat, where impacted habitat occurs outside of the known range of the species	• Fragmentation of mapped habitat, where impacted habitat occurs outside of the known range of the species

* SAII = species that are potentially subject to Serious and Irreversible Impacts as identified through the BCAR process

** Endemic = species that are considered endemic to Cumberland subregion because more than 90 per cent of records of the species occur within the subregion

SPECIES AT HIGH RISK OF DIRECT IMPACTS

29.4 *PIMELEA SPICATA* (SPIKED RICE-FLOWER)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Endangered
DESCRIPTION	A slender, low growing shrub with narrow elliptical leaves, pink tinged white flowers and green fruit. It grows up to 50 cm tall. (DoEE, 2018c)
ECOLOGY	Flowers and fruits throughout the year, although flowering is more common in summer, particularly following rainfall. The species is known to be pollinated by native bees and may also be capable of self-pollination (James, 2018b). While reproduction is the primary means of recruitment, established plants can re-sprout from a taproot after defoliation due to disturbance (James, 2018b). It is estimated that the species requires over three years to develop a sufficient tap root to enable this process to occur. Regrowing from a taproot significantly depletes energy reserves and reduces the plant's capacity to re-sprout from subsequent disturbances. The species maintains a long-lived, persistent soil seed bank. Sites which have been undisturbed for a long period of time, or sites that are subject to a high level of weed infestation, may exhibit strong recruitment following a disturbance event. Optimum disturbance frequencies are unknown for this species. It is estimated that disturbance should not occur at less than 10-year intervals. Seed dispersal is highly localised (within 30 cm of adult plants). The life span of the species could be 20-30 years or more. (DoEE, 2018c; TSSC, 2016f)
DISTRIBUTION AND HABITAT	The species occurs in the Sydney Basin IBRA: in the Cumberland Plain in the west, and Illawarra region on the coast, south of Sydney. Current known distribution in the Cumberland Plain extends from Marayong and Prospect Reservoir south to Narellan Vale and Douglas Park. In Illawarra it exists from Lansdowne past Shellharbour to northern Kiama. Habitat is associated with: • Cumberland Plain Shale Woodlands and Shale Gravel Transition Forest

	• Western Sydney Dry Rainforest and Moist Woodland on Shale Woodland In both vegetation types it occurs on well-structured clay soils derived from Wianamatta shales, in areas of undulating topography. As of 2005, the species had a known area of occupancy of 17 ha. In 2006, 80 per cent of populations had a small area of occupancy of less than 0.5 ha. (DEC, 2005a; TSSC, 2016f)
POPULATIONS	In 2006 the total population was 4,300 individual plants across 30 known populations. Of these populations, 25 were on the Cumberland Plain. They varied in size from a few individuals to more than 500 plants. Over half were populations of less than 50 individuals. (DEC, 2005a; DoEE, 2018c) Since 2006, the species has been shown to respond well to recovery actions, leading to a significant increase in abundance and area of occupancy of some populations, with examples numbering in the thousands (TSSC, 2016f). Assessment of all BioNet records of the species indicates that over 90 per cent of known records occur within the Cumberland subregion. Therefore, for the purposes of this assessment, *P. spicata* is considered to be an endemic species to the region.
SOS SITES	The following SOS sites for the species have been identified: • Prospect Nature Reserve • Narellan
RELEVANT PLANS AND POLICIES	Conservation Advice for *Pimelea spicata* (Spiked Rice-Flower) (TSSC, 2016f) *Pimelea spicata R. Br.* Recovery Plan (DEC, 2005a) Threat abatement plan for competition and land degradation by rabbits (DoEE, 2016a)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	ECOSYSTEM CREDIT SPECIES	CANDIDATE SPECIES CREDIT SPECIES			
		WILTON	GMAC	WSA	GPEC
	No	Yes	Yes	Yes	Yes
EXPERT REPORT (BCAR PROCESS)	Yes, (James, 2018b) and (James, 2018a). Available at Supporting Document C				

	WITHIN THE NOMINATED AREAS

HABITAT MAPPING	**Expert report and expert report polygons:**
	Overview of available information
	Two expert reports have been produced which separately map habitat polygons within GPEC and WSA, and in GMAC and Wilton. Both reports were authored by the same expert, T. James (2018b, 2018a).
	As part of the expert report preparation process, James produced:
	• Expert reports which outline:
	  o The ecological characteristics of *P. spicata*
	  o An overview of available data for *P. spicata* within the region
	  o The method used to map habitat polygons in each nominated area
	  o An overview of the habitat mapped in each nominated area
	• Expert report polygons, which are shapefiles which indicate the areas of potential habitat of *P. spicata* in each of the nominated areas. Note that the expert report polygons were provided to the consulting team in association with the expert reports to enable habitat analysis
	The expert report polygons provided by James have been used directly by the consulting team to conduct assessments of *P. spicata*. These uses include:
	• Calculating the amount of habitat available in each nominated area
	• Calculating the amount of habitat that will be impacted by urban capable and/or transport development
	• Calculating the amount of habitat within avoided and/or excluded land
	It is recognised that *P. spicata* is a cryptic species, which is often difficult to detect when not flowering, and may not be visible above ground during dry periods where it may persist in the soil as rootstock and/or seeds. The species flowers in response to rainfall, and therefore survey following rain is recommended. While surveys were undertaken by the consulting team for the strategic assessment during 2017-18, and then again in 2019 (during which the species was not found), it is noted that field conditions at the time of survey were hot and dry, and therefore the surveys undertaken by the consulting team are not considered to constitute proof of absence for the species. Subsequently, survey results were not used to modify the habitat polygons produced in association with the expert report.
	Overview of discrepancies between expert reports and expert report polygons
	It is noted that the expert report polygons used by the consulting team match the maps of potential habitat included in the two expert reports (Figures 4, 5, 5a, 6, 6a, 7, 8, 9, 10 and 12 in the expert report for GMAC and Wilton, and Figures 5 and 6 in the expert report for GPEC and WSA (James, 2018b, 2018a)).
	However, for all nominated areas, there are some details within the written expert reports which are at odds with the expert report polygons provided by James. Differences include:
	• Differences in the total area of habitat mapped within each nominated area
	• Differences in the identified PCTs which have been mapped to contain habitat for *P. spicata*
	• Differences in the vegetation condition states of vegetation used to identify habitat for *P. spicata*
	Unfortunately, the expert author is unavailable to provide comment or clarification on the discrepancies between the written reports and the expert report polygons. The consulting team have therefore based this assessment upon the data contained within the expert report polygons, where discrepancies with the written reports exist.

Habitat mapped in GPEC and WSA

In the written report, James (2018a) notes that *P. spicata* is known to occur in the following vegetation communities: PCT 849, 850, 806, 807, 830, 835, 1395. James (2018a) then identifies habitat mapped for *P. spicata* within the following vegetation communities: PCT 850, 849, 835, 724, 1395 (as per Table 11 of the expert report). It is noted that the expert report polygons map habitat for *P. spicata* within the following PCTs: 724, 725, 781, 835, 849, 850, 1395 and 1800, in addition to urban native/exotic vegetation with no associated PCT number.

James (2018a) further states that, as *P. spicata* is tolerant of disturbance and may re-appear in disturbed habitat, the following condition states were considered when determining suitable habitat: intact, thinned, scattered trees, derived shrubland and grassland. It is noted that the expert report polygons for *P. spicata* map habitat in vegetation of the following conditions: intact, thinned, scattered trees, derived native grassland, non-offsettable grassland and urban native/exotic.

The characteristics of the physical environment were also used to identify suitable habitat, where suitable sites include slopes in undulating low hilly terrain on Wianamatta Group shales, on moist soils, often on protected south or east facing slopes (James, 2018a).

It is recognised that the expert report identifies a total of 2,168 ha of habitat in GPEC and 564 ha of habitat in WSA (James, 2018a), whilst the associated expert report polygons indicate a total of 2,164 ha of habitat in GPEC and 512 ha of habitat in WSA.

Habitat mapped in GMAC and Wilton

In the written report for GMAC and Wilton, James (2018b) notes that *P. spicata* is known to occur in the following vegetation communities: PCT 849, 850, 806, 807, 830, 1395. James (2018b) then identifies habitat mapped for *P. spicata* within the following vegetation communities: PCT 850, 849, 608, 609, 830, 835, 1395 (as per Table 14 of the expert report). It is noted that the expert report polygons map habitat for *P. spicata* within the following PCTs: 830, 835, 849, 850, 1181, 1395, in addition to urban native/exotic vegetation with no associated PCT number.

James (2018b) further states that, as *P. spicata* is tolerant of disturbance and may re-appear in disturbed habitat, the following condition states were considered when determining suitable habitat: intact, thinned, scattered trees, derived shrubland and grassland. It is noted that the expert report polygons for *P. spicata* map habitat in vegetation of the following conditions: intact, thinned, scattered trees, derived native grassland, non-offsettable grassland and urban native/exotic.

The characteristics of the physical environment were also used to identify suitable habitat, where suitable sites include slopes in undulating low hilly terrain on Wianamatta Group shales, on moist soils, often on protected south or east facing slopes (James, 2018b).

It is recognised that the expert report identifies a total of 542 ha of habitat in GMAC and 405 ha of habitat in Wilton (James, 2018b), whilst the associated expert report polygons indicate a total of 475 ha of habitat in GMAC and 664 ha of habitat in Wilton.

Characteristics of *P. spicata* occurrence with respect to interpretation of mapped habitat

The ideal habitat of *P. spicata* is intact woodland with open, grassy understorey. However, it is recognised that *P. spicata* may persist in disturbed areas (often surviving as a long-lived seedbank), and may re-occur after disturbance to that environment has ceased and vegetation is permitted to regenerate (e.g. after mowing or grazing of a site ceases) (James, 2018b, 2018a)

Habitat that has been mapped within the four nominated areas occurs across a variety of vegetation condition states, from intact vegetation through to non-offsettable grasslands. While *P. spicata* has the potential to be present within vegetation of very low condition, such as heavily grazed paddocks, it is recognised that the species is less likely to be present in these environments than in higher condition, more intact vegetation communities with fewer threatening processes such as livestock grazing.

While it is suitable to map low condition vegetation as potential habitat for *P. spicata* (as the species does have a real potential to be present in these areas), it is recognised that the quality of habitat for the species in these areas is likely to be significantly degraded and therefore, the likelihood that the species persists in these environments is low. The habitat mapping for *P. spicata* is therefore considered to be precautionary, and it is considered unlikely that *P. spicata*, if present, would be present in high densities in degraded areas of vegetation.

	OUTSIDE THE NOMINATED AREAS
	Species distribution model (SDM). Potential habitat outside the nominated areas was mapped using an SDM. The report for this process (Supporting Document F) notes that several of the SDM layers are expected to over-predict the likely areas where mapped flora species occur, and therefore resultant habitat maps may be precautionary. No targeted surveys as part of this project were undertaken outside the nominated areas.

POPULATION MAPPING	**RECORD SELECTION**
	Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset.
	POPULATION DEFINITION
	Biological populations were defined using the records dataset and available information about the nature of the species. Populations of the species were defined to include clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators.
	IMPORTANT POPULATION CRITERIA
	Populations of *P. spicata* were then categorised as important or not-important based on the methodology set out in Section 11.5.3 of Chapter 11. All populations of *P. spicata* are considered to be important as the species is endangered.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.21 for a map of records and habitat across the Strategic Assessment Area

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 29-13 at the end of this species assessment for a breakdown of the occurrence of records and habitat for *P. spicata* in the Strategic Assessment Area.
	Records
	The majority of records for the species occur in the Blacktown, Prospect, Bankstown and Narellan districts. Populations within the vicinity of Campbelltown and Wollondilly LGAs are close to the southern limit of the species' range (James, 2018b).
	Within the Strategic Assessment Area, a total of 25 important populations have been mapped. Five populations are either wholly or partly located in existing conservation reserves. The majority of these tend to be small and scattered. However, population 53 contains 693 records, and is referred to in the Conservation Advice as a large population containing around 6,000 plants. It occurs outside of the nominated areas within the Camden Golf Club in the suburb of Narellan.
	Within the nominated areas the following populations have been recorded:
	• GPEC:
	  o Population 31 – Two records within Cranebrook surrounded by existing urban development. The population does not occur within urban capable land
	  o Population 34 – Two records near Ropes Creek in Wianamatta Regional Park. The population does not occur within urban capable land

	- Population 534 – One record adjacent to the Western Motorway (M4) in Orchard Hills. The population does not occur within the transport corridor footprint • WSA – no records • GMAC: - Population 51 – One record within roadside vegetation near to an existing industrial area. The population does not occur within urban capable land - Population 532 – One record to the east of the Hume Motorway and south of Glenlee Road within urban capable land of the nominated area - Population 533 – One record on the eastern boundary of the nominated area and Strategic Assessment Area. The population does not occur within urban capable land • Wilton – no records **Potential habitat** The baseline mapping for this assessment has mapped approximately 34,859 ha of known and potential habitat within the Strategic Assessment Area. Habitat is present across the majority of the central and eastern areas of the Strategic Assessment Area and occurs as follows: • In the north, habitat is present in the locality of Freemans Reach and Scheyville, with large areas of habitat also present within the Londonderry locality • Habitat is scattered throughout GPEC and WSA, including (but not confined to) localities such as Cranebrook, Mount Druitt, Glenmore Park, Luddenham and Kemps Creek • Large, connected areas of habitat occur to the east and south of the WSA, spanning from Wetherill Park, down through Kemps Creek and Leppington, to Camden in the south and to Theresa Park in the west • Further areas of scattered habitat occur to the south of Theresa Park and Camden, in localities such as Razorback and Wilton It is noted that mapped habitat is present within all nominated areas for this species.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.4.1 NOMINATED AREAS

RECORDS

A total of six known populations of the species occur within the nominated areas (three within GMAC and three within GPEC). Of these:

- Four populations (31, 34, 534 and 51) occur entirely within excluded lands (three in GPEC and one in GMAC)
- One population (533) occurs entirely within land avoided for biodiversity purposes (one in GMAC)
- One population (532) occurs within urban capable land (GMAC)

It is noted that the Plan includes a commitment (Commitment 2.4) to prioritise the avoidance of impacts from essential infrastructure on non-certified land to known populations of *P. spicata*.

POTENTIAL HABITAT

The baseline mapping for this assessment has mapped 1,463 ha of potential habitat within the nominated areas (not including excluded lands). Approximately 616 ha (42 per cent) has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 515 ha was avoided for biodiversity purposes
- 100 ha was avoided for other purposes

Of the land that was avoided for biodiversity purposes, 435 ha is of good to reasonable habitat condition (vegetation condition classes include intact, scattered trees, thinned and derived native grassland) and 80 ha is habitat in highly degraded condition (vegetation condition classes include non-offsettable grasslands and urban native/exotic vegetation). The vast majority (84 per cent) of avoidance of biodiversity purposes therefore includes areas of higher quality habitat for the species.

A breakdown of avoidance of potential habitat across each nominated area is provided in Table 29-14.

It is important to note that the avoidance calculations in Table 29-14, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 29-14 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

29.4.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

It is noted that there is a total of 386.3 ha of potential habitat for *P. spicata* within tunnel footprints within the transport corridors, with large numbers of records in adjacent areas suggesting it is likely that the species does occur in the tunnel footprint. The Plan includes a commitment (Commitment 4.1) to avoid and minimise impacts to *P. spicata* as a result of tunnel construction activities within or adjacent to the footprints of the Outer Sydney Orbital (OSO) and Metro Rail Future Extension. This commitment will ensure that appropriate avoidance of impacts to *P. spicata* will occur during the development of the transport corridors in known habitat for the species.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.4.3 LOSS OF KNOWN POPULATIONS AND POTENTIAL HABITAT

Implementation of the Plan will lead to direct impacts to a known population and a loss of potential habitat. A summary of these impacts is provided in Table 29-15.

IMPACTS TO KNOWN POPULATION

Population 532 is an important population which occurs within the urban capable lands in GMAC. It consists of one record dated from October 2018, with 160 plants noted in the species' record. The record is located within a small (approximately 3 ha) patch of vegetation mapped as Cumberland Plain Shale Woodlands and Shale-Gravel Transition Forest in a thinned condition. This vegetation patch is isolated from other vegetation and occurs in a significantly cleared landscape.

Given that one individual plant may consist of up to 50 stems (TSSC, 2016f), the exact number of individuals within the population is unclear. However, the population is likely to be moderate in size relative to other known populations, noting that a limited number of known populations contain thousands of individuals, while the majority contain 50 or less (TSSC, 2016f).

It is noted that the population is not located on the edge of the species' extent of occurrence and the small, degraded and isolated condition of the habitat potentially limits the long-term viability of the population. However, as described in the species conservation advice, any habitat where populations are known to occur is considered habitat critical to the survival of the species and all populations are considered to be important populations that are necessary for the species' survival and recovery.

For these reasons, it is recommended that the Plan adopt an additional species-specific commitment for *P. spicata* to retain some or all of population 532 within GMAC. This recommendation is an outcome of this impact assessment which has developed too late in the process to be adopted in the draft version of the Plan for public comment. It is very likely the recommendation will be adopted under the Plan prior to finalisation for endorsement and approval.

It should be noted that this recommendation does not change the risk rating applied to the species. This recommendation is taken to mitigate the scale of impact and possible implications for viability by maintaining part of the population but does not remove the likelihood of some impacts to the population from occurring.

LOSS OF POTENTIAL HABITAT

956 ha of potential habitat for the species will be impacted. This is 2.7 per cent of mapped potential habitat across the Strategic Assessment Area. The loss of potential habitat occurs across all of the nominated areas and transport outside the nominated areas.

It is recognised that, of the 956 ha of potential habitat impacted, 438 ha (46 per cent of impacted vegetation) is in a highly degraded state (being classed as either non-offsettable grassland, or urban native/exotic vegetation). As outlined in the habitat mapping approach overview above, while there is a potential that *P. spicata* may persist in areas of degraded habitat, it is considered highly unlikely that the species would be present in high densities in such areas. Therefore, the habitat mapping for *P. spicata* within impacted areas is considered to be precautionary.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of direct impacts to an important population is considered to be high. This risk ranking is triggered for impacts to species' records, as follows:

- The likelihood of actual impacts occurring to the species has been categorised as almost certain. There will be direct impacts to a known population of the species, with high confidence in the accuracy of the records
- The consequence of any impacts to the species (if they did occur) has been categorised as major. There will be a loss of an endangered (endemic) population which is not at the edge of the species' occurrence

The risk of residual adverse impacts occurring to the species as a result of impacts to mapped habitat are considered to be medium. This risk ranking is triggered for impacts to species' habitat, as follows:

- The likelihood of actual impacts occurring to the species within mapped habitat has been categorised as possible. While there will be direct impacts to potential habitat, there is moderate confidence that the species will occur in the impact area (it is noted that habitat mapping for this species includes significant areas (438 ha) of degraded habitat, where there is a lower likelihood of species persistence, and therefore the habitat mapping is considered precautionary)
- The consequence of impacts to the species (if they did occur) has been categorised as major. There will be a loss of 2.7 per cent of mapped potential habitat (endemic species), with moderate confidence that the species occurs in the impact area

29.4.4 FRAGMENTATION OF HABITAT

FRAGMENTATION IMPACTS

The Plan will lead to fragmentation of potential habitat in the following locations:

- Fragmentation of a moderate area of mapped habitat associated with records of the species at Cobbitty due to the development of the OSO
- Fragmentation of a small area of mapped habitat associated with records of the species within GPEC due to the development of the OSO within Wianamatta Regional Park

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of fragmentation is considered to be low. This is because:

- The likelihood of fragmentation has been categorised as possible. This is because:
  - The likelihood that development presents a barrier to dispersal of the species is likely. While seed dispersal of *P. spicata* is highly localised (within 30 cm of adult plants), it is recognised that the species is pollinated by insects and therefore genetic connectivity has potential to be maintained if pollinator movement is not obstructed. While detailed planning for development within the transport corridors has not yet been completed, it is thought to be likely that the OSO will constitute a likely barrier to seed dispersal for the species
  - The type of fragmentation (as defined in the risk assessment approach in Section 29.3) is impact to habitat connected to a population. This is because there are known records located on mapped potential habitat which is fragmented by the OSO development
- The consequence of fragmentation has been categorised as moderate. This is because the area to be fragmented is connected to a known population of the species and is of moderate size

29.4.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

To compensate for the predicted direct impacts to the species, the Plan includes a commitment to secure 3 offset locations for the species as part of the conservation program. This will provide a substantial addition to the level of protection of the species within the Strategic Assessment Area where currently only five populations (out of a total of 25) occur in protected areas. In situ protection of *P. spicata* populations is a fundamental component of the species' recovery plan.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.4.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice (TSSC, 2016f) and Recovery Plan (DEC, 2005a) (and other key documents) for *P. spicata* identify a range of threats to the species. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats in key species documents) are considered relevant to implementation of the Plan:

- Weed invasion
- Inappropriate fire regimes
- Hydrological disturbance such as increased urban run-off
- Illegal dumping of rubbish and garden waste
- High frequency land management (e.g. mowing and slashing, weed control including herbicide use)

Browsing by rabbits and intensive livestock grazing have also been identified as key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate these threats across the Strategic Assessment Area.

WEED INVASION

Weed invasion is identified as a potential threat to *P. spicata*. Weed species which form dense thickets or ground covers are recognised to pose a particular threat to the species. Weeds may out-compete and displace *P. spicata*, reducing reproductive success and re-sprouting potential of adults, and reducing the successful growth of seedlings. Key weed species which threaten *P. spicata* include African olive, lantana (*Lantana camara*), African lovegrass (*Eragrostis curvula*), Rhodes grass (*Chloris gayana*), Kikuyu grass (*Pennisetum clandestinum*) and bridal creeper (*Asparagus asparagoides*) (TSSC, 2016f).

These weeds are already present within the Strategic Assessment Area. However, urban, transport and agricultural development has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

Key risk areas are those that are easily accessible to the public and in close proximity to urban development and roads. Higher risk areas (where *P. spicata* is located in proximity to urban development, roads and publicly accessible land) are located as follows:

- Near Menangle Park, where population 532 occurs adjacent to urban capable development
- Near Twin Creeks, were population 40 occurs in proximity to urban capable development
- North of the Western Motorway, where population 534 occurs adjacent to urban capable development
- Within Wianamatta Regional Park, where population 34 occurs to the west of the OSO footprint
- Where potential habitat for the species is mapped adjacent to urban capable and transport development (which occurs in multiple scattered locations in each nominated area)

The Plan incorporates species-specific measures for the protection of *P. spicata*, which will contribute to the control of weeds within known and potential habitat for the species. Species-specific measures which are relevant to weed control include:

- Protecting three known offset locations for *P. spicata* (Commitment 9.1). It is noted that offset locations will be managed as conservation reserves which will provide for long-term protection of known populations of the species
- Implementation of mitigation measures to address the impacts of the spread of weeds on *P. spicata* associated with urban (Commitment 5) and transport (Commitment 6) development, including a commitment to control weeds associated with the construction of proposed tunnels within the major transport corridors (Commitment 6.2)

The Plan further incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Area (SCA). This includes a number of actions, of which the following are the most relevant to the outcome for *P. spicata*:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes:
  - Partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches

- Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

Also relevant for the *P. spicata* is that a known population of the species (population 533), in addition to mapped potential habitat, is located within the proposed footprint for Stage 1 of the Georges River Koala Reserve (Commitment 10). The establishment of the Koala Reserve is a major focus of the Plan and will be managed for conservation purposes, which will include weed management measures to protect the biodiversity values of the reserve.

The package of measures in the Plan is expected to adequately manage the risk to *P. spicata* from the increased risk of weeds associated with development. This is because:

- Three known offset locations for *P. spicata* will be obtained (Commitment 9.1) and managed for conservation purposes, which will ensure long-term protection of known populations and habitat of this species
- The proposed Georges River Koala Reserve (Commitment 10) intercepts mapped potential habitat and a known population of *P. spicata.* Protection of this reserve and management for conservation purposes will contribute to long-term protection of known populations and habitat of *P. spicata*
- There is a specific requirement for the impact of weeds to be managed with regards to the requirements of *P. spicata* in relation to the development of tunnels within major transport corridors
- There are commitments (Commitment 16 and Commitment 23) which will coordinate, enable and conduct effective weed control programs in strategic locations within the Strategic Assessment Area to manage priority weed species
- Proponents will be required to minimise the risk of weed spread, and to manage weeds, during the design, development and operational stages of development
- Establishment of environmental zoning of approximately 616 ha of mapped potential habitat of *P. spicata* within avoided lands will enable establishment of an adequate framework for management of weeds in these areas

These controls are consistent with a number of suggested management actions in the Conservation Advice, including (TSSC, 2016f):

- "Incorporate weed management/habitat restoration plans in site-specific management plans developed for all known spiked rice-flower populations, including surrounding buffer zones"
- "Implement relevant weed control measures according to site-specific weed management plans"

INAPPROPRIATE FIRE REGIMES

Altered fire regimes are identified as a potential threat to *P. spicata* (TSSC, 2016f). This can be caused by:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

Increased human activity within the nominated areas has the potential to alter fire regimes, through potentially increasing fire frequencies in some areas, and decreasing fire frequencies in others, through the mechanisms outlined above. It is noted *P. spicata* is threatened by both very frequent and very infrequent fire, as frequent fire prevents maturation and reproduction of individuals, whilst infrequent fire reduces the germination of seeds (TSSC, 2016f).

Key risk areas are those that are easily accessible to the public and in close proximity to urban development and roads. As outlined above, higher risk areas include populations 532, 40, 534 and 34, in addition to scattered areas of mapped potential habitat in each nominated area.

The Plan incorporates species-specific measures for the protection of *P. spicata*, which will contribute to the maintenance of appropriate fire regimes within species' habitat and provide for protection for the species. Species-specific measures which are relevant to fire regime management include: protecting three known offset locations for *P. spicata* (Commitment 9.1). It is noted that offset locations will be managed as conservation reserves which will provide for long-term protection of known populations of the species.

The Plan further incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for *P. spicata* being:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for *P. spicata*. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes.

Also relevant for the *P. spicata* is that a known population of the species (population 533), in addition to mapped potential habitat, is located within the proposed footprint for Stage 1 of the Georges River Koala Reserve (Commitment 10). The establishment of the Koala Reserve is a major focus of the Plan and will be managed for conservation purposes, which will include the application of the fire management strategy and a set of measures to control access to bushland which will help minimise risks around arson and accidental fires.

The package of measures in the Plan is expected to adequately manage the risk to *P. spicata* from altered fire regimes as a result of development. This is because:

- Three known offset locations for *P. spicata* will be obtained (Commitment 9.1) and managed for conservation purposes, which will ensure long-term protection of known populations and habitat of this species
- The proposed Georges River Koala Reserve (Commitment 10) intercepts mapped potential habitat and a known population of *P. spicata.* Protection of this reserve and management for conservation purposes will contribute to long-term protection of known populations and habitat of *P. spicata*
- Establishment of environmental zoning of approximately 616 ha of mapped potential habitat of *P. spicata* within avoided lands will enable establishment of an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting mapped potential habitat and/or known records for *P. spicata* which is located adjacent to urban capable lands
- Fire management authorities will be engaged to ensure they understand the requirements of *P. spicata* and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas

These controls are consistent with a number of suggested management actions in the Conservation Advice, including (TSSC, 2016f):

- "Develop and implement a fire management strategy for conservation of the based on research of the species' fire ecology and in consultation with the NSW Rural Fire Service and other relevant stakeholders with regards to fire control measures"
- "Physical damage to the habitat and individuals of the threatened species must be avoided during and after fire operations"

HYDROLOGICAL DISTURBANCE

Hydrological disturbance as a result of changed land use patterns has been identified as a potential threat to *P. spicata* (TSSC, 2016f). Key risk areas are those that are those which are in proximity to areas of development (such as urban and industrial areas and roads), which may experience altered runoff and hydrological patterns as a result of development. As outlined above, higher risk areas include populations 532, 40, 534 and 34, in addition to scattered areas of mapped potential habitat in each nominated area.

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for *P. spicata*. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5) and transport (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through:

- Development controls in the nominated areas in relation to:
  - Water cycle management. For example:
    - Water management measures must comply with council's requirements for detention, drainage and water sensitive urban design principles
    - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
  - Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
  - Soil erosion and sedimentation. For example:
    - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
    - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom 2004) and submitted with each subdivision development application
- The implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the TfNSW Biodiversity Guidelines (Roads and Maritime Service, 2011). These include a range of provisions to mitigate and minimise changes to hydrology

The package of measures in the Plan is expected to adequately manage the risk to *P. spicata* from changes to hydrology because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts to biodiversity values, including potential habitat for *P. spicata*
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to biodiversity values, including potential habitat for *P. spicata*

ILLEGAL DUMPING OF RUBBISH AND GARDEN WASTE

Habitat degradation through illegal dumping of rubbish and garden waste is identified as a threat to *P. spicata* (TSSC, 2016f). Development under the Plan may lead to an increase in human activity within the species' known and potential habitat areas, and this may exacerbate the threat.

Populations on public land are considered most at risk from this impact. While illegal access to privately owned land may increase, the rate of increase is expected to be minor in the context of potential impacts to *P. spicata.* This risk will be managed in areas of public land that are managed for conservation. This will include all new conservation areas established by the Plan. However, the risk will remain and likely increase in areas of public land managed for other purposes.

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for *P. spicata*. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance

- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations (including the three offset locations to be obtained for *P. spicata* in association with Commitment 9.1, as well as *P. spicata* populations and mapped potential habitat within the Georges River Koala Reserve to be established under Commitment 10)
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas. This commitment is consistent with a number of actions in the Conservation Advice around educating the community about *P. spicata*

These measures under the Plan are expected to adequately manage the threat posed by illegal dumping of rubbish and garden waste to *P. spicata.*

HIGH FREQUENCY LAND MANAGEMENT

High frequency land management (e.g. mowing and slashing, and use of herbicides for weed control) has the potential to reduce the viability of populations and cause local extinctions. Although slashing and mowing activities have largely ceased in government reserves that are known to support the species, these are still considered to exist as a broader landscape risk in areas that are unknown to provide habitat. Indirect impacts from use of herbicides are also considered to be a current threat to the species (TSSC, 2016f). The Plan has the potential to exacerbate this risk in these areas that are close to new development.

The Plan includes a species-specific commitment (Commitment 5.4) to consult with relevant public land managers to minimise disturbance and impacts associated with land management to *P. spicata*, particularly with regards mowing, slashing and weed control activities.

Implementation of Commitment 5.4 is considered adequate to mitigate the threat of high frequency land management impacts to *P. spicata*.

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to:

- The development of essential infrastructure within nominated areas but outside the urban capable lands
- Tunnels associated with transport projects

29.4.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

Records of *P. spicata* occur within GMAC and GPEC, and potential habitat for the species is mapped in all nominated areas. One population (population 533) occurs within avoided land within GMAC, between Appin Road and the Georges River near Wedderburn. This population consists of a single recent record (dated from 2019) which is within the proposed footprint for Stage 1 of the Koala Reserve. It is therefore likely that this site will be formally protected for conservation purposes in the future, subject to approval of the proposed layout of the Koala Reserve and implementation of the Reserve. Nonetheless, the Plan includes a commitment to prioritise avoidance of impacts from essential infrastructure on non-certified land to *P. spicata*, which will contribute to the protection of known records of the species.

As outlined in Chapter 37, any proposed essential infrastructure developments on avoided lands within the nominated areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

29.4.8 POTENTIAL IMPACTS FROM TUNNELS

There is a total of 386.3 ha of potential habitat for *P. spicata* within the footprints of the Metro Rail Future Extension and OSO tunnels. While there are no records of *P. spicata* within the tunnel footprints, it is considered to be likely that the species may occur within the tunnel footprints due to known records of the species occurring in close proximity to the tunnels (such as population 53, which is a large population at Camden Golf Club, immediately adjacent to the tunnel footprint).

However, the Plan includes commitments to:

- Avoid and minimise impacts to populations and habitat within or adjacent to the OSO and Metro Rail Future Extension footprints for *P. spicata*
- Mitigate any potential indirect impacts (e.g. changes to hydrology, ground settling or subsidence) from the transport corridors as part of a future environmental impact assessment process

These commitments are expected to adequately address threats to the species from the construction and operation of the tunnels. See Section 36.6 in Chapter 36 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.4.9 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (TSSC, 2016f) and Recovery Plan (DEC, 2005a) identify the following key issues that are likely to have the greatest influence on the long-term viability of *P. spicata* in relation to implementation of the Plan:

- Habitat loss and fragmentation
- Indirect impacts including:
    - Illegal dumping of rubbish and garden waste

- Weed invasion and competition
- High-frequency land-use/management activities
- Inappropriate fire regimes
- Hydrological disturbance

HABITAT LOSS AND FRAGMENTATION

As outlined above, implementation of the Plan will lead to:

- Direct impacts to a known population (population 532) of the species
- Loss of approximately 956 ha of mapped habitat within the nominated areas and transport corridors
- Potential fragmentation of habitat in two locations

Based on the application of the risk assessment method, the overall risk of residual adverse impacts associated with these direct impacts is high.

The likelihood of potential impacts to population 532 within the urban capable lands in GMAC is the key driver for this risk rating. There is a high level of confidence that the population is extant given the locational accuracy, reputable observer and date of observation attached to the record. The population is of a moderate size comprising up to 160 plants. It is likely that this population is important to the ongoing viability and recovery of the species, in line with the species conservation advice that identifies:

- Any habitat where populations are known to occur as habitat critical to the survival of the species and
- All known populations as important populations that are necessary for the species' survival and recovery

Based on this assessment, it is recommended that the Plan adopt an additional species-specific commitment for *P. spicata* to retain some or all of population 532 within GMAC. As noted above, this recommendation has developed too late in the impact assessment process to be adopted in the draft version of the Plan for public comment. It is very likely the recommendation will be adopted under the Plan prior to finalisation for endorsement and approval and there is confidence that some level of protection will be afforded to at least part of the population. The aim of this recommendation is to ensure that the contribution of population 532 to the species' survival and recovery is not lost. It does not change the overall level of risk to the species based on the risk assessment method applied here.

It is also relevant to note that the existing long-term viability of population 532 is questionable because it is located in a small, degraded patch of woodland surrounded by cleared land, roads and rural buildings. Any commitment to retain part of this population will likely improve the overall long-term outcome for the population.

The Plan will deliver three offset locations to address the high risk to *P. spicata* from direct impacts of development. This will provide a substantial addition to the level of protection for the species which is currently under-represented in protected areas. In situ protection of *P. spicata* populations is a fundamental component of the species' recovery plan. The recovery plan's overall objective is to ensure the continued and long-term survival of *P. spicata* in the wild by promoting the in-situ conservation of the species across its natural range; with a specific [sub] objective to conserve *P. spicata* using land-use and conservation planning mechanisms.

In addition, the Plan includes a broader set of commitments and actions which are likely to benefit the species. The SCAs contain approximately 2,296 ha of mapped potential habitat for *P. spicata*. It is very likely that areas of potential habitat in addition to the three offset sites will be protected within these SCAs as part of offset commitments for other species and ecological communities under the Plan. The conservation advice for *P. spicata* notes that populations of the species have significantly increased in abundance and area of occupancy following the removal of threats (including the removal of weeds and fencing to prevent rabbits). The protection and management of potential habitat within the SCA's therefore provides a real opportunity for recovery within areas where the species might currently be suppressed.

On balance, direct impacts associated with implementation of the Plan are not expected to threaten the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts of development within the nominated areas and transport corridors associated with inappropriate habitat disturbance, weed invasion, and inappropriate fire regimes have been analysed and determined to be adequately managed and mitigated through the generic management strategies in the Plan, and through a species-specific commitment to minimise the impacts of high frequency land use. In addition, any potential indirect impacts associated with the construction of tunnels will be managed and mitigated.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

Development under the Plan will lead to impacts to one known population of *P. spicata* and areas of potential habitat. While these impacts are considered to present a high risk of adversely impacting the species, implementation of the Plan is not expected to negatively influence the long-term viability of the species for the following key reasons:

- Direct impacts to the known population are likely to be mitigated through a recommendation to retain all or part of the population as part of detailed precinct planning. The long-term persistence of this population in the absence of any further development is already uncertain given the isolated and degraded nature of habitat. A commitment leading to any retention of plants within this population is likely to contribute to the species' broader recovery survival
- The Plan will lead to the protection of three sites known to support the species. This will contribute substantially to the level of existing protection and support the objective underpinning the species' recovery plan
- Protection and management of known habitat through the offset commitment, as well as the protection and management of additional areas of suitable habitat through the Plan's broader commitments with the SCA's, is likely to contribute meaningful outcomes for *P. spicata,* which has been shown to respond positively to the removal of threats on land where it is known to occur
- Potential indirect impacts are addressed through management measures in the Plan

29.4.10 CONSISTENCY WITH RECOVERY PLAN

In accordance with Section 146K of the EPBC Act, this section considers whether the implementation of the Plan is not inconsistent with the species' Recovery Plan. It considers two questions:

- Does the Plan prevent achievement of the objectives of the Recovery Plan?
- Does the Plan prevent implementation of the Recovery Plan actions?

These questions are discussed below.

DOES THE PLAN PREVENT ACHIEVEMENT OF THE OBJECTIVES OF THE RECOVERY PLAN?

The overall objective of the Recovery Plan (DEC, 2005a) is to ensure the continued and long-term survival of *P. spicata* in the wild by promoting the in-situ conservation of the species across its natural range. Specific objectives include:

- Conserve *P. spicata* using land-use and conservation planning mechanisms
- Identify and minimise the operation of threats at sites where *P. spicata* occurs
- Develop and implement a survey and monitoring program that will provide information on the extent and viability of *P. spicata*
- Provide the community with information that assists in conserving the species
- Raise awareness of the species and involve the community in the recovery program
- Conduct research that will assist future management decisions

Implementation of the Plan will support a number of these strategies and will not prevent the achievement of the objectives of the Recovery Plan.

DOES THE PLAN PREVENT THE IMPLEMENTATION OF THE RECOVERY PLAN ACTIONS?

The Recovery Plan identifies a set of actions to support the overall recovery of *P. spicata*. The Plan will not prevent implementation of any of the actions.

29.4.11 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-12 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For *P. spicata,* there are no relevant Threat Abatement Plans.

Table 29-12: Relevant key Threatening Processes and associated Threat Abatement Plans for *P. spicata*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

29.5 *PULTENAEA PARVIFLORA*

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	A small shrub with single yellow flowers with reddish markings. Usually less than 1 m tall but rarely up to 2 m. (DoEE, 2018c)
ECOLOGY	Flowers mainly from August to November. Fruiting occurs from October to November. There is no evidence of vegetative reproduction for this species. Pollinators for this species are unknown. Seeds may be dispersed by ants. Reproductive maturity is reached after 3-4 years, and peak seed production does not occur until 5-6 years of age. Species is suggested to live for roughly 20 years. Plants are killed by fire and re-establish from soil-stored seed. Plants appear in response to disturbance, such as fire events. Germination can be prolific following medium to high intensity fire events. Repeated and frequent disturbance of populations is likely to result in population decline (when disturbance occurs at intervals of less than 6-8 years) or extinction (when disturbance occurs at intervals of less than 4 years). A fire interval of 10-15 years is required to allow for the development of suitable seed bank, and to create suitably high fuel levels to create moderate to high intensity fires which are required to promote seed germination. Disturbance history is important for influencing the number of individuals present at a site. Fire-induced recruitment tends to produce more evenly-aged populations than soil-disturbance-induced recruitment. (DoEE, 2018c; OEH, 2017f)
DISTRIBUTION AND HABITAT	Confined to the Cumberland Plain, mainly between Penrith and Windsor. Outlier populations are recorded from Kemps Creek and Wilberforce. Grows in dry sclerophyll woodlands, forest or in derived grasslands on laterised Wianamatta Shale or Tertiary alluvium, on infertile sandy to clay soils. (DoEE, 2018c; OEH, 2017f)
POPULATIONS	Populations have been recorded to range in size between 10 and over 5,000 individuals. As of 1995, populations were known to occur within the Blacktown, Hawkesbury, Liverpool and Penrith Local Government Areas.

	As of 2002, the species had been recorded within the following reserved areas: • Scheyville National Park • Windsor Downs Nature Reserve • Castlereagh Nature Reserve • ADI Regional Park (now Wianamatta Regional Park) (DoEE, 2018c) Assessment of all BioNet records of the species indicates that over 90 per cent of known records occur within the Cumberland subregion. Therefore, for the purposes of this assessment, *P. parviflora* is considered to be an endemic species to the region.
SOS SITES	The following SOS sites for the species have been identified: • Scheyville • Castlereagh Nature Reserve • Wianamatta Nature Reserve • Colebee
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Pultenaea parviflora* (DEWHA, 2008k)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=19380

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	No	No	Yes	Yes

EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS** **Knowledge based map (KBM).** Potential habitat polygons were generated for this species using BioNet PCT associations, vegetation condition (intact, thinned) and elevation (less than 120 m). To refine these potential habitat polygons, targeted surveys for the species were then undertaken in a number of locations within the nominated areas. These surveys either confirmed presence (known habitat) or absence (no longer considered potential habitat). The species was recorded during surveys in a number of locations. **OUTSIDE THE NOMINATED AREAS** **Species distribution model (SDM).** Potential habitat outside the nominated areas was mapped using an SDM. No targeted surveys were undertaken outside the nominated areas.

<table>
<tr><td rowspan="6">POPULATION MAPPING</td><td>RECORD SELECTION</td></tr>
<tr><td>Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset.</td></tr>
<tr><td>POPULATION DEFINITION</td></tr>
<tr><td>Biological populations were defined using the records dataset and available information about the nature of the species.
Records within 500 m of each other were considered to be a single population.</td></tr>
<tr><td>IMPORTANT POPULATION CRITERIA</td></tr>
<tr><td>Populations of P. parviflora were then categorised as important or not-important based on the methodology set out in Section 11.5.3 of Chapter 11. For this species, populations were considered important because they met one or more of the following criteria:
• A population is important for maintaining the Extent of Occurrence of a species
• A population within a conservation reserve
• A large population
• Population is associated with a commitment made under the Sydney Growth Centres conservation program
• A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program</td></tr>
</table>

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

<table>
<tr><td>MAP</td><td>See Map 36.24 for a map of records and habitat across the Strategic Assessment Area</td></tr>
<tr><td>OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA</td><td>See Table 29-17 at the end of this species assessment for a breakdown of the occurrence of records and habitat for P. parviflora in the Strategic Assessment Area.
Records
The Strategic Assessment Area is the core location for the species. Records occur in the northern half of the Strategic Assessment Area, with the majority of records occurring in the locality of Londonderry/Marsden Park.
A total of 34 populations have been mapped within the Strategic Assessment Area, 18 are considered important. Nine populations are wholly or partly located in existing conservation reserves.
The majority of populations of this species, including several large populations, are located in the northern region of the Strategic Assessment Area, in the area bounded by Freemans Reach to the north, Scheyville National Park to the east, the northern region of GPEC to the south (including Wianamatta Regional Park), and Agnes Banks to the west.
Scattered populations also exist to the south of this region, including areas within and adjacent to GPEC and WSA, and in areas to the east in localities including Prospect Reservoir, Bass Hill and Cecil Park. It is further noted that there are multiple populations in the vicinity of Kemps Creek, of which one is an important population.
Potential habitat
The baseline mapping for this assessment has mapped approximately 20,208 ha of known and potential habitat within the Strategic Assessment Area. The majority of this habitat is located to the</td></tr>
</table>

	north of GPEC, in the localities of Londonderry, Scheyville and Freemans Reach. In addition to this, there are: • Moderate areas of habitat on the western, eastern and southern boundaries of WSA, in the localities of Mulgoa, Luddenham, Kemps Creek and Erskine Park • Small, scattered areas of habitat in the southern portion of the Strategic Assessment Area, particularly along the boundaries of the assessment area, occupation of these latter areas in the southern part of the Strategic Assessment Area is not known as it is not associated with known records

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.5.1 NOMINATED AREAS

RECORDS

A total of six important populations of this species occur within the nominated areas (all of which are within GPEC). Of these:

- Four populations (126, 128, 131, and 225) occur entirely within excluded lands
- Two populations (118 and 127) occur entirely within the OSO transport corridor

A total of eight non-important populations of this species occur within the nominated areas (two in WSA and six in GPEC). Of these:

- Five populations (219, 223, 224, 517 and 516) occur entirely within excluded lands (four in GPEC, one in WSA)
- One population (181) in WSA occurs partially in land avoided for biodiversity purposes (11 records), partially in the urban capable lands (7 records), and partially in excluded land (60 records)
- One population (226) in GPEC occurs partially in land avoided for biodiversity purposes (1 record) and partially in the urban capable lands (1 record)
- One population (542) in GPEC occurs partially in the OSO transport corridor (23 records) and partially in excluded land (1 record)

POTENTIAL HABITAT

The baseline mapping for this assessment has mapped 131 ha of potential habitat within the nominated areas (not including excluded lands). Approximately 57 ha (43 per cent) of this has been avoided as part of the urban capable lands and transport corridors (not including excluded lands). Almost all of this was avoided for biodiversity purposes.

A breakdown of avoidance across each nominated area is provided in Table 29-18.

It is important to note that the avoidance calculations in Table 29-18, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 29-18 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

29.5.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

It is noted that population 127 of *P. parviflora* is currently mapped to occur entirely within the footprint of transport corridors. It is recognised that the Plan contains a commitment to avoid and minimise impacts to areas of high biodiversity value and threatened species and their habitat during the detailed planning of major infrastructure corridors within the Plan's nominated areas (Commitment 3), and therefore some avoidance of this population is likely to occur. However, as this detailed planning has not yet occurred, for the purposes of this assessment (which takes a precautionary approach), it is assumed that the entirety of the OSO transport corridor at this location will be impacted, and therefore that this population will be lost.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.5.3 LOSS OF KNOWN POPULATIONS AND POTENTIAL HABITAT

Implementation of the Plan will:

- Lead to direct impacts to six populations, of which three are important populations
- Lead to a loss of potential habitat
- Lead to fragmentation of potential habitat

A summary of the direct impacts to populations and habitat is provided in Table 29-19.

IMPACTS TO KNOWN POPULATIONS

Important populations

Population 118

Population 118 is located in Shanes Park which almost entirely occurs outside of the nominated areas and transport corridors to the north of GPEC. A small part of the southern portion of Shanes Park occurs within the M7/Ropes Crossing Link Road on the northern boundary of GPEC.

The majority of Shanes Park consists of native vegetation in good condition; it is one of the last remaining remnants of largely unmodified native vegetation in the Cumberland subregion (URS, 2008). Subsequently, the majority of Shanes Park is listed on the Commonwealth Heritage List in recognition of its high biodiversity values. The site contains a number of threatened species.

The population consists of 416 BioNet records in total. All BioNet records for this population do not specify the number of plants recorded, and so each record is considered to account for a single plant. Of these:

- 289 BioNet records are located outside of the Strategic Assessment Area
- 127 BioNet records are located inside the Strategic Assessment Area

The majority of the records within the Strategic Assessment Area were recorded in 2018 and in 2019 as part of the targeted surveys for this assessment. All 127 of these records are located within the footprint of the M7/Ropes Crossing Link Road.

Population 119

This population is primarily located in a Metro offset site at Colebee to the north east of GPEC outside of the Strategic Assessment Area. This site is mapped as containing Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion (PCT 849), in an intact condition.

In 1999, 2,000 plants were recorded as part of this population, whilst in November 2017, 655 plants were recorded within this population.

One plant from this population has been recorded within the footprint of the proposed M7/Ropes Crossing Link Road. This plant was recorded in 2015 and is the southernmost record of Population 119.

Population 127

This population consists of 87 BioNet records from between 2016 and 2019 in Wianamatta Regional Park in the north of GPEC. This site was surveyed by the consulting team in June of 2019, during which 83 individuals of the species were recorded, indicating the population is extant and common on site. The site contains Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion, ranging from intact to thinned condition.

All records of this population are located within the transport corridor of the Outer Sydney Orbital.

The Plan includes commitments to avoid impacts threatened species and their habitat during the development of major infrastructure corridors within the nominated areas (Commitment 3), and therefore some avoidance of impacts to this community is expected to occur in the future. However, for the purposes of this assessment (which takes a precautionary approach), it is assumed that the entirely of the OSO transport corridor at this location will be impacted, and therefore that this population will be lost.

Non-important populations

Population 181

This population consists of 78 BioNet records near Kemps Creek within the south east of WSA. All BioNet records for this population do not specify the number of plants recorded, and so each record is considered to account for a single plant. Records of this population range in date from 2015 to 2018. The majority of plants are located along the roadside of Clifton Ave.

Vegetation in the locality is mapped to include patches of Broad-leaved Ironbark - Grey Box - *Melaleuca decora* grassy open forest on clay/gravel soils of the Cumberland Plain, Sydney Basin Bioregion (PCT 724, ranging from intact to thinned condition), and Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion (PCT 725, in an intact condition). The wider landscape is otherwise heavily cleared.

Of the 78 records, 7 are mapped within urban capable lands, and will be impacted. Remaining plants outside urban capable land will be avoided.

There is one important population within close proximity of this population (population 130 which is approximately 850 m to the south). This population contains hundreds of plants and is protected under commitments associated with the Sydney Growth Centres Conservation Program.

Population 226

This population consists of two BioNet records near Twin Creeks in Luddenham in the south of GPEC. The first record is from 2013 and does not state the number of individual plants (and so is assumed to constitute a single plant sighting). The second record is from 2016 and reports 150 plants with an accuracy of 100 m.

This site is mapped as containing Grey Box - Forest Red Gum grassy woodland on flats of the Cumberland Plain, Sydney Basin Bioregion (PCT 849), in a thinned condition. Satellite imagery of the site indicates significant areas of the site have been cleared.

The 2013 record is located within the proposed urban capable land, and so will be removed. The 2016 record is sufficiently separated from the proposed urban capable land, and will be avoided.

Population 542

This population is located along the northern boundary of GPEC (near Bidwill and Hassall Grove) largely within the footprint of the M7/Ropes Crossing Link Road.

The site is mapped to contain Cumberland Shale Woodlands and Shale-Gravel Transition Forest (PCT 724 and PCT 849, in a thinned condition). It is noted that this site was surveyed in August of 2019 by the consulting team and therefore there is high confidence in the accuracy of mapped habitat conditions. The vegetation exists as a thin corridor, bounded to the south by urban development and to the north by areas of urban and commercial development.

The population consists of 24 BioNet records, 23 of these are located within the footprint of the M7/Ropes Crossing Link Road. The population is not considered to be large in the context of the species and is not key for maintaining the species' extent of occurrence.

LOSS OF POTENTIAL HABITAT

There will be direct impacts to approximately 188 ha of potential habitat. This represents 0.9 per cent of potential habitat within the Strategic Assessment Area. Habitat loss is primarily associated with transport projects inside the nominated areas (Outer Sydney Orbital and M7/Ropes Crossing Link Road).

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of direct impacts to populations is considered to be high. This risk ranking is triggered for impacts to species' records, as follows:

- The likelihood of actual impacts occurring to the species has been categorised as almost certain. There will be direct impacts to known populations of the species, with high confidence in the accuracy of the records
- The consequence of any impacts to the species has been categorised as major. There will be a loss of an important population (population 127) which is not at the edge of the species' occurrence

The risk of residual adverse impacts occurring to the species as a result of impacts to mapped habitat (away from known populations) is considered to be medium. This risk ranking is triggered for impacts to species' habitat, as follows:

- The likelihood of actual impacts occurring to the species within areas of mapped habitat away from known populations has been categorised as likely. There will be direct impacts to potential habitat, with high confidence that the species occurs in the impact area (given that most mapped habitat for this species is associated with records, it is considered likely that the habitat mapping accurately represents species' occurrence)
- The consequence of impacts to the species (if they did occur) has been categorised as moderate. There will be a loss of 0.5-1 per cent of mapped potential habitat (endemic species), with high confidence that the species occurs in the impact area

29.5.4 FRAGMENTATION OF HABITAT

FRAGMENTATION IMPACTS

The Plan will lead to fragmentation of habitat in relation to two important populations and associated habitat due to the development of the OSO within Wianamatta Regional Park.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of fragmentation is considered to be medium. This is because:

- The likelihood of fragmentation has been categorised as likely. This is because:
  - The likelihood that development is presents a barrier to dispersal of the species is likely. While the pollinators for this species are unknown, it is thought that seed dispersal may occur via ants (OEH, 2017f). It is thought that the development of the OSO is likely to pose a barrier to reproduction and/or dispersal of this species
  - The type of fragmentation is certain impact between populations. This is because the OSO will fragment habitat between two important populations (population 118 and 128. It is noted that population 127 is considered to be lost as a result of direct impacts)
- The consequence of fragmentation has been categorised as major. This is because the Plan will lead to fragmentation between populations which impacts two or more important populations which are not at the edge of occurrence of the species

29.5.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

To compensate for the predicted direct impacts to the species, the Plan includes a commitment to secure two offset locations for the species as part of the conservation program. This will improve the level of protection of the species within the Strategic Assessment Area where nine populations (out of a total of 34) currently occur in protected areas.

In addition to this, two of the Plan's proposed reserves contain areas of mapped habitat for the species. These include:

- 120 ha of mapped habitat in the Georges River Koala Reserve
- 5 ha of mapped habitat in the Gulguer Reserve investigation area

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.5.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice (DEWHA, 2008k) (and other key documents) for *P. parviflora* identifies a range of threats to the species. Where these threats are relevant to the implementation of the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats in the Conservation Advice) are considered relevant to implementation of the Plan:

- Inappropriate habitat disturbance from uncontrolled vehicle access and rubbish dumping
- Weed invasion
- Inappropriate fire regimes

Dryland salinity has also been identified as a key threat. However, it is not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate the threat across the Strategic Assessment Area.

INAPPROPRIATE HABITAT DISTURBANCE

Habitat degradation through uncontrolled vehicular access and rubbish dumping have been identified as a key threat to *P. parviflora* (DEWHA, 2008k). Development within GPEC and WSA may lead to an increase in human activity within the species' known and potential habitat areas, and this may exacerbate the threat.

Populations of *P. parviflora* considered most at risk of this threat are those that occur in:

- Public land, as these areas are accessible without the deterrent that comes with trespassing. Eight important populations occur on public land managed for conservation. They are:
  - Scheyville National Park - population 124
  - Windsor Downs Nature Reserve - population 122
  - Castlereagh Nature Reserve - population 117
  - Agnes Banks Nature Reserve - population 123
  - Wianamatta Nature Reserve - population 116
  - Wianamatta Regional Park - population 128 (note population 127 is considered to be lost as a result of development)
  - Kemps Creek - population 130

- An area of freehold land to the north of GPEC which is often mistaken for Crown land. This area contains a number of access tracks, and issues associated with rubbish dumping have been recorded for the site

It is noted that the national parks, nature reserves and Wianamatta Regional Park are managed (three of these sites are Priority Management Sites under the NSW SOS program for *P. parviflora*). Assuming this management continues and adapts to potential increasing visitation over the life of the Plan, the risk to *P. parviflora* from disturbance is expected to be adequately addressed.

With regards to Kemps Creek, it is noted that this site was briefly visited in association with site surveys which were undertaken during preparation of the expert report for *Acacia pubescens*. The expert report for *A. pubescens* notes that remnant habitat at Kemps Creek was "seen to be largely unmanaged and degrading due to several threats" (Douglas, 2019b). This site is part of the Sydney Growth Centres Program and it is recommended that the management of habitat at Kemps Creek under this program be improved. It is considered that improved and ongoing management of habitat at Kemps Creek will provide protection of *P. parviflora* within this locality from impacts associated with inappropriate habitat disturbance.

With regards to site visitation in public land to the north of GPEC, in the absence of tighter controls over access, there is potential for increased disturbance to occurrences of *P. parviflora* on this site as a result of the Plan.

The Plan includes the following development controls to manage the risk of inappropriate habitat disturbance:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations (including two offset locations for *P. parviflora* under Commitment 9.1)
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas. This commitment is consistent with a number of actions in the Conservation Advice around educating the community about *P. parviflora*

The package of measures in the Plan is expected to adequately manage the risk to *P. parviflora* from inappropriate habitat disturbance as a result of development. This is because:

- Avoided lands where areas of mapped habitat for *P. parviflora* occur will be zoned appropriately to enable an adequate framework for management
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands (including offset sites secured for *P. parviflora* under Commitment 9.1) will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

These controls are consistent with a number of priority actions in the Conservation Advice (DEWHA, 2008k). For example, to “raise awareness of *P. parviflora* within the local community, including education about the effects of rubbish dumping, unauthorised vehicular access…” and “control access routes to suitably constrain public access to known sites on public land”.

WEED INVASION

P. parviflora is threatened with invasion and competition by weeds. This species is particularly threatened by invasive perennial grasses, which increase the risk of high-frequency, high-intensity fires which can destroy propagules of the species (OEH, 2017f).

Weeds are already present within the Strategic Assessment Area. However, urban, transport and agricultural development within the northern half of the Strategic Assessment Area has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

P. parviflora is most susceptible to the threat of weeds from development under the Plan where new urban growth or transport occur adjacent to known populations or habitat. Key risk areas include:

- The southern end of Shanes Park where the M7/Ropes Crossing Link Road occurs adjacent to potential habitat areas
- The north-eastern section of Wianamatta Regional Park, where the Outer Sydney Orbital intersects a known population and potential habitat

The Plan incorporates species-specific measures for the protection of *P. parviflora*, which will contribute to the control of weeds within known and potential habitat for the species. Species-specific measures which are relevant to weed control include:

- Protecting two known offset locations for *P. parviflora* (Commitment 9.1). It is noted that offset locations will be managed as conservation reserves which will provide for long-term protection of known populations of the species
- Implementation of mitigation measures to address the impacts of the spread of weeds on *P. parviflora* within the nominated areas (Commitment 5.1) and from transport development (Commitment 6.1)

The Plan further incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA. This includes a number of actions, of which the following are the most relevant to the outcome for *P. parviflora*:
    - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
    - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
    - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes:
    - Partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
    - Require proponents to undertake the following when applying for/undertaking development:
        - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
        - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
        - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

These measures under the Plan are expected to adequately manage the potential threat to *P. parviflora* from weed invasion. This is because:

- Two known offset locations for *P. parviflora* will be obtained (Commitment 9.1) and managed for conservation purposes, which will ensure long-term protection of known populations and habitat of this species
- There are requirements for the impact of weeds to be managed with regards to the requirements of *P. parviflora* in relation to the urban development in nominated areas (Commitment 5.1) and from transport development (Commitment 6.1)
- There are commitments (Commitment 16 and Commitment 23) which will coordinate, enable and conduct effective weed control programs in strategic locations within the Strategic Assessment Area to manage priority weed species
- Proponents will be required to minimise the risk of weed spread, and to manage weeds, during the design, development and operational stages of development
- Establishment of environmental zoning of approximately 56.9 ha of mapped potential habitat of *P. parviflora* within avoided lands will enable establishment of an adequate framework for management of weeds in these areas

INAPPROPRIATE FIRE REGIMES

P. parviflora largely relies upon fire events in order to successfully germinate. Therefore, occasional fire events are likely to be required to maximise the species' ability to recover and persist. Plants are killed by fire, with subsequent generations germinating from seeds stored within the soil. Fire intervals of 10-15 years are recommended to:

- Enable development of adequate seed reserves in the soil to enable successful germination
- Allow for the development of suitable fuel loads for moderate to high intensity fires, which are required for seed germination

Increased human activity within the nominated areas may result in altered fire frequencies. This can be caused by:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

Increased human activity within the nominated areas has the potential to alter fire regimes, through potentially increasing fire frequencies in some areas, and decreasing fire frequencies in others, through the mechanisms outlined above.

Increased and/or decreased fire intervals poses a threat to the long-term persistence of *P. parviflora* within the Strategic Assessment Area as both too-frequent and too-infrequent fires would negatively impact upon the species' ability to successfully reproduce. Key risk areas are those that are easily accessible to the public and in close proximity to urban development.

Several populations of *P. parviflora* occur in conservation reserves with existing fire management strategies. These conservation reserves are:

- Scheyville National Park
- Agnes Banks Nature Reserve
- Windsor Downs Nature Reserve
- Shanes Park
- Castlereagh Nature Reserve
- Wianamatta Nature Reserve
- Wianamatta Regional Park

The Plan incorporates species-specific measures for the protection of *P. parviflora*, which will contribute to the maintenance of appropriate fire regimes within species' habitat and provide for protection for the species. Species-specific measures which are relevant to fire regime management include: protecting two known offset locations for *P. parviflora* (Commitment 9.1). It is noted that offset locations will be managed as conservation reserves which will provide for long-term protection of known populations of the species

The Plan further incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for *P. parviflora*:
    - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
    - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
    - A process to work with delivery partners to implement the fire management strategy
    - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
    - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for *P. parviflora*. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes.

The package of measures in the Plan is expected to adequately manage the risk to *P. parviflora* from altered fire regimes as a result of development. This is because:

- Two known offset locations for *P. parviflora* will be obtained (Commitment 9.1) and managed for conservation purposes, which will ensure long-term protection of known populations and habitat of this species
- Establishment of environmental zoning of approximately 56.9 ha of mapped potential habitat of *P. parviflora* within avoided lands will enable establishment of an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting mapped potential habitat and/or known records for *P. parviflora* which is located adjacent to urban capable lands
- Fire management authorities will be engaged to ensure they understand the requirements of *P. parviflora* and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to:

- The development of essential infrastructure within nominated areas but outside the urban capable lands
- Tunnels associated with transport projects

29.5.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

The species has been recorded on avoided lands in GPEC and WSA.

Within GPEC, population 226 (a non-important population with a total of two records) contains one record comprising 150 individuals within avoided land. This population is located in the south east of the nominated area, near Twin Creeks.

In WSA, population 181 (a non-important population with a total of 78 records) contains 11 records within avoided lands. This population is located in the south east of the nominated area, near Kemps Creek.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

29.5.8 POTENTIAL IMPACTS FROM TUNNELS

There is a total of 0.4 ha of potential habitat for *P. parviflora* mapped within the tunnel footprint under the Plan. However, there are no records of *P. parviflora* in the locality; it is noted that the tunnel footprints are over 10 km south of the southernmost known record of this species, suggesting that the tunnels are likely to occur outside of the extent of occurrence of this species. It is therefore considered to be unlikely that the development of tunnels under the Plan will negatively impact *P. parviflora.*

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.5.9 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DEWHA, 2008k) identifies the following key issues that are likely to have the greatest influence on the long-term viability of *P. parviflora* in relation to implementation of the Plan:

- Habitat loss and fragmentation
- Indirect impacts including:
  - Inappropriate habitat disturbance
  - Inappropriate fire regimes
  - Weed invasion

HABITAT LOSS AND FRAGMENTATION

As outlined above, implementation of the Plan will lead to:

- Direct impacts to 6 populations, including:
  - The loss of one important population (population 127)
  - Impacts to records of two important populations (population 118 and 119)

  - Impacts to records of three non-important populations (population 181, 226 and 542)
- Loss of approximately 188 ha of potential habitat within the nominated areas and transport corridors
- Potential fragmentation of habitat in one location

Based on the application of the risk assessment method, the overall risk of residual adverse impacts associated with these direct impacts is high.

The likelihood of the loss of population 127 as a result of the development of the OSO within Wianamatta Regional Park in GPEC is the key driver for this risk rating. There is a high level of confidence that the population is extant as the population was detected during site surveys undertaken for this strategic assessment. The population is of a moderate size comprising 83 plants. It is noted that the Plan commits (Commitment 3) to avoid and minimise impacts to *P. parviflora* due to the construction of the Outer Sydney Orbital in GPEC. It will be critical that this process avoids and minimise impacts as far as possible to reduce the scale of impacts.

To address the overall residual risks associated with direct impacts, the Plan will deliver two offset locations to address the high risk to *P. parviflora* from direct impacts of development, which will provide for additional protection for the species. The process of protecting land in the Strategic Assessment Area is likely to support a priority action in the Conservation Advice to "investigate formal conservation arrangements such as the use of covenants, conservation agreements or inclusion in reserve tenure".

In addition, the Plan includes a broader set of commitments and actions which are likely to benefit the species. The SCAs contain approximately 1,371 ha of mapped potential habitat for *P. parviflora*. It is very likely that areas of potential habitat in addition to the two offset sites will be protected within these SCAs as part of offset commitments for other species and ecological communities under the Plan. For example, two of the proposed reserves in the Plan contain mapped habitat for the species (including 120 ha in the Georges River Koala Reserve).

On balance, direct impacts associated with implementation of the Plan are not expected to threaten the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts of development within the nominated areas and transport corridors associated with inappropriate habitat disturbance, weed invasion, and inappropriate fire regimes have been analysed and determined to be adequately managed and mitigated through the generic management strategies in the Plan.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

Development under the Plan will lead to impacts to six known populations of *P. parviflora* and areas of potential habitat. Of the six impacted populations, impacts to population 127 are considered to be the most severe. While these impacts are considered to present a high risk of adversely impacting the species, implementation of the Plan is not expected to negatively influence the long-term viability of the species for the following key reasons:

- Direct impacts to population 127 are likely to be minimised through a commitment (Commitment 3) to avoid and minimise impacts to *P. parviflora* due to the construction of the Outer Sydney Orbital in GPEC
- The Plan will lead to the protection of two sites known to support the species, which will contribute to the level of existing protection
- Protection and management of known habitat through the offset commitment, as well as the protection and management of additional areas of suitable habitat through the Plan's broader commitments with the SCA's, is likely to contribute meaningful outcomes for *P. parviflora,* which has been shown to respond positively to the removal of threats on land where it is known to occur
- Potential indirect impacts are addressed through management measures in the Plan

29.5.10 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

29.5.11 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-16 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For *P. parviflora,* there are no relevant Threat Abatement Plans.

Table 29-16: Relevant key Threatening Processes and associated Threat Abatement Plans for *P. parviflora*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

Table 29-17: Occurrence of *P. parviflora* in the Strategic Assessment Area

SPECIES AT MEDIUM RISK OF DIRECT IMPACTS

29.6 *CYNANCHUM ELEGANS* (WHITE-FLOWERED WAX PLANT)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Endangered
DESCRIPTION	*Cynanchum elegans* is a climber or twiner with a highly variable form, ovate to broadly-ovate leaves, white tubular flowers and dry pointed-pod fruit. Mature stems can climb to 10 m high and be 3.5 cm thick. (DEWHA, 2008b; DoEE, 2018c)
ECOLOGY	Flowering occurs between August and May; seed production is variable and unreliable. Seeds are wind dispersed and it is thought to be unlikely that a soil seed bank exists for this species. Fruit can take four to six months to mature after flowering. Plants are also capable of clonal reproduction from underground suckering stems. Often seen after physical disturbance such as slashing and grazing. (DoEE, 2018c; OEH, 2018k)
DISTRIBUTION AND HABITAT	Occurs in eastern NSW, from Brunswick Heads on the north coast to the Illawarra region. The distribution overlaps with the following TECs: • Shale Sandstone Transition Forest • White Box-Yellow Box-Blakely's Red Gum Grassy Woodland and Derived Native Grassland • Cumberland Plain Woodlands • Upland Wetlands of the New England Tablelands and the Monaro Plateau • Turpentine-Ironbark Forest in the Sydney Basin Bioregion Inhabits the transition zone between dry subtropical rainforest and sclerophyll forest/woodland communities, occurring on steep slopes with varying degrees of soil fertility. (DEWHA, 2008b)
POPULATIONS	Records are restricted from Wollongong (NSW), north to southeast Queensland and west to Mt Danger. Population estimates are old. In 1993 the species was known from 31 sites with around 1,000 plants. Populations usually contain less than 30 individuals. (DoEE, 2018c)

SOS SITES	*C. elegans* has been assigned to the 'Keep-watch species' management stream under the SOS program. Currently, a considerable number (at least 40) populations of *C. elegans* are known to occur within existing conservation reserves in NSW. These sites are already actively managed for conservation purposes. Current management is considered sufficient to protect this species in NSW in the long-term. *C. elegans* is therefore a lower priority species for conservation investment in NSW. (OEH, 2018l)
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Cynanchum elegans* (White-flowered Wax Plant) (DEWHA, 2008b)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species.

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	No	No	No	No

EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS** Not applicable as the species is not a candidate species credit species. Mapping was done as per the species distribution model described below. **OUTSIDE THE NOMINATED AREAS** **Species distribution model (SDM).** Potential habitat outside the nominated areas was mapped using an SDM. The report for this process (Supporting Document F) notes that there were few (23) records of *C. elegans* with which to produce a model (generally, over 50 records are required to produce a reliable SDM). The mapping is considered to be highly precautionary. The SDM produced for *C. elegans* is therefore considered to be indicative and should be treated with caution.

POPULATION MAPPING	**RECORD SELECTION** Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset.

	POPULATION DEFINITION
	Biological populations were defined using the records dataset and available information about the nature of the species. Little is known of the reproduction and dispersal ecology of *C. elegans* (DoEE, 2018c). As part of this assessment, a population was considered to be clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators.
	IMPORTANT POPULATION CRITERIA
	Populations of *C. elegans* were then categorised as important or not-important based on the methodology set out in Section 11.5.3 of Chapter 11. All populations were considered to be important as the species is endangered.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.5 for a map of records and habitat across the Strategic Assessment Area
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 29-21 at the end of this species assessment for a breakdown of the occurrence of records and habitat for *C. elegans* in the Strategic Assessment Area. **Records** Populations are found in small isolated remnant patches of dry rainforest within the Strategic Assessment Area. The baseline mapping for this assessment has mapped a total of nine populations (from 22 BioNet records), of which two population either wholly or partly occur on land which is already protected for conservation purposes. Of these: • One occurs in Kurrajong • One occurs at Cobbitty • One occurs in Abbotsbury • The remaining five occur in the Razorback district None of the identified populations occur within any of the nominated areas. **Potential habitat** Approximately 3,343 ha of potential habitat has been mapped within the Strategic Assessment Area, as follows: • Scattered habitat patches are mapped to occur in the Razorback district, in the locality bounded by Tahmoor in the south, Menangle in the east, Theresa Park in the north and the strategic assessment boundary in the west • Small, scattered habitat patches are mapped within Cobbitty and along the Nepean River to the east of Silverdale • A moderate habitat patch is mapped to occur in remnant vegetation in Abbotsbury, near the intersection of the M7 and Elizabeth Drive • Small, scattered areas of habitat occur in the north and north-east of the Strategic Assessment Area, including localities such as Castlereagh (along the Nepean River), Kurrajong, Freemans Reach and Wilberforce None of the mapped habitat occurs within any of the nominated areas.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.6.1 NOMINATED AREAS

There is no potential habitat for the species mapped within the nominated areas. Avoidance of habitat was therefore not necessary.

29.6.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.6.3 LOSS OF KNOWN POPULATIONS AND POTENTIAL HABITAT

Implementation of the Plan will not lead to any direct impacts to known records. However, it will lead to loss of potential habitat within a transport corridor outside of the nominated areas. A summary of direct impacts is provided in Table 29-22.

LOSS OF POTENTIAL HABITAT

Approximately 19.6 ha of potential habitat will be lost as a result of implementation of the Plan. The impacts relate to a transport project (the Outer Sydney Orbital) at Cobbitty. This is 0.6 per cent of mapped potential habitat across the Strategic Assessment Area. This habitat is in proximity to population 14, a known important population of *C. elegans*.

It is noted that, as detailed planning of the transport corridors has yet to be completed, the Plan includes a commitment (Commitment 4) to ensure that appropriate avoidance of impacts to *C. elegans* is undertaken as part of this process. The commitment requires that the design of the OSO at Cobbitty avoids and minimises impacts to *C. elegans* populations and habitat.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of direct impacts to mapped habitat is considered to be low. This risk ranking is triggered for impacts to species' habitat, as follows:

- The likelihood of actual impacts occurring to the species has been categorised as likely. While there is a commitment to avoid and minimise impacts as part of the design of the OSO, it will not be possible to avoid all mapped potential habitat. In addition, taking a precautionary approach there is high confidence that the species occurs in the impact area (given that the impacted mapped habitat occurs in close proximity to known records of the species, it is thought to be likely that the mapped habitat represents real habitat for the species)
- The consequence of impacts to the species (if they did occur) has been categorised as minor. There will be a loss of <1 per cent of mapped potential habitat (endangered species), with high confidence that the species occurs in the impact area

29.6.4 FRAGMENTATION OF HABITAT

FRAGMENTATION IMPACTS

Implementation of the Plan will lead to fragmentation of a known population (population 14) due to the development of the OSO near Cobbitty. The population comprises six records from 1991 to 1996, with an accuracy of 100 m. The number of individuals in the records range from 0 (presumably 1) to 13.

The population occurs in in vegetation mapped as Grey Myrtle dry rainforest of the Sydney Basin Bioregion and South East Corner Bioregion (PCT 877), which is mapped to occur in association with Grey Box - Forest Red Gum grassy woodland on shale of the southern Cumberland Plain, Sydney Basin Bioregion (PCT 850). This vegetation occurs in a wider landscape of scattered patches and corridors of vegetation within a landscape which has primarily been cleared for agricultural production.

The population will be fragmented because four records containing 5 individuals occur on the western side of the OSO and two records containing 14 individuals occur on the eastern side of the OSO.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of fragmentation is considered to be medium. This is because:

- The likelihood of fragmentation has been categorised as likely. This is because:
    - The likelihood that development is presents a barrier to dispersal of the species is likely. The breeding system for *C. elegans* is poorly understood (NPWS, 2002) although it is thought that seeds are wind dispersed (OEH, 2018k). Given the uncertainty regarding dispersal requirements for the species, the OSO has been considered to be a likely barrier to dispersal for the species based on the precautionary principle
    - The type of fragmentation is likely impact within a population. This is because the OSO will fragment habitat within a single population of the species (population 14), where there is some uncertainty associated with the accuracy of the records
- The consequence of fragmentation has been categorised as major. This is because the Plan will lead to internal fragmentation of a population of an endangered species

29.6.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

To compensate for the predicted direct impacts to the species, the Plan includes a commitment to secure two offset locations for the species as part of the conservation program. While the species is considered to be well protected across its range, these offsets will improve the level of protection of the species within the Strategic Assessment Area where two populations (out of a total of nine) currently occur in protected areas.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.6.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice (and other key documents) for *C. elegans* identifies a range of threats to the species (DEWHA, 2008b). Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to the implementation of the Plan:

- Weed invasion
- Inappropriate fire regimes
- Hydrological disturbance
- Habitat disturbance due to track construction/widening

Disturbance due to landfill development and livestock grazing are also identified as key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate these threats across the Strategic Assessment Area.

WEED INVASION

C. elegans is threatened with invasion and competition by weeds. Weeds are already present within the Strategic Assessment Area. However, urban, transport and agricultural development has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

The species is most susceptible to the threat of weeds from development under the Plan where new urban growth or transport infrastructure occur adjacent to known populations or habitat. The key risk area is where the OSO intersects habitat at Cobbitty in proximity to population 14.

The Plan incorporates species-specific measures for the protection of *C. elegans*, which will contribute to the control of weeds within known and potential habitat for the species. Species-specific measures which are relevant to weed control include:

- Protecting two known offset locations for *C. elegans* (Commitment 9.1). It is noted that offset locations will be managed as conservation reserves which will provide for long-term protection of known populations of the species
- Implementation of mitigation measures to address the impacts of the spread of weeds on *C. elegans* associated with transport development (Commitment 6)

The Plan further incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA. This includes a number of actions, of which the following are the most relevant to the outcome for *C. elegans*:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes:
  - Partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16

These commitments and actions under the Plan are expected to adequately manage the risk to *C. elegans* from weed invasion. This is because:

- Two known offset locations for *C. elegans* will be obtained (Commitment 9.1) and managed for conservation purposes, which will ensure long-term protection of known populations and habitat of this species

- There is a specific requirement for the impact of weeds to be managed with regards to the requirements of *C. elegans* in relation to the development of major transport corridors
- There are commitments (Commitment 16 and Commitment 23) which will coordinate, enable and conduct effective weed control programs in strategic locations within the Strategic Assessment Area to manage priority weed species

INAPPROPRIATE FIRE REGIMES

Altered fire regimes are an identified potential threat to the species (DEWHA, 2008b) although the response to fire is not well understood.

Increased human activity within the Strategic Assessment Area has the potential to alter fire regimes through the following mechanisms:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation or key infrastructure

The area with the highest risk of potential impacts is where the OSO intersects habitat for *C. elegans* at Cobbitty.

The Plan incorporates species-specific measures for the protection of *C. elegans*, which will contribute to the maintenance of appropriate fire regimes within species' habitat and provide for protection for the species. Species-specific measures which are relevant to fire regime management include: protecting two known offset locations for *C. elegans* (Commitment 9.1). It is noted that offset locations will be managed as conservation reserves which will provide for long-term protection of known populations of the species.

The Plan further incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include: a commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for *C. elegans* being:

- Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
- Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
- A process to work with delivery partners to implement the fire management strategy
- Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans

The package of measures in the Plan is expected to adequately manage the risk to *C. elegans* from altered fire regimes as a result of development. This is because:

- Two known offset locations for *C. elegans* will be obtained (Commitment 9.1) and managed for conservation purposes, which will ensure long-term protection of known populations and habitat of this species
- Fire management authorities will be engaged to ensure they understand the requirements of *C. elegans* and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas

HYDROLOGICAL DISTURBANCE

Changes to hydrology are an identified threat to the species (OEH, 2018k). There is potential that the development and subsequent operation of the OSO near Cobbitty may lead to hydrological disturbance of the habitat for *C. elegans* within this locality.

The Plan incorporates species-specific measures for the protection of *C. elegans*, which will contribute to the control of hydrological disturbance within known and potential habitat for the species. Species-specific measures which are relevant to hydrological disturbance include:

- Protecting two known offset locations for *C. elegans* (Commitment 9.1). It is noted that offset locations will be managed as conservation reserves which will provide for long-term protection of known populations of the species

- Implementation of mitigation measures to address the impacts of the hydrological disturbance on *C. elegans* associated with transport development (Commitment 6)

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for *C. elegans*. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from transport development (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through the implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the TfNSW Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology.

The package of measures in the Plan is expected to adequately manage the risk to *C. elegans* from changes to hydrology because:

- Offset sites will be secured to manage habitat for *C. elegans* for conservation purposes
- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to biodiversity values, including potential habitat for *C. elegans*

HABITAT DISTURBANCE DUE TO TRACK CONSTRUCTION/WIDENING

Habitat disturbance due to track construction and/or widening may occur as either a temporary or permanent indirect impact within, or adjacent to, the OSO, and will depend upon the final design elements of the OSO which will influence the likelihood of site visitation and track use in the future. The mapped habitat for *C. elegans* at Cobbitty is more likely to experience site visitation and track creation if the site is made easily accessible to the public due to design decisions associated with the OSO (e.g. placement of a rest stop close to areas of habitat may encourage public visitation of the locality).

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for *C. elegans*. In summary, these include:

- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations (including the two offset locations to be obtained for *C. elegans* in association with Commitment 9.1)
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas. This commitment is consistent with a number of actions in the Conservation Advice around educating the community about *C. elegans*

These measures under the Plan are expected to adequately manage the risk to *C. elegans* from habitat disturbance. This is because:

- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to tunnels associated with transport projects.

Given that it is not present in the nominated areas it is not at risk from essential infrastructure projects.

29.6.7 POTENTIAL IMPACTS FROM TUNNELS

There is a total of 0.4 ha of potential habitat for *C. elegans* mapped within the tunnel footprint under the Plan. While no records of *C. elegans* occur within the tunnel footprint, it is recognised that there are records of the species in the locality of the tunnel footprint near Cobbitty. However, given the small area of mapped potential habitat to be impacted, it is considered unlikely that development of the tunnel will lead to adverse impacts for *C. elegans*.

It is recognised that the Plan includes commitments to mitigate any potential indirect impacts (e.g. changes to hydrology, ground settling or subsidence) from the transport corridors as part of a future environmental impact assessment process.

These commitments are expected to adequately address threats to the species from the construction and operation of the tunnels. See Section 36.6 in Chapter 36 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.6.8 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DEWHA, 2008b) and other key documents identify the following key issues that are likely to have the greatest influence on the long-term viability of *C. elegans* in relation to implementation of the Plan.

- Habitat loss and fragmentation
- Indirect impacts including
  - Degradation of habitat due to weed invasion, grazing and inappropriate fire management
  - Hydrological disturbance

HABITAT LOSS AND FRAGMENTATION

As outlined above, implementation of the Plan will lead to:

- Loss of approximately 19.6 ha of mapped habitat within the transport corridors
- Potential fragmentation of population 14 due to the development of the OSO at Cobbitty

Based on the application of the risk assessment method, the overall risk of residual adverse impacts associated with these direct impacts is <u>medium.</u>

It is considered to be likely that the development of the OSO will result in internal fragmentation of a population of *C. elegans* near Cobbitty, which is the key driver for this risk rating. There is some uncertainty regarding the accuracy of the records, given that the most recent record of this population was recorded in 1996. The population is of moderate size comprising of up to 19 plants. It is likely that this population is important to the ongoing viability and recovery of the species, as this species is endangered.

The Plan will deliver two offset locations to address the medium risk to *C. elegans* from direct impacts of development. Under the NSW Saving Our Species Program, it is noted that *C. elegans* already has a considerable number of populations (over 40) which are known to occur within existing conservation reserves in NSW, which are actively managed for conservation purposes (OEH, 2018l). The addition of two new conservation reserves to protect this species will add to the existing level of protection for *C. elegans* in NSW and contribute to the long-term preservation of the species and its habitat.

In addition, the Plan includes a broader set of commitments and actions which are likely to benefit the species. The SCAs contain approximately 1,502 ha of mapped potential habitat for *C. elegans*. It is very likely that areas of potential habitat in addition to the 2 offset sites will be protected within these SCAs as part of offset commitments for other species and ecological communities under the Plan.

The current level of protection for *C. elegans* within NSW is considered to be sufficient to protect the species in the long-term (OEH, 2018l). The Plan will add to existing protection for *C. elegans* by securing additional populations and areas of habitat within new conservation reserves.

On balance, direct impacts associated with implementation of the Plan are not expected to threaten the long-term viability of the species.

INDIRECT IMPACTS

C. elegans is most at risk from indirect impacts associated with the development of the OSO at Cobbitty. The potential indirect impacts of this development include weed invasion, inappropriate fire regimes, hydrological disturbance and habitat disturbance. Indirect impacts have been analysed and determined to be adequately managed and mitigated through the generic management strategies in the Plan.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

Development under the Plan will lead to fragmentation of one known population of *C. elegans* and impacts to areas of potential habitat. While these impacts are considered to present a medium risk of adversely impacting the species, implementation of the Plan is not expected to negatively influence the long-term viability of the species for the following key reasons:

- The Plan will lead to the protection of two sites known to support the species
- Potential indirect impacts are addressed through management measures in the Plan
- *C. elegans* is well-represented in conservation reserves in NSW, and subsequently its long-term future in the state is considered to be secure (OEH, 2018l)

29.6.9 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

29.6.10 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in **Table** 29-43 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For *C. elegans,* there are no relevant Threat Abatement Plans.

Table 29-20: Relevant key Threatening Processes and associated Threat Abatement Plans for *C. elegans*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Loss of climatic habitat caused by anthropogenic emissions of greenhouse gases	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence and direct impacts. Cross references to the tables are provided throughout the text above.

29.7 *PERSOONIA NUTANS* (NODDING GEEBUNG)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Endangered
DESCRIPTION	*Persoonia nutans* is an erect to spreading shrub with reddish stems and branches and yellow, pendant flowers. Grows from 0.5-2.5 m tall. (DoEE, 2018c)
ECOLOGY	Flowers from November to April. Main pollinators are wasps and native bees. Seed is likely to be dispersed after consumption by large birds such as currawongs and parrots, and mammals such as kangaroos, wallabies and possums. Plants are killed by fire and other disturbances and recruitment is only by seed. Subsequently, populations are dynamic in space and time. It is not known how long seeds persist in the soil, or whether all seeds germinate in a single disturbance event. It is unlikely that high levels of germination would occur without the presence of disturbance as a trigger for germination. (DoEE, 2018c) (Douglas, 2019d)
DISTRIBUTION AND HABITAT	Known records are restricted to the Cumberland subregion. In particular between Richmond and Macquarie Fields, near the Nepean and Georges Rivers. The species is fragmented with 99 per cent occurring in the north at Agnes Banks, Londonderry, Castlereagh, Berkshire Park and Windsor Downs. The species occurs predominantly in the Penrith area. The species has been found in the following vegetation communities: • Agnes Banks Woodland • Castlereagh Scribbly Gum Woodland • Cooks River/Castlereagh Ironbark Forest • Shale Sandstone Transition Forest The species is dependent on aeolian and alluvial sediments and is found in the Agnes Banks and Berkshire Park soil landscapes. It is more common on the deeper sands at the Agnes Banks soil landscape than at the edge of the deposit. It occurs on low rises rather than swales in the Berkshire Park formation. (DoEE, 2018c; NSW DEC, 2005)
POPULATIONS	As of 2005, there were around 5,500 individuals in total from 27 populations. Approximately 99 per cent are found in the north of the species range, and some isolated smaller populations are found in the south. (NSW DEC, 2005)

	Assessment of all BioNet records of the species indicates that over 90 per cent of known records occur within the Cumberland subregion. Therefore, for the purposes of this assessment, *P. nutans* is considered to be an endemic species to the region.
SOS SITES	The following SOS sites for the species have been identified: • Cumberland Plain
RELEVANT PLANS AND POLICIES	*Persoonia nutans R. Br.* (Nodding Geebung) Recovery Plan (NSW DEC, 2005) Threat abatement plan for competition and land degradation by rabbits (DoEE, 2016a) Threat abatement plan for disease in natural ecosystems caused by *Phytophthora cinnamomi* (DoEE, 2018d)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species.

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	**ECOSYSTEM CREDIT SPECIES**	**CANDIDATE SPECIES CREDIT SPECIES**			
		WILTON	**GMAC**	**WSA**	**GPEC**
	No	No	No	Yes	Yes
EXPERT REPORT (BCAR PROCESS)	Yes (Douglas, 2019d). Available at Supporting Document C				
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS** **Expert report polygons.** Potential habitat polygons were generated based on the occurrence of PCT 724, 725, 883, 1081 and 1395, with the application of riparian exclusion buffers to account for the fact that wetter and sometimes more thickly vegetated areas associated with drainage lines are unlikely habitat. All vegetation condition states were included except for derived native grasslands. To refine these potential habitat polygons, targeted surveys for the species were then undertaken in a number of locations within the nominated areas. These surveys either confirmed presence (known habitat) or absence (no longer considered potential habitat). The species was recorded during surveys in GPEC. Results of surveys were used to update the expert report habitat polygons for *P. nutans*. The potential habitat mapped through this process is considered precautionary and does not necessarily equate with actual habitat. The species is naturally rare and patchily distributed, which means that it is unlikely that a large percentage of the potential habitat would actually support the species, even though it can sometimes be locally abundant in favourable conditions. It is noted that different vegetation classes have different potential to be habitat for *P. nutans*; PCT 883 is considered to be highly likely to constitute habitat for this species, while PCT 724 and 725 have moderate likelihood of constituting habitat, and PCT 1081 and 1395 have low and very low likelihoods respectively (Douglas, 2019d).				

	OUTSIDE THE NOMINATED AREAS
	Species distribution model (SDM). Potential habitat outside the nominated areas was mapped using an SDM. The report for this process (Supporting Document F) notes that the model for the species predicts more potential habitat than would be expected in the far south and to the north east of the Strategic Assessment Area. The mapping is considered to be highly precautionary. No targeted surveys as part of this project were undertaken outside the nominated areas.
POPULATION MAPPING	**RECORD SELECTION** Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset. **POPULATION DEFINITION** Biological populations were defined using the records dataset and available information about the nature of the species. Populations of the species were defined to include clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators. **IMPORTANT POPULATION CRITERIA** Populations of *P. nutans* were then categorised as important or not-important based on the methodology set out in Section 11.5.3 of Chapter 11. All populations of *P. nutans* are considered to be important as the species is endangered.

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.19 for a map of records and habitat across the Strategic Assessment Area
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 29-24 at the end of this species assessment for a breakdown of the occurrence of records and habitat for *P. nutans* in the Strategic Assessment Area. **Records** A total of 11 important populations have been mapped within the Strategic Assessment Area and three are wholly or partly located in existing conservation reserves. The largest of these populations (population number 64, which comprises 1,317 records) is located in the Londonderry locality to the north of GPEC. This population partially occurs within existing lands protected for conservation purposes, including Agnes Banks Nature Reserve, Wianamatta Nature Reserve, Castlereagh Nature Reserve and Windsor Downs Nature Reserve. Remaining populations are distributed as follows: • 2 small populations are located to the north west of Agnes Banks Nature Reserve, in Grose Wold • 4 small populations occur within GPEC, in the following localities: o Wianamatta Regional Park and Ropes Crossing o Near Wianamatta (South Creek) in St Marys o Colyton o North of the M4 in Orchard Hills

	• 1 small population occurs near Bill Anderson Park in Kemps Creek, within and adjacent to the southern border of WSA • 2 populations (one large and one small) occur in the Holsworthy/Hammondville locality • 1 moderate population occurs adjacent to the Georges River, near Macquarie Fields and Long Point **Potential habitat** The baseline mapping for this assessment has mapped approximately 14,875 ha of known and potential habitat has been mapped within the Strategic Assessment Area. The majority of habitat is located in the Londonderry area, where the majority of records of the species occurs. Within the nominated areas, habitat is predicted to occur: • In the GPEC and WSA nominated areas, at Wianamatta Regional Park, Ropes Crossing, North St Marys, Claremont Meadows, Colyton and Kemps Creek • In the northern portion of GMAC, including Leumeah, Ingleburn and Macquarie Fields It is noted that there is no habitat mapped for *P. nutans* in Wilton. Outside of the nominated areas, and in addition to the large area of habitat in the Londonderry locality, habitat is mapped to occur: • As moderate and well-connected areas of habitat in the far east of the Strategic Assessment Area, in the Moorebank/Holsworthy/Macquarie Fields/Kentlyn district • As a small area of habitat at Scheyville National Park • As very small scattered patches in the region to the south and east of WSA, ranging from Cobbitty in the south west through to Leumeah in the south east, up to the locality of Bossley Park It is noted that the habitat map for *P. nutans* over-predicts habitat to occur outside the natural range of the species, and therefore habitat mapped in the south, and outside the north-east and north-west boundary of the strategic assssmentis not considered to include real habitat for the species (Ascelin Gordon & Koshkina, 2018). It is thought that the related (and restricted) *Persoonia bargoensis* occupies the equivalent ecological niche in habitat in the south of the Strategic Assessment Area (Douglas, 2019d).

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.7.1 NOMINATED AREAS

RECORDS

A total of five populations of this species occur within the nominated areas (four within GPEC and one within WSA). Of these:

- Three populations (61, 62 and 524) occur entirely within excluded lands (all in GPEC)
- One population (60) has one record that occurs in land avoided for biodiversity purposes in WSA, whilst the remainder of the population occurs outside the boundary of WSA
- One population (63) occurs partially within excluded lands, and partially in certified land for transport development (in GPEC)

It is noted that the Plan includes a commitment (Commitment 2.4) to prioritise the avoidance of impacts from essential infrastructure on non-certified land to known populations of *P. nutans.*

POTENTIAL HABITAT

The baseline mapping for this assessment has mapped 97 ha of potential habitat within the nominated areas (not including excluded lands). Approximately 56 ha (58 per cent) of this has been avoided as part of the urban capable lands and transport corridors (not including excluded lands). Almost all of this was avoided for biodiversity purposes.

A breakdown of avoidance across each nominated area is provided in Table 29-25.

It is important to note that the avoidance calculations in Table 29-25, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 29-25 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

29.7.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.7.3 LOSS OF KNOWN POPULATIONS AND POTENTIAL HABITAT

Implementation of the Plan will lead to direct impacts to a known population, loss of potential habitat, and fragmentation of potential habitat. A summary of these impacts is provided in Table 29-26.

IMPACTS TO KNOWN POPULATIONS

Population 63

This population comprises six records from 1993 to 2019 in and to the north of GPEC. Of these, four records occur within Wianamatta Regional Park, while the remaining two occur within Ropes Crossing. The number of individual plants ranges from 0 (presumed to be 1) to 7 across the records.

Of the records within Wianamatta Regional Park, one was detected during a survey conducted by the consulting team in June 2019, confirming that the species is still present at the site. This site contains Cooks River/Castlereagh Ironbark Forest in the Sydney Basin Bioregion, ranging from intact to thinned condition. Based on the mapped location of the records within BioNet, three of the six records will be lost due to construction of the Outer Sydney Orbital.

LOSS OF POTENTIAL HABITAT

41 ha of potential habitat for the species will be lost. This is 0.3 per cent of mapped potential habitat across the Strategic Assessment Area. The loss of potential habitat occurs predominantly within GPEC and WSA.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of impacts to an important population is considered to be medium. This risk ranking is triggered for impacts to species' records, as follows:

- The likelihood of actual impacts occurring to the species has been categorised as almost certain. There will be direct impacts to a known population of the species, with high confidence in the accuracy of the records
- The consequence of any impacts to the species (if they did occur) has been categorised as moderate. There will be a loss of records within an endangered population which is not at the edge of the species' occurrence

The risk of residual adverse impacts occurring to the species as a result of impacts to mapped habitat are considered to be low. This risk ranking is triggered for impacts to species' habitat, as follows:

- The likelihood of actual impacts occurring to the species within mapped habitat has been categorised as likely. There will be direct impacts to potential habitat with high confidence that the species occurs in the impact area
- The consequence of impacts to the species (if they did occur) has been categorised as minor. There will be a loss of 0.3 per cent of mapped potential habitat (endemic species), with high confidence that the species occurs in the impact area

29.7.4 FRAGMENTATION OF HABITAT

FRAGMENTATION IMPACTS

The Plan will lead to fragmentation of a moderate area of mapped habitat associated with records of the species within GPEC due to the development of the OSO within Wianamatta Regional Park.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of the loss of fragmentation is considered to be low. This is because:

- The likelihood of fragmentation has been categorised as possible. This is because:
  - The likelihood that development presents a barrier to dispersal of the species is possible. The main pollinators of *P. nutans* are thought to be wasps and bees, and seed is likely to be dispersed by large birds and mammals. Transport infrastructure may represent a barrier to gene flow
  - The type of fragmentation is impact to habitat connected to a population. This is because there are known records located on mapped potential habitat which is fragmented by the OSO development
- The consequence of fragmentation has been categorised as moderate. This is because the area to be fragmented is connected to a known population of the species and is of moderate size

29.7.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

To compensate for the predicted direct impacts to the species, the Plan includes a commitment to secure two offset locations for the species as part of the conservation program. This will provide an addition to the level of protection of the species within the Strategic Assessment Area where currently only three populations (out of a total of 11) occur in protected areas. In situ protection of *P. nutans* populations is a fundamental component of the species' recovery plan.

In addition to this, one of the Plan's proposed reserves (the Georges River Koala Reserve) contains 120 ha of mapped habitat for the species.

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.7.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Recovery Plan (NSW DEC, 2005) (and other key documents) for *P. nutans* identifies a range of threats to the species. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Weed invasion
- Habitat degradation and rubbish dumping related to unrestricted access
- Infection by root-rot fungus *Phytophthora cinnamomi*

Honeybee competition and grazing by rabbits have also been identified as key threats. However, these were not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate these threats across the Strategic Assessment Area.

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes constitute one of the major threats to the survival of *P. nutans* (NSW DEC, 2005). The species is an obligate seed regenerator, with fire being an important mechanism to promote germination. Too frequent fire will prevent maturation and reproduction of the species, while too infrequent fire will result in senescence and death of adults with minimal or no recruitment.

Increased human activity within the nominated areas has the potential to alter fire regimes, through potentially increasing fire frequencies in some areas, and decreasing fire frequencies in others, through the following mechanisms:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

Key risk areas are those that are easily accessible to the public and in close proximity to urban development and roads, and include the Londonderry locality to the north of GPEC, potential habitat within and near Wianamatta Regional Park in GPEC, potential habitat near Kemps Creek in WSA, and potential habitat adjacent to the north-east boundary of GMAC near Holsworthy.

The Plan incorporates species-specific measures for the protection of *P. nutans*, which will contribute to the maintenance of appropriate fire regimes within species' habitat and provide for protection for the species. Species-specific measures which are relevant to fire regime management include: protecting two known offset locations for *P. nutans* (Commitment 9.1). It is noted that offset locations will be managed as conservation reserves which will provide for long-term protection of known populations of the species.

The Plan further incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the Strategic Assessment Area. This includes a number of actions with the most relevant to the outcome for *P. nutans* being:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas

- Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for *P. nutans*. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes.

These controls support a range of recovery actions within the species' Recovery Plan which suggests the species' fire requirements be taken into account with regards to site management plans (NSW DEC, 2005).

WEED INVASION

P. nutans is threatened with invasion and competition by weeds. Weeds are already present within the Strategic Assessment Area. However, urban, transport and agricultural development within the northern half of the Strategic Assessment Area has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

P. nutans is most susceptible to the threat of weeds from development under the Plan where new urban growth or transport occur adjacent to known populations or habitat. Key risk areas include:

- The southern end of Shanes Park where the M7/Ropes Crossing Link occurs adjacent to potential habitat areas
- The north-eastern section of Wianamatta Regional Park, where the Outer Sydney Orbital corridors within GPEC in areas of potential habitat

The Plan incorporates species-specific measures for the protection of *P. nutans,* which will contribute to the control of weeds within known and potential habitat for the species. Species-specific measures which are relevant to weed control include:

- Protecting two known offset locations for *P. nutans* (Commitment 9.1). It is noted that offset locations will be managed as conservation reserves which will provide for long-term protection of known populations of the species
- Implementation of mitigation measures to address the impacts of the spread of weeds on *P. nutans* associated with and urban capable (Commitment 5) and transport (Commitment 6) development

The Plan further incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA. This includes a number of actions, of which the following are the most relevant to the outcome for *P. nutans*:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes: partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:
    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies

        - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
    - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

The package of measures in the Plan is expected to adequately manage the risk to *P. nutans* from the increased risk of weeds associated with development. This is because:

- Two known offset locations for *P. nutans* will be obtained (Commitment 9.1) and managed for conservation purposes, which will ensure long-term protection of known populations and habitat of this species
- Commitments 5 and 6 will provide for mitigation measures to be implemented for the benefit of *P. nutans* to address the impacts associated with the spread of weeds associated with urban capable and transport development
- There are commitments (Commitment 16 and Commitment 23) which will coordinate, enable and conduct effective weed control programs in strategic locations within the Strategic Assessment Area to manage priority weed species
- Proponents will be required to minimise the risk of weed spread, and to manage weeds, during the design, development and operational stages of development
- Establishment of environmental zoning of approximately 56.3 ha of mapped potential habitat of *P. nutans* within avoided lands will enable establishment of an adequate framework for management of weeds in these areas

HABITAT DEGRADATION AND RUBBISH DUMPING RELATED TO UNRESTRICTED ACCESS

Habitat degradation through unrestricted public access has been identified as a key threat to *P. nutans*. Development within GPEC and WSA may lead to an increase in human activity within the species' known and potential habitat areas, and this may exacerbate the threat.

Populations of *P. nutans* on public land, and areas which are often mistaken for public land, are considered most at risk from this impact. It is noted that an area of freehold land to the north of GPEC which is often mistaken for Crown land, contains a number of access tracks, and issues associated with rubbish dumping have been recorded for the site.

Two populations occur on public land managed for conservation. They are:

- Population 63 – Wianamatta Regional Park
- Population 64 - Castlereagh Nature Reserve, Wianamatta Nature Reserve, Agnes Banks Nature Reserve, Windsor Downs Nature Reserve

The Plan incorporates species-specific measures for the protection of *P. nutans,* which will contribute to the control of habitat disturbance within known and potential habitat for the species. Species-specific measures which are relevant to habitat disturbance include:

- Protecting two known offset locations for *P. nutans* (Commitment 9.1). It is noted that offset locations will be managed as conservation reserves which will provide for long-term protection of known populations of the species
- Implementation of mitigation measures to address the impacts of the spread of weeds on *P. nutans* associated with and urban capable (Commitment 5) and transport (Commitment 6) development
- A commitment (Commitment 5.4) to manage habitat disturbance within Wianamatta Regional Park through requiring that walking tracks and management trails are located in a way that avoids and minimises exposure of *P. nutans* to human disturbance

The Plan incorporates a range of additional measures to mitigate the risks associated with inappropriate habitat disturbance for *P. nutans*. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance

- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations (including the two offset locations to be obtained for *P. nutans* in association with Commitment 9.1)
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas

The package of measures in the Plan is expected to adequately manage the risk to *P. nutans* from inappropriate habitat disturbance as a result of development. This is because:

- Walking and maintenance trails within Wianamatta Regional Park will be located to minimise the risk of habitat disturbance to the species
- Avoided lands where mapped habitat for *P. nutans* occurs will be zoned appropriately to enable an adequate framework for management
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

INFECTION BY ROOT-ROT FUNGUS PHYTOPHTHORA CINNAMOMI

P. nutans is threatened by exposure to *Phytophthora cinnamomi*, a soil-borne water mould which is fatal to many *Persoonia* species.

Development under the Plan has the potential to increase the spread of *P. cinnamomi* through increased site visitation rates and earthworks activities conducted during construction works. The areas which are most at risk are those which are in close proximity to development sites, in particular available habitat within Wianamatta Regional Park which has potential to be impacted by the development of the OSO.

The Plan incorporates species-specific measures for the protection of *P. nutans*, which will contribute to the control of weeds within known and potential habitat for the species. Species-specific measures which are relevant to weed control include:

- Protecting two known offset locations for *P. nutans* (Commitment 9.1). It is noted that offset locations will be managed as conservation reserves which will provide for long-term protection of known populations of the species
- Implementation of mitigation measures to address the impacts of *Phytophthora cinnamomi* on *P. nutans* associated with and urban capable (Commitment 5) and transport (Commitment 6) development

The Plan incorporates a range of measures to manage the risks associated with *Phytophthora cinnamomi*. In summary, these include:

- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
    - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
    - Entering into written agreements with delivery partners to implement priority disease control programs

- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures methods to protect the environment during construction, including best practice site hygiene protocols to minimise spread of *Phytophthora* and Myrtle Rust

The package of measures in the Plan is expected to adequately manage the risk to *P. nutans* from *Phythophthora cinnamomi* because:

- Conservation lands (including offset sites obtained for *P. nutans*) will be actively managed which will address threats in those areas including disease threats
- Development controls will be put in place to address potential impacts associated with construction
- It supports a landscape scale approach to the issue across the Cumberland subregion

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to development of essential infrastructure within nominated areas but outside the urban capable lands.

There is no mapped habitat within the footprints for the tunnels and the species will not be impacted in those areas.

29.7.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

The species has been recorded in WSA and GPEC. However, no populations in GPEC occur on avoided lands. One population (population 60) has one record within avoided lands in WSA, with the remaining records of this population being located outside of the nominated area boundary.

To ensure that the record of population 60 is protected from impacts from essential infrastructure, the Plan includes a commitment to avoid direct impacts due to essential infrastructure to known populations of *P. nutans* within WSA.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.7.8 IMPLICATIONS FOR LONG-TERM VIABILITY

The Recovery Plan (NSW DEC, 2005) (and other key documents) identify the following key issues that are likely to have the greatest influence on the long-term viability of *P. nutans* in relation to implementation of the Plan:

- Habitat loss
- Indirect impacts including:
  - Inappropriate fire regimes
  - Weed invasion
  - Habitat degradation and rubbish dumping related to unrestricted access
  - Infection by root-rot fungus *Phytophthora cinnamomi*

HABITAT LOSS AND FRAGMENTATION

As outlined above, implementation of the Plan will lead to:

- Direct impacts to a known population (population 63) of the species
- Loss of approximately 41 ha of potential habitat
- Potential fragmentation of habitat in one location

Based on the application of the risk assessment method, the overall risk of residual adverse impacts associated with these direct impacts is <u>medium.</u>

The likelihood of potential impacts to population 63 due to the development of the OSO within Wianamatta Regional Park is the key driver for this risk rating. There is a high level of confidence that the population is extant, as the population was detected on site during surveys conducted for this strategic assessment.

It is noted that the Plan commits (Commitment 3) to avoid and minimise impacts to *P. nutans* due to the construction of the Outer Sydney Orbital in GPEC. It will be critical that this process avoids and minimise impacts as far as possible to reduce the scale of impacts.

The Plan will deliver two offset locations to address the medium risk to *P. nutans* from direct impacts of development, which will provide for additional protection for the species. The process of protecting land in the Strategic Assessment Area is likely to support a performance criterion within the species' recovery plan, which aims to increase the level of protection afforded to *P. nutans* through conservation planning and land use decisions.

In addition, the Plan includes a broader set of commitments and actions which are likely to benefit the species. The SCAs contain approximately 1,617 ha of mapped potential habitat for *P. nutans.* It is very likely that areas of potential habitat in addition to the two offset sites will be protected within these SCAs as part of offset commitments for other species and ecological communities under the Plan.

On balance, direct impacts associated with implementation of the Plan are not expected to threaten the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts associated with inappropriate fire regimes, weed invasion, habitat disturbance and rubbish dumping related to unrestricted access and infection by root-rot fungus *Phytophthora cinnamomi* have been analysed and determined to be adequately managed and mitigated through the generic management strategies in the Plan.

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

Development under the Plan will lead to impacts to a known population of *P. nutans* and areas of potential habitat. While these impacts are considered to present a medium risk of adversely impacting the species, implementation of the Plan is not expected to negatively influence the long-term viability of the species for the following key reasons:

- Direct impacts to population 63 are likely to be mitigated through a commitment (Commitment 3) to avoid and minimise impacts to *P. nutans* due to the construction of the Outer Sydney Orbital in GPEC
- The Plan will lead to the protection of two sites known to support the species, which will contribute to the level of existing protection
- Protection and management of known habitat through the offset commitment, as well as the protection and management of additional areas of suitable habitat through the Plan's broader commitments with the SCA's, is likely to contribute meaningful outcomes for *P. nutans*, which has been shown to respond positively to the removal of threats on land where it is known to occur
- Potential indirect impacts are addressed through management measures in the Plan

29.7.9 CONSISTENCY WITH RECOVERY PLAN

In accordance with Section 146K of the EPBC Act, this section considers whether the implementation of the Plan is not inconsistent with the species' Recovery Plan. It considers two questions:

- Does the Plan prevent achievement of the objectives of the Recovery Plan?
- Does the Plan prevent implementation of the Recovery Plan actions?

These questions are discussed below.

DOES THE PLAN PREVENT ACHIEVEMENT OF THE OBJECTIVES OF THE RECOVERY PLAN?

The overall objective of the Recovery Plan (NSW DEC, 2005) to ensure the continued and long-term survival of *P. nutans* in the wild by promoting the in situ conservation of the species across its natural range. Specific objectives include:

- Minimise the loss and fragmentation of *P. nutans* habitat using land-use planning mechanisms
- Identify and minimise the operation of threats at sites where *P. nutans* occurs
- Implement a survey and monitoring program that will provide information on the extent and viability of *P. nutans*
- Provide public authorities with information that assists in conserving the species
- Raise awareness of the species and involve the community in the recovery program
- Promote research questions that will assist future management decisions.

Implementation of the Plan will support a number of these strategies and will not prevent the achievement of the objectives of the Recovery Plan.

DOES THE PLAN PREVENT THE IMPLEMENTATION OF THE RECOVERY PLAN ACTIONS?

The Recovery Plan identifies a set of actions to support the overall recovery of *P. nutans*. The Plan will not prevent implementation of any of the actions.

29.7.10 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-23 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The consistency of the Plan with relevant Threat Abatement Plans is discussed in detail in Chapter 15. The Plan is not inconsistent with any Threat Abatement Plans.

Table 29-23: Relevant key Threatening Processes and associated Threat Abatement Plans for *P. nutans*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Dieback caused by the root-rot fungus (*Phytophthora cinnamomi*)	Threat abatement plan for disease in natural ecosystems caused by *Phytophthora cinnamomi* (DoEE, 2018d)
Land clearance	There is no relevant TAP

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

SPECIES AT LOW RISK OF DIRECT IMPACTS

29.8 *EUCALYPTUS BENTHAMII* (CAMDEN WHITE GUM, NEPEAN RIVER GUM)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	*Eucalyptus benthamii* is a smooth, white barked tree with loose bark ribbons and a flaky bark stocking at its base. Has long thin leaves and white flowers. Grows to approximately 40 m tall. (OEH, 2017b)
ECOLOGY	Flowers in summer and autumn. Sporadic flowering may occur throughout the year. Depends on flooding for seedling establishment. (DoE, 2014a)
DISTRIBUTION AND HABITAT	Occurs west of Sydney in the Cumberland subregion and Blue Mountains. Distribution overlaps with the following EPBC Act-listed TECs: • Cumberland Plain Shale Woodlands and Shale Gravel Transition Forest • Shale Sandstone Transition Forest Inhabits open forest in areas with deep, fertile alluvial sands and a flooding regime that permits the establishment of seedlings. Recruitment is successful on bare sediment deposits in rivers and streams after flooding. (DoE, 2014a)
POPULATIONS	Records occur on the flats of the Nepean River and its tributaries. As of 2005, two major sub-populations have been recorded: up to 6,500 individuals in Kedumba Valley of the Blue Mountains National Park and up to 300 plants in the Bents Basin State Recreation Area. (DoE, 2014a)
SOS SITES	The following SOS sites for the species have been identified: • Kedumba • Bents Basin • Camden Airport

RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Eucalyptus benthamii* (Camden White Gum) (DoE, 2014a) Threat abatement plan for predation, habitat degradation, competition and disease transmission by feral pigs (*Sus scrofa*) (DoEE, 2017c)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species.
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=2821

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	ECOSYSTEM CREDIT SPECIES	CANDIDATE SPECIES CREDIT SPECIES			
		WILTON	GMAC	WSA	GPEC
	No	Yes	Yes	No	No

EXPERT REPORT (BCAR PROCESS)	There is no expert report available for this species.
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS** **Knowledge based map (KBM).** Habitat maps were generated using BioNet PCT associations, vegetation condition parameters (intact, thinned, scattered trees), waterways (habitat restricted to within a 350 m buffer of the 'Nepean River Hydro Area'), geology ('Alluvium', 'Bringelly Shale', 'Hawkesbury Sandstone') and elevation (between 25 m and 300 m). **OUTSIDE THE NOMINATED AREAS** **Species distribution model (SDM).** Potential habitat outside the nominated areas was mapped using an SDM. The report notes that there were a moderate number (582) of records of *E. benthamii* with which to produce a model (generally, over 50 records are required to produce a reliable SDM). The approach to SDM mapping may over-predict habitat for the species. No targeted surveys as part of this project were undertaken outside the nominated areas.
POPULATION MAPPING	**RECORD SELECTION** Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset. **POPULATION DEFINITION** Biological populations were defined using the records dataset and available information about the nature of the species. There is limited information available regarding pollination and dispersal thresholds for *E. benthamii.*

	Therefore, a population was considered to constitute clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators.
	IMPORTANT POPULATION CRITERIA
	Populations of *E. benthamii* were then categorised as important or not-important based on the methodology set out in Section 11.5.3 of Chapter 11. Populations of *E. benthamii* were considered important because they met one or more of the following criteria: • A population identified or inferred in a Commonwealth conservation advice, plan, final determination, or other relevant policy document as being important • A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program • A large population • A population within a conservation reserve • A population that is important for maintaining the Extent of Occurrence of a species

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.8 for a map of records and habitat across the Strategic Assessment Area
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 29-28 at the end of this species assessment for a breakdown of the occurrence of records and habitat for *E. benthamii* in the Strategic Assessment Area. **Records** A total of eight important populations (from 578 records) have been mapped within the Strategic Assessment Area. Of these: • One occurs along Werriberri Creek and its tributaries, near The Oaks in the south-west region of the Strategic Assessment Area • Remaining populations occur in scattered localities along the Nepean River and its tributaries, with populations occurring at Yarramundi, Glenmore Park, Wallacia, Gulguer, Theresa Park, the area spanning from Brownlow Hill through to Spring Farm, and Menangle Park It is noted that no records occur within the nominated areas. **Potential habitat** The baseline mapping for this assessment has mapped approximately 4,800 ha of potential habitat within the Strategic Assessment Area (see Table 29-28). Habitat is primarily associated with riparian corridors, particularly those associated with the Nepean River and its tributaries. Specifically, habitat is mapped to occur in the following localities: • Well-connected areas of habitat incorporating the Nepean River and its tributaries in the south-western area of the Strategic Assessment Area, in the locality bounded by Picton to the south, Belimbla Park in the west, Mulgoa in the north, and Menangle Park in the east • Scattered habitat along the Nepean River between Richmond and Jamisontown • Scattered occurrences along Wianamatta (South Creek), between Windsor and Wianamatta Regional Park, near Erskine Park, and between Badgerys Creek and Oran Park • Small, scattered occurrences along Hinchinbrook Creek, Georges River and Bunbury Curran Creek in the eastern section of the Strategic Assessment Area • Along Badgerys Creek, Bardwell Gully and Lowes Creek and Rileys Creek to the south of WSA

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.8.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 0.5 ha of potential habitat within the nominated areas (not including excluded lands). Of this land, <0.1 ha was avoided for biodiversity purposes, with the remaining land avoided for other reasons.

A breakdown of avoidance across each nominated area is provided in Table 29-29.

It is important to note that the avoidance calculations in Table 29-29, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 29-29 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

29.8.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

It is noted that the Plan contains a species-specific commitment (Commitment 4.1) to avoid and minimise impacts to *E. benthamii* as a result of tunnel construction activities in transport corridors.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.8.3 LOSS OF KNOWN POPULATIONS AND POTENTIAL HABITAT

Implementation of the Plan will lead to loss of potential habitat. A summary of these impacts is provided in Table 29-30.

LOSS OF POTENTIAL HABITAT

There will be approximately 47 ha of impacts to potential habitat (1 per cent of mapped habitat across the Strategic Assessment Area). These impacts are primarily due to the Outer Sydney Orbital as it traverses north from Cobbitty across a tributary of the Nepean River.

There is also one other very small and discrete loss of habitat where a transport corridor crosses Cosgroves Creek outside GPEC, in the vicinity of Twin Creeks.

The areas being impacted upon do not support known records or populations of *E. benthamii*.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of impacts to mapped habitat are considered to be very low. This risk ranking is triggered for impacts to species' habitat, as follows:

- The likelihood of actual impacts occurring to the species within mapped habitat has been categorised as possible. While there will be direct impacts to potential habitat, there is moderate confidence that the species will occur in the impact area (it is noted that the impacted habitat was modelled via the SDM process, which is considered to be precautionary and may over-predict habitat. There are no records in close proximity to the impacted areas of habitat)
- The consequence of impacts to the species (if they did occur) has been categorised as negligible. There will be a loss of 1 per cent of mapped potential habitat (vulnerable species), with moderate confidence that the species occurs in the impact area

29.8.4 FRAGMENTATION OF HABITAT

FRAGMENTATION IMPACTS

The Plan will lead to fragmentation of potential habitat in the following locations:

- Fragmentation of a small area of mapped habitat associated with records of the species at Cobbitty due to the development of the OSO
- Fragmentation of a very small area of mapped habitat that is not associated with records of the species in the vicinity of Twin Creeks, where a proposed transport corridor crosses Cosgroves Creek to the south of GPEC

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of the loss of fragmentation is considered to be low. This is because:

- The likelihood of fragmentation has been categorised as possible. This is because:
  - The likelihood that development presents a barrier to dispersal of the species is possible While seedling establishment is thought to occur in association with flooding events, there is otherwise limited information available regarding pollination and dispersal thresholds for *E. benthamii.* It is therefore thought to be possible that development of the OSO may constitute a dispersal barrier for this species
  - The type of fragmentation is impact to habitat connected to a population. This is because there are known records located on mapped potential habitat which is fragmented by the OSO development
- The consequence of fragmentation has been categorised as minor. This is because the area to be fragmented is connected to a known population of the species and is of small size

29.8.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the low risk of residual adverse impacts to the species, offsets were not considered necessary for *E. benthamii.*

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.8.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice (and other key documents) for the *E. benthamii* identifies a range of threats to the species. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats) are considered relevant to implementation of the Plan:

- Inappropriate fire regimes
- Changed hydrology
- Myrtle rust
- Weed invasion

Inappropriate revegetation works (impacting genetic diversity), isolated populations, impacts on genetic integrity (such as through hybridisation with *E. viminalis*), raising the height of the Warragamba Dam wall, construction of smaller dams, loss of regeneration opportunities and feral pigs have also been identified as key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate these threats across the Strategic Assessment Area.

INAPPROPRIATE FIRE REGIMES

E. benthamii is threatened by altered fire regimes. The Plan has the potential to impact fire regimes as a result of increased human activity associated with development of urban capable land within the nominated areas and development of transport corridors outside of the nominated areas.

Small areas of mapped potential habitat occur in close proximity with urban capable development in the vicinity of Twin Creeks (outside of the nominated areas), and in the vicinity of Kemps Creek (outside of the nominated areas). Otherwise, mapped potential habitat is spatially removed from urban capable lands, and as such the likelihood of potential habitat being impacted by urban capable development is low.

Transport corridor development outside of the nominated areas has the potential to impact habitat for *E. benthamii* as a result of development of the OSO near Cobbitty, in addition to near Twin Creeks where a proposed transport corridor crosses Cosgroves Creek.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity associated with development of transport corridors. In summary, these include: a commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for *E. benthamii* being:

- Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
- Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values (it is noted that the SCA contains approximately 1,495 ha of mapped potential habitat for *E. benthamii*).
- A process to work with delivery partners to implement the fire management strategy
- Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans

The package of measures in the Plan is expected to adequately manage the risk to *E. benthamii* from altered fire regimes as a result of development. This is because fire management authorities will be engaged to ensure they understand the requirements of *E. benthamii* and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas.

CHANGED HYDROLOGY

Changes to hydrology and nutrient runoff are an identified threat to the species. The Plan has the potential to impact hydrology as a result of development within urban capable land and transport corridors. As outlined above, the areas which are most at risk of indirect impacts from development are those in close proximity to areas of development, and include mapped potential habitat near urban capable development at Twin Creeks, Kemps Creek, and mapped potential habitat close to the OSO footprint near Cobbitty.

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for *E. benthamii*. In particular, these include commitments which relate to mitigating indirect and prescribed impacts from transport development (Commitment 6). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through the implementation of mitigation measures to transport projects based on the outcomes of environmental assessment of detailed designs in accordance with published, best practice guidelines, including but not limited to, the TfNSW Biodiversity Guidelines. These include a range of provisions to mitigate and minimise changes to hydrology.

It is further noted that the Plan includes a species-specific commitment to control indirect impacts (including changed hydrology) to *E. benthamii* associated with the development of tunnels within the major transport corridors (Commitment 6.2). This commitment is discussed further below in Section 29.8.8, and will provide additional protection to *E. benthamii* from potential impacts associated with hydrological disturbance.

The package of measures in the Plan is expected to adequately manage the risk to *E. benthamii* from changes to hydrology because transport projects will apply best practice approaches to avoiding and minimising any potential impacts to biodiversity values, including potential habitat for *E. benthamii*.

MYRTLE RUST

E. benthamii is threatened by exposure to myrtle rust, an exotic fungus which is can lead to growth defects and mortality of *Eucalyptus* species.

Development under the Plan has the potential to increase the spread of myrtle rust through increased site visitation rates and earthworks activities conducted during construction works. The areas which are most at risk are those which are in close proximity to development sites, and include mapped potential habitat near urban capable development at Twin Creeks, Kemps Creek, and mapped potential habitat close to the OSO footprint near Cobbitty.

The Plan incorporates a range of measures to manage the risks associated with disease including myrtle rust. In summary, these include:

- A commitment (Commitment 6) will result in implementation of mitigation measures to address indirect and prescribed impacts to threatened species associated with the development of transport corridors
- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
  - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
  - Entering into written agreements with delivery partners to implement priority disease control programs
- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures methods to protect the environment during construction, including best practice site hygiene protocols to minimise spread of *Phytophthora* and Myrtle Rust

It is further noted that the Plan includes a species-specific commitment to control indirect impacts (including spread of disease) to *E. benthamii* associated with the development of tunnels within the major transport corridors (Commitment 6.2). This commitment is discussed further below in Section 29.8.8, and will provide additional protection to *E. benthamii* from potential impacts associated with myrtle rust.

The package of measures in the Plan is expected to adequately manage the risk to *E. benthamii* from myrtle rust because:

- Development controls will be put in place to address potential impacts associated with construction
- It supports a landscape scale approach to the issue across the Cumberland subregion

WEED INVASION

E. benthamii is threatened with invasion and competition by weeds. Weeds are already present within the Strategic Assessment Area. However, urban, transport and agricultural development within the northern half of the Strategic Assessment Area has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

The species is most susceptible to the threat of weeds from development under the Plan where urban capable lands or transport occur adjacent to known populations or habitat. The areas most at risk include mapped potential habitat near urban capable development at Twin Creeks, Kemps Creek, and mapped potential habitat close to the OSO footprint near Cobbitty.

The Plan incorporates a range of measures to manage the risks associated with weed invasion. In summary, these include:

- A commitment (Commitment 6) will result in implementation of mitigation measures to address indirect and prescribed impacts to threatened species associated with the development of transport corridors
- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA. This includes a number of actions, of which the following are the most relevant to the outcome for *E. benthamii*:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16

It is further noted that the Plan includes a species-specific commitment to control indirect impacts (including weed invasion) to *E. benthamii* associated with the development of tunnels within the major transport corridors (Commitment 6.2). This commitment is discussed further below in Section 29.8.8, and will provide additional protection to *E. benthamii* from potential impacts associated with weed invasion.

The package of measures in the Plan is expected to adequately manage the risk to *E. benthamii* from the increased risk of weeds associated with development. This is because:

- Transport projects will apply best practice approaches to avoiding and minimising any potential impacts to biodiversity values, including potential habitat for *E. benthamii*
- There are commitments (Commitment 16 and Commitment 23) which will coordinate, enable and conduct effective weed control programs in strategic locations within the Strategic Assessment Area to manage priority weed species
- Proponents will be required to minimise the risk of weed spread, and to manage weeds, during the design, development and operational stages of development

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to:

- The development of essential infrastructure within nominated areas but outside the urban capable lands
- Tunnels associated with transport projects

29.8.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

The species has been recorded in none of the nominated areas, and there is only a very small (0.5 ha) amount of potential habitat mapped for this species within avoided lands.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

29.8.8 POTENTIAL IMPACTS FROM TUNNELS

Both the Metro Rail Future Extension and the OSO tunnels intercept mapped potential habitat for *E. benthamii.* Of these two tunnels, however, only the OSO is considered to have potential to negatively impact upon *E. benthamii*.

The Metro Rail Future Extension has a total of 1.7 ha of mapped potential habitat for *E. benthamii* within the impact footprint. This habitat is a small, isolated patch of habitat associated with Narellan Creek, which is in a heavily cleared and highly disturbed landscape in close proximity to existing urban development. There are no records of the species in the proximity of this habitat. It is considered to be unlikely that the species would be present at this site.

The OSO tunnel intercepts approximately 44 ha of potential habitat for *E. benthamii*, in addition to an important population of the species (population 95), which is partially located in two conservation reserves (a Registered Property Agreement site, and the Mater Dei BioBank site), in addition to occurring outside of the reserve boundaries in the Camden locality between Spring Farm and Cobbitty Road along the Nepean River. This population is recognised to be important for maintaining the genetic diversity of the species (DoE, 2014a).

The Plan includes commitments to:

- Avoid and minimise impacts to populations and habitat within or adjacent to the OSO and Metro Rail Future Extension footprints for *E. benthamii* (Commitment 4.1)
- Mitigate any potential indirect impacts (e.g. changes to hydrology, ground settling or subsidence) from the transport corridors as part of a future environmental impact assessment process (Commitment 6.2)

These commitments are expected to adequately address threats to the species from the construction and operation of the tunnels. See Section 36.6 in Chapter 36 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.8.9 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DoE, 2014a) and other key documents identifies the following key issues that are likely to have the greatest influence on the long-term viability of *E. benthamii* in relation to implementation of the Plan:

- Habitat loss and fragmentation
- Indirect impacts including:

- Inappropriate fire regimes
- Changed hydrology
- Myrtle rust
- Weed invasion

HABITAT LOSS AND FRAGMENTATION

As outlined above, implementation of the Plan will lead to:

- Loss of 47 ha of mapped habitat within the nominated areas and transport corridors
- Potential fragmentation of habitat in two locations

Based on the application of the risk assessment method, the overall risk of residual adverse impacts associated with these direct impacts is low. The total area of potential habitat which will be impacted is a small proportion of available habitat for the species with only moderate confidence of the species' presence in impacted areas. Fragmentation of a small area of mapped potential habitat connected with species' records will also occur. It is noted that no known records of the species are directly impacted or fragmented from other known records.

It is noted that *E. benthamii* occurs within the footprint of the proposed OSO tunnel. The Plan contains a species-specific commitment (Commitment 4.1) to avoid and minimise impacts to *E. benthamii* as a result of tunnel construction activities in transport corridors, which is considered to protect the individuals within the tunnel footprint from direct impacts.

The Plan includes a broader set of commitments and actions which are likely to benefit the species, which includes commitments to protect land within the SCAs which contain approximately 1,495 ha of potential habitat for *E. benthamii*.

On balance, direct impacts associated with implementation of the Plan are not expected to threaten the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts of development corridors associated with inappropriate fire regimes, changed hydrology, myrtle rust and weed invasion have been analysed and determined to be adequately managed and mitigated through the generic management strategies in the Plan, and through a species-specific commitment to minimise the impacts of high frequency land use. In addition, any potential indirect impacts associated with the construction of tunnels will be managed and mitigated through a species-specific commitment (Commitment 6.2).

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

The limited scale of direct impacts to the species habitat and the management measures in the Plan to address potential indirect impacts will ensure that the implementation of the Plan does not adversely influence the long-term viability of the species.

29.8.10 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

29.8.11 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-27 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The consistency of the Plan with relevant Threat Abatement Plans is discussed in detail in Chapter 15.

Table 29-27: Relevant key Threatening Processes and associated Threat Abatement Plans for *E. benthamii*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP
Predation, habitat degradation, competition and disease transmission by feral pigs	Threat abatement plan for predation, habitat degradation, competition and disease transmission by feral pigs (*Sus scrofa*) (DoEE, 2017c)

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

29.9 *GREVILLEA PARVIFLORA* SUBSP. *PARVIFLORA* (SMALL-FLOWER GREVILLEA)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	*Grevillea parviflora* subsp. *parviflora* is a low, open to erect shrub with narrow leaves and white flowers. Grows from 0.3-1 m high. (DEWHA, 2008d)
ECOLOGY	Flowers between July – December and between April – May. Reproduces vegetatively via rootstocks. Following fire, recruitment from seed is unlikely. Individuals can live for 25-60 years. (DoEE, 2018c)
DISTRIBUTION AND HABITAT	Endemic to NSW, occurring in the Picton, Bargo and Appin areas. Other disjunct populations occur in Holsworthy, the Lower Hunter Valley, on the Central Coast and in the Port Stephens area. It grows on crests, upper slopes or flat plains on sandy to gravelly clay soils. Distribution overlaps with the following TECs: • Shale Sandstone Transition Forest • Cumberland Plain Woodlands • Turpentine-Ironbark Forest in the Sydney Basin Bioregion • Castlereagh Scribbly Gum and Agnes Banks Woodland • Cooks River/Castlereagh Ironbark Forest of the Sydney Basin Bioregion (DEWHA, 2008d)
POPULATIONS	Populations vary between small populations of less than 20 stems, medium populations of 50-100 stems, to a small number of large populations of over 2,000 individuals. It is hard to establish the number of plants within a population due to its suckering nature (DoEE, 2018c).
SOS SITES	The species is managed under the data-deficient species management stream under the SOS program. Currently there are no identified management sites.
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Grevillea parviflora* subsp. *parviflora* (Small-flower Grevillea) (DEWHA, 2008d)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species.

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

<table>
<tr><td rowspan="3">NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)</td><td>ECOSYSTEM CREDIT SPECIES</td><td colspan="4">CANDIDATE SPECIES CREDIT SPECIES</td></tr>
<tr><td rowspan="2">No</td><td>WILTON</td><td>GMAC</td><td>WSA</td><td>GPEC</td></tr>
<tr><td>Yes</td><td>Yes</td><td>Yes</td><td>Yes</td></tr>
<tr><td>EXPERT REPORT (BCAR PROCESS)</td><td colspan="5">There is no expert report for this species.</td></tr>
<tr><td rowspan="4">HABITAT MAPPING</td><td colspan="5">WITHIN THE NOMINATED AREAS</td></tr>
<tr><td colspan="5">Knowledge based map (KBM). Potential habitat polygons were generated using BioNet PCT associations, vegetation condition parameters (intact, thinned), elevation (between 25m and 300m), soil units (‘Berkshire Park’, ‘Lucas Heights’, ‘South Creek’) and rock units (‘alluvial channel deposits-in-channel bar’, ‘alluvial floodplain deposits’, ‘alluvium’, ‘Mittagong Formation’, ‘alluvial terrace deposits’). Additional habitat added where PCTs occur on or within 200m of Hawkesbury soils and sandstone geology.
To refine these potential habitat polygons, targeted surveys for the species were then undertaken in a number of locations within the nominated areas. These surveys either confirmed presence (known habitat) or absence (no longer considered potential habitat). The species was recorded in Wilton during surveys.</td></tr>
<tr><td colspan="5">OUTSIDE THE NOMINATED AREAS</td></tr>
<tr><td colspan="5">Species distribution model (SDM). Potential habitat outside the nominated areas was mapped using an SDM. The mapping is considered to be highly precautionary. No targeted surveys as part of this project were undertaken outside the nominated areas.</td></tr>
<tr><td rowspan="4">POPULATION MAPPING</td><td colspan="5">RECORD SELECTION</td></tr>
<tr><td colspan="5">Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset.</td></tr>
<tr><td colspan="5">POPULATION DEFINITION</td></tr>
<tr><td colspan="5">Biological populations were defined using the records dataset and available information about the nature of the species.
Little is known about the life cycle of G. parviflora subsp. parviflora. Flowers are insect pollinated, and it is likely that seeds have limited dispersal distances (probably <2 m) (DoEE, 2018c).
Populations were identified as clustered records connected by relatively intact and continuous vegetation and/or riparian corridors, or if separated, not by permanent barriers likely to obstruct pollinators.</td></tr>
</table>

	IMPORTANT POPULATION CRITERIA
	Populations of *G. parviflora* subsp. *parviflora* were then categorised as important or not-important based on the methodology set out in Section 11.5.3 of Chapter 11. Populations of *G. parviflora* subsp. *parviflora* were considered important because they met one or more of the following criteria: • A population that is important for maintaining the Extent of Occurrence of a species • A population within a conservation reserve • A large population

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.10 for a map of records and habitat across the Strategic Assessment Area

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 29-32 at the end of this species assessment for a breakdown of the occurrence of records and habitat for *G. parviflora* subsp. *parviflora* in the Strategic Assessment Area.
	Records
	A total of 11 important populations have been identified within the Strategic Assessment Area, of which five populations are either wholly or partly located in existing conservation reserves. Important populations are distributed as follows:
	• Within GPEC:
	  ○ Population 103: this population consists of 86 records and partially occurs within GPEC in the locality of Bingara Gorge, in addition to occurring in the land in between GPEC and GMAC, including within the Appin West Biobanking Agreement site and St Marys Tower Biobanking Agreement site. The majority of records within GPEC that are associated with this population are in an area subject to a previously approved EPBC Act approval (EPBC 2014/7400)
	  ○ Population 104: this population consists of 13 records and partially occurs in the north-west of Wilton, in addition to occurring outside the western boundary of Wilton. This is a large population with over 300 individuals recorded. Records of this population were detected during site surveys for this strategic assessment
	  ○ Population 518: this population consists of a single record of 50 individuals, and occurs to the south of population 104 within the western boundary of GMAC
	• To the south of WSA within Kemps Creek, in a site protected through the previous Growth Centres Program
	• One large population occurs adjacent to Anzac Creek near Holsworthy
	• Remaining populations are scattered throughout the southern portion of the Strategic Assessment Area
	A total of five non-important populations have been identified within the Strategic Assessment Area. These occur as follows:
	• One occurs wholly within GPEC (adjacent to Ropes Creek near Colyton)
	• One occurs adjacent to Kemps Creek, to the south of WSA
	• One occurs partially within GMAC, adjacent to the Georges River to the east of Appin
	• One occurs to the south of the Nepean River, between GMAC and Wilton
	• One occurs in the south of the Strategic Assessment Area
	Potential habitat

	The baseline mapping for this assessment has mapped 7,504.7 ha of known and potential habitat within the Strategic Assessment Area. The majority of this habitat occurs in a band spreading along the south-eastern boundary of the Strategic Assessment Area. Other areas of habitat occur as follows: • Small, scattered patches of habitat occur in the locality of Ruse, Minto Heights, Ingleburn and Denham Court • A moderate patch occurs near Holsworthy and Moorebank, to the north-east of GMAC • Small, scattered patches of habitat occur to the north and north-east of Holsworthy, in Chipping Norton, Fairfield and Miller • Small, scattered patches of habitat occur within and near to the GPEC and WSA, in locations including Kemps Creek, Claremont Meadows, North St Marys, within and near Wianamatta Regional Park, within and near Castlereagh Nature Reserve and near Windsor Downs Nature Reserve

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.9.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 594.4 ha of potential habitat within the nominated areas (not including excluded lands). Approximately 578.4 ha (97.3 per cent) of this has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 434.2 ha was avoided for biodiversity purposes.
- 144.2 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 29-33.

It is important to note that the avoidance calculations in Table 29-33 including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 29-33 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

It is noted that there is a species-specific commitment under the Plan (Commitment 2.4) to prioritise avoidance of impacts from essential infrastructure on non-certified land to *Grevillea parviflora* subsp. *parviflora*.

29.9.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.9.3 LOSS OF KNOWN POPULATIONS AND POTENTIAL HABITAT

Implementation of the Plan will lead to direct impacts to mapped potential habitat. A summary of these impacts is provided in Table 29-34.

It is noted that population 101 is an important population that predominantly occurs in the Kemps Creek area of the existing South West Growth Centre. One record of this population is mapped to occur within the urban capable land footprint within WSA (to the north of Kemps Creek), however, information associated with this record indicates that the positional accuracy of the record is 100 m, and that the record is located within Kemps Creek Park at the western end of park in buffer zone between playing field and bushland, along a track. Therefore, this record is considered to be located within Kemps Creek Park (to the south of WSA), and placement of this record within WSA is not considered to be accurate. There will be no direct impacts to known records of this species as a result of implementation of the Plan.

The Plan will not result in fragmentation of habitat for *G. parviflora* subsp. *parviflora*.

Loss of potential habitat

16 ha of potential habitat for the species will be lost. This is 0.2 per cent of mapped potential habitat across the Strategic Assessment Area. These impacts primarily relate to a transport project (the Outer Sydney Orbital within GPEC).

Risk of residual adverse impacts to the species

The risk of residual adverse impacts occurring to the species as a result of impacts to an important population is considered to be low. This risk ranking is triggered for impacts to species' habitat, as follows:

- The likelihood of actual impacts occurring to the species has been categorised as likely. There will be direct impacts to potential habitat with high confidence that the species occurs in the impact area
- The consequence of any impacts to the species (if they did occur) has been categorised as minor. There will be a loss of <2 per cent of mapped potential habitat with high confidence of species' occurrence in the impact area

29.9.4 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the low risk of residual adverse impacts to the species, offsets were not considered necessary for *G. parviflora* subsp. *parviflora.*

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the relevant potential indirect impacts to the species that may occur as a result of development under the Plan. Indirect impacts were identified as being relevant to the species if:

- *The indirect impact is identified as a threat in a relevant profile, conservation advice, or recovery plan, and*
- *The threat is present in the Cumberland subregion, and*
- *The Plan has the potential to exacerbate the threat*

It discusses each relevant potential indirect impact in detail and outlines how the Plan addresses it.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.9.5 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice (DEWHA, 2008d) (and other key documents) for *G. parviflora* subsp. *parviflora* identify a range of threats to the species. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats in key species documents) are considered relevant to implementation of the Plan:

- Weed invasion
- Inappropriate fire regimes
- Habitat disturbance from recreational activities, rubbish dumping and road maintenance

Agriculture has also been identified as a key threat. However, this is not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate this threat across the Strategic Assessment Area.

The important populations of *G. parviflora* subsp. *parviflora* which are most at risk of indirect impacts are those in close proximity to development associated with the Plan. Important populations which are in close proximity to development include:

- Population 103: This important population occurs in Wilton and between Wilton and GMAC, and includes records within: the Appin West Biobanking Agreement site, the St Marys Tower Biobanking Agreement site, and land subject to a previously approved EPBC Act approval (EPBC 2014/7400)
- Population 104: This is a large population which occurs along the north-western boundary of Wilton, on either side of the Nepean River
- Population 518: This is a moderate population which occurs within Wilton, to the south of population 104

Of these three populations, population 104 is the most at risk from indirect impacts, given its large size (and subsequent importance for species conservation), proximity to development and lack of current protection. Comparatively, population 103 already has a level of protection, through its inclusion in two Biobanking sites and conservation land associated with EPBC approval 2014/7400. Population 50, while not located in a conservation reserve, is not as large as population 104 and therefore is not considered to be as important for conservation of the species. Given the high risk associated with population 104, a number of species-specific measures will be implemented under the Plan to protect this population from indirect impacts, as outlined below.

It is noted that population 101 is an important population which occurs to the south of WSA at Kemps Creek, in a site associated with the Sydney Growth Centres Program. This site was briefly visited in association with site surveys which were undertaken during preparation of the expert report for *Acacia pubescens*. The expert report for *A. pubescens* notes that remnant habitat at Kemps Creek was "seen to be largely unmanaged and degrading due to several threats" (Douglas, 2019b). This site is part of the Sydney Growth Centres Program and it is recommended that the management of habitat at Kemps Creek under this program be improved. It is considered that improved and ongoing management of habitat at Kemps Creek will provide protection of *G. parviflora* subsp. *parviflora* within this locality from impacts associated with indirect impacts.

The following sections consider the potential indirect impacts of development and proposed mitigation measures under the Plan on important populations 103, 104 and 518 of *Grevillea parviflora* subsp. *parviflora*.

INAPPROPRIATE HABITAT DISTURBANCE

Habitat degradation through unrestricted public access and rubbish dumping has been identified as a key threat to *G. parviflora* subsp. *parviflora* (DEWHA, 2008d).

The Plan includes a species-specific measure to consult with land managers of land containing population 104 of *Grevillea parviflora* subsp. *parviflora*, to mitigate indirect impacts from human disturbance during construction and operation of the development, including controlling public access, managing maintenance activities such as mowing and slashing, and managing rubbish dumping.

The Plan further incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for *G. parviflora* subsp. *parviflora*. In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance. It is noted that 578.4 ha of potential habitat for *G. parviflora* subsp. *parviflora* to the outcome
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values

- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations. It is noted that approximately 2,975 ha of potential habitat for *G. parviflora* subsp. *parviflora* is mapped to occur within SCAs
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas. This commitment is consistent with a number of actions in the Conservation Advice around educating the community about *G. parviflora* subsp. *parviflora*

The package of measures in the Plan is expected to adequately manage the risk to *G. parviflora* subsp. *parviflora* from inappropriate habitat disturbance as a result of development. This is because:

- The Plan contains a species-specific measure to protect population 104 from impacts associated with habitat disturbance
- Avoided lands where mapped habitat for *G. parviflora* subsp. *parviflora* occurs will be zoned appropriately to enable an adequate framework for management
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

WEED INVASION

G. parviflora subsp. *parviflora* is threatened with invasion and competition by weeds. Weeds are already present within the Strategic Assessment Area. However, urban, transport and agricultural development have the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

The Plan includes a species-specific measure to implement mitigation measures to manage weeds for population 104 of *G. parviflora* subsp. *parviflora*, taking into account relevant guidance in the Weed Control Implementation Strategy.

The Plan further incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the Strategic Conservation Area. This includes a number of actions, of which the following are the most relevant to the outcome for *G, parviflora* subsp. *parviflora*:
  - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
  - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
  - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes:
  - Partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
  - Require proponents to undertake the following when applying for/undertaking development:

    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

The package of measures in the Plan is expected to adequately manage the risk to *G. parviflora* subsp. *parviflora* from the increased risk of weeds associated with development. This is because:

- There is a specific requirement for the impact of weeds to be managed for population 104 of *G. parviflora* subsp. *parviflora*
- There are commitments (Commitment 16 and Commitment 23) which will coordinate, enable and conduct effective weed control programs in strategic locations within the Strategic Assessment Area to manage priority weed species
- Proponents will be required to minimise the risk of weed spread, and to manage weeds, during the design, development and operational stages of development
- Establishment of environmental zoning of 578.4 ha of mapped potential habitat of *G. parviflora* subsp. *parviflora* within avoided lands will enable establishment of an adequate framework for management of weeds in these areas

INAPPROPRIATE FIRE REGIMES

Inappropriate fire regimes are an identified threat to *G. parviflora* subsp. *parviflora* (DEWHA, 2008d). Increased human activity within the nominated areas has the potential to alter fire regimes, through potentially increasing fire frequencies in some areas, and decreasing fire frequencies in others, through the following mechanisms:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

The Plan includes a species-specific measure to consult with land managers of population 104 for *G. parviflora* subsp. *parviflora* to mitigate indirect impacts from fire during construction and operation of the development, taking into account guidance in the Fire Management Strategy.

The Plan further incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for *G. parviflora* subsp. *parviflora* being:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the Strategic Conservation Areas that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas

  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for *G. parviflora* subsp. *parviflora*. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes.

The package of measures in the Plan is expected to adequately manage the risk to *G. parviflora* subsp. *parviflora* from altered fire regimes as a result of development. This is because:

- There is a species-specific measure to protect population 104 from impacts associated with altered fire regimes
- Establishment of environmental zoning of approximately 578.4 ha of mapped potential habitat of *G. parviflora* subsp. *parviflora* within avoided lands will enable establishment of an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting mapped potential habitat and/or known records for *G. parviflora* subsp. *parviflora* which is located adjacent to urban capable lands
- Fire management authorities will be engaged to ensure they understand the requirements of *G. parviflora* subsp. *parviflora* and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas (it is noted there is 2,295.9 ha for *G. parviflora* subsp. *parviflora* mapped within the SCAs)

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to the development of essential infrastructure within nominated areas but outside the urban capable lands.

It is noted that no habitat or records are mapped for *G. parviflora* subsp. *parviflora* within the footprints of the proposed tunnels associated with transport corridors, and therefore it is considered that there is negligible potential for this species to be negatively impacted by the development of the tunnels.

29.9.6 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

Records of this species occur within GPEC, GMAC and Wilton. Of these, records within GMAC and Wilton occur within avoided land.

A non-important population (519) within GMAC occurs on avoided lands to the east of Appin, near the Georges River. Within GMAC, this population occurs within the proposed footprint for Stage 1 of the Georges River Koala Reserve (Commitment 10). Given the proposed use of this land for conservation purposes under the Plan, population 519 is not considered to be at risk of impacts from essential infrastructure development.

Within Wilton, important population 104 and important population 518 occur within land avoided for biodiversity purposes. To minimise potential impacts to these populations, the Plan includes a species-specific commitment (Commitment 2.4) to prioritise the avoidance of impacts from essential infrastructure on non-certified land to *G. parviflora* subsp. *parviflora.*

Further, as outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area

- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.9.7 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DEWHA, 2008d) (and other key documents) identifies the following key issues that are likely to have the greatest influence on the long-term viability of *G. parviflora* subsp. *parviflora* in relation to implementation of the Plan:

- Habitat loss and fragmentation
- Indirect impacts including:
  - Weed invasion
  - Inappropriate fire regimes
  - Habitat disturbance from recreational activities, rubbish dumping and road maintenance

HABITAT LOSS AND FRAGMENTATION

As outlined above, the Plan will lead to impacts to potential habitat.

Based on the application of the risk assessment method, the overall risk of residual adverse impacts associated with these direct impacts is <u>low.</u> The total area of potential habitat which will be impacted is a small proportion of the total habitat available for the species, and there will be no other direct impacts (such as impacts to known records or fragmentation) under the Plan.

It is noted that the Plan includes a species-specific commitment (Commitment 2.4) to prioritise the avoidance of impacts from essential infrastructure on non-certified land to *G. parviflora* subsp. *parviflora.*

The Plan includes a broader set of commitments and actions which are likely to benefit the species, which includes commitments to protect land within the SCAs which contain approximately 2,975 ha of potential habitat for *G. parviflora* subsp. *parviflora.*

On balance, direct impacts associated with implementation of the Plan are not expected to threaten the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts associated with inappropriate habitat disturbance, weed invasion, and inappropriate fire regimes have been analysed and determined to be adequately managed and mitigated through the generic management strategies in the Plan, and through a range of species-specific commitments to protect important population 104 from indirect impacts associated with development under the Plan.

Indirect impacts are not expected to influence the long-term viability of the species.

Conclusion

The limited scale of direct impacts to the species habitat and the management measures in the Plan to address potential indirect impacts will ensure that the implementation of the Plan does not adversely influence the long-term viability of the species.

29.9.8 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

29.9.9 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-31 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For *G. parviflora* subsp. *parviflora,* there are no relevant Threat Abatement Plans.

Table 29-31: Relevant key Threatening Processes and associated Threat Abatement Plans for *G. parviflora* subsp. *parviflora*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

29.10 *PERSOONIA BARGOENSIS* (BARGO GEEBUNG)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	*Persoonia bargoensis* is an erect, bushy shrub with small thin leaves and yellow tubular flowers. Fruits are pear-shaped, green and grow to 12mm long. Ranges from 0.6-2.5m tall. (DoEE, 2018c)
ECOLOGY	Flowers appear mainly in summer. Fruits hang on the plant for an indefinite period. Recruitment is solely from seed. This species is expected to live for up to 20 years. Disturbance, including fire, plays an important role in the germination of the seed bank. As a result, this species often appears along trail margins. Populations at sites which have been undisturbed for 10 years or so may not be representative of the potential population size of that site. This species is likely to be killed by fire. Frequent disturbance (such as regular track maintenance, slashing, and/or fire frequencies of less than 10-15 year intervals) are likely to result in a decline of a population of this species, as an adequate seedbank will not have time to develop between disturbance events. This species is pollinated by native bees. Populations within 500m are likely to be interbreeding. Urban development which discourages native bees from travelling between *P. bargoensis* populations and individuals is likely to result in increased isolation of populations and individuals. Seeds of this species are likely to be dispersed by birds and marsupials. Developments which prevent dispersal of seeds would also increase population isolation. (DoE, 2014e; DoEE, 2018c; NPWS, 2000a)
DISTRIBUTION AND HABITAT	Records are restricted to a small area south-west of Sydney on the western edge of the Woronora Plateau and the northern edge of the Southern Highlands. It is known to occur in the Burragorang, Cumberland and Sydney Cataract IBRA subregions (OEH, 2019a). Inhabits dry sclerophyll eucalypt woodland or forest. Occurs on the heavier, well-drained, gravelly soils of Hawkesbury Sandstone and Wianamatta Shale. (DoEE, 2018c)
POPULATIONS	As of 1999, the total number of individuals was likely to be less than 250. Populations at this time were small (often less than eight plants) and fragmented. (DoEE, 2018c)
SOS SITES	The following SOS sites for the species have been identified:

	• Wilton (proposed) • Bargo (proposed) • Hume Highway (proposed)
RELEVANT PLANS AND POLICIES	Approved Conservation Advice for *Persoonia bargoensis* (DoE, 2014e) Threat abatement plan for disease in natural ecosystems caused by *Phytophthora cinnamomi* (DoEE, 2018d)
SPECIES-SPECIFIC GUIDELINES	*Persoonia bargoensis* Environmental Impact Assessment Guidelines (NPWS, 2000a)
SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=56267

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

NOMINATED AREA CANDIDATE SPECIES (BCAR PROCESS)	ECOSYSTEM CREDIT SPECIES	CANDIDATE SPECIES CREDIT SPECIES			
		WILTON	GMAC	WSA	GPEC
	No	Yes	Yes	No	No

EXPERT REPORT (BCAR PROCESS)	There is no expert report for this species.
HABITAT MAPPING	**WITHIN THE NOMINATED AREAS** **Knowledge based map (KBM).** Habitat maps were generated using BioNet PCT associations, vegetation condition parameters (intact, thinned), elevation (between 0m and 450m), rock units (Hawkesbury Sandstone', 'Minchinbury Sandstone', 'Mount Hercules Sandstone Member', 'Razorback Sandstone Member') and soil units (Blacktown, Glenorie, Picton, Luddenham) within 80m of the edge of the sandstone geology. To refine these potential habitat polygons, targeted surveys for the species were then undertaken in a number of locations within the nominated areas. These surveys either confirmed presence (known habitat) or absence (no longer considered potential habitat). The species was recorded in Wilton during surveys. **OUTSIDE THE NOMINATED AREAS** **Species distribution model (SDM).** Potential habitat outside the nominated areas was mapped using an SDM. The report notes that there 390 records of *P. bargoensis* with which to produce a model (generally, over 50 records are required to produce a reliable SDM). The approach to SDM mapping may over-predict habitat for the species. No targeted surveys as part of this project were undertaken outside the nominated areas.
POPULATION MAPPING	**RECORD SELECTION** Species records were compiled from BioNet and surveys undertaken for the project. The BioNet records were cleaned using a process that interrogated the likelihood of persistence based on the

	historical removal of, or disturbance to, habitat. Where it was considered unlikely that a record still existed, it was removed from the dataset.
	POPULATION DEFINITION
	Biological populations were defined using the records dataset and available information about the nature of the species. All recorded plants were mapped as a single population as occurrence of the species within the Plan Area spans 20 km, and genetic flow (fruit dispersal by birds and pollination) could potentially move across the population within the life span of each plant (expected to be 20 years (OEH, 2019a)).
	IMPORTANT POPULATION CRITERIA
	Populations of *P. bargoensis* were then categorised as important or not-important based on the methodology set out in Section 11.5.3 of Chapter 11. Populations of *P. bargoensis* were considered important within the Strategic Assessment Area because they met one or more of the following criteria: • A large population (number of individuals) • Only known population of this species

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.16 for a map of records and habitat across the Strategic Assessment Area
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 29-36 at the end of this species assessment for a breakdown of the occurrence of records and habitat for *P. bargoensis* in the Strategic Assessment Area. **Records** *P. bargoensis* occurs as a single important population in the Strategic Assessment Area. The population spans from Bargo, to Picton in the north west, through to Appin in the east, and is bounded by the Strategic Assessment Area boundary in the south. This population is large and comprises 342 BioNet records. **Potential habitat** The baseline mapping for this assessment has mapped 12,338.6 ha of potential habitat within the Strategic Assessment Area. Mapped habitat is located in the southern portion of the assessment area, aligning with the location of known records. Potential habitat occurs within Wilton and GMAC. Within these nominated areas, potential habitat is generally associated with vegetation along riparian corridors as the majority of remaining land is cleared.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.10.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 2,396.8 ha of potential habitat within the nominated areas (not including excluded lands). Approximately 2,315.4 ha (96.6 per cent) has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 1,709.8 ha was avoided for biodiversity purposes
- 605.5 ha was avoided for other reasons

A breakdown of avoidance across each nominated area is provided in Table 29-37.

It is important to note that the avoidance calculations in Table 29-37, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 29-37 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

It is noted that there is a species-specific commitment (Commitment 2.4) to prioritise the avoidance of impacts from essential infrastructure to *P. bargoensis* on non-certified land.

29.10.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at <u>medium</u> or <u>high</u> risk of residual adverse impacts. Offsets are not provided for species that are considered to be at <u>low</u> or <u>very low</u> risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.10.3 LOSS OF KNOWN POPULATIONS AND POTENTIAL HABITAT

Implementation of the Plan will lead to impacts to mapped potential habitat. A summary of these impacts is provided in Table 29-38.

LOSS OF POTENTIAL HABITAT

Approximately 81.4 ha of potential habitat will be impacted as a result of the implementation of the Plan. This represents 0.7 per cent of potential habitat within the Strategic Assessment Area. The loss of potential habitat is associated with urban development in Wilton and GMAC. In both cases, direct impacts relate to the fringes of habitat areas.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of impacts to mapped habitat are considered to be <u>low</u>. This risk ranking is triggered for impacts to species' habitat, as follows:

- The likelihood of actual impacts occurring to the species within mapped habitat has been categorised as <u>likely</u>. The proximity of impacted habitat to multiple known records of the species suggests that it is likely that the species would be present within habitat areas
- The consequence of impacts to the species (if they did occur) has been categorised as <u>minor</u>. There will be a loss of <2 per cent of mapped potential habitat (vulnerable species), with high confidence that the species occurs in the impact area

29.10.4 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the low risk of residual adverse impacts to the species, offsets were not considered necessary for *P. bargoensis.*

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the potential indirect impacts to the species that may occur as a result of development under the Plan. It also outlines if the generic management strategies in the Plan will be adequate for addressing indirect impacts, or if species-specific commitments are necessary.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.10.5 RELEVANT POTENTIAL INDIRECT IMPACTS

The Conservation Advice for *P. bargoensis* (DoE, 2014e) (and other key documents) identifies a range of threats to the species. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats in key species documents) are considered relevant to implementation of the Plan:

- Inappropriate fire regimes and fire maintenance activities
- Inappropriate habitat disturbance associated with maintenance activities, illegal dumping and recreational activities
- Infection by *Phytophthora cinnamomi*

Inbreeding depression due to small and scattered populations and lack of genetic diversity, feral European honeybees making effective pollination unlikely, grazing by domestic animals and subsidence associated with underground coal extraction have also been identified as key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate these threats across the Strategic Assessment Area.

INAPPROPRIATE FIRE REGIMES AND MAINTENANCE ACTIVITIES

P. bargoensis plants are killed by fire, with subsequent generations germinating from seeds stored within the soil. A minimum interval of approximately 10-15 years between fire events is required to enable the development of a suitable seed bank to ensure the species' persistence following a fire event.

However, it is also noted that *P. bargoensis* relies upon disturbance events in order to successfully germinate. Therefore, occasional fire events are likely to be required to maximise the species' ability to recover and persist.

The ideal frequency of fire for the conservation purpose of *P. bargoensis* is unknown. It is noted that the Conservation Advice for the species identifies research into determining the optimal fire regime for regeneration of the species as a research priority (DoE, 2014e).

Increased human activity within the nominated areas has the potential to alter fire regimes, through potentially increasing fire frequencies in some areas, and decreasing fire frequencies in others, through the following mechanisms:

- Increased fire frequency due to arson and accidental lighting of fires
- Increased fire frequency due to the application of fire by authorities to manage fire risk
- In other cases, a lack of fire due to challenges in burns in proximity to human habitation

Burning and slashing activities for hazard reduction purposes, and increased unnatural ignition sources, have increased the disturbance and fire frequency within the species' habitat and is considered a threat (OEH, 2019a). Increased fire risk poses a threat to the long-term persistence of *P. bargoensis* within the Plan Area, as frequent fires would negatively impact upon the species' ability to successfully reproduce.

The areas which are most at risk from inappropriate fire regimes are those in close proximity to areas of development. This includes known populations and mapped habitat for the species within and near Wilton and the southern portion of GMAC.

For *P. bargoensis,* a species-specific measure relating to fire management is appropriate given its sensitivity to inappropriate fire regimes, and the fact that the species is only known from the area within and around Wilton and GMAC, significantly increasing the level of risk.

The Plan includes a species-specific measure to consult with land managers of containing known habitat or populations of *P. bargoensis* to mitigate indirect impacts from fire during construction and operation of the development, taking into account guidance in the Fire Management Strategy.

The Plan further incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for *P. bargoensis* being:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the Strategic Conservation Areas that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for *P. bargoensis.* While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes.

The package of measures in the Plan is expected to adequately manage the risk to *P. bargoensis* from altered fire regimes as a result of development. This is because:

- There is a species-specific measure to protect the species from impacts associated with altered fire regimes
- Establishment of environmental zoning of approximately 2,315.4 ha of mapped potential habitat of *P. bargoensis* within avoided lands will enable establishment of an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting mapped potential habitat and/or known records for *P. bargoensis* which is located adjacent to urban capable lands
- Fire management authorities will be engaged to ensure they understand the requirements of *P. bargoensis* and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas (it is noted there is 5,173.8 ha of potential habitat for *P. bargoensis* mapped within the SCAs)

INAPPROPRIATE HABITAT DISTURBANCE ASSOCIATED WITH MAINTENANCE ACTIVITIES, ILLEGAL DUMPING AND RECREATIONAL ACTIVITIES

A large proportion of the species occurs on road verges, suggesting that *P. bargoensis* may be dependent on disturbance, and that the species may benefit from reduced competition and increased light available on disturbance margins. As a result, most known sites of the species are managed by relevant infrastructure authorities (including TfNSW, Wollondilly Council and Transgrid) (DoE, 2014e).

P. bargoensis is also threatened by illegal dumping, recreational activities and vehicle use within areas of the species' habitat (OEH, 2019a). The areas which are most at risk of impacts include those in close proximity to development, particularly around Wilton and the southern portion of GMAC.

The Plan includes a species-specific measure to consult with land managers of land containing known populations or habitat for *P. bargoensis* to mitigate indirect impacts from habitat disturbance during construction and operation of the development, including controlling public access, managing maintenance activities such as mowing and weed control, and managing rubbish dumping.

The Plan also includes the following development controls to manage the risk of inappropriate habitat disturbance:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping and vegetation clearing
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas. This commitment is consistent with a number of actions in the Conservation Advice around educating the community about *P. bargoensis*

The package of measures in the Plan is expected to adequately manage the risk to *P. bargoensis* from inappropriate habitat disturbance as a result of development. This is because:

- A species-specific measure will require consultation with land managers to ensure protection of *P. bargoensis* from inappropriate habitat disturbance
- Avoided lands where areas of mapped habitat for *P. bargoensis* occur will be zoned appropriately to enable an adequate framework for management (this includes 2,315.4 ha of mapped potential habitat for the species)
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas (it is noted there is 5,173.8 ha of potential habitat for *P. bargoensis* mapped within the SCAs)
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

INFECTION BY PHYTOPHTHORA CINNAMOMI

P. bargoensis is threatened by exposure to *Phytophthora cinnamomi,* a soil-borne water mould which is fatal to many *Persoonia* species.

Development within GMAC and Wilton has the potential to increase the spread of *P. cinnamomi* through increased site visitation rates and earthworks activities conducted during construction works.

The Plan includes a species-specific measure to incorporate best practice site hygiene protocols to manage the potential spread of pathogens, such as *P. cinnamomi* and myrtle rust adjacent to potential habitat for *P. bargoensis.*

The Plan incorporates a range of measures to manage the risks associated with *Phytophthora cinnamomi*. In summary, these include:

- A commitment (Commitment 19) to support new or existing programs to control key diseases affecting threatened species and ecological communities in the Cumberland subregion. This will include:
  - Consulting with researchers, government agencies and other delivery partners to identify programs that contribute to the management of disease and dieback in the Cumberland subregion
  - Entering into written agreements with delivery partners to implement priority disease control programs

- Development controls to require the preparation of Construction Environmental Management Plans (CEMP) that must set out the measures methods to protect the environment during construction, including best practice site hygiene protocols to minimise spread of *Phytophthora* and Myrtle Rust

The package of measures in the Plan is expected to adequately manage the risk to *P. bargoensis* from *Phythophthora cinnamomi* because:

- Development controls will be put in place to address potential impacts associated with construction
- It supports a landscape scale approach to the issue across the Cumberland subregion

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*
- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to:

- The development of essential infrastructure within nominated areas but outside the urban capable lands
- Tunnels associated with transport projects

29.10.6 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

Three records of *P. bargoensis* occur within avoided land in Wilton. To minimise potential impacts to these populations, the Plan includes a species-specific commitment (Commitment 2.4) to prioritise the avoidance of impacts from essential infrastructure on non-certified land to *P. bargoensis*.

Further, as outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

29.10.7 POTENTIAL IMPACTS FROM TUNNELS

There is a total of 0.1 ha of potential habitat for *P. bargoensis* mapped within the tunnel footprint under the Plan. However, there are no records of *P. bargoensis* in the locality; it is noted that the tunnel footprints are over 10 km north of the northernmost known record of this species, suggesting that the tunnels are likely to occur outside of the extent of occurrence of this species. It is therefore considered to be unlikely that the development of tunnels under the Plan will negatively impact *P. bargoensis*.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.10.8 IMPLICATIONS FOR LONG-TERM VIABILITY

The Conservation Advice (DoE, 2014e) (and other key documents) identifies the following key issues that are likely to have the greatest influence on the long-term viability of *P. bargoensis* in relation to implementation of the Plan:

- Habitat loss
- Indirect impacts including:
  - Inappropriate fire regimes and fire maintenance activities
  - Inappropriate habitat disturbance associated with maintenance activities, illegal dumping and recreational activities
  - Infection by *Phytophthora cinnamomi*

HABITAT LOSS

As outlined above, the Plan will lead to impacts to potential habitat.

Based on the application of the risk assessment method, the overall risk of residual adverse impacts associated with these direct impacts is <u>low.</u> The total area of potential habitat which will be impacted is a small proportion of the total habitat available for the species, and there will be no other direct impacts (such as impacts to known records or fragmentation) under the Plan.

It is noted that the Plan includes a species-specific commitment (Commitment 2.4) to prioritise the avoidance of impacts from essential infrastructure on non-certified land to *P. bargoensis.*

The Plan includes a broader set of commitments and actions which are likely to benefit the species, which includes commitments to protect land within the SCAs which contain approximately 5,174 ha of potential habitat for *P. bargoensis.*

On balance, direct impacts associated with implementation of the Plan are not expected to threaten the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts associated with inappropriate fire regimes and fire maintenance activities, inappropriate habitat disturbance associated with maintenance activities, illegal dumping and recreational activities and infection by *Phytophthora cinnamomi* have been analysed and determined to be adequately managed and mitigated through the generic management strategies in the Plan, and through a range of species-specific commitments to protect *P. bargoensis* from indirect impacts associated with development under the Plan.

CONCLUSION

The limited scale of direct impacts to the species habitat and the management measures in the Plan to address potential indirect impacts will ensure that the implementation of the Plan does not adversely influence the long-term viability of the species.

29.10.9 CONSISTENCY WITH RECOVERY PLAN

There is no recovery plan for the species.

29.10.10 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-35 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

The consistency of the Plan with relevant Threat Abatement Plans is discussed in detail in Chapter 15. The Plan is not inconsistent with any of the Threat Abatement Plans.

Table 29-35: Relevant key Threatening Processes and associated Threat Abatement Plans for *P. bargoensis*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Dieback caused by the root-rot fungus (*Phytophthora cinnamomi*)	Threat abatement plan for disease in natural ecosystems caused by *Phytophthora cinnamomi* (DoEE, 2018d)
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

29.11 *POMADERRIS BRUNNEA* (RUFOUS POMADERRIS)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	*Pomaderris brunnea* is a compact shrub with hairy stems, leaves with toothed margins and small yellowish or cream clustered flowers. Grows from 1-4 m in height. (DoEE, 2018c; OEH, 2019c)
ECOLOGY	Limited information is available for the ecology of this species. Flowers between September and October. Expected to live for 10-20 years. Minimum time for the plant to produce seeds is approximately 4-6 years. (DoEE, 2018c)
DISTRIBUTION AND HABITAT	Endemic to south-eastern Australia. Occurs in eastern NSW in the Sydney Basin, NSW North Coast and New England Tableland IBRA bioregions and in eastern Victoria. Inhabits moist woodland or forest on clay and alluvial soils of flood plains and creek lines. (Sutter, Department of Sustainability and Environment et al., 2011) The Strategic Assessment Area is one of the core locations for the species.
POPULATIONS	As of 2011, sixteen populations of about 1,000 individuals had been recorded. However, at this time, records for some occurrences were over 30 years old, and it was not known if the species was still extant at all sites. (Sutter, Department of Sustainability and Environment et al., 2011)
SOS SITES	The following SOS sites for the species have been proposed: • Oakwood property • Gundengarra Reserve – Spring Farm • Wirrumburra Wildlife Sanctuary • Upper Nepean SCA
RELEVANT PLANS AND POLICIES	National Recovery Plan for Rufous Pomaderris (*Pomaderris brunnea*) (Sutter, Department of Sustainability and Environment et al., 2011)
SPECIES-SPECIFIC GUIDELINES	There are no specific guidelines for this species

SPRAT LINK	http://www.environment.gov.au/cgi-bin/sprat/public/publicspecies.pl?taxon_id=16845

APPROACH TO BASELINE DATA

This section provides a summary of the baseline information used in the assessment. It sets out:

- *If the species is a candidate species under the BCAR process*
- *If an expert report was prepared for the species under the BCAR process*
- *An overview of the habitat mapping for the species within and outside the nominated areas*
- *An overview of the population mapping for the species*

Please refer to Section 11.5 in Chapter 11 for further details about the threatened species baseline data, including the various approaches to habitat and population mapping.

Where it was considered unlikely that a record still existed, it was removed from the dataset.</td></tr>
<tr><td colspan="5">POPULATION DEFINITION</td></tr>
<tr><td colspan="5">Biological populations were defined using the records dataset and available information about the nature of the species.
Records within 1 km of one another are considered a single population.</td></tr>
<tr><td colspan="5">IMPORTANT POPULATION CRITERIA</td></tr>
<tr><td colspan="5">Populations of P. brunnea were then categorised as important or not-important based on the methodology set out in Section 11.5.3 of Chapter 11.</td></tr>
</table>

	Populations of *P. brunnea* were considered important because they met one or more of the following criteria: • A population that is a site-managed species or iconic species targeted for conservation under the NSW Saving our Species program • A population within a conservation reserve • A large population

OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA

This section describes the occurrence of the species in the Strategic Assessment Area. It includes reference to a map of records and habitat which can be viewed as a separate file. The map provides critical context for the assessment and should be viewed in conjunction with the text presented in this assessment. This section also provides a qualitative description of where records and habitat occur.

MAP	See Map 36.22 for a map of records and habitat across the Strategic Assessment Area
OCCURRENCE IN THE STRATEGIC ASSESSMENT AREA	See Table 29-40 at the end of this species assessment for a breakdown of the occurrence of records and habitat for *P. brunnea* in the Strategic Assessment Area. **Records** A total of 21 populations have been mapped within the Strategic Assessment Area. They occur from Camden, south east into GMAC, and around Bargo. Seven are mapped as important and 14 are not. Five populations are either wholly or partly located in existing conservation reserves. Of the four nominated areas, only GMAC contains known records of *P. brunnea*. These are located as follows: • Important populations: o Population 469 – one record within the nominated area in an existing conservation reserve. The population occurs in excluded land o Population 586 - occurs within vegetation associated with Ousedale Creek, in the centre of southern GMAC, partially in avoided lands and partially in excluded land. This population was detected during site surveys conducted in 2018 for this strategic assessment o Population 587 - occurs within the southern boundary of GMAC, in land avoided for biodiversity purposes. This population was detected during site surveys conducted in 2018 for this strategic assessment • Non-important populations: o Population 468 – one record on the western boundary of the nominated area, which occurs in excluded land o Population 470 – one record in the centre of the nominated area. The population occurs in land avoided for biodiversity purposes o Population 471 - one record on the western boundary of the nominated area. The population occurs in avoided lands o Populations 513/514/515 – three populations with two to eight records each, on the eastern boundary of the nominated area. These populations occur in avoided lands There are no records of *P. brunnea* within Wilton, GPEC or WSA. Outside of the nominated areas, populations are located as follows: • Important populations: o Population 73 - Occurs along the Nepean River near Spring Farm. This population partially occurs within the Gungungurra Biobanking Agreement site o Population 177 - Occurs within the south of the Strategic Assessment Area, and is partially located in a site protected by a conservation agreement

	- Population 465 - Occurs adjacent to the Nepean River within the footprint of the proposed OSO tunnel, within a site protected by a Registered Property Agreement - Population 510 - A record within the St Marys Tower Biobanking Agreement, just outside the north-eastern border of Wilton • Non-important populations include: - A number of populations in the south of the Strategic Assessment Area - One population near Douglas Park, between Wilton and GMAC, near the Nepean River and Hume Motorway - A number of populations in the vicinity of Menangle Park and Spring Farm (near important population 73), outside of the western boundary of GMAC **Potential habitat** The baseline mapping for this assessment has mapped 26,092.1 ha of known and potential habitat within the Strategic Assessment Area. Due to the broad habitat associations in the model, potential habitat has been identified widely across the Strategic Assessment Area, with habitat primarily occurring as thin corridors associated with drainage lines within the region. It is noted that the area to the west of GMAC, between Spring Farm and Menangle has been identified as a more substantial patch of mapped potential habitat. Habitat is not mapped within GPEC and WSA because the species is not a candidate species credit species in those nominated areas.

AVOIDANCE OF IMPACTS

This section provides an overview of the area of potential habitat that was avoided for the species through the design of the urban capable lands within the nominated areas. Avoidance of impacts to biodiversity was a critical part of the process to develop the Plan. A detailed explanation of the avoidance process and terminology is provided in Chapter 14.

29.11.1 NOMINATED AREAS

The baseline mapping for this assessment has mapped 959.3 ha of potential habitat within the nominated areas (not including excluded lands). Approximately 924.7 ha (96.4 per cent) has been avoided as part of the design of the urban capable lands and transport corridors (not including excluded lands). Of this:

- 733.1 ha was avoided for biodiversity purposes
- 191.5 ha was avoided for other purposes

A breakdown of avoidance across each nominated area is provided in Table 29-41.

It is important to note that the avoidance calculations in Table 29-41, including for 'avoidance for biodiversity purposes', 'avoidance for other reasons', and 'total avoidance', have been calculated without including excluded lands as these lands are not covered by the Plan. Table 29-41 shows the amounts of habitat within excluded lands for context only, and Chapter 14 defines the land types that are excluded.

29.11.2 TRANSPORT

Results are only reported for the nominated areas, as detailed planning within the transport corridors outside the nominated areas has not yet occurred.

It is noted that the Plan includes a species-specific commitment (Commitment 4.1) to avoid and minimise impacts to *P. brunnea* as a result of tunnel construction activities in transport corridors.

DIRECT IMPACTS AND OFFSETS

This section provides an analysis of any direct impacts and (if appropriate) identifies the need for any offsets to compensate for these direct impacts.

Direct impacts are assessed in relation to known populations, loss of potential habitat, or fragmentation of habitat. The risk of residual adverse impacts to the species occurring as a result of any direct impacts is characterised as per the methodology set out in Section 29.3.

Offsets are provided for species that are considered to be at medium or high risk of residual adverse impacts. Offsets are not provided for species that are considered to be at low or very low risk of residual adverse impacts. The rationale and process for setting offset targets for species is set out in Section 8.5.2 of Chapter 8.

29.11.3 LOSS OF KNOWN POPULATIONS AND POTENTIAL HABITAT

Implementation of the Plan will lead to a loss of potential habitat and fragmentation of habitat. A summary of these impacts is provided in Table 29-42.

LOSS OF POTENTIAL HABITAT

Approximately 202.5 ha of potential habitat for the species will be lost. This is 0.8 per cent of mapped potential habitat across the Strategic Assessment Area. The loss of potential habitat occurs across Wilton, GMAC, and transport corridors in the south of the Strategic Assessment Area. The majority of impacts to potential habitat occur due to transport outside the nominated areas.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of impacts to mapped habitat are considered to be low. This risk ranking is triggered for impacts to species' habitat, as follows:

- The likelihood of actual impacts occurring to the species within mapped habitat has been categorised as likely. The presence of records of the species within the vicinity of impacted habitat suggests that it is likely the species would be present within impacted areas
- The consequence of impacts to the species (if they did occur) has been categorised as minor. There will be a loss of <2 per cent of mapped potential habitat (vulnerable species), with high confidence that the species occurs in the impact area

29.11.4 FRAGMENTATION OF HABITAT

FRAGMENTATION IMPACTS

The development of the OSO to the south of Camden Park will fragment mapped potential habitat for *P. brunnea*.

RISK OF RESIDUAL ADVERSE IMPACTS TO THE SPECIES

The risk of residual adverse impacts occurring to the species as a result of fragmentation is considered to be low. This is because:

- The likelihood of fragmentation has been categorised as possible. This is because:
  - The likelihood that development presents a barrier to dispersal of the species is likely. Limited information is available regarding the reproductive and dispersal ecology of *P. brunnea*, and therefore a precautionary approach has been taken and it is thought to be likely that the development of the OSO would fragment habitat for the species
  - The type of fragmentation (as defined in the risk assessment approach in Section 29.3) is impact to habitat connected to a population. This is because there are known records located on mapped potential habitat which is fragmented by the OSO development
- The consequence of fragmentation has been categorised as moderate. This is because the area to be fragmented is connected to a known population of the species and is of moderate size

29.11.5 OFFSETS FOR RESIDUAL DIRECT IMPACTS

Given the low risk of residual adverse impacts to the species, offsets were not considered necessary for *P. brunnea.*

POTENTIAL INDIRECT IMPACTS AND MITIGATION

This section identifies the potential indirect impacts to the species that may occur as a result of development under the Plan. It also outlines if the generic management strategies in the Plan will be adequate for addressing indirect impacts, or if species-specific commitments are necessary.

Please refer to Chapter 15 for a detailed discussion and analysis of indirect impacts and mitigation measures included in the Plan. It is critical to read Chapter 15 in order to understand the conclusions reached in this section.

29.11.6 RELEVANT POTENTIAL INDIRECT IMPACTS

The Recovery Plan (Sutter, Department of Sustainability and Environment et al., 2011) (and other key documents) for *P. brunnea* identify a range of threats to the species. Where these threats are present in the Strategic Assessment Area and have the potential to be exacerbated under the Plan, the Plan includes management strategies to mitigate their impacts. The following potential indirect impacts (identified as threats in key species documents) are considered relevant to implementation of the Plan:

- Weed invasion
- Disturbance from trampling and recreational vehicle use
- Stormwater run-off
- Altered fire regimes

Sand extraction, browsing by cattle and timber harvesting have also been identified as key threats. However, these are not considered relevant to implementation of the Plan as the Plan is unlikely to exacerbate these threats across the Strategic Assessment Area.

WEED INVASION

P. brunnea is threatened with invasion and competition by weeds. Weeds are already present within the Strategic Assessment Area. However, urban, transport and agricultural development within the Strategic Assessment Area has the potential to increase the spread of these weeds by providing more opportunities for weed dispersal or inadvertently changing conditions to favour weeds.

P. brunnea is most susceptible to the threat of weeds from development under the Plan where new urban growth or transport occur adjacent to known populations or habitat. Key risk areas include development within Wilton and GMAC.

The Plan incorporates a range of general measures to manage the risk posed by weed invasion to biodiversity. In summary, these include:

- A commitment (Commitment 16) to manage priority weeds in strategic locations in the Cumberland subregion to reduce threats to land secured within the SCA. This includes a number of actions, of which the following are the most relevant to the outcome for *P. brunnea*:
    - Preparation of a Weed Control Implementation Strategy, and entering into written agreements with delivery partners to implement the weed control program
    - Integration of weed control actions for conservation land into biodiversity stewardship agreements and reserve management plans
    - Provision of grants to relevant stakeholders to reduce weeds in the following locations: on public land adjoining or near conservation land, and on Aboriginal-owned land adjoining or near to conservation land
- A commitment (Commitment 23) to provide extension services to community groups, councils, Local Aboriginal Land Councils, and landholders to support biodiversity conservation on public and private land, which includes:
    - Partnering with Local Land Services, councils, Local Aboriginal Land Councils and other delivery partners to provide community workshops on managing weeds, consistent with the weed implementation strategy outlined in Commitment 16
- The introduction of planning controls that will:
    - Require proponents to undertake the following when applying for/undertaking development:

    - Submit a weed eradication and management plan with development applications for subdivisions, outlining weed control measures during and after construction
    - Subdivision design and earthworks to minimise environmental weed spread, and require the inclusion of measures to eradicate weeds in accordance with relevant council weed policies
    - Manage and eradicate Weeds of National Significance and weeds on the National Environmental Alert List under the National Weeds Strategy. The proponent is to refer to NSW Weed Wise for current weed identification and management approaches
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering management of weeds for biodiversity protection in these areas

Also relevant for the *P. brunnea* is that three known populations of the species (513, 514 and 515), in addition to mapped potential habitat, is located within the proposed footprint for Stage 1 of the Georges River Koala Reserve (Commitment 10). The establishment of the Koala Reserve is a major focus of the Plan and will be managed for conservation purposes, which will include weed management measures to protect the biodiversity values of the reserve.

The package of measures in the Plan is expected to adequately manage the risk to *P. spicata* from the increased risk of weeds associated with development. This is because:

- The proposed Georges River Koala Reserve (Commitment 10) intercepts mapped potential habitat and three known populations of *P. brunnea.* Protection of this reserve and management for conservation purposes will contribute to long-term protection of known populations and habitat of *P. brunnea*
- There are commitments (Commitment 16 and Commitment 23) which will coordinate, enable and conduct effective weed control programs in strategic locations within the Strategic Assessment Area to manage priority weed species
- Proponents will be required to minimise the risk of weed spread, and to manage weeds, during the design, development and operational stages of development
- Establishment of environmental zoning of approximately 925 ha of mapped potential habitat of *P. brunnea* within avoided lands will enable establishment of an adequate framework for management of weeds in these areas

DISTURBANCE FROM TRAMPLING AND RECREATIONAL VEHICLE USE

Habitat degradation through unrestricted public access and rubbish dumping has been identified as a key threat. Development within the nominated areas (particularly Wilton and GMAC) may lead to an increase in human activity within the species' known and potential habitat areas, and this may exacerbate the threat. In particular, populations at risk include important populations 586 and 587, and non-important populations 470, 471, each of which occur directly adjacent to urban capable land within GMAC. It is noted that each of these populations occur on avoided land.

The Plan incorporates a range of measures to mitigate the risks associated with inappropriate habitat disturbance for *P. brunnea.* In summary, these include:

- The introduction of planning controls that will establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for minimising a number of mechanisms for potential disturbance
- Development controls to minimise any potential inadvertent disturbance during construction. This includes measures such as temporary fencing to protect areas with high biodiversity value, and ensuring that parking, and equipment and laydown areas will be located away from land with biodiversity values
- Active management of land secured for conservation through the Plan which will address any issues associated with inappropriate habitat disturbance in those locations (including *P. brunnea* populations and mapped potential habitat within the Georges River Koala Reserve to be established under Commitment 10)
- A commitment (Commitment 28) to implement a compliance program to ensure compliance with the Plan and conditions of approval. This will include funding for at least three council-based compliance officers to ensure compliance with the conservation program. These officers will work closely with council rangers to monitor illegal dumping
- A commitment (Commitment 21) that will provide opportunities for the residents of Western Sydney to learn about and actively participate in biodiversity conservation. This process will ideally help the local community understand

and appreciate the biodiversity values that occur nearby, and potentially reduce the level of disturbance to natural areas. This commitment is consistent with a number of actions in the Conservation Advice around educating the community about *P. brunnea*

The package of measures in the Plan is expected to adequately manage the risk to *P. brunnea* from inappropriate habitat disturbance as a result of development. This is because:

- Avoided lands where mapped habitat for *P. brunnea* occurs will be zoned appropriately to enable an adequate framework for management
- Development controls will be put in place to address potential impacts associated with construction
- Conservation lands will be actively managed which will address disturbance in those areas
- There will be funded compliance with a focus on minimising habitat disturbance
- A program of education for the community will be run to help them understand the biodiversity values they live near

STORMWATER RUN-OFF

Stormwater runoff is identified as a threat to *P. brunnea*. The areas that are most at risk include populations which occur adjacent to urban capable development within GMAC.

The Plan incorporates a range of measures to mitigate the risks associated with changes to hydrology for *P. brunnea.* In particular, these include commitments which relate to mitigating indirect and prescribed impacts from urban development (Commitment 5). As part of these commitments, potential impacts in relation to hydrology are proposed to be managed through development controls in nominated areas in relation to:

- Water cycle management. For example:
  - Water management measures must comply with council's requirements for detention, drainage and water sensitive urban design principles
  - Water management measures must be designed to prevent damage by stormwater to the natural environment and minimise urban water run-off and sediment and pollutants to waterways
- Water quality. For example, stormwater systems must be constructed and maintained to achieve EES water quality targets
- Soil erosion and sedimentation. For example:
  - Development must incorporate measures to minimise soil erosion and sedimentation during construction and following completion of development
  - Soil and Water Management Plans must be prepared in accordance with Managing Urban Stormwater (Landcom 2004) and submitted with each subdivision development application

The package of measures in the Plan is expected to adequately manage the risk to *P. brunnea* from stormwater runoff because:

- Development controls in urban areas will be put in place to ensure development is designed, constructed and operated in a way that avoids and minimises any potential impacts to biodiversity values, including potential habitat for *P. brunnea*

ALTERED FIRE REGIMES

The sensitivity of *P. brunnea* to fire is unknown, although the species is known to occur in moist habitats where fire is infrequent and which may be sensitive to fire, and other *Pomaderris* species do not resprout after fire. As *P. brunnea* requires 4-6 years to reach maturity and produce seed, it is considered that a fire interval of less than 10 years would be detrimental to the species (Sutter, Department of Sustainability and Environment et al., 2011).

Increased human activity within the nominated areas has the potential to the risk of fire to habitat areas supporting the species, through the following mechanisms:

- Arson and accidental lighting of fires
- The application of fire by authorities to manage fire risk

The areas which are most at risk of increased fire frequency are where the species occurs in proximity to development under the Plan, and includes known populations and mapped potential habitat within GMAC.

The Plan incorporates a range of general measures to manage the bushfire risk to biodiversity. In summary, these include:

- A commitment (Commitment 18) to manage fire in strategic locations across the strategic assessment area. This includes a number of actions with the most relevant to the outcome for *P. brunnea* being:
  - Consultation with fire management authorities and traditional owners about how best to manage fire and maintain biodiversity values
  - Preparation of a fire management strategy for the SCAs that will (amongst other things) provide guidance on fire management to maintain and promote biodiversity values
  - A process to work with delivery partners to implement the fire management strategy
  - Integration of the fire management actions for conservation land identified in the fire management strategy in stewardship agreements and reserve management plans
- The introduction of planning controls that will:
  - Establish environmental zoning (E2) on avoided lands. This zoning will set out objectives that a consent authority must consider when considering development applications, as well as the land uses that are permissible and prohibited. It will provide a framework for considering bushfire management for biodiversity in these areas
  - Require precinct plans to have asset protection zones (APZs) wholly within the urban-capable land. This will ensure the highest intensity bushfire risk mitigation activities occur away from habitat for *P. brunnea*. While these APZs are designed to provide a buffer zone between a bushfire hazard and buildings or other infrastructure that need to be protected, they will also act as a protective buffer for the bushland areas from the sorts of activities within the urban capable land and transport corridors that might increase fire frequency or changes to natural fire regimes.

Also relevant for the *P. brunnea* is that three known population of the species (populations 513, 514 and 515), in addition to mapped potential habitat, is located within the proposed footprint for Stage 1 of the Georges River Koala Reserve (Commitment 10). The establishment of the Koala Reserve is a major focus of the Plan and will be managed for conservation purposes, which will include the application of the fire management strategy and a set of measures to control access to bushland which will help minimise risks around arson and accidental fires.

The package of measures in the Plan is expected to adequately manage the risk to *P. brunnea* from altered fire regimes as a result of development. This is because:

- The proposed Georges River Koala Reserve (Commitment 10) intercepts mapped potential habitat and three known populations of *P. brunnea.* Protection of this reserve and management for conservation purposes will contribute to long-term protection of known populations and habitat of *P. brunnea*
- Establishment of environmental zoning of approximately 925 ha of mapped potential habitat of *P. brunnea* within avoided lands will enable establishment of an adequate framework for management
- APZs for fire management are required to be located within urban capable lands which will reduce the risk of fire mitigation activities impacting mapped potential habitat and/or known records for *P. brunnea* which is located adjacent to urban capable lands
- Fire management authorities will be engaged to ensure they understand the requirements of *P. brunnea* and incorporate them in their fire management practices. This will include specific fire management approaches for conservation areas

POTENTIAL ADDITIONAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE AND TUNNELS

This section considers the potential additional impacts to the species from essential infrastructure and tunnels. Please refer to the following chapters for details about these development types and the predicted outcomes for matters protected by the EPBC Act:

- *Chapter 36 – Summary of transport program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with tunnels*

- *Chapter 37 – Summary of urban program impacts which includes an analysis of the potential impacts on EPBC Act protected matters associated with essential infrastructure outside the urban capable lands (but still within the nominated areas)*

In addition to predicted impacts within the urban capable lands and transport corridors, there is the potential for impacts to the species to occur due to:

- The development of essential infrastructure within nominated areas but outside the urban capable lands
- Tunnels associated with transport projects

29.11.7 POTENTIAL IMPACTS FROM ESSENTIAL INFRASTRUCTURE

The species has been recorded within avoided lands in GMAC. There is a total of seven populations (five non-important and two important) within GMAC which occur within avoided lands. Of these, three are located within the footprint of the proposed Georges River Koala Reserve, and will be managed for conservation purposes. The remaining four populations occur either entirely or partially within avoided lands adjacent to urban capable development.

As outlined in Chapter 37, any proposed essential infrastructure developments in these areas will be subject to the processes of the NSW BAM and require approval under the BC Act. These processes will include:

- On-ground surveys to determine the biodiversity values within the potential development area
- Measures to avoid impacts to the species through development design
- Measures to mitigate any potential indirect impacts
- Measures to offset any residual impacts in accordance with the requirements of the BAM

It is not expected that substantial impacts to the species will occur as a result of essential infrastructure, and that any impacts that did occur would be adequately mitigated and offset. See Section 37.6 in Chapter 37 for more details.

29.11.8 POTENTIAL IMPACTS FROM TUNNELS

Both the Metro Rail Future Extension and the OSO tunnels intercept mapped potential habitat for *P. brunnea.* In total, 137.9 ha of potential habitat for *P. brunnea* occurs within the two tunnel footprints.

The Metro Rail Future Extension has a total of 71.8 ha of mapped potential habitat for *P. brunnea* within the impact footprint. This habitat occurs mostly as small scattered patches which are not associated with known records of the species. The largest area of impacted habitat is located in association with Narellan Creek the vicinity of Harrington Park, in an area which is already extensively cleared and developed. The potential habitat values of this locality for *P. brunnea* are considered to be marginal.

The OSO tunnel intercepts approximately 66.1 ha of potential habitat for *P. brunnea* which is associated with an important population of the species (population 465), which is wholly located in a conservation reserve (a Registered Property Agreement site). This is a large population, comprising 22 records of the species (it is noted that most known populations of the species are small).

The Plan includes commitments to:

- Avoid and minimise impacts to populations and habitat within or adjacent to the OSO and Metro Rail Future Extension footprints for *P. brunnea* (Commitment 4.1)
- Mitigate any potential indirect impacts (e.g. changes to hydrology, ground settling or subsidence) from the transport corridors as part of a future environmental impact assessment process (Commitment 6.2)

These commitments are expected to adequately address threats to the species from the construction and operation of the tunnels. See Section 36.6 in Chapter 36 for more details.

LIKELY EFFECTS OF IMPLEMENTATION OF THE PLAN ON THE LONG-TERM VIABILITY OF THE SPECIES

This section considers the likely effects of implementation of the Plan on the long-term viability of the species. The assessment of viability has regard for the guidance in the Conservation Advice and (if applicable) the Recovery Plan, and draws on the analysis of avoidance, direct impacts and offsets, and indirect impacts and mitigation presented above.

Where applicable, this section also discusses the consistency of the Plan with any Recovery Plans and relevant Threat Abatement Plans. The general consistency of the Plan with Threat Abatement Plans is discussed in detail in Section 15.9 of Chapter 15.

29.11.9 IMPLICATIONS FOR LONG-TERM VIABILITY

The Recovery Plan identifies the following key issues that are likely to have the greatest influence on the long-term viability of the species in relation to implementation of the Plan

- Habitat loss
- Indirect impacts including:
  - Weed invasion
  - Disturbance from trampling and recreational vehicle use
  - Stormwater run-off
  - Altered fire regimes

HABITAT LOSS AND FRAGMENTATION

As outlined above, implementation of the Plan will lead to:

- Loss of 202.5 ha of mapped habitat within the nominated areas and transport corridors
- Potential fragmentation of habitat in one location

Based on the application of the risk assessment method, the overall risk of residual adverse impacts associated with these direct impacts is <u>low.</u> The total area of potential habitat which will be impacted is a small proportion of available habitat for the species. Fragmentation of a moderate area of mapped potential habitat connected with species' records may also occur. It is noted that no known records of the species are directly impacted or fragmented from other known records.

It is noted that *P. brunnea* occurs within the footprint of the proposed OSO and Metro Rail Future Extension tunnels. The Plan contains a species-specific commitment (Commitment 4.1) to avoid and minimise impacts to *P. brunnea* as a result of tunnel construction activities in transport corridors, which is considered to protect the individuals within the tunnel footprint from direct impacts.

The Plan includes a broader set of commitments and actions which are likely to benefit the species, which includes commitments to protect land within the SCAs which contain 7,605.6 ha of potential habitat for *P. brunnea.* It is also recognised that three known populations of the species occur within the proposed footprint of the Georges River Koala Reserve, which will be managed for conservation purposes and is expected to deliver benefits for these populations

On balance, direct impacts associated with implementation of the Plan are not expected to threaten the long-term viability of the species.

INDIRECT IMPACTS

The potential indirect impacts of development corridors associated with weed invasion, disturbance from trampling and recreational vehicle use, stormwater run-off and altered fire regimes have been analysed and determined to be adequately managed and mitigated through the generic management strategies in the Plan. In addition, any potential indirect impacts associated with the construction of tunnels will be managed and mitigated through a species-specific commitment (Commitment 6.2).

Indirect impacts are not expected to influence the long-term viability of the species.

CONCLUSION

The limited scale of direct impacts to the species habitat and the management measures in the Plan to address potential indirect impacts will ensure that the implementation of the Plan does not adversely influence the long-term viability of the species.

29.11.10 CONSISTENCY WITH RECOVERY PLAN

In accordance with Section 146K of the EPBC Act, this section considers whether the implementation of the Plan is not inconsistent with the species' Recovery Plan. It considers two questions:

- Does the Plan prevent achievement of the objectives of the Recovery Plan?
- Does the Plan prevent implementation of the Recovery Plan actions?

These questions are discussed below.

DOES THE PLAN PREVENT ACHIEVEMENT OF THE OBJECTIVES OF THE RECOVERY PLAN?

The overall objective of the Recovery Plan (Sutter, Department of Sustainability and Environment et al., 2011) is to minimise the probability of extinction of *P. brunnea* in the wild and to increase the probability of populations becoming self-sustaining in the long-term. Specific objectives include:

- Determine current status and threats
- Determine habitat requirements
- Protect and manage populations on public and private land
- Monitor response of populations to active management
- Identify key biological functions
- Establish a population in cultivation
- Build community support for conservation

Implementation of the Plan will support a number of these strategies and will not prevent the achievement of the objectives of the Recovery Plan.

DOES THE PLAN PREVENT THE IMPLEMENTATION OF THE RECOVERY PLAN ACTIONS?

The Recovery Plan identifies a set of actions to support the overall recovery of *P. brunnea*. The Plan will not prevent implementation of any of the actions.

29.11.11 KEY THREATENING PROCESSES AND CONSISTENCY WITH THREAT ABATEMENT PLANS

Relevant Key Threatening Processes (KTPs) and any of their associated Threat Abatement Plans (TAPs) have been identified in Table 29-39 where they relate to:

- The potential direct impacts of the Plan, or
- The relevant indirect impacts

For *P. brunnea,* there are no relevant Threat Abatement Plans.

Table 29-39: Relevant key Threatening Processes and associated Threat Abatement Plans for *P. brunnea*

RELEVANT KEY THREATENING PROCESS	ASSOCIATED THREAT ABATEMENT PLAN
Land clearance	There is no relevant TAP
Loss and degradation of native plant and animal habitat by invasion of escaped garden plants, including aquatic plants	There is no relevant TAP
Novel biota and their impact on biodiversity	There is no relevant TAP

DATA TABLES

This section sets out the data tables for occurrence, avoidance and direct impacts. Cross references to the tables are provided throughout the text above.

Table 29-40: Occurrence of *P. brunnea* in the Strategic Assessment Area

SPECIES AT VERY LOW RISK OF DIRECT IMPACTS

29.12 *ACACIA BYNOEANA* (BYNOE'S WATTLE)

This species assessment analyses the implications of implementation of the Cumberland Plain Conservation Plan in accordance with the EPBC Terms of Reference. It sets out:

- *Species background*
- *Approach to baseline data*
- *Occurrence in the Strategic Assessment Area*
- *Avoidance of impacts*
- *Direct impacts and offsets*
- *Potential indirect impacts and mitigation*
- *Potential additional impacts from essential infrastructure and tunnels*
- *Likely effects of implementation of the Plan on the long-term viability of the species*
- *Data tables*

SPECIES BACKGROUND

This section sets out the basic information about the species. It provides an overview of the species' ecology, distribution, habitat, and populations. These provide context for the impact assessment. At the end of the section are links to key species' documents that provide additional background information.

EPBC ACT LISTING	Vulnerable
DESCRIPTION	A semi-prostrate shrub with narrow leaves and cream to yellow flowers. It grows to 0.2-1 m tall. (DoEE, 2018c)
ECOLOGY	Flowers from September to March. Seedpods occur from September to January. Pollination is likely to be carried out by small native bees and wasps. Seed dispersal is likely to be by ants. Seeds are likely to remain viable for many years, which can lead to the development of a persistent soil-stored seed bank in the absence of cues for germination. The species may also reproduce vegetatively (Douglas, 2019a). This species may appear in response to disturbance. It is not always apparent, and can be cryptic and difficult to detect (particularly when not in flower) (Douglas, 2019a).
DISTRIBUTION AND HABITAT	Records occur in central-eastern NSW. They range from the Hunter District in the north to the Southern Highlands in the south and the Blue Mountains in the west. It is known to occur in the Cumberland IBRA subregion (OEH, 2019b). Inhabits heath or dry sclerophyll forests on sandy soils. It is recorded in open and sometimes slightly disturbed sites such as trail margins, edges of roadside, grading spoil mounds and in recently burnt patches (OEH, 2017a).
POPULATIONS	As of 2006, populations were known in around 113 locations and most were small in size (Douglas, 2019a). A natural population is considered at a critically low level if it contains less than 50 mature individuals (DoE, 2013a).
